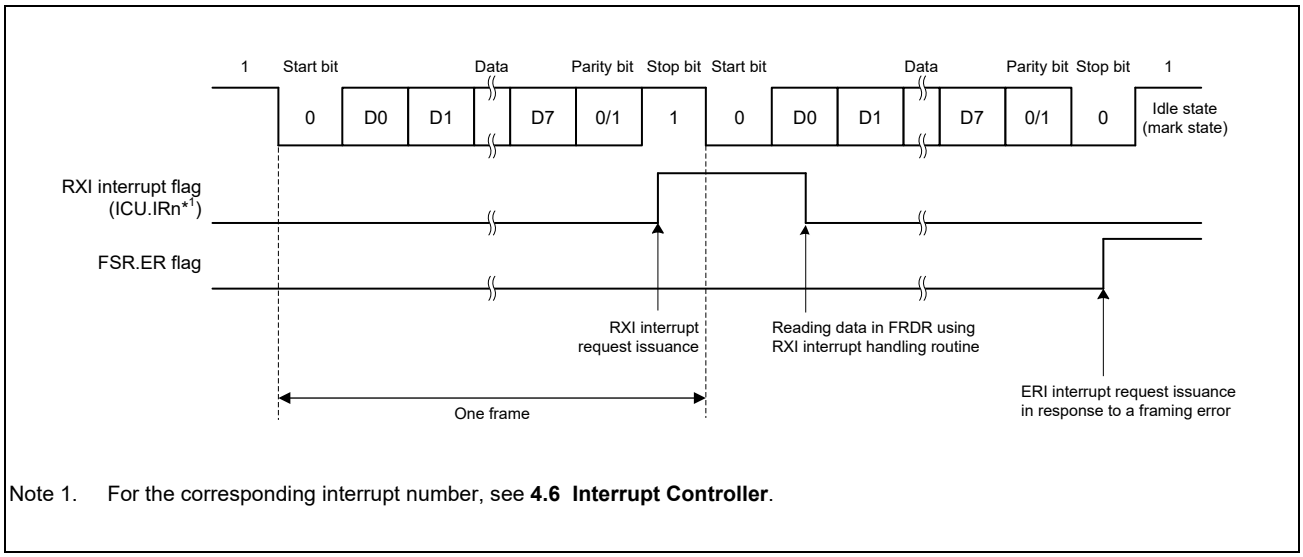
   d) Overrun error check: The SCIFA checks whether the ORER flag is 0, indicating that the overrun error has not occurred.
   e) Break check: The SCIFA checks whether the BRK flag is 0, indicating that the break state is not set.



If all the above checks are passed, the receive data is stored in the FRDR register.

Remark When a parity error or a framing error occurs, reception is not suspended.

4. When receive data units equaling or exceeding the specified reception trigger number are stored in the receive FIFO data register (FRDR) and the RDF flag is changed to 1, a receive FIFO data full interrupt (RXI) request is generated while the RIE bit in the SCR register is set to 1. When the quantity of data in the FRDR register falls below the specified reception trigger number and the RIE bit in the SCR register is set to 1, a receive data ready interrupt (DRI) request is generated if no next data is received after the elapse of 15 ETUs*[1] from the last stop bit (the DR flag in the FSR register is 1). When the ER flag in the FSR register is changed to 1, a receive error interrupt (ERI) request is generated while the RIE or REIE bit in the SCR register is set to 1. When the BRK or ORER flag is changed to 1 in the FSR register, a break reception interrupt (BRI) request is generated while the RIE or REIE bit in the SCR register is set to 1.

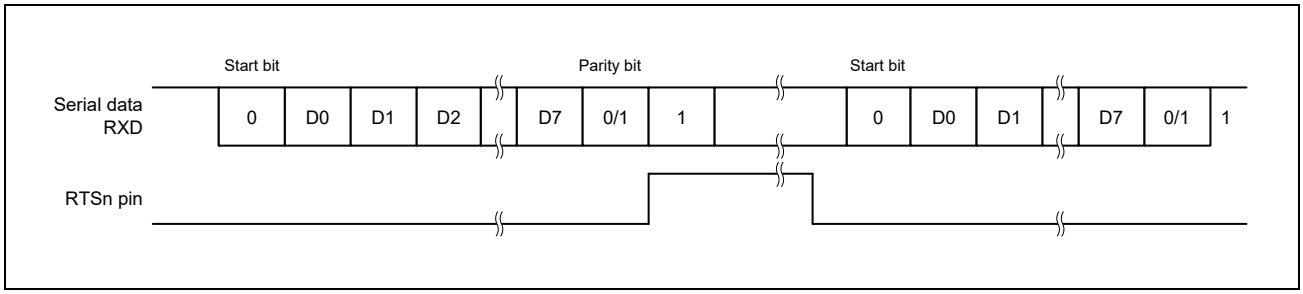
Note 1. It is equivalent to 1 and half frames of 8-bit format with one stop bit (ETU: Element Time Unit).

Figure 7.4-9 shows an example of the operation for reception in asynchronous mode.

Note 1. For the corresponding interrupt number, see **4.6 Interrupt Controller**.

Figure 7.4-9 Example of SCIFA Receive Operation in Asynchronous Mode
(8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected)

5. When modem control is enabled, the RTS# signal that indicates the FRDR register has space is output. When the RTS# pin is at low level, reception is possible. The RTS# pin being at the high level indicates that the number of entries in the FRDR register is equal to or greater than the threshold for output of the active level of the RTS# signal and that the transmission of further data needs to be suspended until the FRDR register has enough space. **Figure 7.4-10** shows an example of the operation for reception in asynchronous mode when using the modem control function.



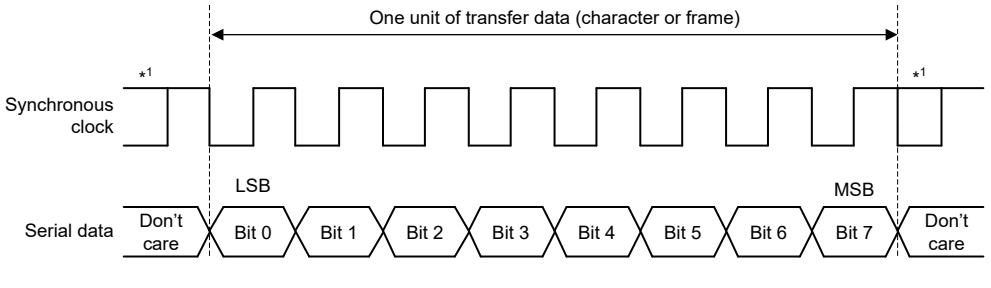


Figure 7.4-10 Example of SCIFA Receive Operation in Asynchronous Mode Using Model Control Function (RTS#)

7.4.3.3 Operation in Clock Synchronous Mode

In clock synchronous mode, the SCIFA transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

Full-duplex communication is possible because the SCIFA transmitter and receiver are independent and share the same clock. Since the transmitter and the receiver have 16-stage FIFO buffers, respectively, continuous transmission or reception is possible by reading or writing data while transmission or reception is in progress.

Figure 7.4-11 shows the general format in clock synchronous serial communication.

Note 1. High level except in continuous transmission/reception

Figure 7.4-11 Data Format in Clock Synchronous Communication (when LSB-First Transfer is Selected)

In clock synchronous serial communication, each data bit is output on the communication line from one falling edge of the synchronous clock to the next. Data is guaranteed valid at the rising edge of the synchronous clock.

In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB (when LSB-first transfer is selected).

In clock synchronous mode, the SCIFA receives data by synchronizing with the rising edge of the synchronous clock.

(1) Transmit/Receive Formats

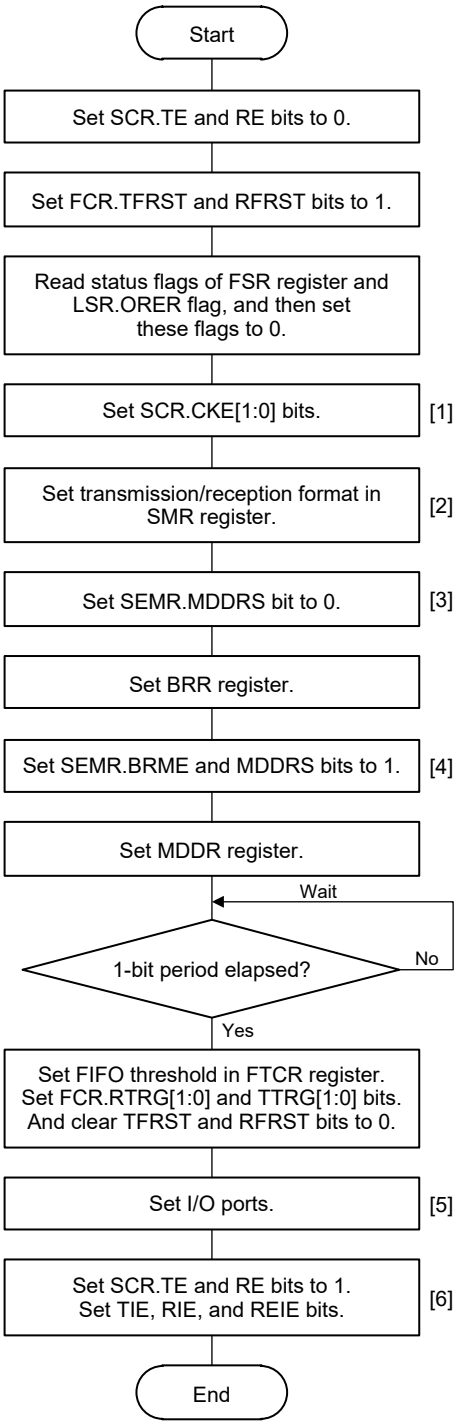
The data length is fixed at eight bits.

No parity bit can be added.

(2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCIFA transmit/receive clock according to the settings of the CM bit in the serial mode register (SMR) and the CKE[1:0] bits in the serial control register (SCR).

When the SCIFA operates on an internal clock, it outputs the synchronous clock signal at the SCK pin. Eight synchronous clock pulses are output per transmitted or received character. Unless the SCIFA is transmitting or receiving, the synchronous clock signal remains in the high state. When the SCIFA only receives data on an internal clock, the internal clock signal outputs while the RE bit in the SCR register is 1 until the number of data units in the receive FIFO reaches the specified reception trigger number.



(3) Transmitting and Receiving Data

SCIFA Initialization (in Clock Synchronous Mode)

Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCR), and then initialize the SCIFA by performing the following procedure.

Similarly, before changing the mode or communication format, clear the TE and RE bits to 0, and then change it by performing the following procedure. Clearing TE to 0 initializes the transmit shift register (TSR). Clearing RE to 0, however, does not initialize the RDF, PER, FER, and ORER flags and the receive FIFO data register (FRDR), which retain their previous contents.

Figure 7.4-12 shows a sample flowchart for initializing the SCIFA in clock synchronous mode.

[1] Set the TIE, RIE, TE, and RE bits in the SCR register to 0 before setting the CKE[1:0] bits.

[2] Set the transmission/reception format in the SMR register.

[3] Clear the SEMR.MDDRS bit to 0 and write a value corresponding to the bit rate in the BRR register. Not necessary if an external clock is used.

[4] Set the SEMR.BRME and MDDRS bits to 1 and write a value corresponding to the bit rate in the MDDR register. Not necessary if an external clock is used. Wait for at least 1-bit period before proceeding to the next step.

[5] Set I/O ports and the MPC register so that they can be used as the SCK, TXD, and RXD pin.

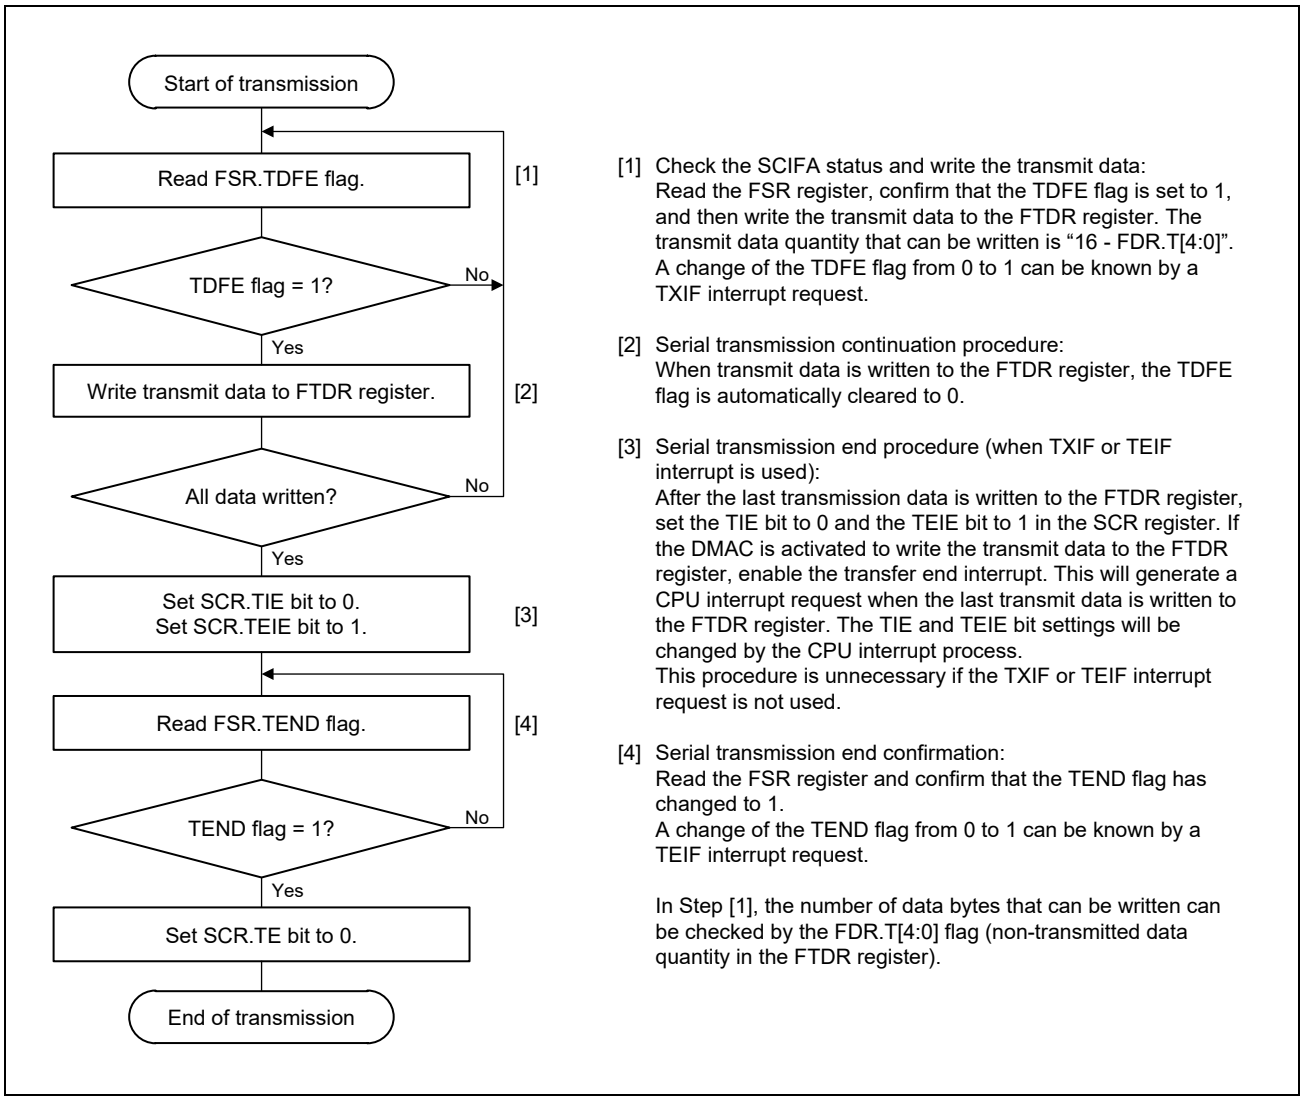
[6] After setting the MDDR register, wait for at least 1-bit, and then write 1 to the SCR.TE or RE bit. To permit interrupt requests, set TIE, RIE, and REIE bits to 1. Setting the TE and RE bits to 1 makes the TXD and RXD pins available to be used. In transmission, those pins enter the mark state, and in reception, they enter the idle state waiting for a start bit.

Figure 7.4-12 Sample Flowchart for SCIFA Initialization in Clock Synchronous Mode

Transmitting Serial Data (in Clock Synchronous Mode)

Figure 7.4-13 shows a sample flowchart for transmitting serial data in clock synchronous mode.

Follow the procedure given below for serial data transmission after enabling the SCIFA for transmission.



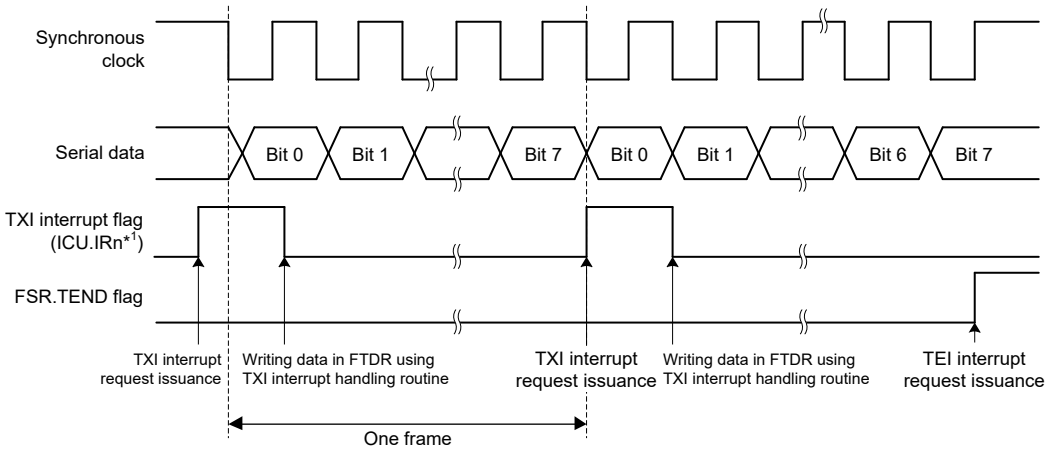


Figure 7.4-13 Sample Flowchart for Transmitting Serial Data in Clock Synchronous Mode

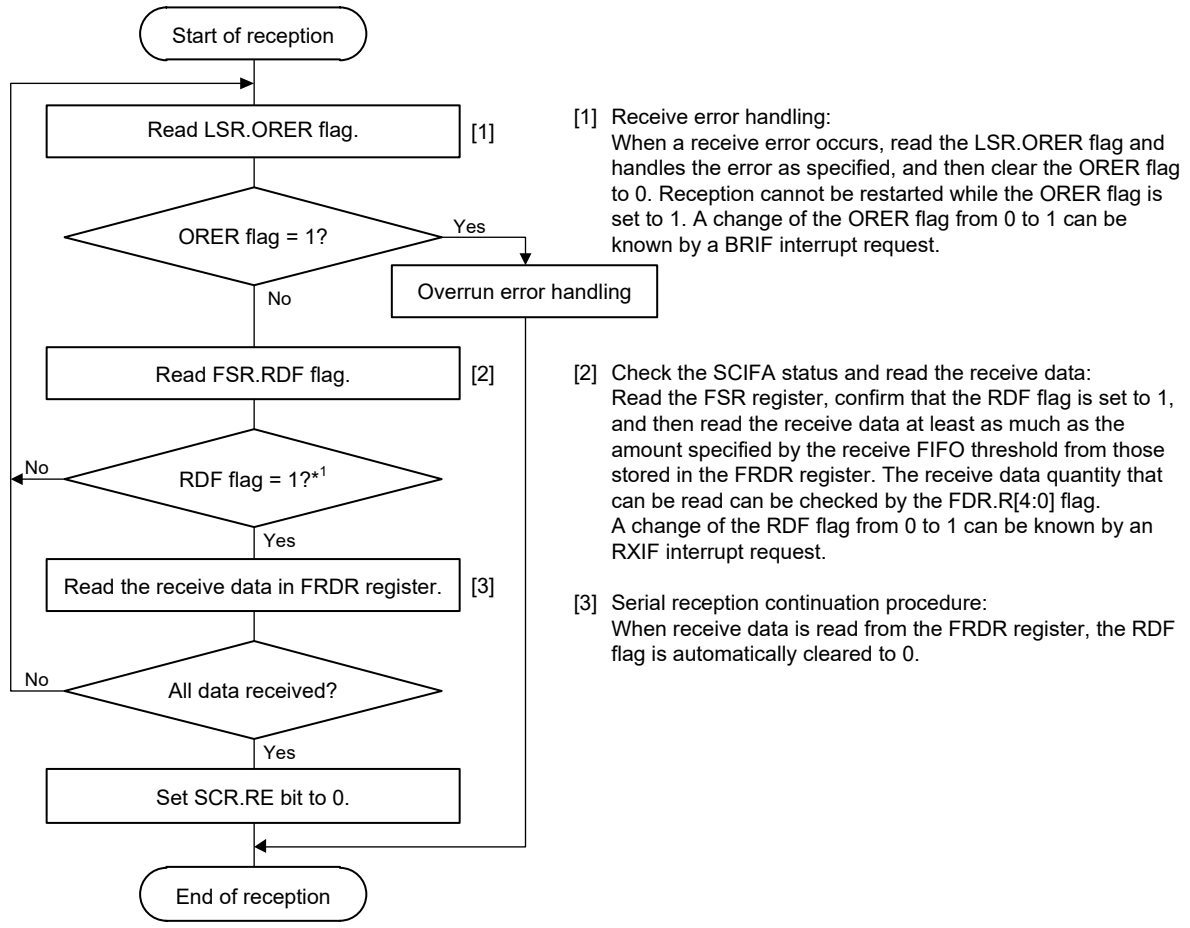
In clock synchronous mode, the SCIFA performs serial transmission as described below.

1. When data is written into the transmit FIFO data register (FTDR) by the TXI interrupt processing routine, the SCIFA transfers the data from the FTDR register to the transmit shift register (TSR) and starts transmission. Confirm that the TDFE flag in the serial status register (FSR) is set to 1 before writing transmit data to the FTDR register. The number of data bytes that can be written is “16 minus the specified number of non-transmitted data units”.
2. When data is transferred from the FTDR register to the TSR register and transmission is started, consecutive transmit operations are performed until there is no transmit data left in the FTDR register. When the number of transmit data bytes in the FTDR register becomes equal to or less than the transmission trigger number set in the FIFO control register (FCR) or FIFO trigger control register (FTCR), the TDFE flag in the FSR register is set. If the TIE bit in the serial control register (SCR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.
   If clock output mode is selected, the SCIFA outputs eight synchronous clock pulses. If an external clock source is selected, the SCIFA outputs data in synchronization with the input clock. Data is output from the TXD pin in order from the LSB (b0) to the MSB (b7) (when LSB-first transfer is selected).
3. The SCIFA checks the transmit data of the FTDR register at the timing for sending the MSB (bit 7). If data is present, the data is transferred from the FTDR register to the TSR register, and then serial transmission of the next frame is started. If there is no data, the TXD pin holds the output level of the last data after TEND flag in the FSR register is set to 1 and the MSB (bit 7) is output.
4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 7.4-14 shows an example of SCIFA transmit operation in clock synchronous mode.



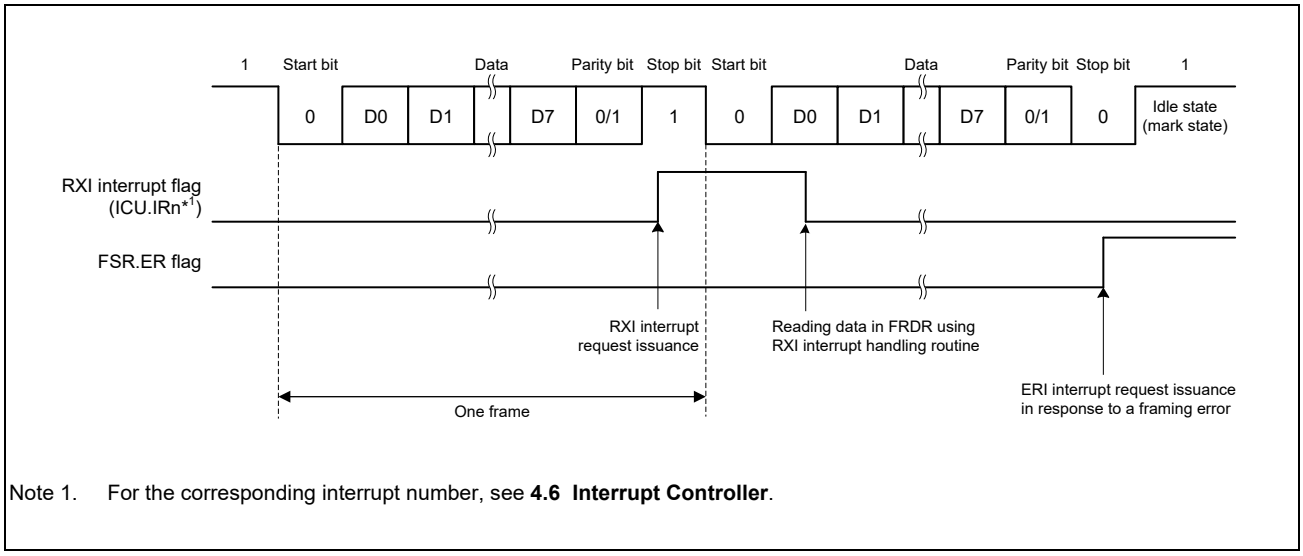
Note 1. For the corresponding interrupt number, see **4.6 Interrupt Controller**.

Figure 7.4-14 Example of SCIFA Transmit Operation in Clock Synchronous Mode (when LSB-First Transfer is Selected)

Receiving Serial Data (in Clock Synchronous Mode)

Figure 7.4-15 and **Figure 7.4-16** show sample flowcharts for receiving serial data in clock synchronous mode.

Follow the procedure given below for serial data reception after enabling the SCIFA for reception. When switching from asynchronous mode to clock synchronous mode without SCIFA initialization, make sure that the ORER, PER, and FER flags in the line status register (LSR) are cleared to 0.



Note 1. The number of all the received data units should be an integral multiple of the receive FIFO threshold. If not, process returns to Step [1] and enters an infinite loop. In this case, it is necessary to set the timeout processing using a timer.

Figure 7.4-15 Sample Flowchart for Receiving Serial Data in Clock Synchronous Mode

In clock synchronous mode, the SCIFA performs serial reception as described below.

1. The SCIFA synchronizes with the synchronous clock input or output and starts reception.
2. Receive data is stored into the receive shift register (RSR) in order from the LSB to the MSB (when LSB-first transfer is selected). After receiving the data, the SCIFA checks whether the receive data can be transferred from the RSR register to the FRDR register. If data can be transferred, the SCIFA stores the received data in the FRDR register. If an overrun error is detected during the error check, further reception is not performed.
3. After the received data units equaling or exceeding the specified reception trigger number are stored in the FRDR register and the RDF flag is set to 1, a receive-data-full interrupt (RXI) request is generated when the RIE bit in the serial control register (SCR) is set to 1. When the ORER flag in the line status register (LSR) is set to 1 and the RIE or REIE bit in the SCR register is also set to 1, a break interrupt (BRI) request is generated.

Figure 7.4-16 shows an example of SCIFA receive operation in clock synchronous mode.

Note 1. For the corresponding interrupt number, see **4.6 Interrupt Controller**.

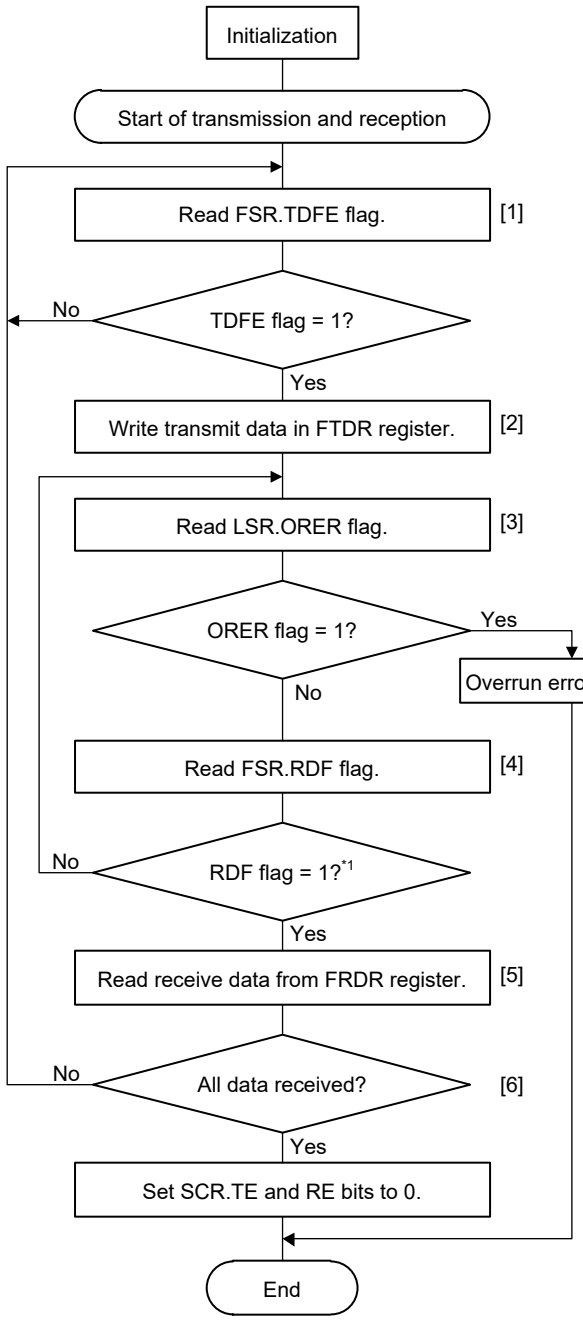


Figure 7.4-16 Example of SCIFA Receive Operation (when LSB-First Transfer is Selected)

Transmitting and Receiving Serial Data Simultaneously (in Clock Synchronous Mode)

Figure 7.4-17 shows a sample flowchart for transmitting and receiving serial data simultaneously in clock synchronous mode.

In simultaneous transmission/reception of serial data, number of receive data = number of transmit data = number of transmit data to be written to the FTDR register.

Follow the procedure given below for the simultaneous transmission/reception of serial data, after enabling the SCIFA for transmission/reception.

[1] Check the SCIFA status and write the transmit data:
Read the FSR register, confirm that the TDFE flag is set to 1, and then write the transmit data in the FTDR register.
A change of the TDFE flag from 0 to 1 can be known by a TXIF interrupt request.

[2] Serial transmission continuation procedure:
When transmit data is written to the FTDR register, the TDFE flag is automatically cleared to 0.

[3] Receive error handling:
When a receive error occurs, read the LSR.ORER flag and handles the error as specified, and then clear the ORER flag to 0. Reception cannot be restarted while the ORER flag is set to 1.
A change of the ORER flag from 0 to 1 can be known by a BRIF interrupt request.

[4] Check the SCIFA status and read the receive data:
Read the FSR register, confirm that the RDF flag is set to 1, and then read the receive data stored in the FRDR register.
A change of the RDF flag from 0 to 1 can be known by an RXIF interrupt request.

[5] Serial reception continuation procedure:
When receive data is read from the FRDR register, the RDF flag is automatically cleared to 0.

[6] Serial transmission/reception continuation procedure (supplementary):
To continue serial transmission/reception, read the FRDR register and clear the RDF flag to 0 before the FRDR register overflows and the ORER flag changes to 1. In addition, before the last bit of the last data written to the FTDR register is transmitted, write the data in the FTDR register and clear the TDFE flag to 0.
When writing data to the FTDR register or reading data from the FRDR register, the TDFE flag and RDF flag are automatically cleared to 0.

Note: When switching the operation from transmission or reception to the simultaneous transmission and reception, clear the TE and RE bits to 0 and then simultaneously set these bits to 1.

Note 1. The number of all the received data units should be an integral multiple of the receive FIFO threshold. If not, process returns to Step [1] and enters an infinite loop. In this case, it is necessary to set the timeout processing using a timer.

Figure 7.4-17 Sample Flowchart for Simultaneous Transmitting/Receiving Serial Data in Clock Synchronous Mode

7.4.4 Bit Rate Modulation

Using the bit rate modulation, the bit rate can be corrected by skipping the specified number of clock pulses input to the baud rate generator. To correct the bit rate, only the number of clock pulses specified in the MDDR register are enabled among 256 internal clock pulses specified by the CKS1 and CKS0 bits in the SMR register in a way that forms average intervals.

Figure 7.4-18 shows an example where P0φ is selected by the CKS[1:0] bits in SMR and BRR and MDDR are set to 0 and 160, respectively, in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). Note that skipping an internal clock causes bias and expansion or contraction is generated in the pulse width of the base clock.

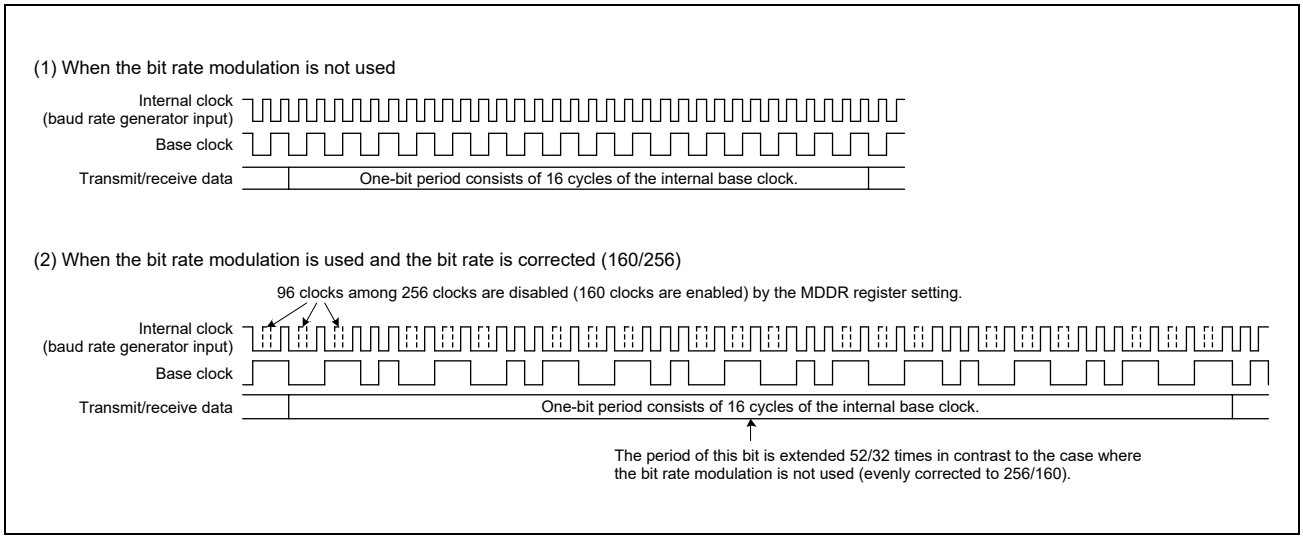

Figure 7.4-18 Example of Internal Base Clock when Bit Modulation is Used

7.4.5 Interrupt Sources

The SCIFA has six interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive-FIFO-data-full (RXI), break (BRI), transmit-end (TEI), receive-data-ready (DRI). The TEI, DRI, ERI, and BRI interrupts share the same vector number.

Table 7.4-19 shows the interrupt sources and priority. The interrupt sources can be enabled or disabled using the TIE, RIE, REIE, TEIE bits in the SCR register and are separately input to the interrupt controller.

When the quantity of transmit data written in the FTDR register as a result of transmission is equal to or less than the specified transmission trigger number, the TDFE flag in the serial status register (FSR) is set to 1 and a TXI interrupt request is generated.

When the data units equaling or exceeding the specified transmission trigger number are stored in the receive FIFO register (FRDR) and the RDF flag in the FSR register is set to 1, a receive data full interrupt (RXI) request is generated. When the quantity of received data in the FRDR register is below the specified reception trigger number and no next data has been received yet even after the period of 15 ETUs elapsed*1 from the last stop bit, the DR flag in the FSR register is set to 1 and a receive data ready interrupt (DRI) request is generated. In clock synchronous mode, a DRI interrupt request is not generated.

When the BRK flag in the FSR register or the ORER flag in the LSR register is set to 1, a BRI interrupt request is issued. When the ER flag in the FSR register is set to 1, an ERI interrupt request is issued.

When TEND flag in the FSR register is set to 1, a TEI interrupt request is issued.

When the RIE bit is cleared to 0 and the REIE bit in the SCR register is set to 1, an ERI and a BRI interrupt requests are issued but an RXI interrupt request is not.

An TXI interrupt indicates that transmit data can be written and an RXI interrupt indicates that receive data is stored in the FRDR register.

Note 1. It is equivalent to 1 and half frames of 8-bit format with one stop bit (ETU: Element Time Unit).

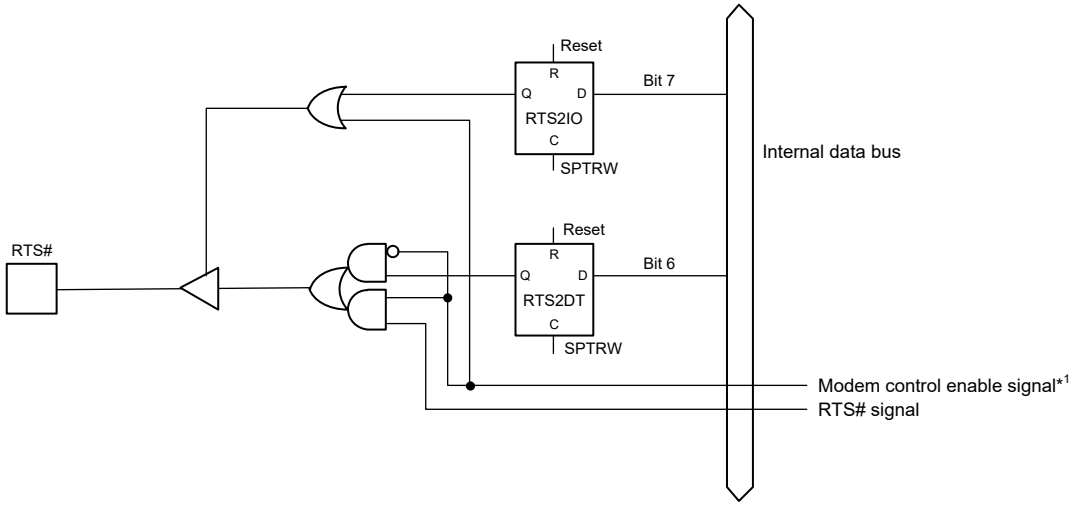

Table 7.4-19 SCIFA Interrupt Sources

Name	Level/Edge	Interrupt Source	Interrupt Enable Bit	DMAC Activation	Priority
BRI	Level	Interrupt caused by break (BRK) or overrun (ORER).	RIE or REIE	Impossible	High
ERI	Level	Interrupt caused by framing or parity (ER).	RIE or REIE	Impossible	↕
RXI	Level	Interrupt caused by receive FIFO data full (RDF).	RIE	Possible	
TXI	Level	Interrupt caused by transmit FIFO data empty (TDFE).	TIE	Possible	
TEI	Level	Interrupt caused by transmit end (TEND).	TEIE	Impossible	
DRI	Level	Interrupt caused by receive data ready (DR).	RIE	Impossible	Low

Note: The TEI and DRI interrupts share the same vector number.
The ERI and BRI interrupts share the same vector number.
If CPU processing is used, clear the flag after the block transfer. If the DMAC is activated, access to the flags is prohibited.

7.4.6 Serial Port Register (SPTR) and SCIFA-Related Pins

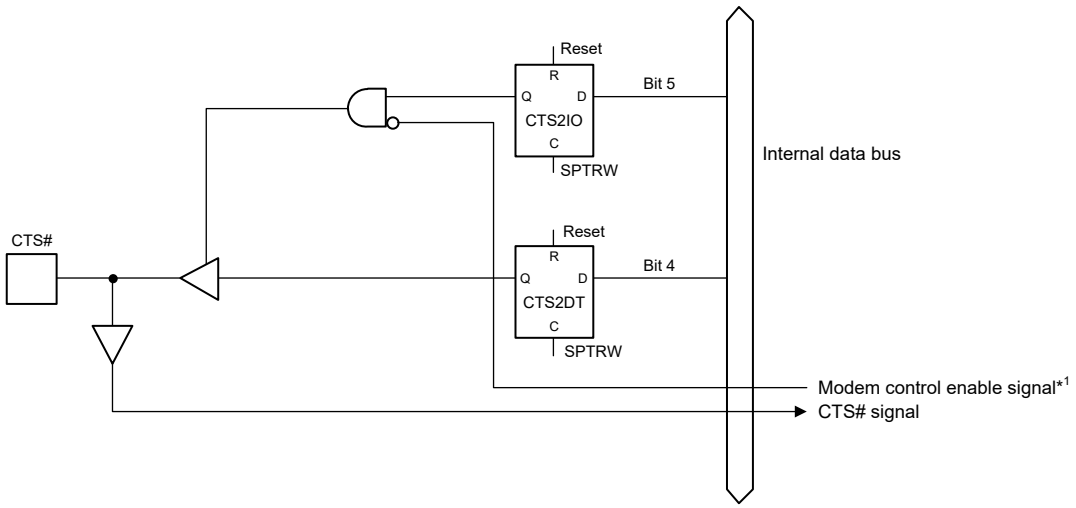

Figure 7.4-19 to **Figure 7.4-22** show the relationships between the SPTR register and the SCIFA-related pins.

Note: SPTRW: SPTR write

Note 1. These signals allow the RTS# pin to enter the modem control state with the MCE bits in FCR.

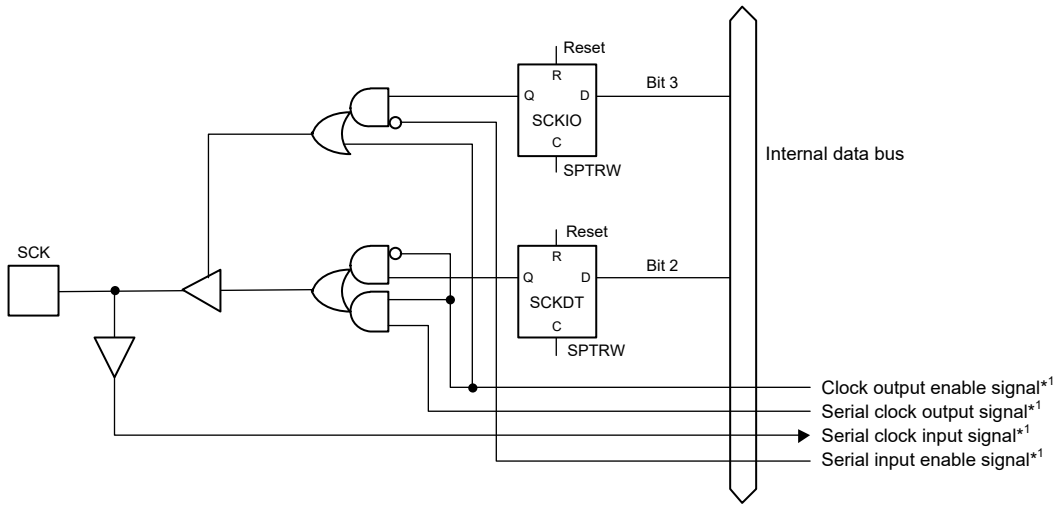

Figure 7.4-19 RTS2IO Bit and RTS2DT Bit in the SPTR Register, and RTS# Pin

Note: SPTRW: SPTR write

Note 1. These signals allow the CTS# pin to enter the modem control state with the MCE bits in FCR.

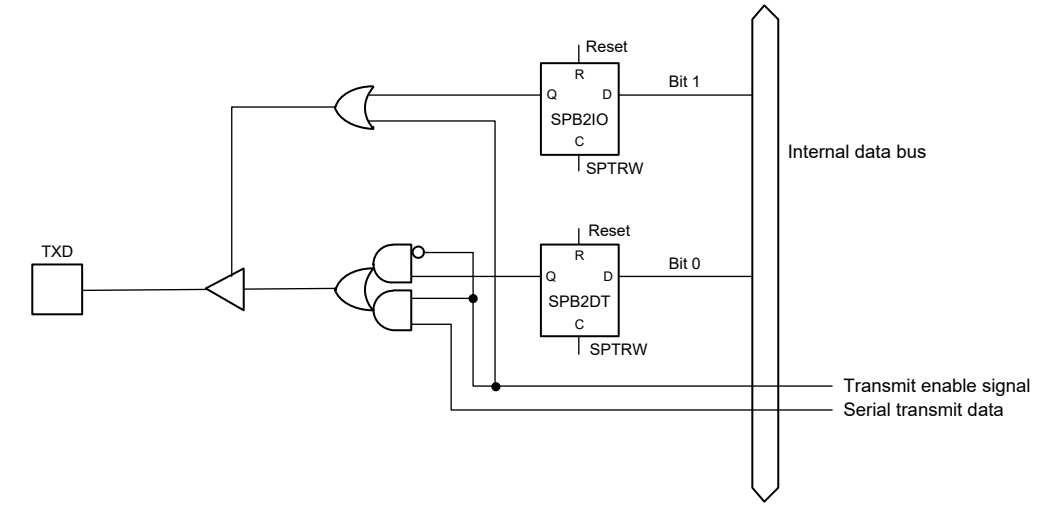

Figure 7.4-20 CTS2IO Bit and CTS2DT Bit in the SPTR Register, and CTS# Pin

Note: SPTRW: SPTR write

Note 1. These signals control the SCK pin according to the settings of the CM bit in SMR and CKE[1:0] bits in SCR.

Figure 7.4-21 SCKIO Bit and SCKDT Bit in the SPTR Register, and SCK Pin

Note: SPTRW: SPTR write

Figure 7.4-22 SPB2IO Bit and SPB2DT Bit in the SPTR Register, and TXD Pin

7.4.7 Noise Cancellation

Figure 7.4-23 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits and a match detection circuit. When the input signals of the noise filter and the output signals of the two-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. (When the levels sampled on three consecutive cycles of the sampling clock of the noise filter match, the signal is considered valid. If three consecutive sampled values do not match, the signal is considered to be noise rather than a received signal).

In asynchronous mode, the noise cancellation can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn pin is taken in the flip-flop circuit of the noise filter on the base clock (the clock with a frequency 16 or 8 times the transfer rate*[1]).

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.RE is set to 0 during input of the base clock, the noise filter outputs 0 as the internal RxDn signal. The internal match detector continues operating even while operations for reception are stopped, and the result from the last time previous consecutive samples matched is output at the same time as operations for reception are resumed.

Note 1. A frequency 16 times bit rate when the SEMR.ABCS0 bit and the SEMR.BGDM bit are both 0, and a frequency 8 times bit rate when either the SEMR.ABCS0 bit or the SEMR.BGDM bit is 1.

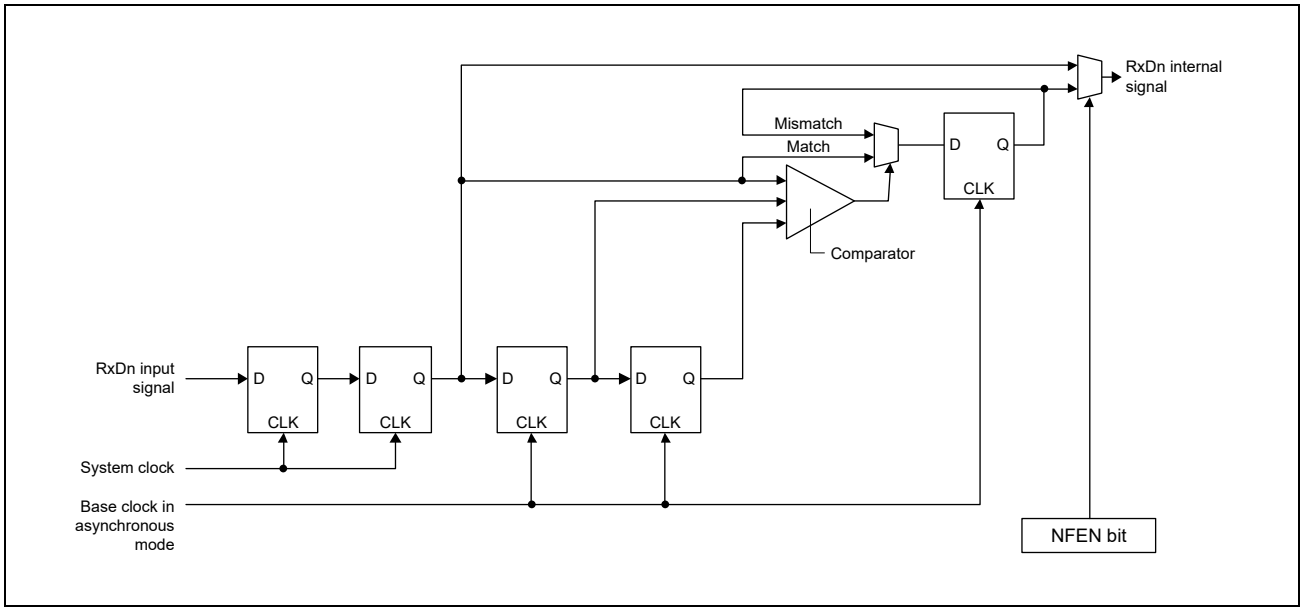

Figure 7.4-23 Block Diagram of Digital Noise Filter Circuit

7.4.8 Usage Notes

The following is the notes on using the SCIFA.

7.4.8.1 FTDR Register Writing and TDFE Flag

The TDFE flag in the serial status register (FSR) is set when the number of transmit data bytes written in the transmit FIFO data register (FTDR) has fallen below the transmission trigger number set by bits TTRG[1:0] in the FIFO control register (FCR) or bits TFTC[4:0] in the FIFO trigger control register (FTCR). After the TDFE flag is set, transmit data up to the number of empty bytes in the FTDR register can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in the FTDR register is equal to or less than the specified transmission trigger number, the TDFE flag will be set to 1 again even after being read as 1 and cleared to 0.

The number of transmit data bytes in the FTDR register can be checked by the 8 higher-order bits of the FIFO data count register (FDR).

7.4.8.2 FRDR Register Reading and RDF Flag

The RDF flag in the serial status register (FSR) is set when the number of receive data bytes in the receive FIFO data register (FRDR) has become equal to or greater than the reception trigger number set by bits RTRG[1:0] in the FIFO control register (FCR) or bits RFTC[4:0] in the FIFO trigger control register (FTCR). After the RDF flag is set, receive data equivalent to the trigger number can be read from the FRDR register, allowing efficient continuous reception.

However, if the number of data bytes in the FRDR register exceeds the reception trigger number, the RDF flag will be set to 1 again even after being read as 1 and cleared to 0.

The number of receive data bytes in the FRDR register can be checked by the 8 lower-order bits of the FIFO data count register (FDR).

7.4.8.3 Break Detection and Processing

When a framing error (FER) is detected, a break signal can be detected by reading the RXD pin value directly. In a break, the input from the RXD pin becomes all low. Therefore, the FER flag in the serial status register (FSR) is set to 1 and the parity error flag (PER) may also be set to 1.

Upon detection of a break signal, the SCIFA stops the received data transfer to the FRDR register but continues the receive operation.

7.4.8.4 Writing to the SPTR Register

b6, b4, b2, and b0 of the SPTR register respectively indicate the input status of their corresponding pins. (See the description of each bit of **7.4.2.12 Serial Port Register (SPTR)** for details.)

Writings to these bits in 1-bit unit are handled as read-modify-write, which may lead to undesired values to be written. To avoid this, when modifying the SPB2DT or SPB2IO bit, for example, write the other bit (the bit used in combination) at the same time.

7.4.8.5 Break Signal Transmission

The output signal from the TXD pin is determined by the SPB2IO bit and the SPB2DT bit in the serial port register (SPTR). The break signal can be sent by using these bits.

The TXD pin does not function as a transmit data output pin during the period from when the SCIFA is initialized to when the TE bit in the SCR register is set to 1 (transmission possible). The TXD pin status during this period is replaced by the SPB2DT bit value. Therefore, the SPB2IO and SPB2DT bits in the SPTR register must have been set to 1 (high output) at first (mark (high) status).

To transmit the break signal during serial transmission, set the SPB2IO bit in the SPTR register to 1, clear the SPB2DT bit to 0 (specify a low level), and then clear the TE bit in the SCR register to 0 (transmission stop). Clearing the TE bit to 0 initializes the transmitter regardless of the current transmission status, and outputs a low level from the TXD pin.

7.4.8.6 Receive Data Sampling Timing and Receive Margin in Asynchronous Mode

The SCIFA operates on a base clock with a frequency 16 times the transfer rate*[1]. In reception, the SCIFA internally latches the received data at the rising edge of the eighth base clock pulse*[1]. The timing is shown in **Figure 7.4-24**.

Note 1. This is an example when the SEMR.ABCS0 bit is 0. When the ABCS0 bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

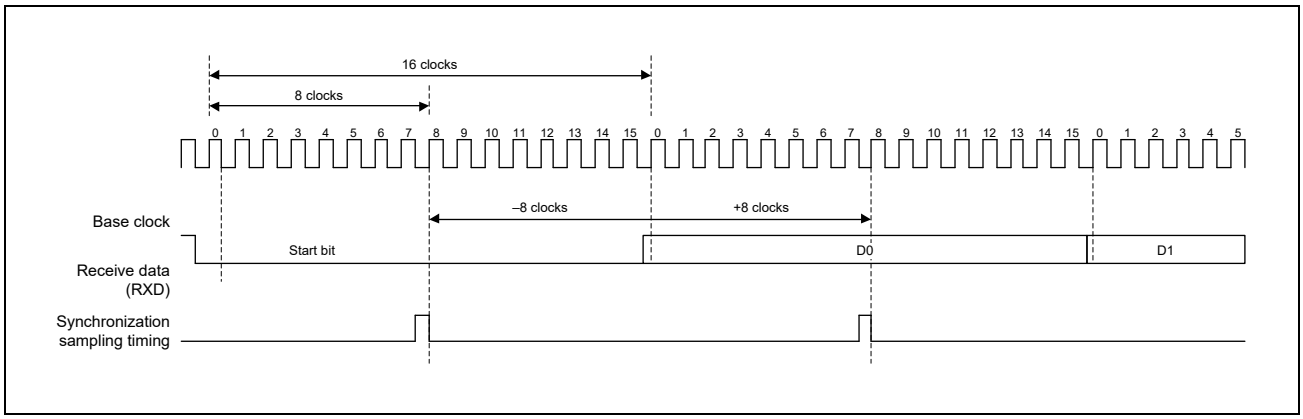

Figure 7.4-24 Receive Data Sampling Timing in Asynchronous Mode

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

[Equation 1]

$$M = \left\{0.5 - \frac{1}{2N} - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right\} \times 100[\%]$$

Where: M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

[Equation 2]

When D = 0.5 and F = 0:

$$M = \left(0.5 - \frac{1}{(2 \times 16)}\right) \times 100\% = 46.875\%$$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

7.4.8.7 Note on FER Flag and PER Flag in Serial Status Register (FSR)

The FER flag and PER flag in the serial status register (FSR) are status flags that apply to next entry to be read from the receive FIFO data register (FRDR). After the CPU or DMAC reads the receive FIFO data register, the flags of framing errors and parity errors in the receive data will be cleared. To check the received data for the states of framing errors and parity errors, only read the receive FIFO data register after reading the serial status register.

7.4.8.8 Notes on External Clock Input in Clock Synchronous Mode

Before setting the TE and RE bits in the serial control register (SCR) to 1, wait for four or more cycles of the peripheral operating clock after the external clock (SCK) is changed from 0 (low) to 1 (high). To input the external clock (SCK) (to start communication), wait for one or more cycles of the external clock after the TE and RE bits in the SCR register are set to 1.

7.4.8.9 Module Standby Mode Setting

SCIFA operation can be disabled or enabled using the standby control register. As the initial setting, the SCIFA operation is halted. Register access is enabled by clearing module standby mode. For details, refer to **4.5 Low Power Management**.

7.4.8.10 Notes on Operation for Reception when an Internal Clock is Selected in Clock Synchronous Mode

When an internal clock is selected as the clock for reception in clock-synchronous mode, if the number of data stored through the receive FIFO data register (FRDR) becomes equal to or greater than the specified reception trigger number, the RDF flag is set, the RXI interrupt request is generated and, at the same time, output of the synchronizing clock and reception of serial data are stopped. Once the number of data are again less than the specified reception trigger number, output of the synchronizing clock and the reception of serial data are restarted. In addition, if an internal clock is selected for reception in clock synchronous mode, the ORER flag is not set to 1 since no overrun occurs. Accordingly, overruns (indicated by the ORER flag) cannot be used as a BRI interrupt source.

SECTION 7 LOW-SPEED INTERFACE

7.5 Serial Peripheral Interface (RSPI)

7.5.1 Overview

The RSPI (hereafter SPI) supports serial communications for transmit-receive, transmit only, and receive only. The SPI is provided with a function for high-speed serial communication with multiple processors and peripheral devices.

7.5.1.1 Features

Table 7.5-1 lists the specifications of the SPI, and **Figure 7.5-1** shows a block diagram of the SPI.

Table 7.5-1 SPI Specifications (1/3)

Item	Description
Number of channels	3 channels
Transfer functions	• SPI serial communication (4-wire) and clock synchronous (3-wire) serial communication are possible by using the MOSI (Master Out Slave In), MISO (Master In Slave Out), SSL (Slave Select), and RSPCK (SPI Clock) signals. • Transmit-only operation is available • Receive-only operation is available • Serial communication is possible in master mode and slave mode • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB first or LSB first selectable. • Transfer bit length selectable from 4 to 32 bits • 32 bit × 16 stage FIFO transmit and receive buffers • Up to four frames transferable in one round of transmission or reception (each frame consisting of up to 32 bits) • Byte swap operating function • Transmit/receive data inversion
Bit rate	• In master mode, the on-chip baud rate generator divides the RSPI_n_TCLK to generate RSPCK. A division ratio of 2 to 4096 is settable. • In slave mode, an external input clock is used as a serial clock. The maximum frequency = RSPI_n_TCLK/2 (High width: 1 RSPI_n_TCLK cycle, low width: 1 RSPI_n_TCLK cycle) *Note*: RSPIn_TCLK/4 when RSPIn_TCLK is over 100 MHz.
Buffer configuration	• Transmit buffer and receive buffer are configured independently.
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection • Parity error detection

Table 7.5-1 SPI Specifications (2/3)

Item	Description
SSL control function	**[Motorola SPI mode]** • Four SSL pins (SSLn0 to SSLn3) each channel • In single master mode, SSLn0 to SSLn3 pins are output. • In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused • In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Configurable delay between frames in burst transfer • Function for changing SSL polarity **[TI SSP mode]** • Four SSL pins (SSL0 to SSL3) each channel • In single master mode, SSLn0 to SSLn3 pins are output. • In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused • In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused • Controllable delay from SSL output assertion to SSL output negation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to Output disable (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Configurable delay between frames in burst transfer • Function for changing SSL polarity
Communication Protocol	• Motorola SPI • TI SSP (Synchronous Serial Protocol)
Synchronization bypass function	• Synchronization circuit can be bypassed using bus clock (RSCI_n_PCLK) as operation clock (RSCI_n_TCLK)
Control in master transfer	**[Motorola SPI mode]** • Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay, next-access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function **[TI SSP mode]** • Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay (Output disable delay), next- access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function
Interrupt sources	• Maskable Interrupt sources SPI receive buffer full / Receive data ready interrupt SPI transmit buffer empty interrupt SPI communication end interrupt SPI error interrupt (mode fault, overrun, parity error, receive data ready) SPI idle interrupt (SPI idle)

Table 7.5-1 SPI Specifications (3/3)

Item	Description
Others	• Switching between CMOS output and open-drain output • SPI disable (initialization) function • Loopback mode function
Module-stop function	Module-stop state can be set to reduce power consumption*1

Note 1. Module stop condition: It depends on the setting higher than this module. This module is not reset, and the clock stops on module stop condition. It contributes to low power consumption, because the clock stops.

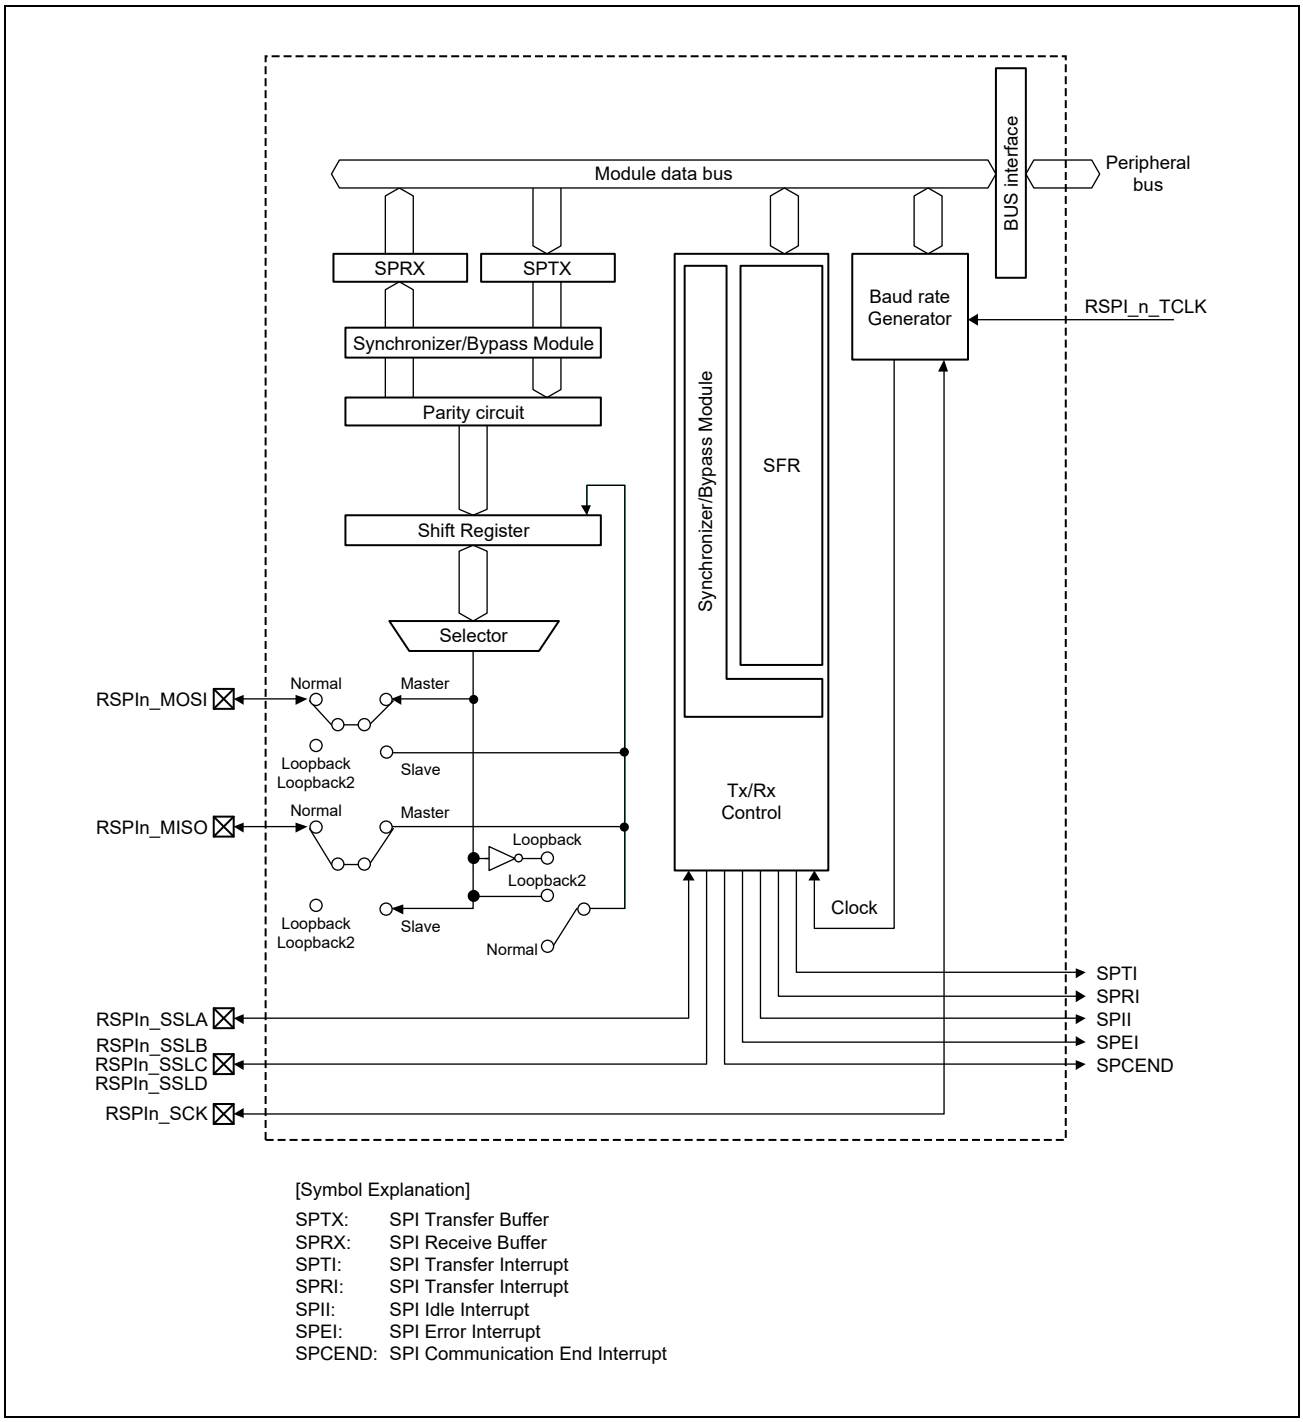

Figure 7.5-1 SPI Block Diagram

The SPI automatically switches the SSL0 pin input and output directions. The SSL0 pin is switched to output when single master is set, and it is switched to input when multi-master or slave is set. Furthermore, the SPI automatically switches the input and output directions of pins RSPCK, MOSI, MISO, SSL1 to SSL3 according to the master/slave setting and SPI operation (4-wire)/clock synchronous operation (3-wire) SSL0 input level. (See **7.5.3.2 SPI Pin Control**.)

Table 7.5-2 lists the I/O pins used in the SPI.

Table 7.5-2 SPI Pin Configuration

Channel	Pin Name	Signal Name in This Section	Input/Output	Functional Description
0 to 2	RSPIn_MOSI	MOSI	I/O	Master transmit data I/O
	RSPIn_MISO	MISO	I/O	Slave transmit data I/O
	RSPIn_SCK	RSPCK	I/O	Clock I/O
	RSPIn_SSL_A	SSL0	I/O	Slave selection signal I/O
	RSPIn_SSL_B	SSL1	Output	Slave selection signal output
	RSPIn_SSL_C	SSL2	Output	Slave selection signal output
	RSPIn_SSL_D	SSL3	Output	Slave selection signal output

Note: n = 0 to 2

7.5.2 Registers

The base addresses for the respective channels are as follows.

Table 7.5-3 Register Base Addresses

Base Register Name	Channel	Base Address
<RSPI0_base>	RSPI0	0_100B_0000h (500B_0000h*1, 400B_0000h*2)
<RSPI1_base>	RSPI1	0_100E_9000h (500E_9000h*1, 400E_9000h*2)
<RSPI2_base>	RSPI2	0_100E_A000h (500E_A000h*1, 400E_A000h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.5.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
SPI Data Register	RSPIm_SPDR/SPDR_HA/SPDR_BY	0000_0000h	0000h	8, 16, 32*1
SPI Clock Delay Register	RSPIm_SPCKD	00h	0004h	8
SPI Slave Select Negation Delay Register	RSPIm_SSLND	00h	0005h	8
SPI Next-Access Delay Register	RSPIm_SPND	00h	0006h	8
SPI Clock Digital Control Register for Master Receive	RSPIm_MRCKD	00h	0007h	8
SPI Control Register	RSPIm_SPCR	0000_0000h	0008h	8, 16, 32*1
SPI Control Register for Master Receive only	RSPIm_SPCRRM	00h	000Ch	8
SPI Control Register for Received Data Ready Detection	RSPIm_SPDRCR	00h	000Dh	8
SPI Pin Control Register	RSPIm_SPPCR	00h	000Eh	8
SPI Control Register 2	RSPIm_SPCR2	00h	000Fh	8
SPI Slave Select Polarity Register	RSPIm_SSLP	00h	0010h	8
SPI Bit Rate Register	RSPIm_SPBR	FFh	0011h	8
Reserve	-	-	0012h	-
SPI Sequence Control Register	RSPIm_SPSCR	00h	0013h	8
SPI Command Register 0	RSPIm_SPCMD0	0007_0000h	0014h	8, 16, 32*1
SPI Command Register 1	RSPIm_SPCMD1	0007_0000h	0018h	8, 16, 32*1
SPI Command Register 2	RSPIm_SPCMD2	0007_0000h	001Ch	8, 16, 32*1
SPI Command Register 3	RSPIm_SPCMD3	0007_0000h	0020h	8, 16, 32*1
SPI Command Register 4	RSPIm_SPCMD4	0007_0000h	0024h	8, 16, 32*1
SPI Command Register 5	RSPIm_SPCMD5	0007_0000h	0028h	8, 16, 32*1
SPI Command Register 6	RSPIm_SPCMD6	0007_0000h	002Ch	8, 16, 32*1
SPI Command Register 7	RSPIm_SPCMD7	0007_0000h	0030h	8, 16, 32*1
Reserve	-	-	0034h to 003Fh	-
SPI Data Control Register	RSPIm_SPDCR	0000h	0040h	8, 16
Reserve	-	-	0042h to 0043h	-
SPI Data Control Register 2	RSPIm_SPDCR2	0000h	0044h	8, 16
Reserve	-	-	0046h to 0050h	-
SPI Sequence Status Register	RSPIm_SPSSR	00h	0051h	8
SPI Status Register	RSPIm_SPSR	2000h	0052h	8, 16
Reserve	-	-	0054h to 0057h	-
SPI Transfer FIFO Status Register	RSPIm_SPTFSR	10h	0058h	8
Reserve	-	-	0059h to 005Bh	-
SPI Receive FIFO Status Register	RSPIm_SPRFSR	00h	005Ch	8
Reserve	-	-	005Dh to 005Fh	-
SPI Polling Register	RSPIm_SPPSR	0000_0000h	0060h	8, 16, 32*1
Reserve	-	-	0064h to 0069h	-
SPI Status Clear Register	RSPIm_SPSRC	0000_0000h	006Ah	8, 16
SPI FIFO Clear Register	RSPIm_SPFCR	0000_0000h	006Ch	8

Note 1. The read access size is fixed at 32 bits.

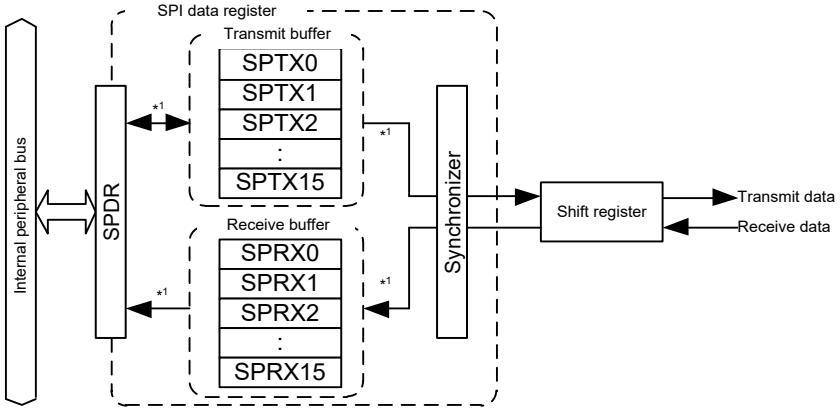
7.5.2.2 Register Description

The prefix (RSPIm_) of the register names is omitted in this and subsequent sections.

7.5.2.2.1 SPI Data Register (RSPIm_SPDR/SPDR_HA/SPDR_BY)

Access Size : 8, 16, 32 bits
Address : <RSPIm_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPD[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPD[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SPD[31:0]	0h	RW	The SPI data register (SPDR) is used to store SPI's transmit data and receive data. Transmit buffers and receive buffers independently function.

Note: The read access size is fixed at 32 bits.

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI.

Figure 7.5-2 shows the structure of SPDR.

Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 7.5-2 Structure of SPDR

32 bit × 16 stage transmit FIFO and 32 bit × 16 receive FIFO are provided. These 32 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 15) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

Bus Interface

The SPI data register has 32 bit × 16 stage transmit FIFO and 32 bit × 16 receive FIFO (32 bytes in total). These 128 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

a) Write

A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

Figure 7.5-3 shows the configuration of the bus interface with the transmission buffer in the case of writing to SPDR.

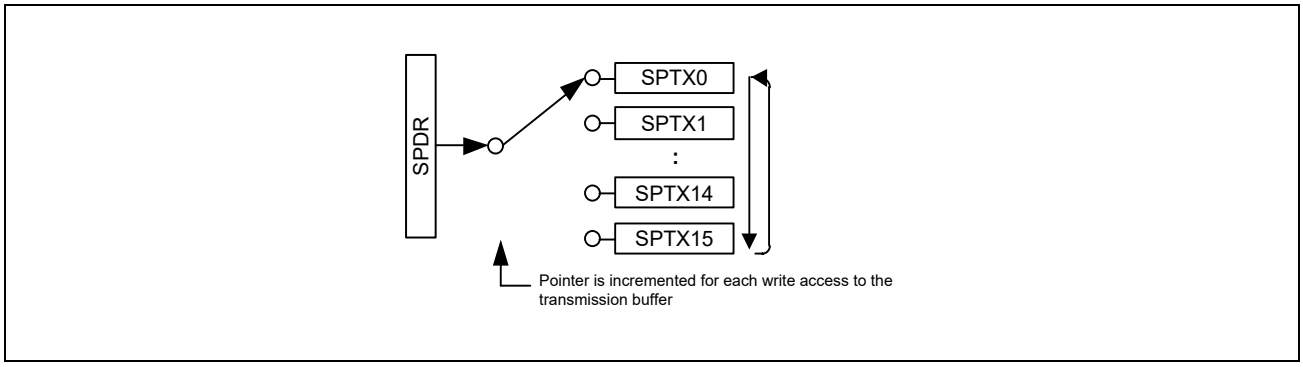


Figure 7.5-3 Structure of SPDR (Write)

The transmit buffer (SPTX0 to SPTX3) switching order:

SPTX0→SPTX1→SPTX2→SPTX3→…→SPTX15→SPTX0→SPTX1→…

When writing transmit data to transmit buffers (SPTXn), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of SPI data control register 2 (SPDCR2.TTRG[1:0]) while an SPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1b). Writing to the transmit buffer (SPTXn, n = 0 to 15) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

b) Read

Values can be read from receive buffers (SPRXn, n = 0 to 15) or transmit buffers (SPTXn, n = 0 to 15) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the SPI receive data or transmit data select bit (SPDCR.SPRDTD).

The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer.

The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

Figure 7.5-4 shows the configuration of the bus interface with the receive and transmission buffers in the case of reading from SPDR.

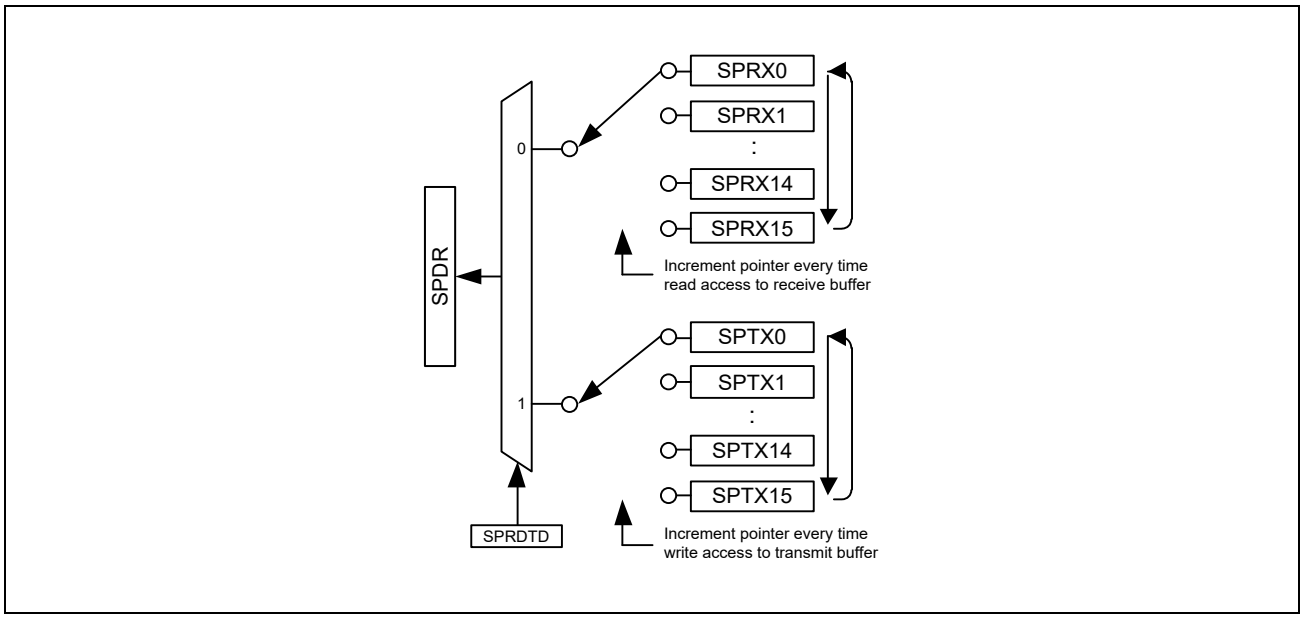

Figure 7.5-4 Structure of SPDR (Read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer.

The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

7.5.2.2.2 SPI Clock Delay Register (RSPIm_SPCKD)

Access Size : 8 bits
Address : <RSPIm_base> + 0004h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SCKDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SCKDL[2:0]	0h	RW	RSPCK Delay Setting 000b: 1 RSPCK 001b: 2 RSPCK 010b: 3 RSPCK 011b: 4 RSPCK 100b: 5 RSPCK 101b: 6 RSPCK 110b: 7 RSPCK 111b: 8 RSPCK

[In the Motorola-SPI case]

The SPCKD register is used to set the period (RSPCK delay) from the start of assertion of the SSL signal to the RSPCK oscillation while SPCMD.SCKDEN = 1b. If SPCKD is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SPCKD register is used to set the period (RSPCK delay) from the start of assertion of the SSL signal to the RSPCK oscillation while SPCMD.SCKDEN = 1b. Also, it is used to set the period until the SSL signal is negated. If SPCKD is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

SCKDL[2:0] bits (RSPCK Delay Setting)

These bits are used to set the RSPCK delay value when SPCMD.SCKDEN = 1b.

To use the SPI in slave mode, set SCKDL[2:0] bits to 0b.

7.5.2.2.3 SPI Slave Select Negation Delay Register (RSPIm_SSLND)

Access Size : 8 bits
Address : <RSPIm_base> + 0005h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SLNDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SLNDL[2:0]	0h	RW	SSL Negation Delay Bits This is the synchronization delay for replacing the RSPCK input with RSPI_n_TCLK. RSPCK Delay Setting 000b: 1 RSPCK [Master mode] 1 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 001b: 2 RSPCK [Master mode] 2 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 010b: 3 RSPCK [Master mode] 3 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 011b: 4 RSPCK [Master mode] 4 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 100b: 5 RSPCK [Master mode] 5 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 101b: 6 RSPCK [Master mode] 6 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 110b: 7 RSPCK [Master mode] 7 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 111b: 8 RSPCK [Master mode] 8 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode]

[In the Motorola-SPI case]

The SSLND register is used to set the period (SSL negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while SPCMD.SCKDEN = 1b. If SSLND is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SSLND register is used to set the period (Output disable delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the Output enable signal while SPCMD.SCKDEN = 1b. Also, that is used to set the period from when the SPI in slave mode detects the last RSPCK edge of serial transfer to when the Output enable signal is negated. If SSLND is modified while the SPE bit in SPCR.SPE = 1b, subsequent operation is not guaranteed.

SLNDL[2:0] bits (SSL Negation Delay Bits)

[In the Motorola-SPI case]

These bits are used to set the SSL negation delay value when SPCMD.SLNDEN = 1b.
To use the SPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 0b.

[In the TI-SSP case]

These bits are used to set the Output disable delay value when SPCMD.SLNDEN = 1b.

7.5.2.2.4 SPI Next-Access Delay Register (RSPIm_SPND)

The SPND register is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while SPCMD.SCKDEN = 1b. If SPND is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 0006h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SPNDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SPNDL[2:0]	0h	RW	SPI Next-Access Delay Bits RSPCK Delay Setting 000b: 1 RSPCK + 5 RSPI_n_TCLK 001b: 2 RSPCK + 5 RSPI_n_TCLK 010b: 3 RSPCK + 5 RSPI_n_TCLK 011b: 4 RSPCK + 5 RSPI_n_TCLK 100b: 5 RSPCK + 5 RSPI_n_TCLK 101b: 6 RSPCK+ 5 RSPI_n_TCLK 110b: 7 RSPCK + 5 RSPI_n_TCLK 111b: 8 RSPCK + 5 RSPI_n_TCLK

SPNDL[2:0] bits (SPI Next-Access Delay Bits)

These bits are used to set the next-access delay value when SPCMD.SCKDEN = 1b. To use the SPI in slave mode, set SPNDL[2:0] bits to 0b.

7.5.2.2.5 SPI Clock Digital Control Register for Master Receive (RSPIm_MRCKD)

The MRCKD register is a register for adjusting the reception sampling timing in master mode. If the ARST[2:0] bits are rewritten while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 0007h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	ARST[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	ARST[2:0]	0h	RW	Receive Sampling Timing Adjustment Bits The sampling of the serial data (MISO) input in master mode can be adjusted by delaying 0 to 7 RSPI_n_TCLK from the center of the bit. 000b: 0 RSPI_n_TCLK delay 001b: 1 RSPI_n_TCLK delay 010b: 2 RSPI_n_TCLK delay 011b: 3 RSPI_n_TCLK delay 100b: 4 RSPI_n_TCLK delay 101b: 5 RSPI_n_TCLK delay 110b: 6 RSPI_n_TCLK delay 111b: 7 RSPI_n_TCLK delay

ARST[2:0] bits (Receive Sampling Timing Adjustment Bits)

These bits are used to select the amount of reception sampling timing adjustment. The sampling timing can be adjusted by delaying 0 to 7 RSPI_n_TCLK from the center of the bit.

Delay setting exceeding the dividing ratio is prohibited.

This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0b, when MRCLK is selected (SPCR.SPSCKSEL = 1b), and SPPCR.SPLP2 = 0b) and in master mode. For details, see SPSCKSEL bit of **7.5.2.2.6 SPI Control Register (RSPIm_SPCR)**.

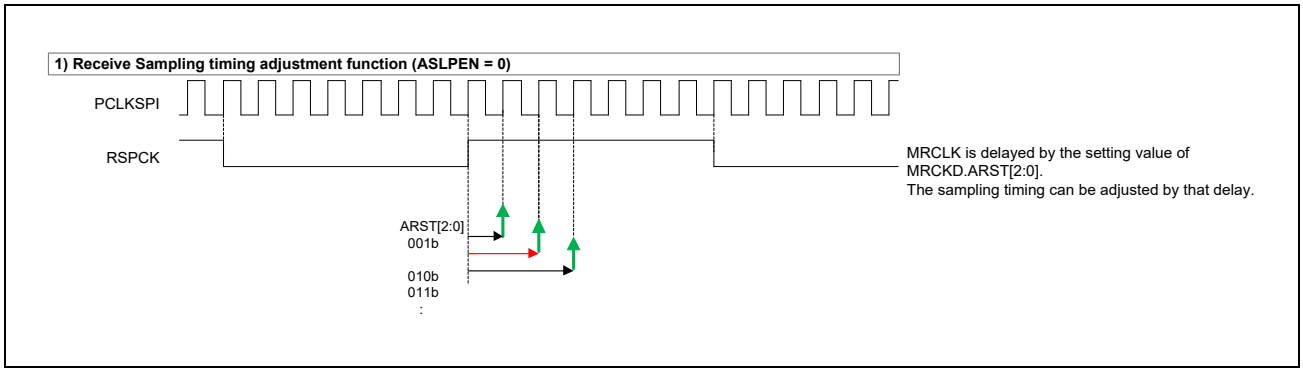

Figure 7.5-5 Description about Receive Sampling Timing Adjustment Function

7.5.2.2.6 SPI Control Register (RSPIm_SPCR)

The SPCR register is used to set operating mode of the SPI. If the set MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE, SPSCKSEL, and BPEN bit value is modified while SPCR.SPE = 1b, subsequent operation is not guaranteed.

Access Size : 8, 16, 32 bits
Address : <RSPIm_base> + 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9	SPOE	0h	RW	Parity Mode 0b: Even parity is used for transmission and reception. 1b: Odd parity is used for transmission and reception.
8	SPPE	0h	RW	Parity Enable 0b: A parity bit is not added to transmit data. Received-data parity check is not performed. 1b: A parity bit is added to transmit data. Received-data parity check is performed.
7	SPSCKSEL	0h	RW	SPI Master Receive Clock Select 0b: MRIOCLK (Adjust with Analog Delay (SPCR2.SPSCKDL)) 1b: MRCLK (Adjust with Digital Delay (MRCKD.ARST))
6 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	SPE	0h	RW	SPI Function Enable 0b: SPI function is disabled. 1b: SPI function is enabled.

Note: The read access size is fixed at 32 bits.

SPE bit (SPI Function Enable)

The SPE bit is used to enable or disable SPI functions. Setting this bit to 1b enables SPI functions. When SPSR.MODF = 1b, the SPCR.SPE bit is cleared to 0b and the SPCR.SPE bit cannot be set to 1b until the MODF flag is cleared to 0b. (See **7.5.3.10 Error Detection**.) Setting the SPE bit to 0b disables SPI functions and initializes a part of module functions. (See **7.5.3.12 SPI Initialization**.)

SPSCKSEL bit (SPI Master Receive Clock Select)

The SPSCKSEL bit selects the clock used to sample the received data in master mode. By setting this bit, the sampling timing of the MISO can be adjusted. This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0b and SPPCR.SPLP2 = 0b) and in master mode.

Figure 7.5-6 shows a Master Receive Clock Delay configuration. By selecting this bit, you can select MRIOCLK (adjust with analog delay (SPCR2.SPSCKDL)) or MRCLK (adjust with digital delay (MRCKD.ARST)).

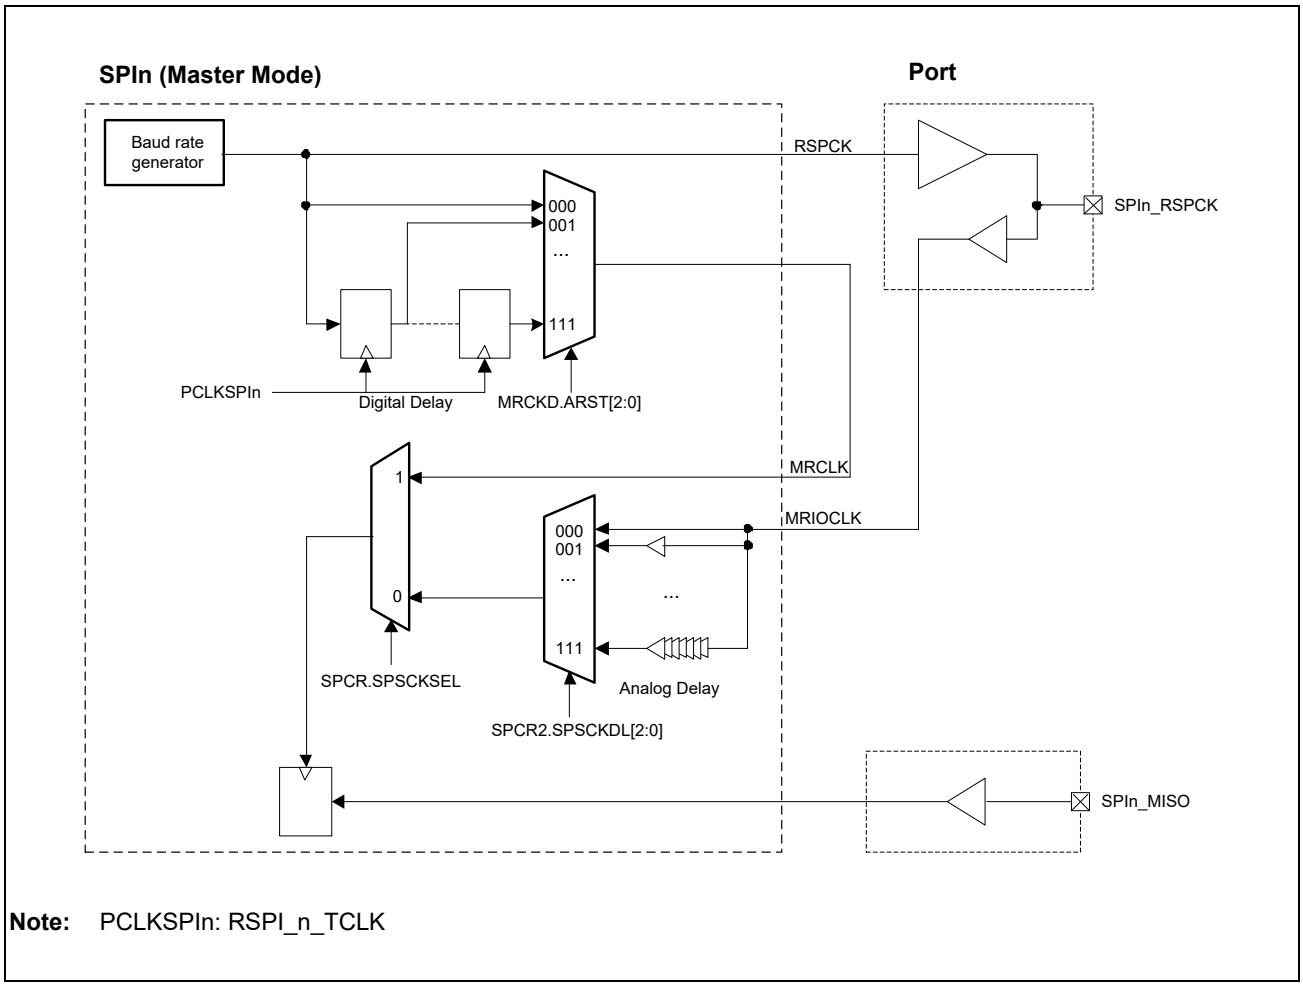

Figure 7.5-6 Master Receive Clock Delay Configuration (Master Mode)

SPPE bit (Parity Enable)

The SPPE bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

The SPOE bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPCR.SPPE is set to 1b.

PTE bit (Parity Self-Diagnosis Enable)

The PTE bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see **7.5.3.10.1 Overrun error**.

BFDS bit (Between Burst Transfer Frames Delay Select)

The BFDS bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1b) for frames with the SPCMDm.SSLKP bit set to 1b.

This bit should be set to 0b in slave mode. The usage of SSL delay control between transfer frames is shown as below.

For details, see **(4) Burst transfer** in **7.5.3.13.2 Slave mode operation**.

(1) Non-burst transmits

(2) Burst transmit with delay between frames
(2-1) From the 1st frame to the last previous frame
(2-2) The last frame

(3) Burst transmit with no delay between frames
(3-1) From the 1st frame to the last previous frame
(3-2) The last frame

Table 7.5-4 Usage of SSL Delay Control between Transfer Frames (Master Mode)

No.	RSPIm_SPCMDn SSLKP Bit	RSPIm_SPCR BFDS Bit	SSL Delay Control Register*1 (RSPCK clock delay, SSL negation delay, next access delay)
(1)	0b	0b	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay, and next access delay.
(2-1)	1b	0b	
(2-2)	0b	0b	
(3-1)	1b	1b	Any given value. But delay is inserted only below. • RSPCK clock delay of the 1st frame • SSL negation delay and next access delay of the last frame
(3-2)	0b	1b	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (See **7.5.2.2.14 SPI Command Register n (RSPIm_SPCMDn) (n = 0 to 7)**.)
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

[Setting/Operation Example] (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1b → Burst transfer/no interframe delay between 0 and 1 (SSL keep active)
SPCMD1.SSLKP = 1b → Burst transfer/no interframe delay between 1 and 2 (SSL keep active)
SPCMD2.SSLKP = 1b → Burst transfer/no interframe delay between 2 and 3 (SSL keep active)
SPCMD3.SSLKP = 1b → Burst transfer/no interframe delay between 3 and 4 (SSL keep active)
SPCMD4.SSLKP = 0b → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1b → Burst transfer/no interframe delay between 5 and 6 (SSL keep active)
SPCMD6.SSLKP = 1b → Burst transfer/no interframe delay between 6 and 7 (SSL keep active)
SPCMD7.SSLKP = 0b → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit is used to enable or disable detection of a mode fault error. (See **7.5.3.10 Error Detection**.) The SPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See **7.5.3.2 SPI Pin Control**.)

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit is used to enable or disable an SPI error interrupt request when the SPI detects a mode fault error or an underrun error and sets the MODF flag in the SPI status register (SPSR) to 1b, when the SPI detects an overrun error and sets the OVRF flag in SPSR to 1b, or when the SPI detects a parity error and sets the PERF flag in SPSR to 1b. (See **7.5.3.10 Error Detection**.)

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit is used to enable or disable a receive buffer full interrupt request of the SPI.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit is used to enable or disable an idle interrupt request of the SPI after the SPI detects the idle state and sets the IDLNF flag in the SPI status register (SPSR) to 0b.

SPDRES bit (SPI Receive Data Ready Error Select)

When a receive data ready is detected (SPSR.SPDRF = 1b), select whether to use SPRI interrupt request or SPEI interrupt request.

SPTIE bit (SPI Transmit Buffer Empty Interrupt Enable)

The SPTIE bit is used to enable or disable a transmit buffer empty interrupt request of the SPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1b simultaneously when or after the SPTIE bit is set to 1b. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1b even though SPI functions are disabled (SPE bit = 0b).

CENDIE bit (SPI Communication End Interrupt Enable)

The CENDIE bit controls generation of a communication end interrupt request.

SPMS bit (SPI Function Enable)

The SPMS bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1b (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1b), the SPCMD.CPHA bit can be set to 0b or 1b. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0b), set the CPHA bit to 1b. If this bit is set to 0b for clock synchronous operation in slave mode (SPCR.MSTR = 0b), subsequent operation is not guaranteed.

The communication status according to the settings of SPCR.MSTR, SPCR.TXMD[1:0], SPCR.SPFRF, and SPCR.SPMS as follows.

Table 7.5-5 SPI Communication Status (1/2)

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master / Clock synchronous operation (3-wire)	1-(3)
1	0	1	0	0	Transmit only Master / Motorola SPI / SPI operation (4-wire)	1-(4)
1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)

Table 7.5-5 SPI Communication Status (2/2)

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	0	1	—	1	Transmit only Master / Clock synchronous operation (3-wire)	1-(6)
1	1	—	0	0	Receive only Master / Motorola SPI / SPI operation (4-wire)	1-(7)
1	1	—	1	0	Receive only Master / TI-SSP / SPI operation (4-wire)	1-(8)
1	1	—	—	1	Receive only Master / Clock synchronous operation (3-wire)	1-(9)
0	0	0	0	0	Transmit-Receive Slave / Motorola SPI / SPI operation (4-wire) (default)	0-(1)
0	0	0	1	0	Transmit-Receive Slave / TI-SSP / SPI operation (4-wire)	0-(2)
0	0	0	—	1	Transmit-Receive Slave / Clock synchronous operation (3-wire)	0-(3)
0	0	1	0	0	Transmit only Slave / Motorola SPI / SPI operation (4-wire)	0-(4)
0	0	1	1	0	Transmit only Slave / TI-SSP / SPI operation (4-wire)	0-(5)
0	0	1	—	1	Transmit only Slave / Clock synchronous operation (3-wire)	0-(6)
0	1	—	0	0	Receive only Slave / Motorola SPI / SPI operation (4-wire)	0-(7)
0	1	—	1	0	Receive only Slave / TI-SSP / SPI operation (4-wire)	0-(8)
0	1	—	—	1	Receive only Slave / Clock synchronous operation (3-wire)	0-(9)

SPFRF bit (SPI Frame Format Select)

The SPFRF bit selects the communication protocol.

The format of the SPI terminal (RSPCK, SSL0h to 3h) can be set according to the set communication protocol.

When SPMS = 1b (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bits (Communication Mode Select)

The TXMD[1:0] bits are used to select the transmit-receive, transmit-only, and receive-only serial communication.

TXMD[1:0] = 01b

→ Transmit-only is performed without reception.
→ Receive buffer full interrupt request cannot be used.

TXMD[1] = 1b

→ Receive-only is performed without transmission.
→ Transmit buffer empty interrupt request cannot be used.

For details, see **7.5.3.6 Communications Operating Mode**.

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit is used to select master mode or slave mode of the SPI. The SPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

BPEN bit (Synchronization Circuit Bypass Enable)

When BPEN = 1b, bus clock (RSPI_n_PCLK) is used as operation clock (RSPI_n_TCLK) and synchronization circuit is bypassed.

7.5.2.2.7 SPI Control Register for Master Receive Only (RSPIm_SPCRRM)

The SPCRRM register controls the start and completion of communication for master mode reception only operation. If the RMFM[4:0] bits are rewritten while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Ch
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	RMSTTG	RMEDTG	-	RMFM[4:0]				
Initial Value	0	0	0	0	0	0	0	0
R/W	W	W	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	RMSTTG	0h	W	1b: Receive Start (writable only when in Master Receive) Reading value is always 0b.
6	RMEDTG	0h	W	1b: Receive End (writable only when in Master Receive) Reading value is always 0b.
5	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4 to 0	RMFM[4:0]	0h	RW	Frame processing count setting in Master Receive only 00h: This function is not used.*1 01h: Automatically stop communication after processing 1 received frame. : 1Fh: Automatically stop communication after processing 31 received frames.

Note 1. See **(9) Software processing flow** in **7.5.3.13.1 Master mode operation**.

RMFM[4:0] bits (Frame processing count setting in Master Receive only)

The number of received frames can be adjusted when operating in master receive only. Valid only when the master mode (SPCR.MSTR = 1b) and the communication operation mode select bits (SPCR.TXMD[1:0]) are 10b.

Only the start bit in master mode reception automatically stops communication after “starts frame processing according to the value set in this bit” after reception starts.

RMEDTG bit (1b: Receive End (writable only when in Master Receive))

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1b) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

RMSTTG bit (1b: Receive Start (writable only when in Master Receive))

This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1b) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

Writing 1b to this bit during reception is not accepted. Write again after reception is completed.

7.5.2.2.8 SPI Control Register for Received Data Ready Detection (RSPIm_SPDRCR)

The SPDRCR register is used to set the SPI receive data ready detection function. If the set value is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Dh
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	SPDRC[7:0]							
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SPDRC[7:0]	0h	RW	SPI Receive Data Ready Detect Adjustment 00h: Disable receive data ready detection function 01h: Performs reception data ready judgment after 1 RSPI_n_TCLK : FFh: Performs reception data ready judgment after 255 RSPI_n_TCLK

SPDRC[7:0] bits (SPI Receive Data Ready Detect Adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 RSPI_n_TCLK.

The value set in the SPDRC[7:0] bits is used to 1b set the SPDRF flag. For details, see the description of SPDRF in **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)**.

7.5.2.2.9 SPI Pin Control Register (RSPIm_SPPCR)

The SPPCR register is used to set pin mode of the SPI. If SPPCR is modified with the SPCR.SPE bit = 1b, subsequent operation is not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Eh
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	MOIFE	MOIFV	-	SPOM	SPLP2	SPLP
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7, 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	MOIFE	0h	RW	MOSI Idle Value Fixing Enable 0b: The MOSI output value is the last data of previous transfer. 1b: The MOSI output value is the set MOIFV bit value.
4	MOIFV	0h	RW	MOSI Idle Fixed Value 0b: The fixed value of MOSI idle = 0. 1b: The fixed value of MOSI idle = 1.
3	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	SPOM	0h	RW	SPI Output Pin Mode 0b: CMOS output 1b: Open-drain output
1	SPLP2	0h	RW	SPI Loopback 2 0b: Normal mode 1b: Loopback mode (data is not inverted for transmission)
0	SPLP	0h	RW	SPI Loopback 0b: Normal mode 1b: Loopback mode (data is inverted for transmission)

SPLP bit (SPI Loopback)

When the SPLP bit is set to 1b, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1b) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when SPCR.MSTR = 0b) (loopback mode).

SPLP2 bit (SPI Loopback 2)

When the SPLP2 bit is set to 1b, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1b) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when SPCR.MSTR = 0b) (loopback mode). If this bit is set to 1b together with the SPLP bit, setting this bit takes precedence.

SPOM bit (SPI Output Pin Mode)

This bit is used to select CMOS output pin or open drain output pin as SPI's output pins.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when SPCR.MOIFE = 1b in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

This bit is used for the SPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When SPCR.MOIFE = 0b, the SPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When SPCR.MOIFE = 1b, the SPI outputs the fixed MOIFV bit value to MOSI.

7.5.2.2.10 SPI Control Register 2 (RSPIm_SPCR2)

The SPCR2 register is used to set the analog delay of the master receive clock. If the value set in this register is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Fh
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SPSCKDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SPSCKDL[2:0]	0h	RW	SPI Master Receive Clock Analog Delay Valid only in master mode 000b: No delay 001b: 1.1 ns (max) 010b: 2.2 ns (max) 011b: 3.3 ns (max) 100b: 4.4 ns (max) 101b: 5.5 ns (max) 110b: 6.6 ns (max) 111b: 7.7 ns (max)

SPSCKDL[2:0] bits (SPI Master Receive Clock Analog Delay)

These bits set the analog delay for MRIOCLK input to SPI in master mode. By setting these bits, the sampling timing of the received data can be adjusted. For details, see the SPSCKSEL bit of **7.5.2.2.6 SPI Control Register (RSPIm_SPCR)**.

7.5.2.2.11 SPI Slave Select Polarity Register (RSPIm_SSLP)

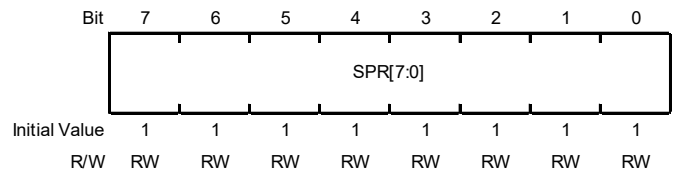
The SSLP register is used to set the polarity of SSL0 to SSL3 signals of the SPI. If any of these SSLP bits is modified with the SPCR.SPE bit = 1b, subsequent operation is not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 0010h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	SSL3P	SSL2P	SSL1P	SSL0P
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	SSL3P	0h	RW	SSL3 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL3 signal is active low (0). In the TI-SSP case, the SSL3 signal is active high (1). 1b: In the Motorola-SPI case, the SSL3 signal is active high (1). In the TI-SSP case, the SSL3 signal is active low (0).
2	SSL2P	0h	RW	SSL2 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL2 signal is active low (0). In the TI-SSP case, the SSL2 signal is active high (1). 1b: In the Motorola-SPI case, the SSL2 signal is active high (1). In the TI-SSP case, the SSL2 signal is active low (0).
1	SSL1P	0h	RW	SSL1 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL1 signal is active low (0). In the TI-SSP case, the SSL1 signal is active high (1). 1b: In the Motorola-SPI case, the SSL1 signal is active high (1). In the TI-SSP case, the SSL1 signal is active low (0).
0	SSL0P	0h	RW	SSL0 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL0 signal is active low (0). In the TI-SSP case, the SSL0 signal is active high (1). 1b: In the Motorola-SPI case, the SSL0 signal is active high (1). In the TI-SSP case, the SSL0 signal is active low (0).

SSLnP bits (SSLn Signal Polarity Setting)



These bits are used to specify the polarity of SSL signals. The set SSLnP bit (n = 3 to 0) values indicate the active polarity of SSLn signals.

SSL0 is different from SSL1, SSL2, and SSL3. In slave or multi-master mode, it functions as an input.

For details, see **7.5.3.3.2 Single master/single slave (this LSI = slave)** and **7.5.3.3.5 Multi-master/multi-slave (with this LSI acting as master)**.

7.5.2.2.12 SPI Bit Rate Register (RSPIm_SPBR)

Access Size : 8 bits
Address : <RSPIm_base> + 0011h
Initial Value : FFh

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SPR[7:0]	FFh	RW	The SPBR register is used to set the bit rate in master mode. If SPBR is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

When the SPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPBR.BRDV setting. (Specify a bit rate that meets electrical characteristics.)

The bit rate is determined by a combination of the set SPBR and BRDV[1:0] in the SPCMDm register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where “n” is the set SPBR value (0 to 255) and “N” is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{\text{f(RSPI_n_TCLK)}}{2 \times (\text{n} + 1) \times 2^{\text{N}}}$$

Note: Since the maximum operating frequency of PSPCKn is 50 MHz, configurations that result in a division ratio of 2 (N = 0, n = 0) are not supported when RSPI_n_TCLK is over 100 MHz.

Table 7.5-6 shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 7.5-6 Corresponding between Bit Rates and Set Values (Examples)

SPBR (n)	BRDV[1:0] Bits (N)	Division Ratio	Bit Rate
			RSPI_n_TCLK = 200 MHz
1	0	4	50.0 Mbps
2	0	6	33.4 Mbps
3	0	8	25.0 Mbps
4	0	10	20.0 Mbps
5	0	12	16.66 Mbps
5	1	24	8.34 Mbps
5	2	48	4.16 Mbps
5	3	96	2.08 Mbps
255	3	4096	48.8 kbps

7.5.2.2.13 SPI Sequence Control Register (RSPIm_SPSCR)

The SPSCR register is used to set the sequence length for the SPI to perform master operation.

Before modifying the SPSLN[2:0] bits in SPSCR while SPCR.MSTR = 1b and SPCR.SPE = 1b, confirm that SPSR.IDLNF = 0b.

Access Size : 8 bits
Address : <RSPIm_base> + 0013h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SPSLN[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SPSLN[2:0]	0h	RW	SPI Sequence Length Specification The order in which the SPCMD0 to SPCMD07 registers are to be referenced is changed in accordance with the sequence length that is set in these bits. The relationship among the setting of these bits, the sequence length, and the SPCMD0 to SPCMD7 register numbers referenced by SPI is as follows. However, the SPI in slave mode always refers to SPCMD0. 000b: Sequence Length = 1 (0→0→···) 001b: Sequence Length = 2 (0→1→0→···) 010b: Sequence Length = 3 (0→1→2→0→···) 011b: Sequence Length = 4 (0→1→2→3→0→···) 100b: Sequence Length = 5 (0→1→2→3→4→0→···) 101b: Sequence Length = 6 (0→1→2→3→4→5→0→···) 110b: Sequence Length = 7 (0→1→2→3→4→5→6→0→···) 111b: Sequence Length = 8 (0→1→2→3→4→5→6→7→0→···)

Note: The read access size is fixed at 32 bits.

SPSLN[2:0] bits (SPI Sequence Length Specification)

These bits are used to set the sequence length for the SPI in master mode to perform sequence operation.

According to the sequence length specified by SPSLN[2:0] bits, the SPI in master mode changes the SPCMDm registers (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see **7.5.3.14.1(3) Sequence control**.

The SPI in slave mode always references SPCMD0.

7.5.2.2.14 SPI Command Register n (RSPIm_SPCMDn) (n = 0 to 7)

The SPI has eight SPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the SPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the SPI in slave mode.

The SPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of SPSCR.SPSLN[2:0], and then performs serial transfer specified in the referenced SPCMD.

SPCMD should be set while the transmit buffer is empty (next-transfer data is not set) and data which refers to SPCMD has not been written.

The SPCMD referenced by the SPI in master mode is indicated by SPCP[2:0] in the SPSSR register. If SPCMD0 is modified while the SPI in slave mode is enabled (SPCR.SPE = 1b), subsequent operation is not guaranteed.

Access Size : 8, 16, 32 bits

Address : <RSPIm_base> + 0014h + n x 0004h

Initial Value : 0007_0000h

20 to 16	SPB[4:0]	7h	RW	SPI Data Length 00h: Setting prohibited 01h: Setting prohibited 02h: Setting prohibited 03h: 4 bits 04h: 5 bits 05h: 6 bits : 1Eh: 31 bits 1Fh: 32 bits
15	SCKDEN	0h	RW	RSPCK Delay Setting Enable 0b: RSPCK delay is 1 RSPCK. [In the Motorola-SPI case] RSPCK delay is 0 RSPCK. [In the TI-SSP case] 1b: RSPCK delay is the set value of the RSPCK delay register (SPCKD).
14	SLNDEN	0h	RW	SSL Negation Delay Setting Enable 0b: [Master] SSL negation delay is 1 RSPCK. [Slave in the TI-SSP] SSL negation delay is 1 RSPI_n_TCLK + 2~3 RSPI_n_TCLK (Synchronization delay) 1b: SSL negation delay is the set value of the slave select negation delay register (SSLND).

Bit	Bit Name	Initial Value	R/W	Description
13	SPNDEN	0h	RW	SPI Next-Access Delay Enable 0b: Next-access delay is 1 RSPCK + 5 RSPI_n_TCLK 1b: Next-access delay is the set value of the SPI next-access delay register (SPND).
12	LSBF	0h	RW	SPI LSB First 0b: MSB first 1b: LSB first
11 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	SSLKP	0h	RW	SSL Signal Level Hold 0b: All SSL signals are negated at the end of transfer. 1b: SSL signal level is held after the transfer ends until the next access starts.
6 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3, 2	BRDV[1:0]	0h	RW	Bit Rate Division 00b: The base bit rate is selected. 01b: Two-divided base bit rate is selected. 10b: Four-divided base bit rate is selected. 11b: Eight-divided base bit rate is selected.
1	CPOL	0h	RW	RSPCK Polarity 0b: RSPCK in idle state is 0. 1b: RSPCK in idle state is 1.
0	CPHA	0h	RW	RSPCK Phase This register is valid only for Motorola-SPI cases. (In the TI-SSP case, it is fixed at 1). 0b: Data is sampled at an odd edge and changes at an even edge. 1b: Data changes at an odd edge and is sampled at an even edge.

Note: The read access size is fixed at 32 bits.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0b and SPCR.SPFRF = 1b (in TI SSP mode), setting CPHA = 0b is invalid.

This register is valid only for Motorola-SPI cases.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bits (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the SPBR register. The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the SPI in master mode performs serial transfer. Setting this bit to 1b enables burst transfer in SPI operation master mode. For details, see **(4) Burst transfer** in **7.5.3.13.1 Master mode operation**.

To use the SPI in slave mode, set SSLKP bit to 0b.

LSBF bit (SPI LSB First)

This bit is used to set the data format of the SPI in master mode or slave mode to MSB first or LSB first.

SPNDEN bit (SPI Next-Access Delay Enable)

This bit is used to set the period from SSL negation to SSL assertion in SPI master mode. When SPNDEN = 0b, the SPI sets the next-access delay to 1 RSPCK + 5 RSPI_n_TCLK. When SPNDEN = 1b, the SPI inserts the next-access delay in accordance with the SPND register setting.

To use the SPI in slave mode, set SPNDEN bit to 0b.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period from RSPCK oscillation stop to SSL negation in SPI master mode. When SLNDEN = 0b, the SPI sets the SSL negation delay to 1 RSPCK. When SLNDEN = 1b, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.
To use the SPI in slave mode, set SLNDEN bit to 0b.

[In the TI-SSP case]

This bit is used to set the period from RSPCK oscillation stop to output disable in SPI master mode, or last edge of RSPCK to output disable in slave mode. When the SLNDEN bit is 0b, the SSL negate delay is 1 RSPCK in master mode and 1 RSPI_n_TCLK + 2 to 3 RSPI_n_TCLK (Synchronization delay) in slave mode. When SLNDEN = 1b, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.
When using SPI in slave mode except TI SSP setting, set the SLNDEN bit to 0b.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the SPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN = 0b, the SPI sets the RSPCK delay to 1 RSPCK. When SCKDEN = 1b, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.
To use the SPI in slave mode, set SCKDEN bit to 0b.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the SPI in master mode. When SCKDEN = 0b, the SPI does not set the RSPCK delay. When SCKDEN = 1b, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.
To use the SPI in slave mode, set SCKDEN bit to 0b.

SPB[4:0] bits (SPI Data Length)

These bits are used to set the transfer data length of the SPI in master mode or slave mode.

SSLA[1:0] bits (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the SPI in master mode to perform serial transfer. The set SSLA[1:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the SSLP register. When SSLA[1:0] bits are set to 0b in multi-master mode, serial transfer is performed with all SSL signals negated (because SSL0 is input).

To use the SPI in slave mode, set SSLA[1:0] bits to 0b.

7.5.2.2.15 SPI Data Control Register (RSPIm_SPDCR)

The SPDCR register controls the data format.

If the value set in this register is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8, 16 bits
Address : <RSPIm_base> + 0040h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	SPFC[3:0]				-	-	-	SINV	SPRDTD	SLSEL[1:0]		BYSW
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11 to 8	SPFC[3:0]	0h	RW	Frame Count Number of Frames Specification 0000b: 1 frame 0001b: 2 frames 0010b: 3 frames 0011b: 4 frames : 1110b: 15 frames 1111b: 16 frames
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	SINV	0h	RW	Serial data invert 0b: Not invert serial data 1b: Invert serial data
3	SPRDTD	0h	RW	SPI Receive Data or Transmit Data Selection 0b: The SPDR reads the receive buffer 1b: The SPDR reads the transmit buffer
2, 1	SLSEL[1:0]	0h	RW	SSL Pin Output Select See **Table 7.5-7**.
0	BYSW	0h	RW	Byte Swap Operating Mode Select 0b: Byte swap is disabled 1b: Byte swap is enabled

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32 bits or 16 bits. Other case of data length (for example, 4 to 15, 17 to 31 bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see **7.5.3.4 Data Format** and **7.5.3.4.5 Byte swap reception**.

When the parity function set to valid, the behavior is not guaranteed.

SLSEL[1:0] bits (SSL Pin Output Select)

The SLSEL[1:0] bits are used to select SSL output or I/O as an SSL pin function in master mode.

Table 7.5-7 SSL Pin Output Selection

SSLn Pin	SLSEL[1:0] = 0b	SLSEL[1:0] = 01b	SLSEL[1:0] = 10b	SLSEL[1:0] = 11b
SSL0	Output or Input	Output or Input	Output or Input	Setting prohibited
SSL1	Output	I/O	Output	
SSL2, SSL3	Output	I/O	I/O	

Note: Input or output of SSL0 is determined by the SPCR.MODFEN bit. For details, see **Table 7.5-8**.

SPRDTD bit (SPI Receive Data or Transmit Data Selection)

The SPRDTD bit is used to select receive buffer or transmit buffer from which the SPI data register (SPDR) value is read.

When the transmit buffer is read, the value written to SPDR the last time is read.

SINV bit (Serial data invert)

The SINV bit is used to invert transmit data and receive data.

When the SINV bit is set to 1b, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/ reception data.

SPFC[1:0] bits (Frame Count)

The SPFC[1:0] bits are used for the condition to set the CENDF flag in slave receive only mode. For details on the CENDF flag setting conditions, see **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)**.

The SPFC[1:0] bits are invalid except in the slave receive only mode.

7.5.2.2.16 SPI Data Control Register 2 (RSPIm_SPDCR2)

The SPDCR2 register controls the FIFO threshold. If the value set in this register is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8, 16 bits
Address : <RSPIm_base> + 0044h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	TTRG[3:0]				-	-	-	-	RTRG[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11 to 8	TTRG[3:0]	0h	RW	Transmission FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0000b: Threshold 0 0001b: Threshold 1 0010b: Threshold 2 0011b: Threshold 3 : 1111b: Threshold 15
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3 to 0	RTRG[3:0]	0h	RW	Receive FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0000b: Threshold 0 0001b: Threshold 1 0010b: Threshold 2 0011b: Threshold 3 : 1111b: Threshold 15

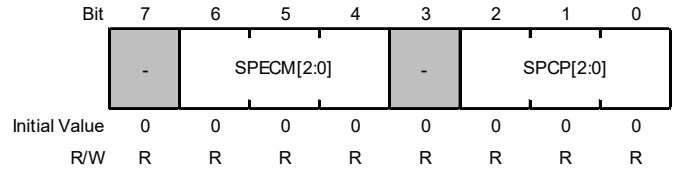
Note: The read access size is fixed at 32 bits.

RTRG[3:0] bits (Receive FIFO threshold setting)

Set the receive FIFO threshold.

When the number of data stored in the receive FIFO > the number of frames set by RTRG[3:0], the receive buffer full flag is set.

TTRG[3:0] bits (Transmission FIFO threshold setting)



Set the transmit FIFO threshold.

When the number of empty stages in the transmit FIFO > the number of frames set in TTRG[3:0], the transmit buffer empty flag is set.

7.5.2.2.17 SPI Sequence Status Register (RSPIm_SPSSR)

The SPSSR register indicates the sequence control status when the SPI performs master operation. Write access to SPSSR is ignored.

Access Size : 8 bits
Address : <RSPIm_base> + 0051h
Initial Value : 00h

Bit	Bit Name	Initial Value	R/W	Description
7	-	0h	R	Reserved Whenever it is read, 0b is read.
6 to 4	SPECM[2:0]	0h	R	SPI Error Command 000b: SPCMD0 001b: SPCMD1 010b: SPCMD2 011b: SPCMD3 100b: SPCMD4 101b: SPCMD5 110b: SPCMD6 111b: SPCMD7
3	-	0h	R	Reserved Whenever it is read, 0b is read.
2 to 0	SPCP[2:0]	0h	R	SPI Command Pointer 000b: SPCMD0 001b: SPCMD1 010b: SPCMD2 011b: SPCMD3 100b: SPCMD4 101b: SPCMD5 110b: SPCMD6 111b: SPCMD7

SPCP[2:0] bits (SPI Command Pointer)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the SPI sequence control. For details about the SPI sequence control, see **7.5.3.13.1 Master mode operation**.

SPECM[2:0] bits (SPI Error Command)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the SPI sequence control. The SPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (SPSR.OVRF = 0b, SPSR.MODF = 0b, SPSR.PERF = 0b), the SPECM[2:0] bits value has no meaning. For the SPI's error detection function, see **7.5.3.10 Error Detection**. For the SPI's sequence control, see **7.5.3.13.1 Master mode operation**.

7.5.2.2.18 SPI Status Register (RSPIm_SPSR)

Access Size : 8, 16 bits
Address : <RSPIm_base> + 0052h
Initial Value : 2000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPRF	CENDF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	SPDRF	-	-	-	-	-	-	-
Initial Value	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	SPRF	0h	R	SPI Receive Buffer Full Flag 0b: The number of data stored in the receive FIFO ≤ number of frames set by the SPDCR2.RTRG bit. 1b: The number of data stored in the receive FIFO > number of frames set by the SPDCR2.RTRG bit.
14	CENDF	0h	R	Communication End Flag 0b: The SPI is not communicating or communicating. 1b: The SPI communication completed.
13	SPTEF	1h	R	SPI Transmit Buffer Empty Flag 0b: The number of empty stages in the transmit FIFO ≤ the value set in SPDCR2.TTRG 1b: The number of empty stages in the transmit FIFO > the value set in SPDCR2.TTRG
12	UDRF	0h	R	Underrun Error Flag This bit indicates error status in combination with the MODF flag. The UDRF bit is valid when MODF flag is 1. 0b: Mode fault error occurred (MODF = 1) 1b: Underrun error occurred (MODF = 1)
11	PERF	0h	R	Parity Error Flag 0b: No parity error is present. 1b: A parity error is present.
10	MODF	0h	R	Mode Fault Error Flag 0b: Neither mode fault error nor underrun error is present. 1b: A mode fault error or underrun error is present.
9	IDLNF	0h	R	SPI Idle Flag 0b: The SPI is in the idle state. 1b: The SPI is in the transfer state.
8	OVRF	0h	R	Overrun Error Flag 0b: No overrun error is present. 1b: An overrun error is present.
7	SPDRF	0h	R	SPI Receive Data Ready Flag 0b: Receive data ready not detected 1b: Receive data ready detected
6 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

SPDRF bit (SPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1b), a certain period of time has elapsed while the number of data stored in the reception FIFO ≤ the reception FIFO threshold.

This bit is set to 0b when the reception operation is not performed (SPCR.TXMD[1:0] = 01b).

[Setting (to 1b) condition]

All the following two conditions are met:

- SPDRCR.SPDRC[7:0] ≠ 00h
- After the receive FIFO has been written, when the number of data stored in the receive FIFO ≤ the receive FIFO threshold and the value set by SPDRC[7:0] has elapsed

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.SPDRFC bit

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE bit = 1b) in master mode (SPCR.MSTR bit = 1b), no overrun error occurs and, therefore, this flag is not set to 1b. For details, see **7.5.3.10.1 Overrun error**.

[Setting (to 1b) condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- The SPCR.TXMD[1:0] bits = 00b. (transmit-receive mode)
- The SPCR.TXMD[1:0] bits = 10b. (receive only)

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.OVRFC bit

IDLNF bit (SPI Idle Flag)

This flag indicates transfer status of the SPI.

[Setting (to 1b) condition]

[Transmit-Receive, Transmit-only Master mode]

- None of the [Transmit-Receive, Transmit-only Master mode] in [Clearing (to 0b) conditions]

[Receive-only Master mode]

- When 1b is written to SPCRRM.RMSTTG bit

[Slave mode]

- SPCR.SPE = 1b (SPI function enabled)

[Clearing (to 0b) conditions]

Communication status: 1-(1) to (6) For details of communication status, see **Table 7.5-5**.

[Transmit-Receive, Transmit-only Master mode]

Any of the following two conditions is met:

- SPCR.SPE = 0b (SPI initialization)
- All the following three conditions are met:
  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 15)
  - SPSSR.SPCP[2:0] = 000b (at the beginning of sequence control)
  - The operation completed until the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following two conditions is met:

- SPCR.SPE = 0b (SPI initialization)
- Any of the following three conditions is met:
  - When RMFM[4:0] = 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)

- When RMFM[4:0] ≠ 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 00h, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Slave mode]

Communication status: 0-(1) to (9)

- SPCR.SPE = 0b (SPI initialization)

MODF bit (Mode Fault Error Flag)

This flag indicates whether a mode fault error or an underrun error is present. The UDRF flag allows you to see which error (mode fault error or underrun error) has occurred.

[Setting (to 1b) condition]

[Multi-master mode]

- The SSL0 pin input level becomes active level while the SPCR.MSTR bit = 1b (master mode) and the SPCR.MODFEN bit = 1b (mode fault error detection enabled), and then the SPI has detected a mode fault error.

[Slave, Motorola-SPI mode]

Any of the following two conditions is met:

- The SSL0 pin is negated before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0b (slave mode), SPCR.SPFRF bit = 0b (Motorola-SPI) and the SPCR.MODFEN bit = 1b (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1b (SPI function enabled), and then the SPI has detected an underrun error.

[Slave, TI-SSP mode]

Any of the following two conditions is met:

- The SSL0 pin is asserted before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0b (slave mode), SPCR.SPFRF bit = 1b (TI-SSP) and the SPCR.MODFEN bit = 1b (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1b (SPI function enabled), and then the SPI has detected an underrun error.

The SSL signal active level depends on the SSLP.SSLiP bits (SSL signal polarity bits).

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.MODFC bit

PERF bit (Parity Error Flag)

This flag indicates whether a parity error is present.

[Setting (to 1b) condition]

When the serial transfer ends and a parity error is detected with the SPCR.SPPE bit set to 1b under any of the following two conditions:

- The SPCR.TXMD[1:0] bits = 00b (transmit-receive)
- The SPCR.TXMD[1:0] bits = 10b (receive-only)

[Clearing (to 0b) condition]

- When 1 is written to the SPSRC.PERFC bit

UDRF bit (Underrun Error Flag)

This flag indicates that a mode fault error or an underrun error is present.

[Setting (to 1) condition]

- Serial transfer is started before transmit data output becomes ready while the SPCR.MSTR bit = 0b (slave mode) and the SPCR.TXMD[1:0] bits = 00b or 01b (transmit-receive or transmit-only) and the SPCR.SPE bit = 1b (SPI function enabled), and then the SPI has detected an underrun error.

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.UDRFC bit

SPTEF bit (SPI Transmit Buffer Empty Flag)

This flag indicates the transmit buffer (SPTX) status in the SPI data register (SPDR).

[Setting (to 1) condition]

Any of the following three conditions is met:

- The SPCR.SPE bit is set to 0b (SPI initialization)
- When the number of empty transmission FIFO stages > SPDCR2.TTRG[3:0]
- When 1b is written to SPFCR.SPFRST

[Clearing (to 0b) condition]

Any of the following two conditions is met:

- At the time of final access when transmission data is written to SPDR (SPTXn, n = 0 to 15) in one processing routine using DMAC
- When 1b is written to the SPSRC.SPTEFC bit

Writing a value to the SPDR register is enabled only while the SPTEF flag = 1b. If a value is written to the SPDR register while the SPTEF flag = 0b, transmit buffer data is not updated.

CENDF bit (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting (to 1b) condition]

- Transmit-Receive/Transmit-only Master mode

  Communication status: 1-(1) to (6). For details of communication status, see **Table 7.5-5**.
  The following three conditions are met:

  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 15)
  - The SPSSR.SPCP[2:0] are 000b (it means the head of the sequential control)
  - Operation completed until the next access delay (the master main state machine has transitioned to the idle state)

- Receive-only Master mode

  Communication status: 1-(7) to (9)
  Any of the following three conditions is met:

- When RMFM[4:0] = 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 00h, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

- Transmit-receive/transmit-only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(1), (4)
  The following three conditions are met:
  - The next transfer data is not set in the transmission buffer
  - The transmission shift register is empty (it means SPI does not do serial transfer)
  - SSL0 was negated

- Transmit-receive/transmit-only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(2), (5)
  The following three conditions are met:
  - The next transfer data is not set in the transmission buffer
  - The transmission shift register is empty (it means SPI does not do serial transfer)
  - When the SSL negate delay is completed

- Transmit-receive/transmit only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1b)

  Communication status: 0-(3), (6)
  The following three conditions are met:
  - The next transfer data is not set in the transmission buffer
  - The transmission shift register is empty (it means SPI does not do serial transfer)
  - The last even edge of RSPCK of the frame was detected (when the SPCMD.CPHA bit is 1b)

- Receive only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(7)
  The following condition is met:
  - SSL0 input was negated after getting frames for SPDCR.SPFC set value in the receive buffer

- Receive only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(8)
  The following condition is met:
  - SSL0 negate delay is completed after getting frames for SPDCR.SPFC set value in the receive buffer

- Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1b).

  Communication status: 0-(9)
  The following condition is met:
  - The last even edge of RSPCK of the last frame received for SPFC set value was detected (when the SPCMD.CPHA bit is 1b)

[Clearing (to 0b) condition]

- Transmit-Receive/transmit-only Master mode

  Communication status: 1-(1) to (6)
  Any of the following two conditions is met:

  - The next transmit data was written to the transmit buffer (SPTX)
  - When 1b is written to the SPSRC.CENDFC bit

- Receive-only Master mode

  Communication status: 1-(7) to (9)
  Any of the following two conditions is met:

  - When 1b is written to the SPCRRM.RMSTTG bit with SPCR.SPE = 1b
  - When 1b is written to the SPSRC.CENDFC bit

- Transmit-receive/transmit only slave mode

  Communication status: 0-(1) to (6)
  Satisfy one of following conditions:

  - The next transmit data is written to the transmit buffer (SPTX)
  - When 1b is written to the SPSRC.CENDFC bit

- Receive-only slave mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(7) to (8)
  Satisfy one of following conditions:

  - SSL0 assertion of next data is detected
  - When 1b is written to the SPSRC.CENDFC bit

- Receive-only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1b).

  Communication status: 0-(9)
  Satisfy one of following conditions:

  - The first edge of RSPCK of the next data is detected
  - When 1b is written to the SPSRC.CENDFC bit

SPRF bit (SPI Receive Buffer Full Flag)

This flag indicates the receive buffer (SPRX) status in the SPDR register.

[Setting (to 1b) condition]

When the number of data stored in the receive FIFO > the number of frames set in the SPDCR2.RTRG[3:0] bits in Transmit-Receive, Receive-only modes. However, the SPRF flag does not change from 0b to 1b while the OVRF flag = 1b. (See **7.5.3.10 Error Detection**.)

[Clearing (to 0b) condition]

Any of the following three conditions is met:

- At the last access when read data is read from SPDR (SPRXn, n = 0 to 15) in one processing routine using DMAC
- When 1b is written to the SPSRC.SPRFC bit
- When 1b is written to the SPFCR.SPFRST bit

7.5.2.2.19 SPI Transfer FIFO Status Register (RSPIm_SPTFSR)

Access Size : 8 bits

Address : <RSPIm_base> + 0058h

Initial Value : 10h

Bit	7	6	5	4	3	2	1	0
	-	-	-	TFDN[4:0]				
Initial Value	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read.
4 to 0	TFDN[4:0]	10h	R	Transmit FIFO data empty stage number 0_0000b: Number of empty stages 0 0_0001b: Number of empty stages 1 0_0010b: Number of empty stages 2 0_0011b: Number of empty stages 3 0_0100b: Number of empty stages 4 : 1_0000b: Number of empty stages 16

Note: TFDN[4:0] is initialized by SPCR.SPE = 0b.

7.5.2.2.20 SPI Receive FIFO Status Register (RSPIm_SPRFSR)

Access Size : 8 bits

Address : <RSPIm_base> + 005Ch

Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	RFDN[4:0]				
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read.
4 to 0	RFDN[4:0]	0h	R	Receive FIFO data store stage number 0_0000b: Number of store stages 0 0_0001b: Number of store stages 1 0_0010b: Number of store stages 2 0_0011b: Number of store stages 3 0_0100b: Number of store stages 4 : 1_0000b: Number of empty stages 16

Note: RFDN[4:0] is initialized by SPCR.SPE = 0b.

7.5.2.2.21 SPI Polling Register (RSPIm_SPPSR)

Access Size : 8, 16, 32 bits

Address : <RSPIm_base> + 0060h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SPEPS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read.
0	SPEPS	0h	R	SPI Polling Status 0b: SPCR.SPE is 0 1b: SPCR SPE is 1

Note: This bit shows a result of SPCR.SPE after synchronization by the operation clock (RSPI_n_TCLK).

Note: The read access size is fixed at 32 bits.

7.5.2.2.22 SPI Status Clear Register (RSPIm_SPSRC)

The SPSRC register clears the status flag (SPSR) that indicates the operating status of SPI.

Access Size : 8, 16 bits

Address : <RSPIm_base> + 006Ah

Initial Value : 0000_0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPRFC	CENDFC	SPTEFC	UDRFC	PERFC	MODFC	-	OVRFC	SPDRFC	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	R	W	W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	SPRFC	0h	W	SPI Receive Buffer Full Flag Clear By writing 1b, the SPI Receive Buffer Full Flag can be cleared. The read value is always 0b.
14	CENDFC	0h	W	Communication End Flag Clear By writing 1b, the Communication End Flag can be cleared. The read value is always 0b.
13	SPTEFC	0h	W	SPI Transmit Buffer Empty Flag Clear By writing 1b, the SPI Transmit Buffer Empty Flag can be cleared. The read value is always 0b.
12	UDRFC	0h	W	Underrun Error Flag Clear By writing 1b, the Underrun Error Flag can be cleared. The read value is always 0b. When clearing the UDRF flag, clear the MODF flag at the same time (MODFC = 1).
11	PERFC	0h	W	Parity Error Flag Clear By writing 1b, the Parity Error Flag can be cleared. The read value is always 0b.
10	MODFC	0h	W	Mode Fault Error Flag Clear By writing 1b, the Mode Fault Error Flag can be cleared. The read value is always 0b. Before setting MODFC and UDRFC, make sure that SPSR.MODF and UDRF are set to 1b.
9	-	0h	R	Reserved Whenever it is read, 0b is read.
8	OVRFC	0h	W	Overrun Error Flag Clear By writing 1b, the Overrun Error Flag can be cleared. The read value is always 0b.
7	SPDRFC	0h	W	SPI Receive Data Ready Flag Clear The SPI receive data ready flag can be cleared by writing 1b. When read, 0b is read.
6 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

7.5.2.2.23 SPI FIFO Clear Register (RSPIm_SPFCR)

The SPFCR register is used to clear the FIFO.

If SPFCR is rewritten while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits

Address : <RSPIm_base> + 006Ch

Initial Value : 0000_0000h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SPFRST
Initial Value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	-	All 0	W	Reserved The written value should always be 0b.
0	SPFRST	0h	W	SPI FIFO clear By writing 1b, the pointer in the FIFO and the stored data are initialized. Reading value is always 0b.

7.5.3 Operation

In this section, a word “serial transfer period” is used as a word that means a period from the start of valid data drive to latching of the final valid data.

7.5.3.1 Overview of SPI Operations

The SPI can transfer data in the following five modes.

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

SPI modes can be set by the MSTR, MODFEN, SPMS and SPFRF bits in the SPCR register.

Table 7.5-8 lists the relationship between SPI modes and SPCR settings, and outline of each mode.

Table 7.5-8 Relationship between SPI Modes and SPCR Settings and Description of Each Mode (1/2)

Mode	Slave (SPI Operation)	Single-Master (SPI Operation)	Multi-Master (SPI Operation)	Slave (Clock Synchronous Operation)	Master (Clock Synchronous Operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
SPFRF bit setting	valid	valid	valid	In-valid	In-valid
RSPCK signal	Input	Output	Output/Hi-Z	Input	Output
MOSI signal	Input	Output	Output/Hi-Z	Input	Output
MISO signal	Output/Hi-Z	Input	Input	Output	Input
SSL0 signal	Input	Output	Input	Hi-Z (not used)	Hi-Z (not used)
SSL1 to SSL3 signals	Hi-Z (not used)	Output	Output/Hi-Z	Hi-Z (not used)	Hi-Z (not used)
Output pin mode	CMOS/open drain	CMOS/open drain	CMOS/open drain	CMOS/open drain	CMOS/open drain
SSL polarity modification function	Supported	Supported	Supported	—	—
Transfer rate	Up to RSPI_n_TCLK/2 (Up to RSPI_n_TCLK/4 when RSPI_n_TCLK is over 100 MHz)				
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	2 types				
Clock phase	2 types*1	2 types*5	2 types*5	One (CPHA = 1b)	2 types
First transfer bit	MSB/LSB				
Transfer data length	4 to 32 bits				
Burst transfer	Enabled (CPHA = 1b)	Enabled (CPHA = 0b, 1b)	Enabled (CPHA = 0b, 1b)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*6	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported

Table 7.5-8 Relationship between SPI Modes and SPCR Settings and Description of Each Mode (2/2)

Mode	Slave (SPI Operation)	Single-Master (SPI Operation)	Multi-Master (SPI Operation)	Slave (Clock Synchronous Operation)	Master (Clock Synchronous Operation)
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1b	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1b	RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1b
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmission buffer empty detection	Supported*4	Supported	Supported	Supported*4	Supported
Reception buffer full detection	Supported*1				
Overrun error detection	Supported*1	Supported*1,*3	Supported*1,*3	Supported*1	Supported*1 *3
Parity error detection	Supported*1,*2				
Mode fault error detection	Supported (MODFEN = 1b)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*4	Not supported	Not supported	Supported*4	Not supported

Note 1. When SPI is transmit-master mode or transmit-slave mode (see **Table 7.5-5**), none of receive buffer full error, overrun error, and parity error is detected.

Note 2. When the SPCR.SPPE bit is 0b, parity error is not detected.

Note 3. When the SPCR.SCKASE bit is 1b, overrun error is not detected.

Note 4. When SPI is receive only slave mode (see **Table 7.5-5**), none of transmit buffer empty and underrun error is detected.

Note 5. CPHA = 0b is invalid in TI SSP mode. (Even if it is set, the operation is the same as when CPHA = 1b.)

Note 6. Available only in TI SSP mode.

7.5.3.2 SPI Pin Control

The SPI automatically switches pin directions and output modes according to the settings of the SPCR.MSTR, SPCR.MODFEN and SPCR.SPMS bits and the SPPCR.SPOM bit.

When the SPPCR.SPOM bit is set to 0b, each output becomes CMOS output, when the SPOM bit is set to 1b, each output becomes open drain output.

Table 7.5-9 shows the relationship between pin state and set values of each bit.

For details of OE function, see **7.5.3.5 Transfer Format (Frame Format)**.

Table 7.5-9 Relationship between Pin States and Set Control Bit Values (1/2)

Mode	Pin	Pin State*1	
		SPOM = 0	SPOM = 1
Single-master mode (SPI operation) (MSTR = 1b, MODFEN = 0b, SPMS = 0b)	RSPCK	CMOS output	Open-drain output
	SSL0 to SSL3	CMOS output	Open-drain output
	MOSI	CMOS output	Open-drain output
	MISO	Input	Input
Multi-master mode (SPI operation) (MSTR = 1b, MODFEN = 1b, SPMS = 0b)	RSPCK*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSL0	Input	Input
	SSL1 to SSL3*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSI*2	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISO	Input	Input

Table 7.5-9 Relationship between Pin States and Set Control Bit Values (2/2)

Mode	Pin	Pin State*1	
		SPOM = 0	SPOM = 1
Slave mode (SPI operation) (MSTR = 0b, SPMS = 0b)	RSPCK	Input	Input
	SSL0	Input	Input
	SSL1 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	Input	Input
	MISO*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (Clock synchronous operation) (MSTR = 1b, MODFEN = 0b, SPMS = 1b)	RSPCK	CMOS output	Open-drain output
	SSL0 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	CMOS output	Open-drain output
	MISO	Input	Input
Slave mode (Clock synchronous operation) (MSTR = 0b, SPMS = 1b)	RSPCK	Input	Input
	SSL0 to SSL3*4	Hi-Z (not used)	Hi-Z (not used)
	MOSI	Input	Input
	MISO	CMOS output	Open-drain output

Note 1. The set SPI value is not applied to multi-function pins for which the SPI function is not selected.

Note 2. When SSL0 is at the active level, the pin state is Hi-Z. Motorola-SPI: When SSL0 is active level, the pin state becomes Hi-Z. TI-SSP: The terminal status becomes Hi-Z until SSL0 is asserted after SPCR.SPE = 1b and communication completed.

Note 3. Motorola-SPI: When SSL0 is inactive level or when SPCR.SPE = 0b, the pin state becomes Hi-Z. TI-SSP: When SSL0 is except the communication period or when SPCR.SPE = 0b (assertion after SPE = 1b and communication completed), the pin status changes to Hi-Z.

Note 4. These pins are available for use as I/O port pins.

The SPI in single master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal value in the SSL negation period (including the SSL hold period in burst transfer) according to the settings of the SPPCR.MOIFE and SPPCR.MOIFV bits, as listed in **Table 7.5-10**.

Table 7.5-10 Determining the MOSI Signal Value in the SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSI Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Always low
1	1	Always high

7.5.3.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL signals is active level. When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola-SPI or TISSP.

7.5.3.3.1 Single master/single slave (this LSI = master)

Figure 7.5-7 shows an example of single master/single slave SPI system configuration where this LSI is used as a master. In the single master/single slave configuration, the SSL0 to SSL3 output signals of this LSI (master) are not used.

SSL input signals of the SPI slave are fixed to 0 level to always select the SPI slave. When SPCMD.CPHA = 0b, some slave devices cannot fix SSL signals to active level in the relevant transfer format. If the SSL signal level cannot be fixed, connect the SSL output of this LSI to the SSL input of the slave device.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

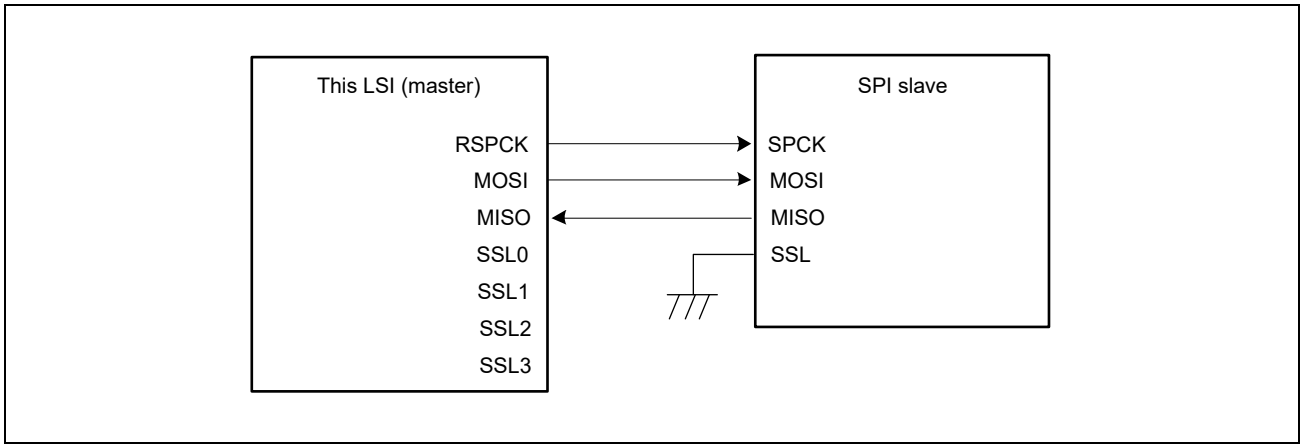


Figure 7.5-7 Single-Master/Single-Slave Configuration Example (This LSI = Master)

7.5.3.3.2 Single master/single slave (this LSI = slave)

Figure 7.5-8 shows an example of single master/single slave SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave, the SSL0 pin is used as SSL input. The SPI master always drives the RSPCK and MOSI pins. This LSI (slave) always drives the MISO pin. When the SSL0 level is inactive, the pin state becomes Hi-Z.

In the single slave configuration with the SPCMD.CPHA bit set to 1b, set the SPCR.SPFRF bit to 0b, and set the SPMS bit to 0b. There is the SSL0 input level of this LSI (slave) is fixed to 0 so that this LSI (slave) can be always selected and serial transfer can also be performed (**Figure 7.5-9**). However, the communication end interrupt does not output when SSL0 input was fixed as **Figure 7.5-9**.

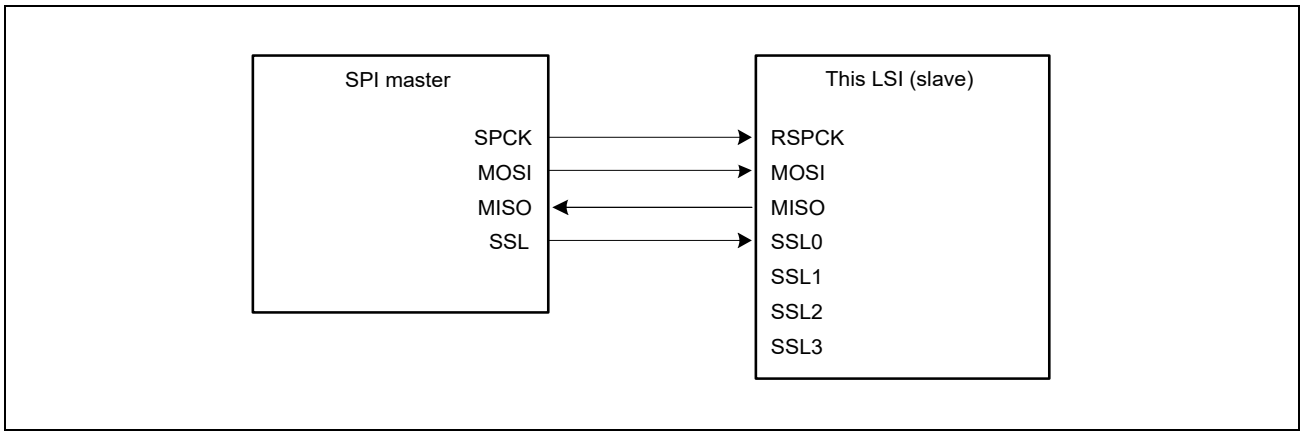

Figure 7.5-8 Single-Master/Single-Slave Configuration Example (This LSI = Slave, CPHA = 0b)

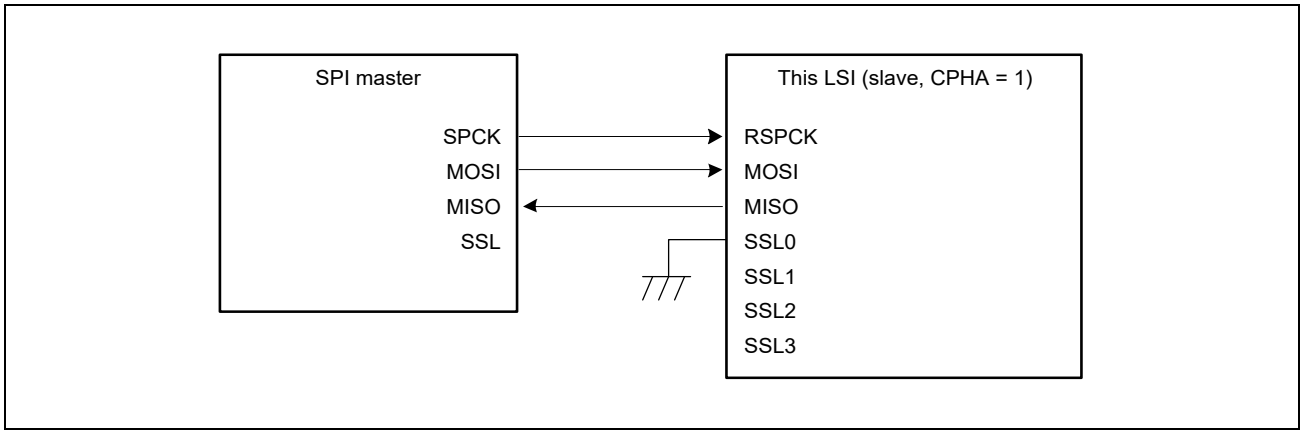

Figure 7.5-9 Single-Master/Single-Slave Configuration Example (This LSI = Slave, CPHA = 1b)

7.5.3.3.3 Single master/multi-slave (this LSI = master)

Figure 7.5-10 shows an example of single master/multi-slave SPI system configuration where this LSI is used as a master. In the example in **Figure 7.5-10**, the SPI system is comprised of this LSI (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCK output and MOSI output pins of the master are connected to the RSPCK input and MOSI input pins of SPI slave 0 to SPI slave 3. All of the MISO output pins of SPI slave 0 to SPI slave 3 are connected to the MISO input pin of the master. The SSL0 to SSL3 output pins of this LSI (master) are connected to the SSL input pin of SPI slave 0 to SPI slave 3.

The master always drives RSPCK, MOSI, and SSL0 to SSL3 pins. The slave (out of SPI slave 0 to SPI slave 3) where 0 level is input to SSL input pin drives the MISO pin.

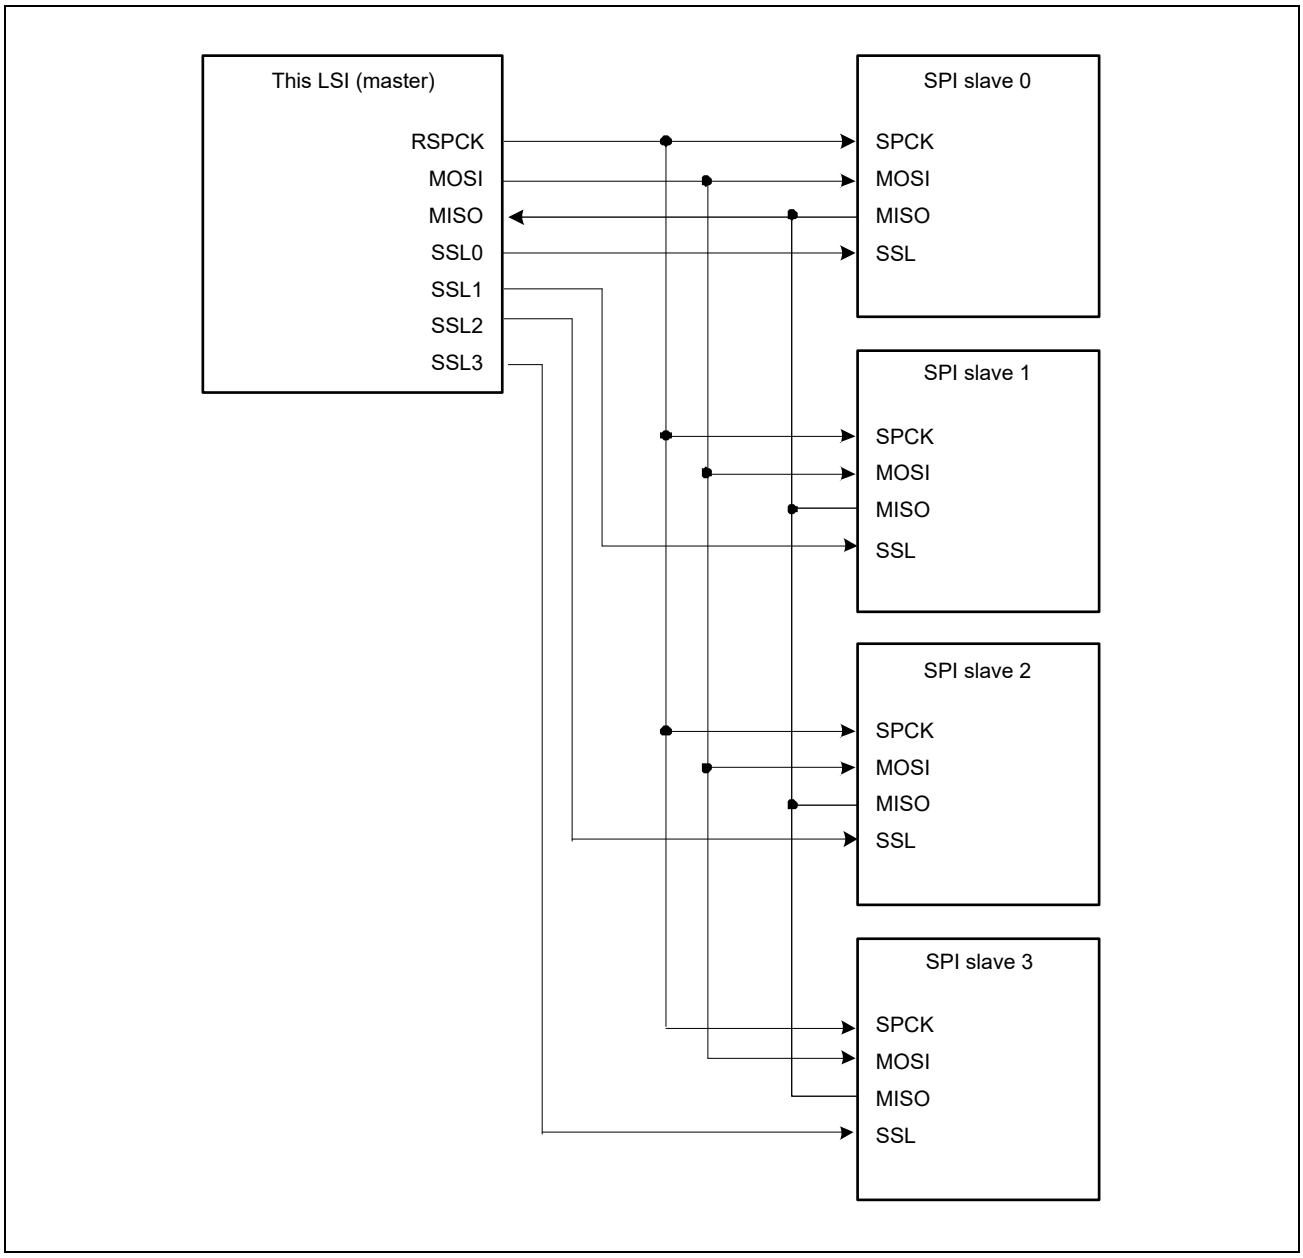

Figure 7.5-10 Single-Master/Multi-Slave Configuration Example (This LSI = Master)

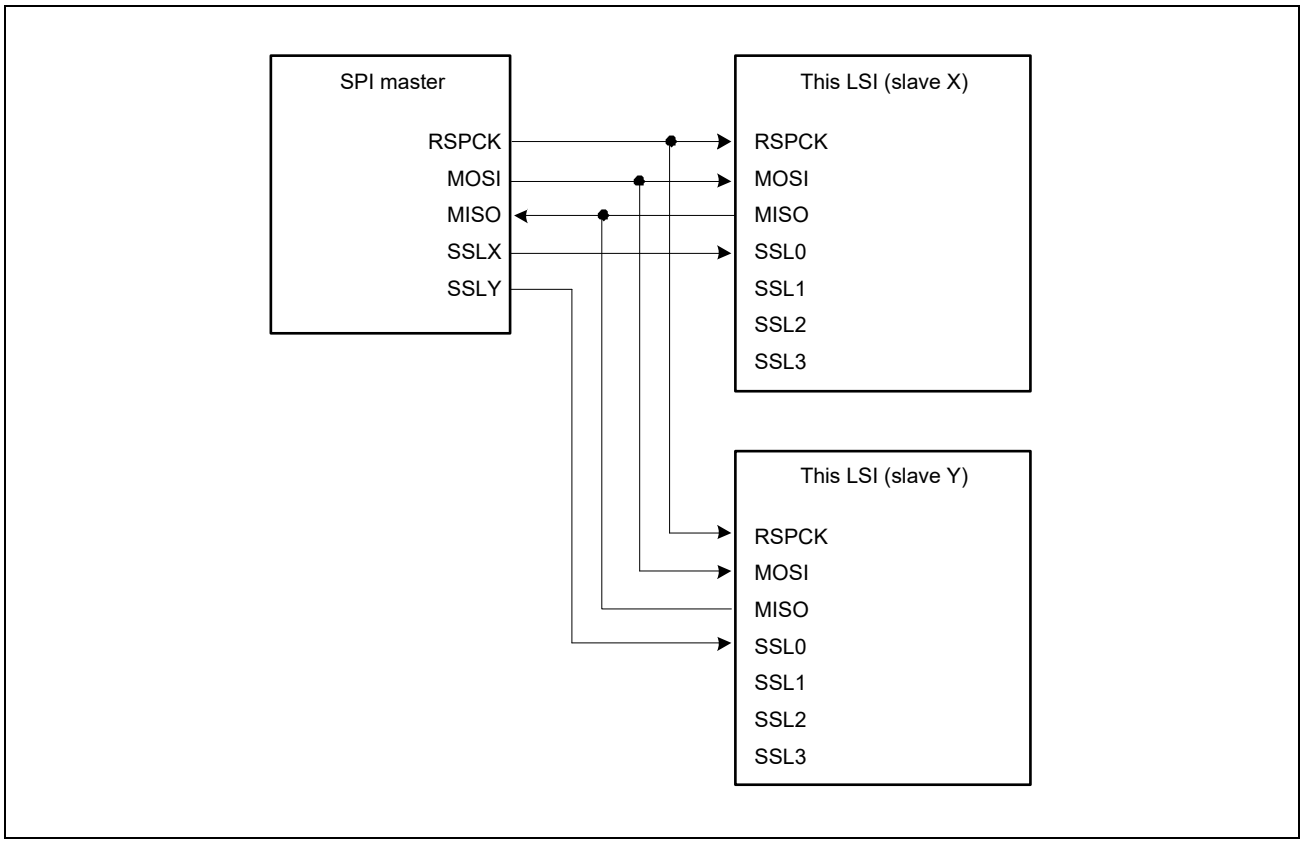
7.5.3.3.4 Single master/multi-slave (with this LSI acting as slave)

Figure 7.5-11 shows an example of single master/multi-slave SPI system configuration where this LSI is used as a slave. In the example in **Figure 7.5-11**, the SPI system consists of the SPI master and two these LSIs (slave X, slave Y).

The RSPCK output and MOSI output pins of the SPI master are connected to the RSPCK input and MOSI input pins of the LSIs (slave X, slave Y). The MISO output pin of the LSIs (slave X, slave Y) is connected to the MISO input pin of the SPI master. The SSLX output and SSLY output pins of the SPI master are connected to the SSL0 input pin of the LSIs (slave X, slave Y).

The SPI master always drives the RSPCK, MOSI, SSLX, and SSLY pins. The slave X or slave Y (this LSI) where 0 level is input to the SSL0 input pin drives the MISO pin.



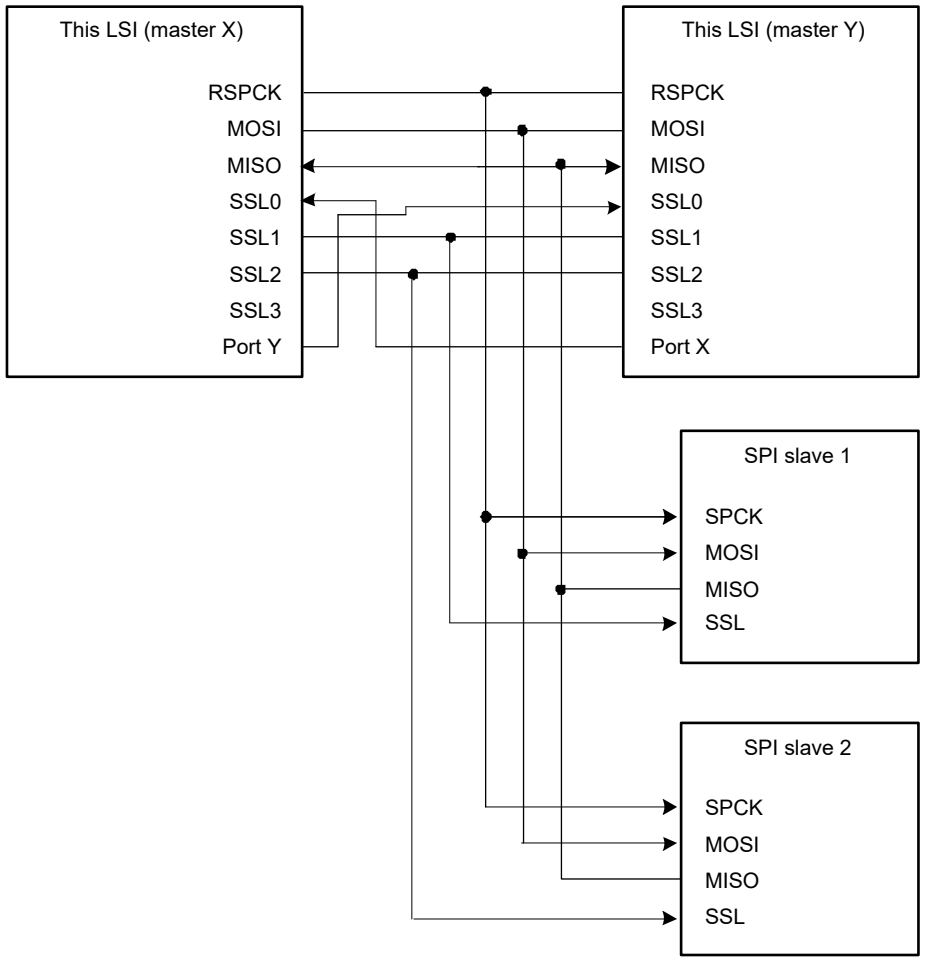


Figure 7.5-11 Single-Master/Multi-Slave Configuration Example (This LSI = Slave)

7.5.3.3.5 Multi-master/multi-slave (with this LSI acting as master)

Figure 7.5-12 shows an example of multi-master/multi-slave SPI system configuration where this LSI is used as a master. In the example in **Figure 7.5-12**, the SPI system consists of two these LSIs (master X, master Y) and two SPI slaves (SPI slave 1, SPI slave 2).

The RSPCK output and MOSI output pins of these LSIs (master X, master Y) are connected to the RSPCK input and MOSI input pins of SPI slave 1 and SPI slave 2. The MISO output pin of SPI slave 1 and SPI slave 2 is connected to the MISO input pin of these LSIs (master X, master Y). The Port Y (general port) output pin of this LSI (master X) is connected to the SSL0 input pin of this LSI (master Y). The Port X (general port) output pin of this LSI (master Y) is connected to the SSL0 input pin of this LSI (master X). The SSL1 output and SSL2 output pins of these LSIs (master X, master Y) are connected to the SSL input pin of SPI slave 1 and SPI slave 2. In this configuration example, SSL3 output pins of this LSI are not used because the system can be configured only with SSL0 input pin and SSL1 output and SSL2 output pins for connecting slaves.

While the SSL0 input level is 1, this LSI drives the RSPCK, MOSI, SSL1, and SSL2 pins. While the SSL0 input level is 0, this LSI detects a mode fault error and changes the RSPCK, MOSI, SSL1, SSL2 pin levels to Hi-Z to release the SPI bus mastership for another master. SPI slave 1 or SPI slave 2 where 0 level is input to the SSL input pin drives the MISO pin.

Note: When setting TI SSP, enter the following levels for port X and port Y.
- Start of communication: the value of SSLP.SSL0P of the other master.
- End of communication: the inverted value of SSLP.SSL0P of the other master.

Figure 7.5-12 Multi-Master/Multi-Slave Configuration Example (This LSI = Master)

7.5.3.3.6 Master (clock synchronous operation)/slave (clock synchronous operation) (this LSI = master)

Figure 7.5-13 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a master. In this configuration, the SSL0 to SSL3 output pins of this LSI (master) are not used.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

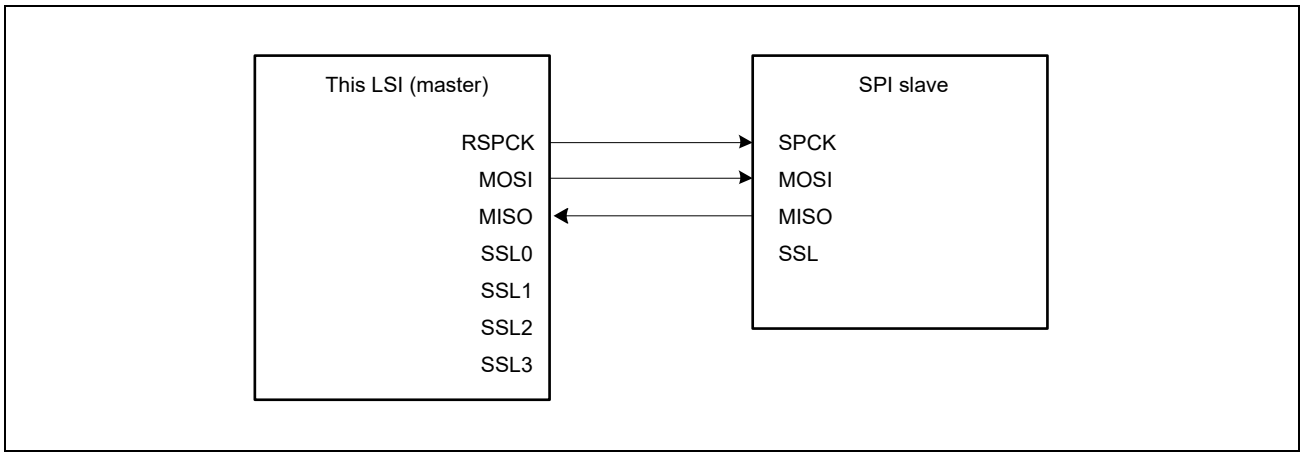

Figure 7.5-13 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This LSI = Master)

7.5.3.3.7 Master (clock synchronous operation)/slave (clock synchronous operation) (this LSI = slave)

Figure 7.5-14 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave (clock synchronous operation), this LSI (slave) always drives the MISO pin and the SPI master always drives the RSPCK and MOSI pins.

Only in the single slave configuration with the SPCMD.CPHA bit set to 1b, this LSI (slave) can perform serial transfer.

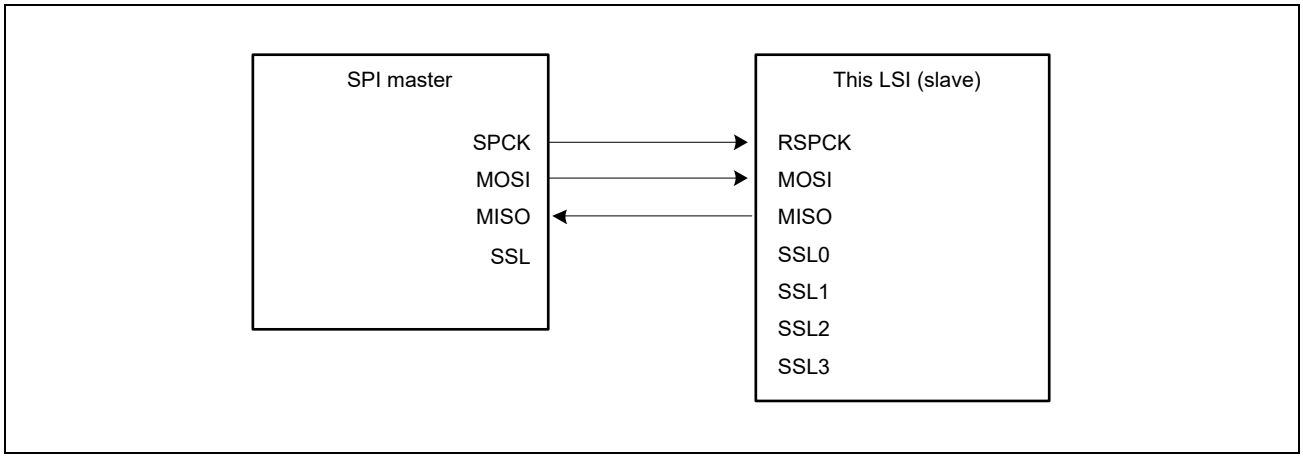

Figure 7.5-14 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This LSI = Slave, CPHA = 1b)

7.5.3.4 Data Format

Data format of the SPI depends on the set values of the SPCMD register and the SPCR.SPPE bit. The SPI handles data of the set data length from the LSB in the SPDR register as transfer data regardless of MSB first or LSB first.

7.5.3.4.1 Data format of one frame

The data format of one frame for transmission and reception is shown below.

(1) With parity disabled (SPPE = 0b)

When the parity function is disabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received.

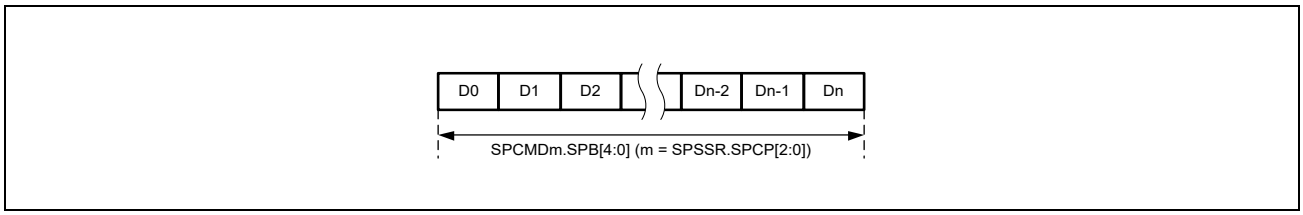

Figure 7.5-15 Outline of Data Format (when Parity Function is Disabled)

(2) With parity enabled (SPPE = 1b)

When the parity function is enabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received. However, the final bit is used as a parity bit.

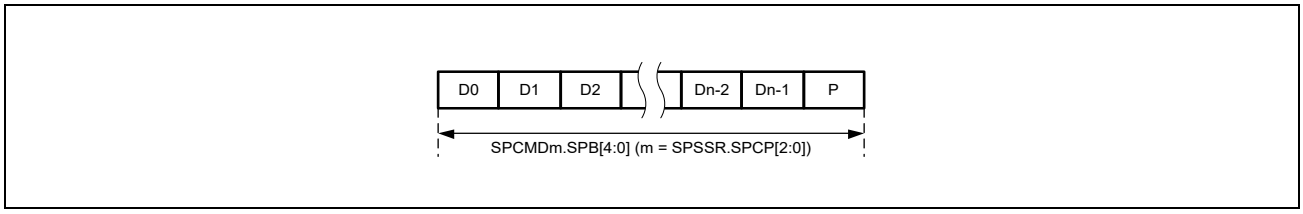

Figure 7.5-16 Outline of Data Format (when Parity Function is Enabled)

7.5.3.4.2 When parity is disabled (SPPE = 0b)

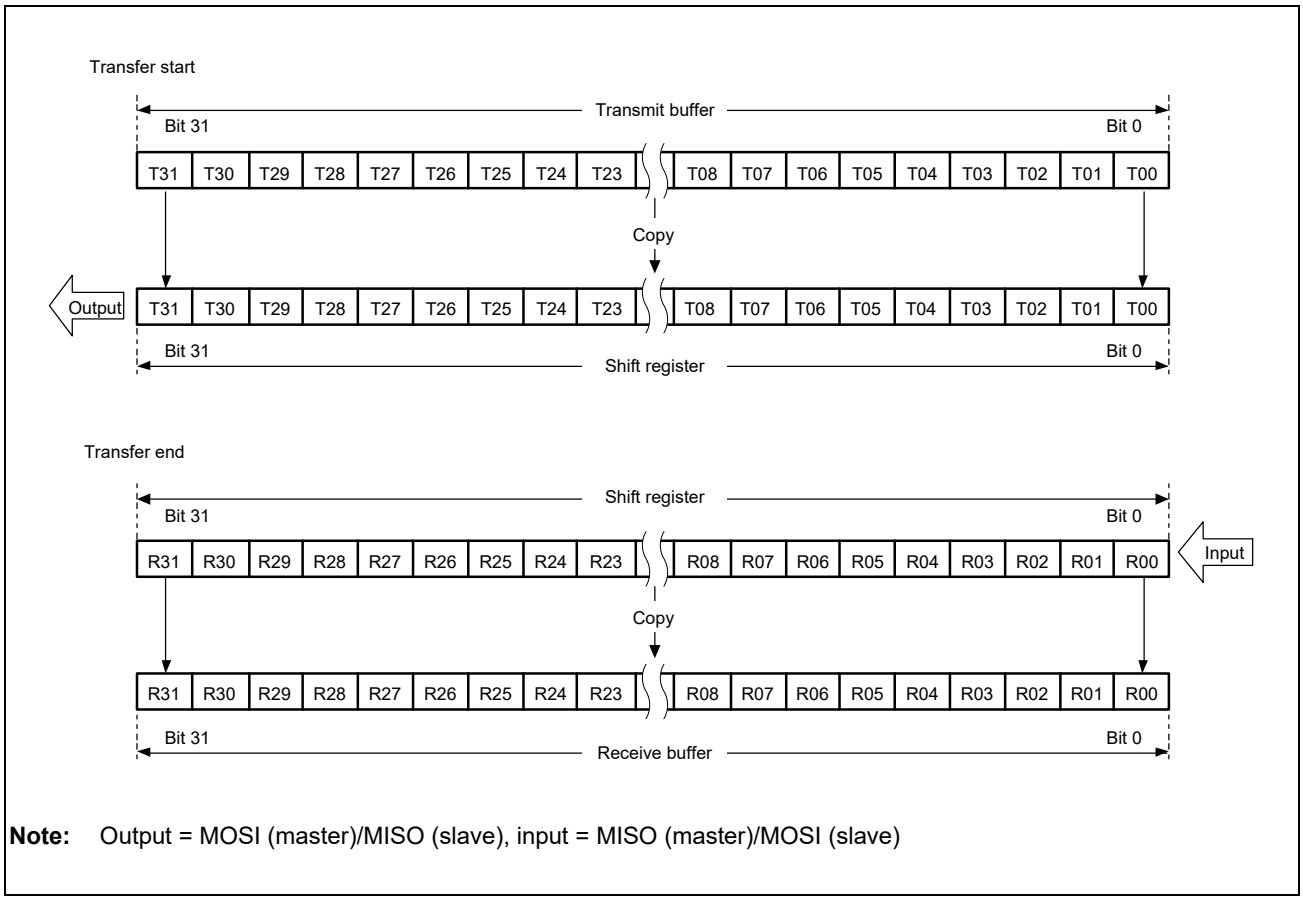
When the parity function is disabled, transmit buffer data is copied to the shift register without processing it. The following describes the relationship between SPDR, and shift register by using a combination of MSB first/LSB first and bit length.

(1) MSB first transfer (32-bit data)

Figure 7.5-17 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function disabled.

In transmission, T31 to T00 in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R31 to R00, the shift register value is copied to the receive buffer.



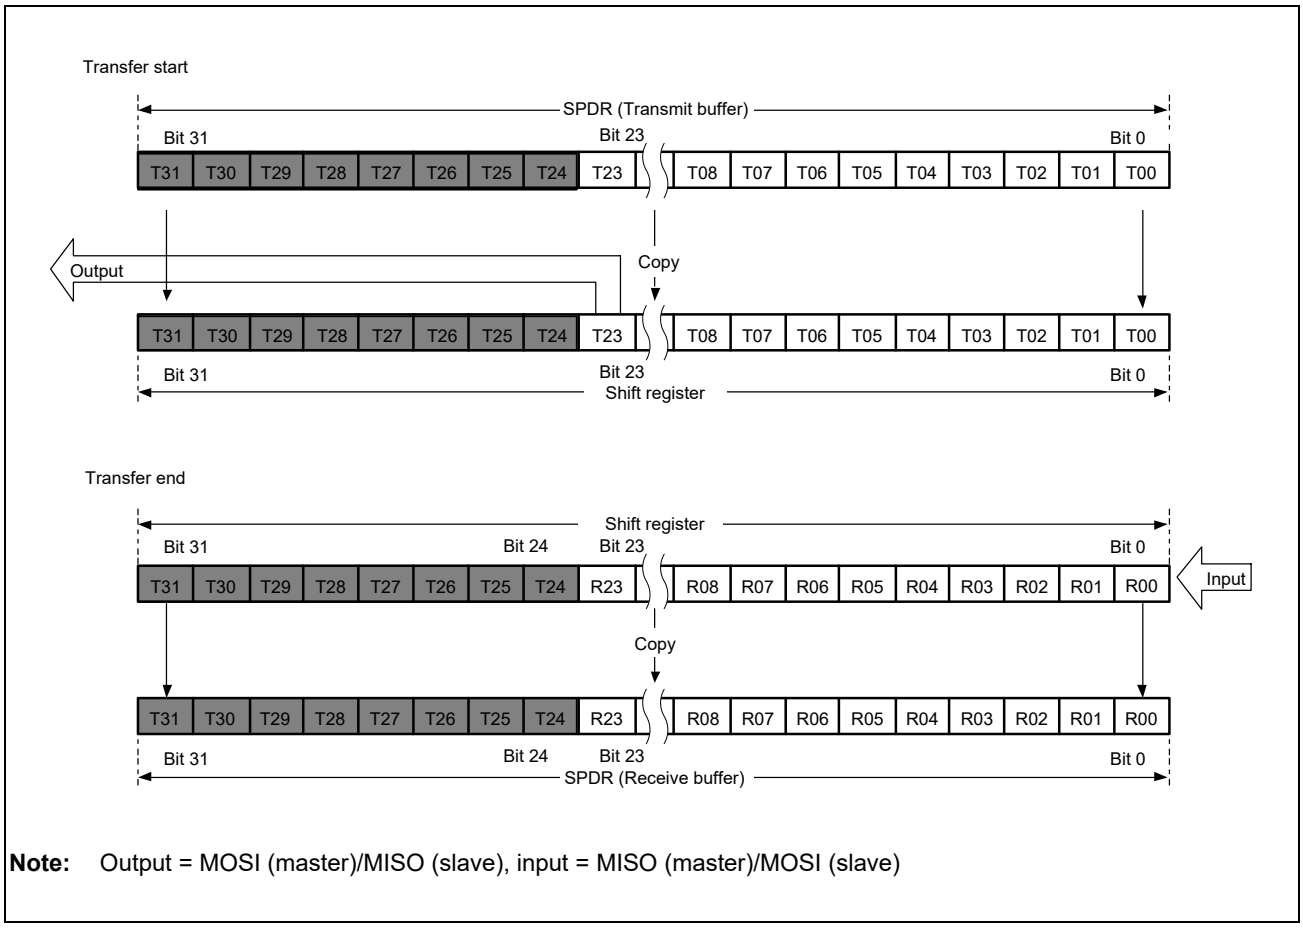


Figure 7.5-17 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB first transfer (24-bit data)

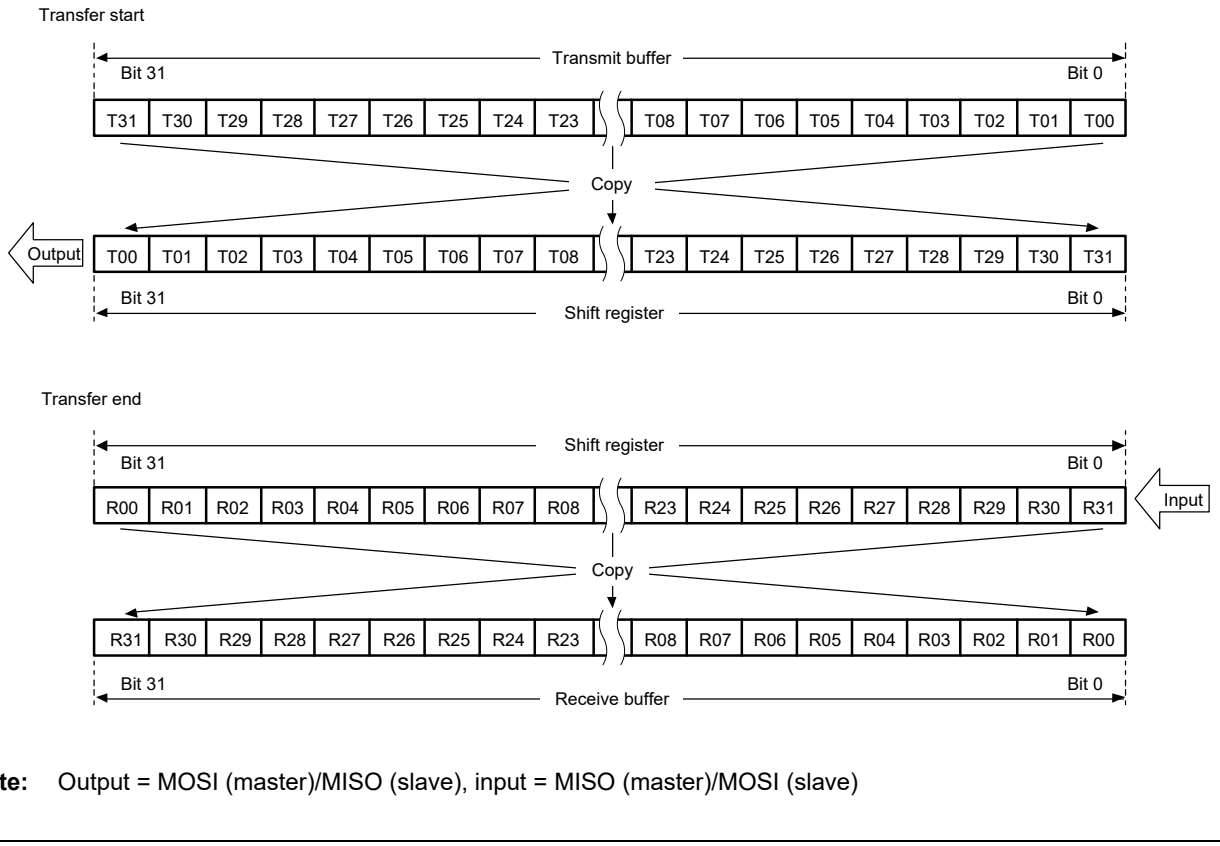
As an example of MSB-first transfer of data other than 32 bits with the parity function disabled, **Figure 7.5-18** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24 bits (T23 to T00) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T23 → T22 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R23 to R00, the shift register value is copied to the receive buffer.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 7.5-18 MSB First Transfer (24-Bit Data, Parity Disabled)



(3) LSB first transfer (32-bit data)

Figure 7.5-19 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function disabled.

In transmission, bit values of the transmit buffer (T31 to T00) are reversed in bit units and are copied to the shift register in the order of T00 to T31. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

In reception, the first received data is stored in bit 0 of the shift register, and received data is shifted in units of data.

When necessary RSPCK cycles are input and data is stored from R00 to R31, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R31 to R00.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

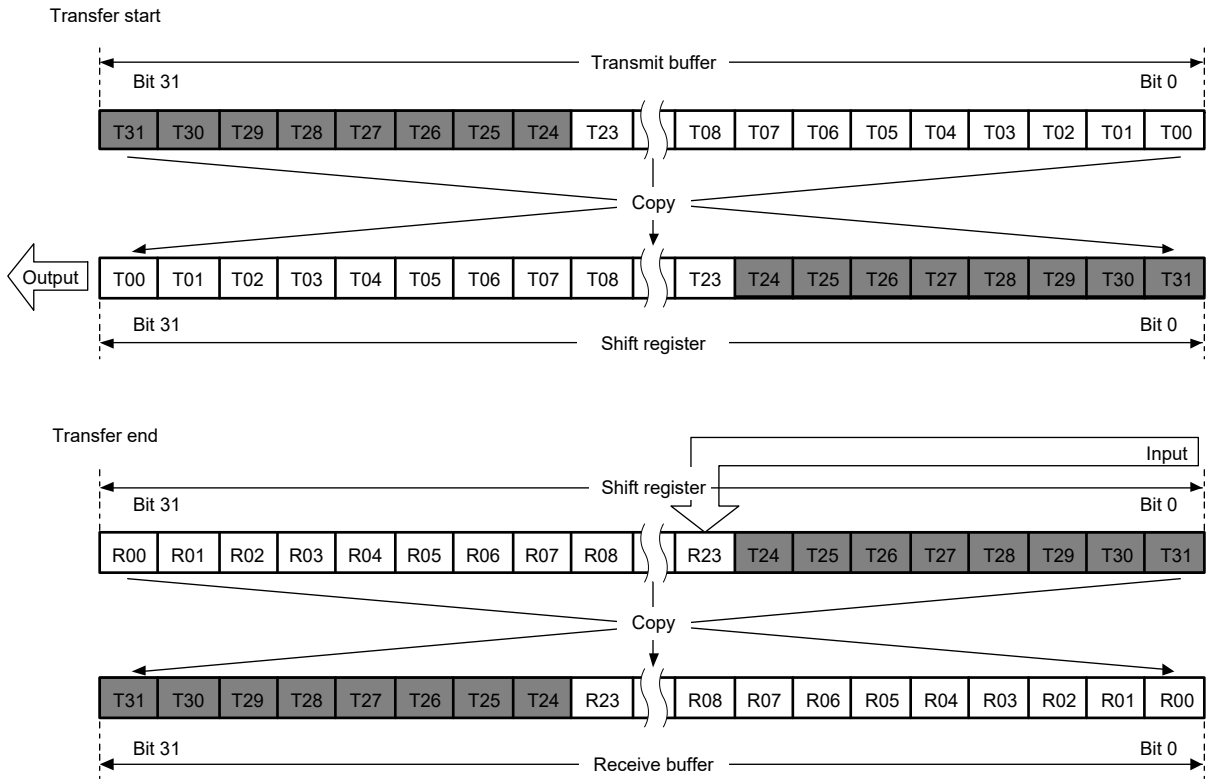


Figure 7.5-19 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB first transfer (24-bit data)

As an example of LSB-first transfer of data other than 32 bits with the parity function disabled, **Figure 7.5-20** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

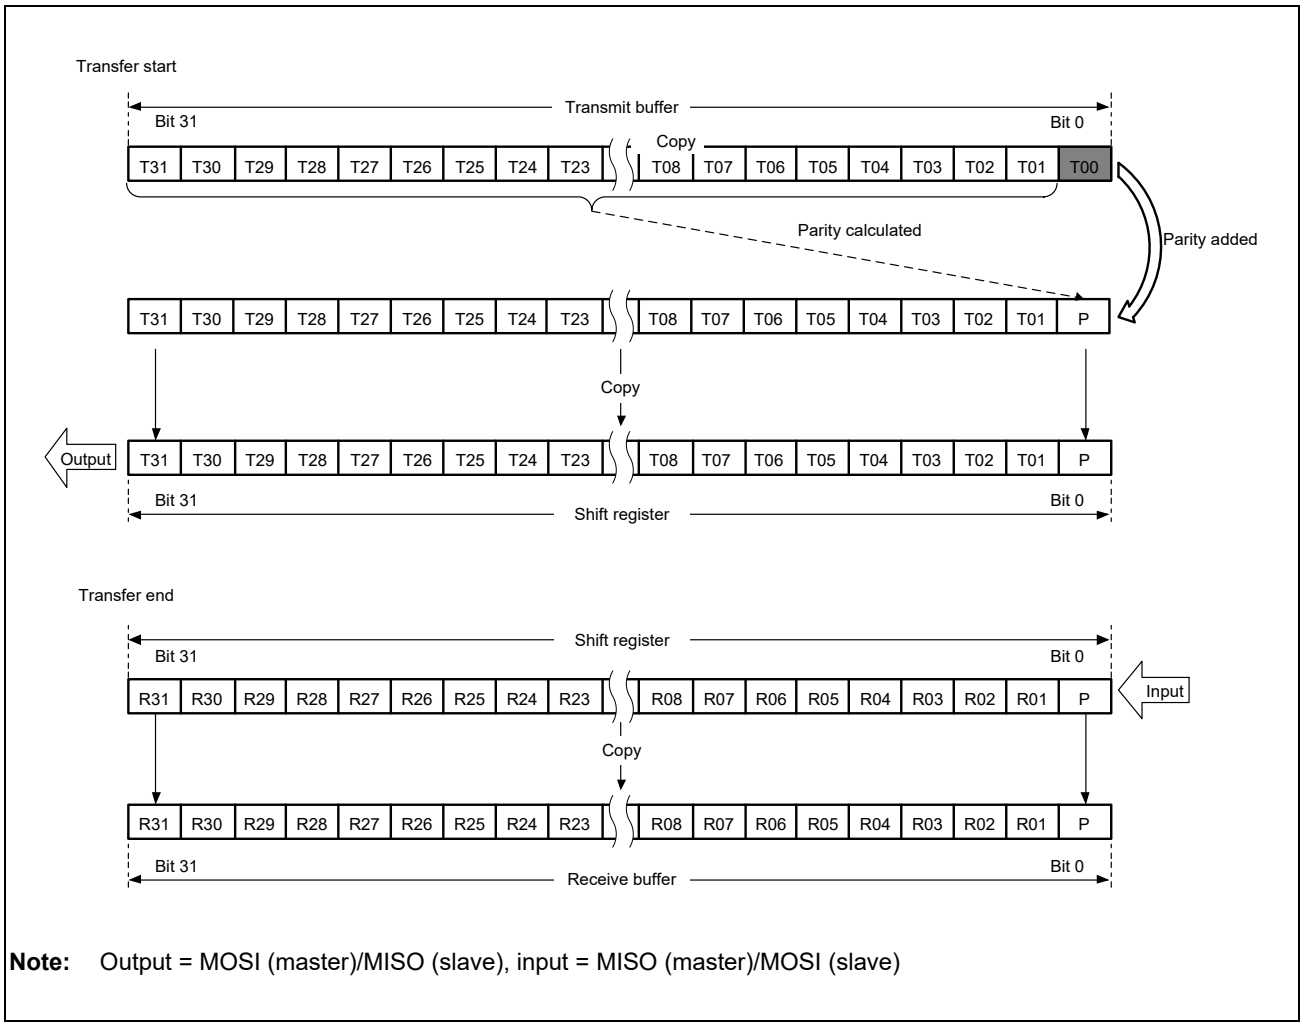
In transmission, lower 24-bit values of the transmit buffer (T23 to T00) are reversed to the order from T00 to T23 in bit units and are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T23 as transmit data.

In reception, received data is stored in bit 8 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R00 to R23, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R23 (bit 23) to R00 (bit 0).

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 7.5-20 LSB First Transfer (24-Bit Data, Parity Disabled)

7.5.3.4.3 When parity is enabled (SPPE = 1b)



When the parity function is enabled, the LSB of transmit data or received data is converted to a parity bit. The parity bit value is calculated and converted by the hardware.

(1) MSB first transfer (32-bit data)

Figure 7.5-21 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T31 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T31 → T30 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R31 to P, the shift register value is copied to the receive buffer, and at the same time, R31 to P data is checked to determine whether a parity error is present.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

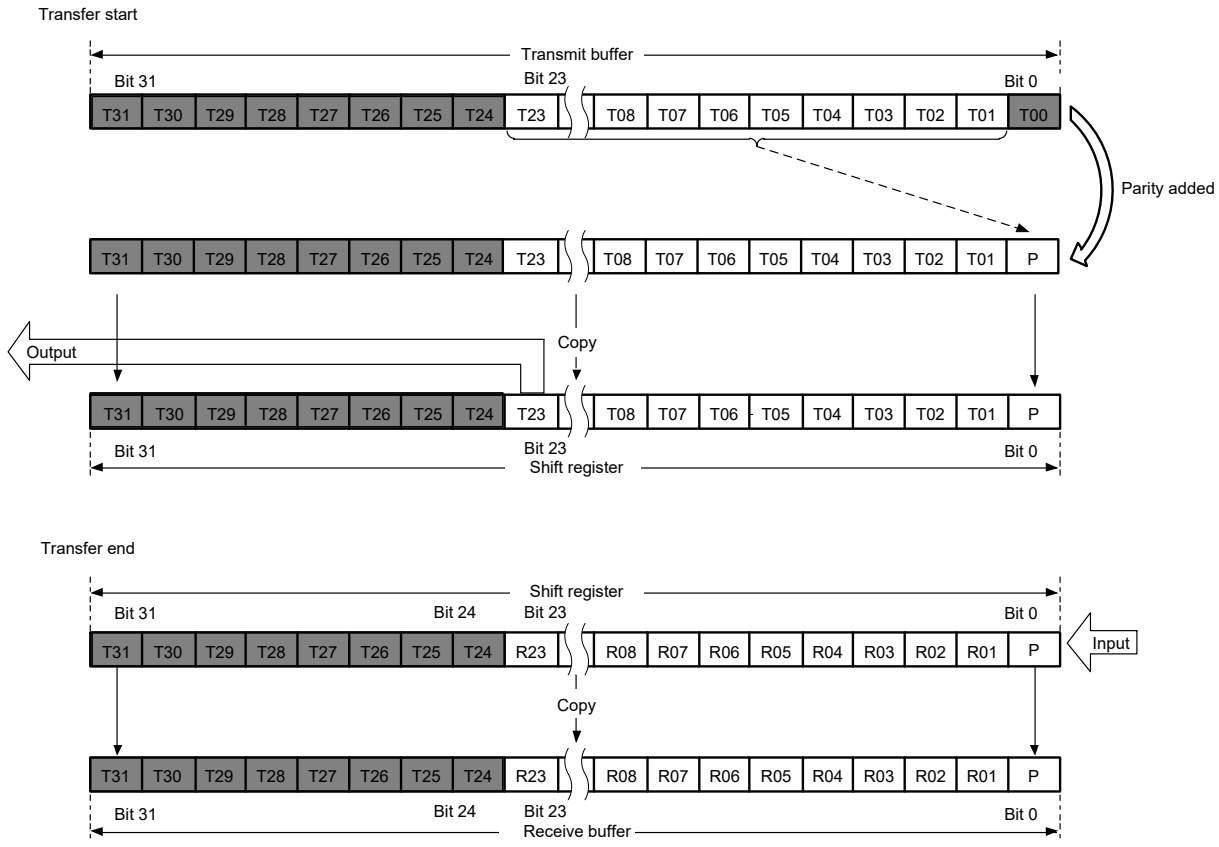


Figure 7.5-21 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB first transfer (24-bit data)

As an example of MSB-first transfer of data other than 32 bits with the parity function enabled, **Figure 7.5-22** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T23 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T23 → T22 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R23 to P, the shift register value is copied to the receive buffer, and at the same time, R23 to P data is checked to determine whether a parity error is present.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

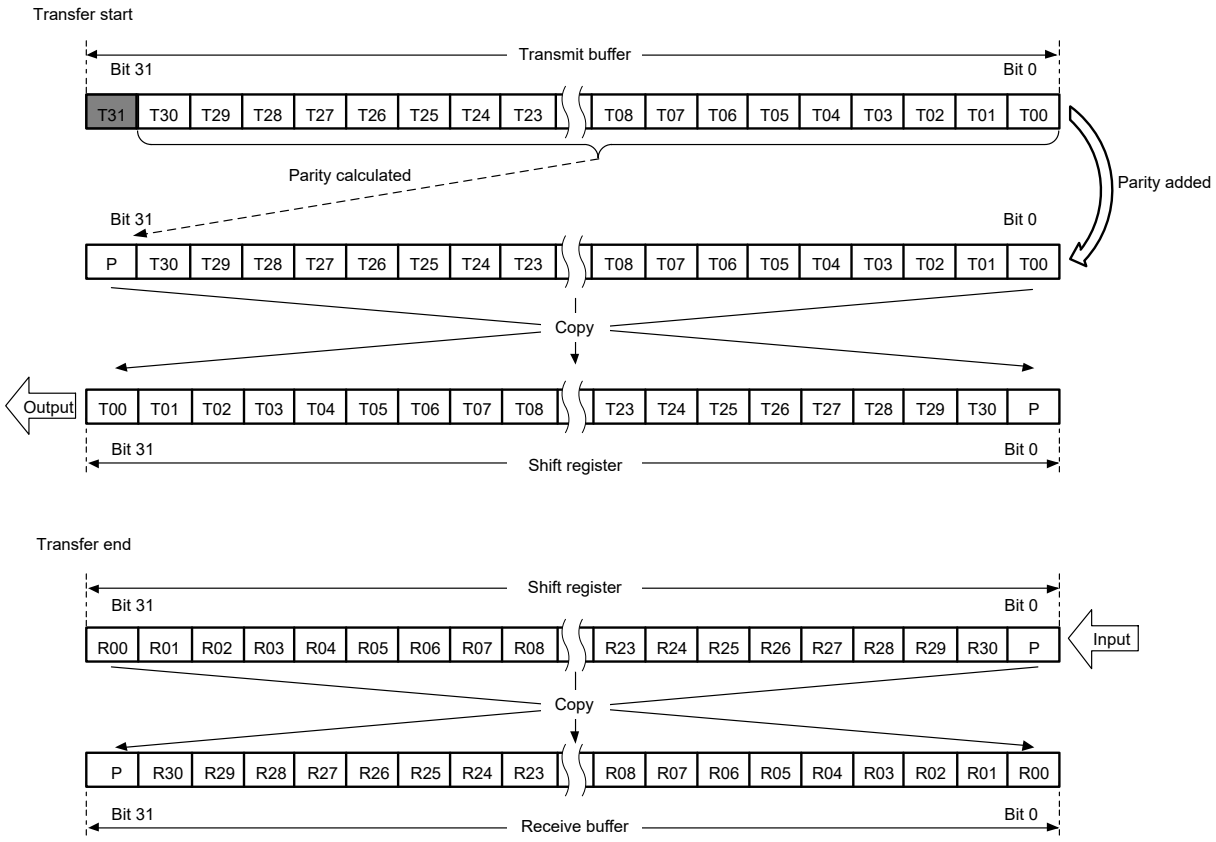

Figure 7.5-22 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB first transfer (32-bit data)

Figure 7.5-23 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T30 to T00, then the final bit T31 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00 → T01 → … → T30 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P to R00, and at the same time, R00 to P data is checked to determine whether a parity error is present.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

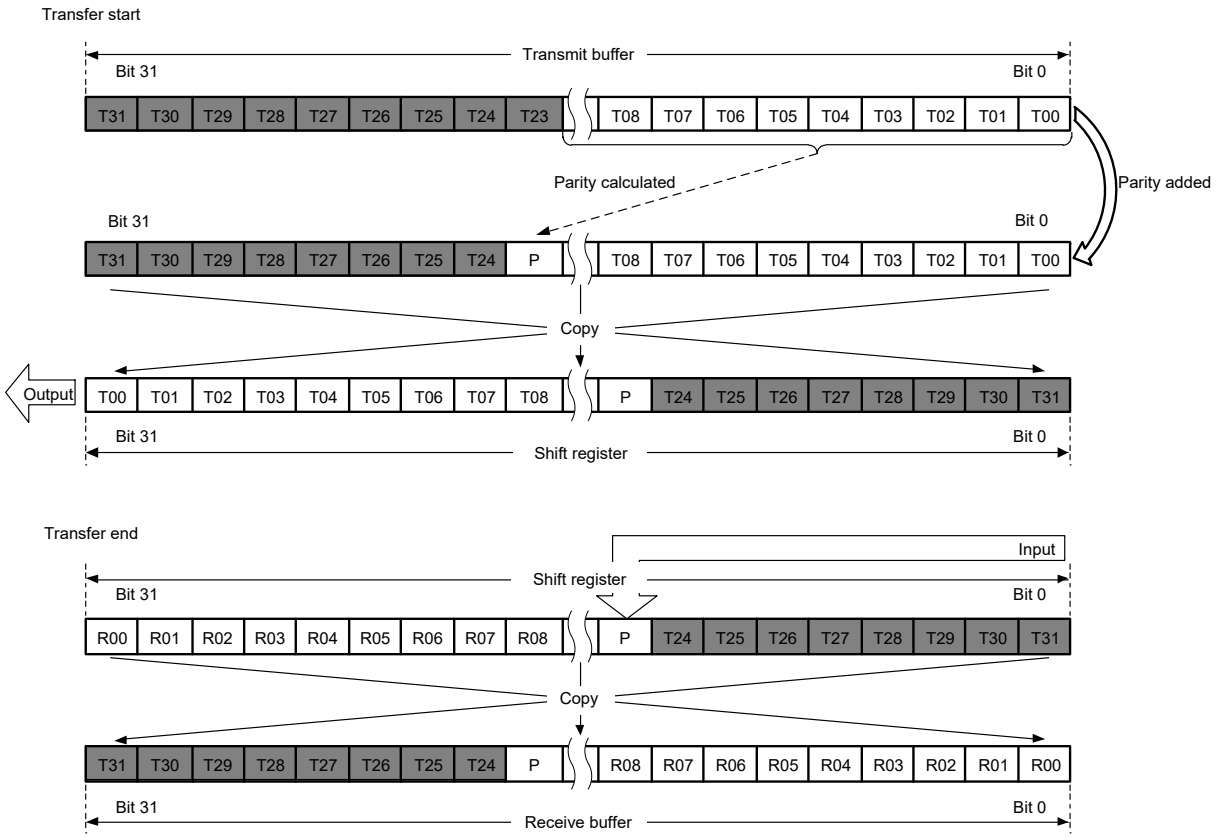

Figure 7.5-23 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB first transfer (24-bit data)

As an example of LSB-first transfer of data other than 32 bits with the parity function enabled, **Figure 7.5-24** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T22 to T00, then the final bit T23 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00 → T01 → … → T22 → P.

In reception, received data is stored in bit 8 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P (bit 23) to R00 (bit 0), and at the same time, R00 to P data is checked to determine whether a parity error is present.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 7.5-24 LSB First Transfer (24-Bit Data, Parity Enabled)

7.5.3.4.4 Byte swap transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register.

(1) 32-bit data length

Figure 7.5-25 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.
2. MSB First Transfer (When the byte swap is enabled.)
   Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.

3. LSB-first transfer (When the byte swap is disabled.)
   Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].
   Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.
4. LSB-first transfer (When the byte swap is enabled.)
   Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].
   Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

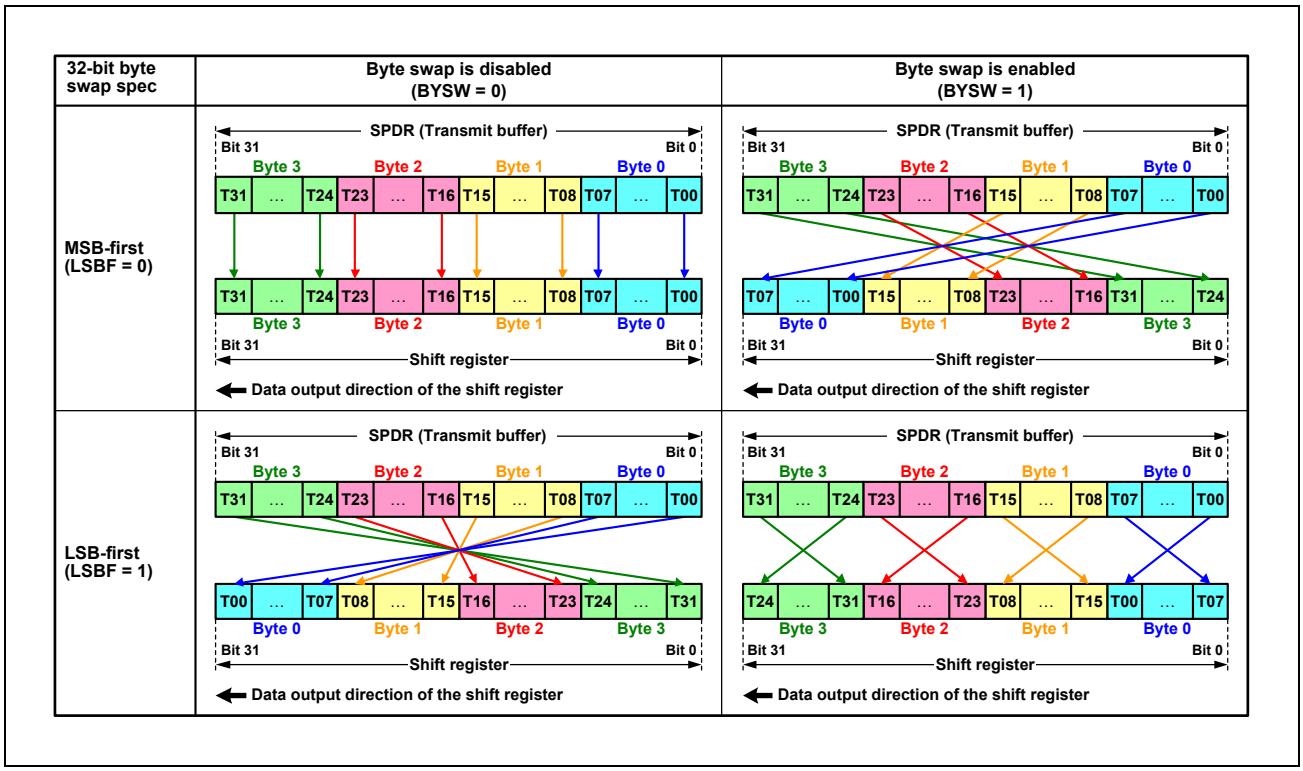

Figure 7.5-25 Byte Swap with MSB/LSB Transfer (32 Bits)

(2) 16-bit data length

Figure 7.5-26 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → … → T00 as transmit data.
2. MSB First Transfer (When the byte swap is enabled.)
   Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte1 [T07 to T00] to Byte0 [T15 to T08].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 as transmit data.
3. LSB-first transfer (When the byte swap is disabled.)
   Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are

copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15].
Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T15 as transmit data.

4. LSB-first transfer (When the byte swap is enabled.)
Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

Figure 7.5-26 Byte Swap with MSB/LSB Transfer (16 Bits)

NOTE

- When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting).
If setting the other length, the behavior is not guaranteed.
- When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0b).
If setting the parity function as valid (SPPE bit = 1b), the behavior is not guaranteed.
- Set SPDCR.BYSW bit, when SPCR.SPE bit is 0b. If rewriting BYSW bit, when SPE bit is 1b, the behavior after it is not guaranteed.

7.5.3.4.5 Byte swap reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer.

(1) 32-bit data length

Figure 7.5-27 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32- bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. MSB First Transfer (When the byte swap is enabled.)
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. LSB-first transfer (When the byte swap is disabled.)
   The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
4. LSB-first transfer (When the byte swap is enabled.)
   The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

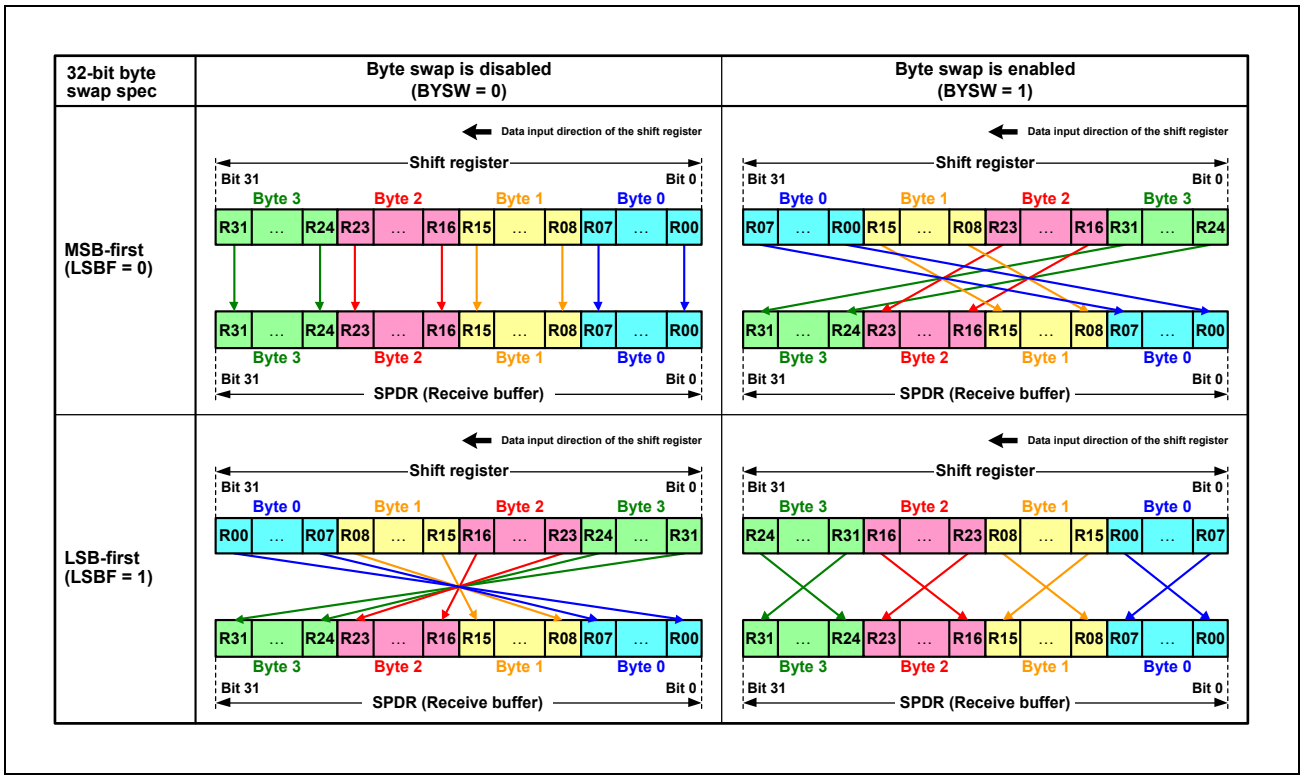

Figure 7.5-27 Byte Swap with MSB/LSB Reception (32 Bits)

(2) 16-bit data length

Figure 7.5-28 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16- bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte1 [R15 to R08] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

2. MSB First Transfer (When the byte swap is enabled.)
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

3. LSB-first transfer (When the byte swap is disabled.)
   The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → … → R15.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

4. LSB-first transfer (When the byte swap is enabled.)
   The first received data (R08) is stored in bit 0 of the shift register, and received data is shifted in the order of R08 → R09 → … → R15 → R00 → R01 → … → R07.

When necessary RSPCK cycles are input and data is stored from Byte1 [R08 to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

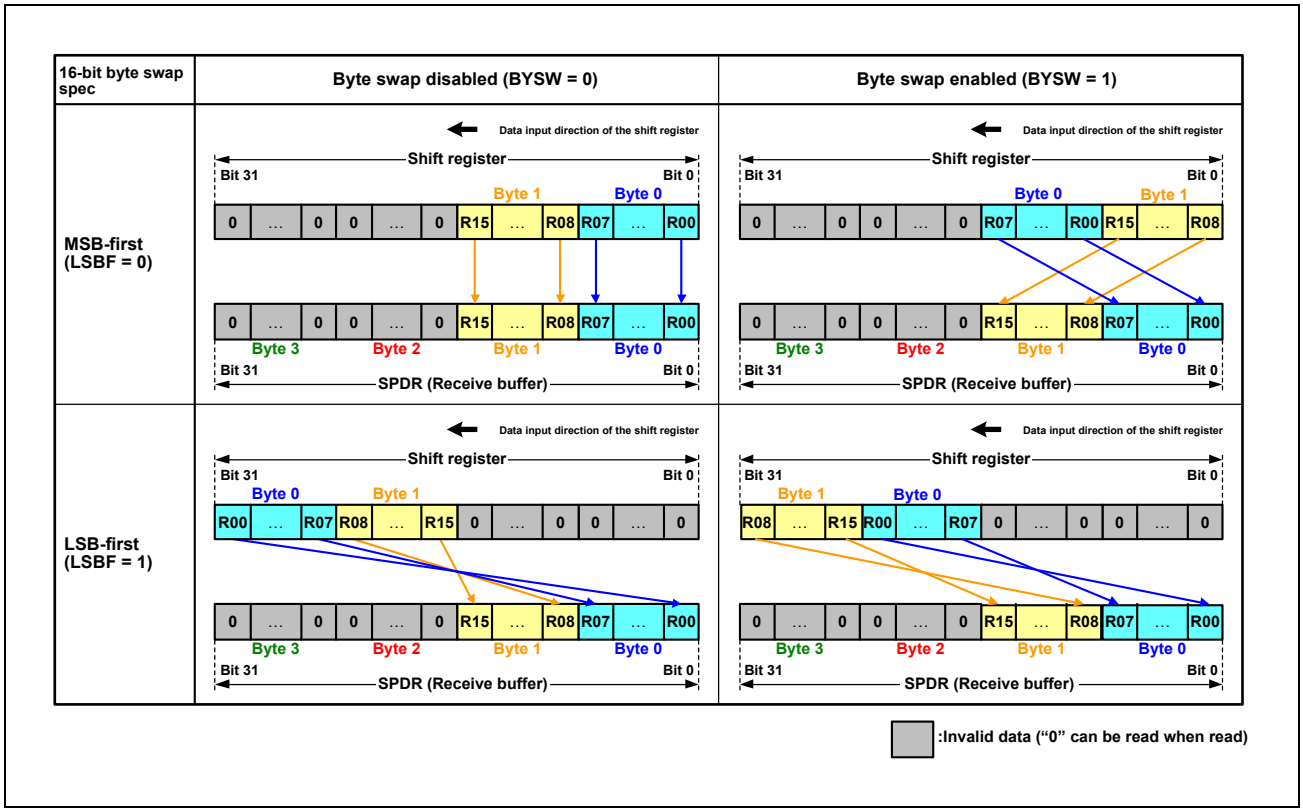

Figure 7.5-28 Byte Swap with MSB/LSB Reception (16 Bits)

NOTE

- When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting) .
  If setting the other length, the behavior is not guaranteed.
- When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0b).
  If setting the parity function as valid (SPPE bit = 1b), the behavior is not guaranteed.
- Set SPDCR2.BYSW bit, when SPCR.SPE bit is 0b. If rewriting BYSW bit, when SPE bit is 1b, the behavior after it is not guaranteed.

7.5.3.5 Transfer Format (Frame Format)

7.5.3.5.1 CPHA = 0b

Figure 7.5-29 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 0b. However, when the SPI is in slave mode (SPCR.MSTR = 0b) with the CPHA bit set to 0b, clock synchronous operation (SPCR.SPMS = 1b) is not guaranteed. In **Figure 7.5-29**, RSPCK (CPOL = 0b) is the RSPCK signal waveform when SPCMD.CPOL = 0b, and RSPCK (SPCMD.CPOL = 1b) is the RSPCK signal waveform when SPCMD.CPOL = 1b. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI settings. (See **7.5.3.2 SPI Pin Control**.)

When SPCMD.CPHA = 0b, output of valid data to the MOSI signal and valid data drive to the MISO signal start at the SSL signal assertion timing. The first RSPCK signal change timing after the SSL signal is asserted is the first transfer data latch timing. After this timing, data is sampled in each RSPCK cycle. The MOSI signal and the MISO signal change always after the half RSPCK cycles of the transfer data latch timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Period t1 is the period (RSPCK delay) from SSL signal assertion to RSPCK oscillation. Period t2 is the period (SSL negation delay) from RSPCK oscillation stop to SSL signal negation. Period t3 is the period (next-access delay) to inhibit SSL signal assertion for the next transfer after serial transfer is completed. Periods t1, t2, and t3 are controlled by the master device in the SPI system. For t1, t2, and t3 when this LSI (SPI) is in master mode, see **7.5.3.13.1 Master mode operation**.

[In the Motorola-SPI case]

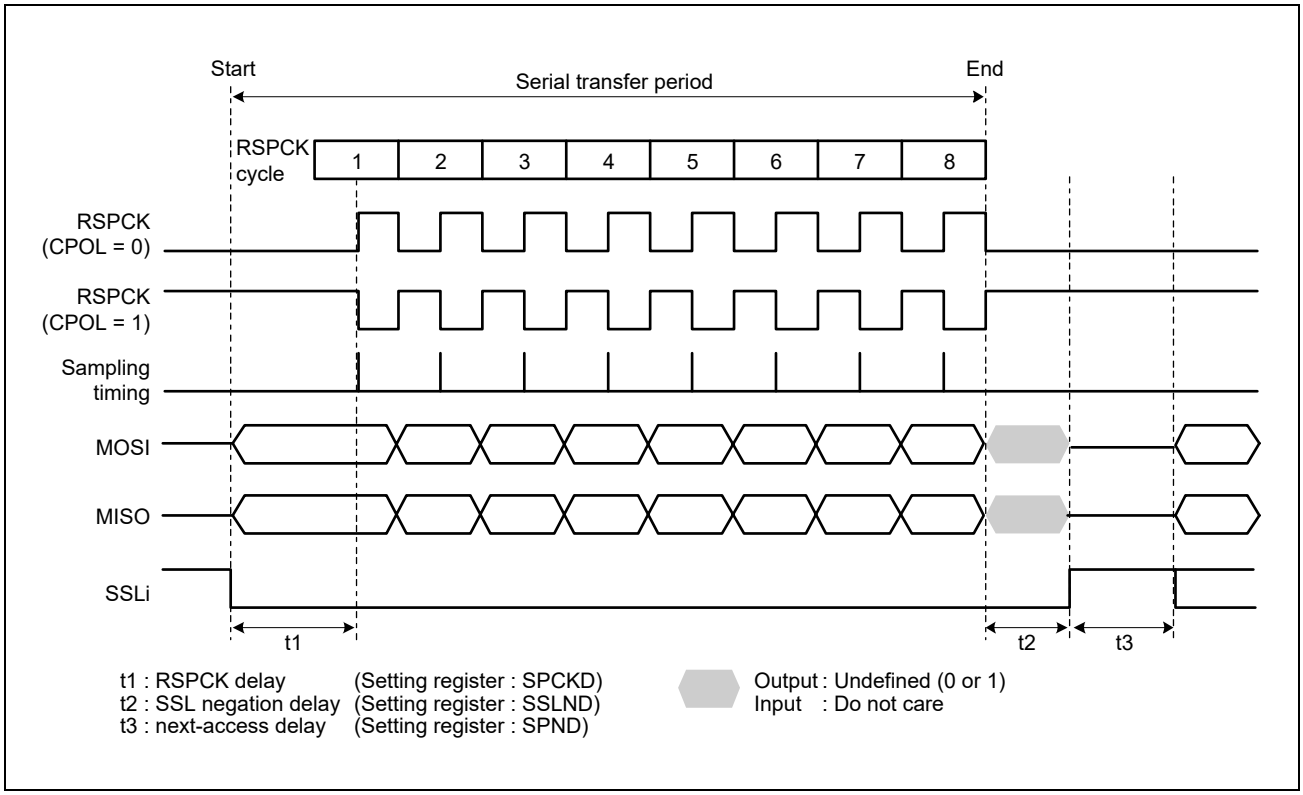

Figure 7.5-29 SPI Transfer Format (CPHA = 0b, SPFRF = 0b)

7.5.3.5.2 CPHA = 1b

Figure 7.5-30 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 1b. However, when SPCR.SPMS = 1b, communication is performed by using only RSPCK, MOSI, and MISO signals without using the SSL signal. In **Figure 7.5-30**, RSPCK (CPOL = 0b) is the RSPCK signal waveform when SPCMD.CPOL = 0b, and RSPCK (SPCMD.CPOL = 0b) is the RSPCK signal waveform when SPCMD.CPOL = 0b. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI mode (master or slave mode). (See **7.5.3.2 SPI Pin Control**.)

When SPCMD.CPHA = 1b, invalid data drive to the MISO signal starts at the SSL signal assertion timing. Output of valid data to the MOSI and MISO signals starts at the first RSPCK signal change timing after the SSL signal is asserted.

After this timing, data is updated in each RSPCK cycle. Transfer data is always latched after 1/2 RSPCK cycle of this timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Periods t1, t2, and t3 are the same as when CPHA = 0b. For t1, t2, and t3 when this LSI (SPI) is in master mode, see **7.5.3.13.1 Master mode operation**.

[In the Motorola-SPI case]

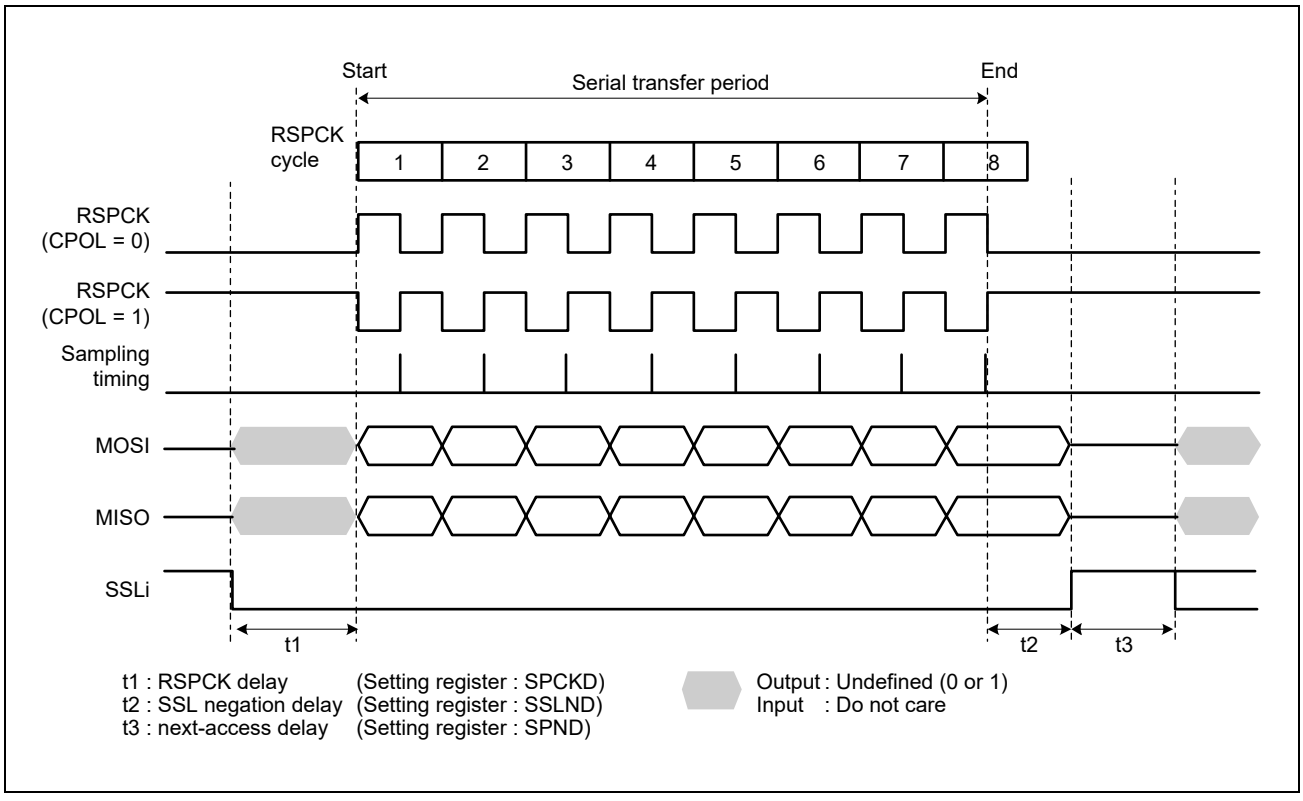

Figure 7.5-30 SPI Transfer Format (CPHA = 1b, SPFRF = 0b)

7.5.3.6 Communications Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD[1:0]) of the SPCR register.

SPDR access described in **Figure 7.5-31**, **Figure 7.5-32**, and **Figure 7.5-33** shows an access to the SPDR register. W shows a write cycle.

7.5.3.6.1 Transmit-receive serial communication (TXMD[1:0] = 00b)

Figure 7.5-31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example in **Figure 7.5-31**, the SPI performs 8-bit data serial transfer with the settings of RTRG = FIFO stage - 1, SPDCR2.TTRG = 0b, SPCMD.CPHA = 1b, and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

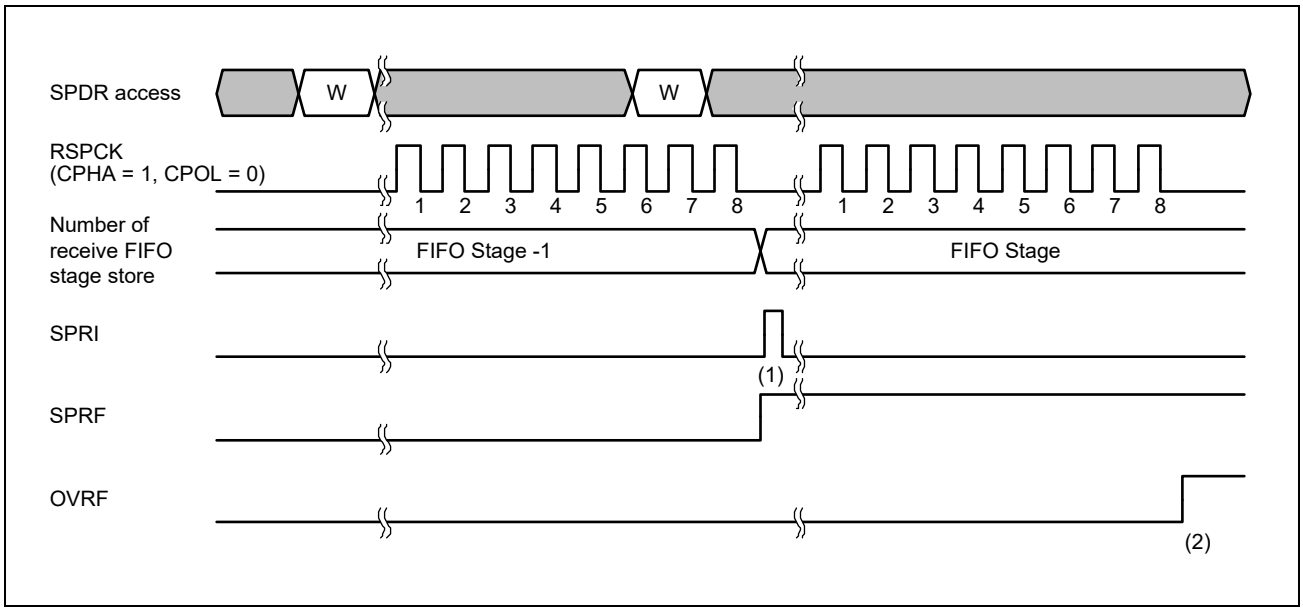

Figure 7.5-31 Operation Example of TXMD[1:0] = 00b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1b) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR register to 1 and discards the received data in the shift register.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1b at timings (1) and (2) respectively.

7.5.3.6.2 Transmit-only serial communication (TXMD[1:0] = 01b)

Figure 7.5-32 shows an example of operation when the communication mode select bits (TXMD[1:0]) in the SPCR register are set to 01b. In the example in **Figure 7.5-32**, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 00b, SPDCR2.RTRG[1:0] = 00b, SPCMD.CPHA = 1b, and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

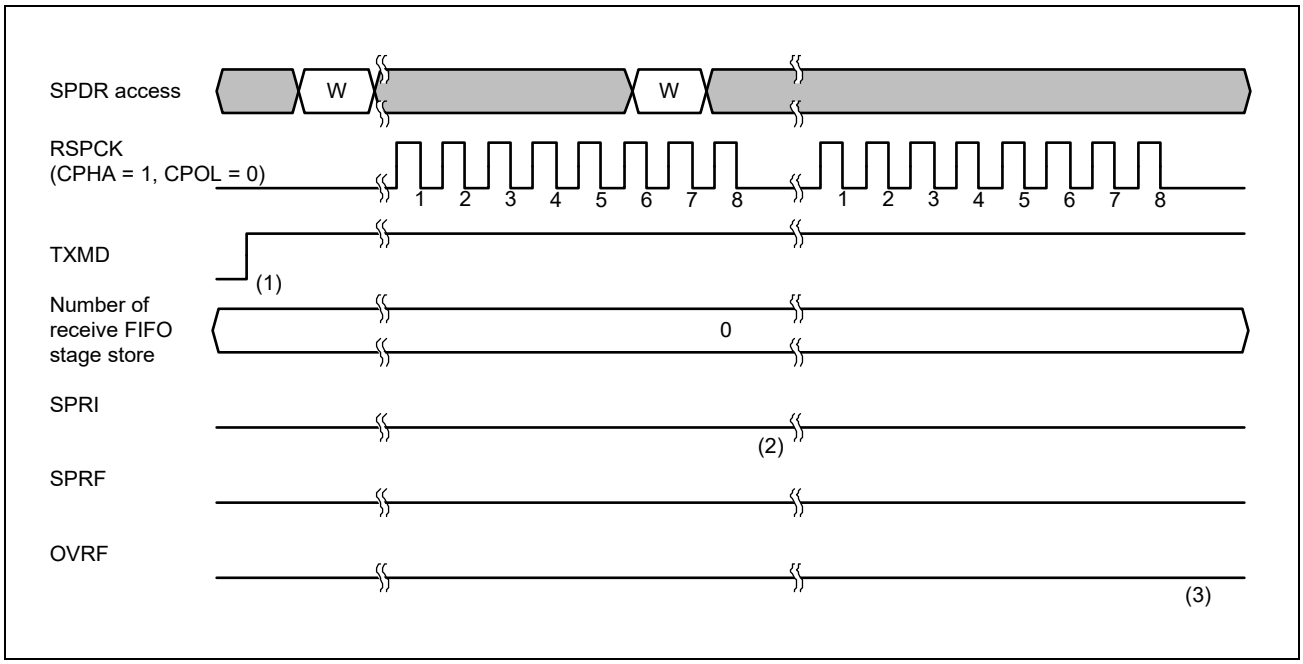

Figure 7.5-32 Operation Example of TXMD[1:0] = 01b

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) Before setting TXMD[1:0] to 01b (transmit-only serial communication), confirm that the receive buffer is empty and that the SPRF and OVRF flags in the SPSR register are 0b.

(2) In transmit-only serial communication (TXMD[1:0] = 01b), when serial transfer ends without receiving data in the receiving FIFO of SPDR, the SPRF flag remains 0 and the shift register data is not copied to the receive buffer.

(3) The OVRF flag remains 0 even after serial transfer ends because previously received data is not remaining in the SPDR's receive buffer, and the shift register data is not copied to the receive buffer.

In transmit-only serial communication (TXMD[1:0] = 01b), transmit data is transmitted but receive data is not received. Therefore, the SPRF flag and the OVRF flag remain 0 at each timing of (1) to (3).

7.5.3.6.3 Receive-only serial communication (TXMD[1:0] = 10b)

Figure 7.5-33 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1b. In the example in **Figure 7.5-33**, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 0b, SPDCR2.RTRG[1:0] = FIFO stage - 1, SPCMD.CPHA = 1b, and CPOL in SPCMD = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

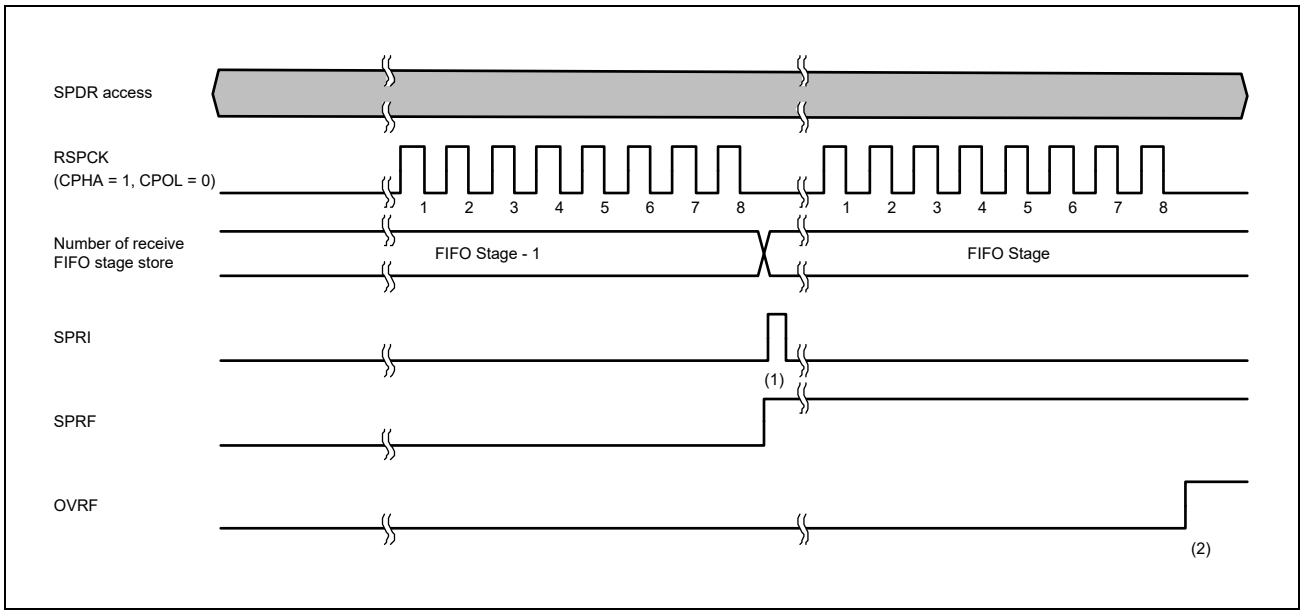

Figure 7.5-33 Operation Example of TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR.SPI register to 1b and discards the received data in the shift register.

7.5.3.7 Transmission buffer empty/receive buffer full interrupt

Figure 7.5-34 show an example of operation of SPI transmit buffer empty interrupt (SPTI) and SPI receive buffer full interrupt (SPRI) respectively. “SPDR access” described in **Figure 7.5-34** and shows an access to the SPDR register. W shows a write cycle and R shows a read cycle. In each example of operation, the SPI performs 8-bit data serial transfer with the settings of SPCR.TXMD[1:0] = 00b, SPDCR2.TTRG = 0b, SPDCR2.RTRG = 0b, SPCMD.CPHA = 0b (**Figure 7.5-34**), and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

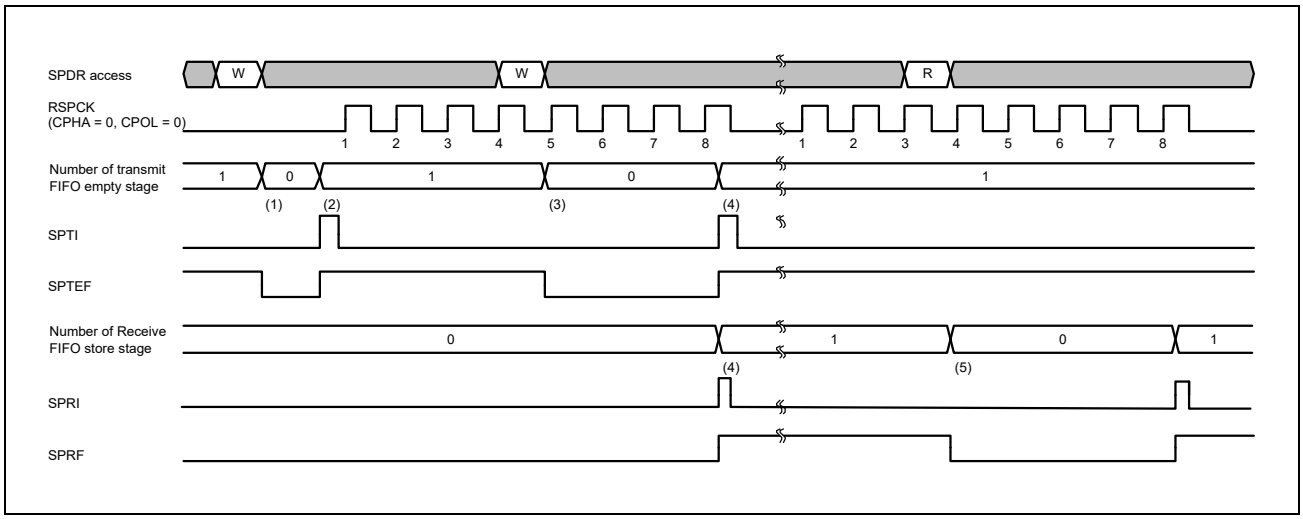

Figure 7.5-34 Example of SPTI Interrupt and SPRI Interrupt Operations

The following describes operation at timings (1) to (5) in the figure above.

(1) When transmit data is written to SPDR before the data for the next transfer is not set to the FIFO of the SPDR, the SPI writes data to the transmission buffer. When transmit data is written to SPDR in one processing routine using DMAC, the SPSR.SPTEF flag is cleared to 0b at the last access.

(2) When the shift register is empty, the SPI copies transmit buffer data to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPTI) and sets the SPTEF flag to 1. How to start serial transfer depends on SPI mode. (See **7.5.3.13 SPI Operation** and **7.5.3.14 Clock Synchronous Operation**.)

(3) When transmit data is written to SPDR upon a transmit buffer empty interrupt request (SPTI) or in the transmit buffer empty determination processing due to the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DMAC, the SPTEF flag is cleared to 0b at the last access. The SPI does not copy transmit buffer data to the shift register because the shift register contains serial transfer data.

(4) When serial transfer ends (data sampling clock edge in the final bit is detected) while the receive buffer of SPDR > FIFO stage number, the SPI copies the received data in the shift register to the receive buffer. At this time, a receive buffer full interrupt request is generated and the SPRF flag is set to 1b. When serial transfer ends, the shift register becomes empty. If the next transfer data is set in the transmit FIFO before serial transfer ends, the SPI set the SPTEF flag to 1b and copies transmit buffer data to the shift register. Even if received data is not copied from the shift register to the receive buffer while an overrun error is present, the SPI determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(5) When SPDR is read upon a receive buffer full interrupt request (SPRI) or in the receive buffer full determination processing due to the SPRF flag, received data can be read. If the received data is read from SPDR in one processing routine using DMAC, the SPRF flag is cleared to 0b at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update transmit buffer data. Write transmit data to the SPDR register upon a transmit buffer empty interrupt request or check the empty or not the transmission buffer by the SPTEF flag.

While SPCR.SPTIE = 1b, when the SPI is disabled (SPCR.SPE = 0b), an SPI transmit buffer empty interrupt is generated. However, SPI transmit buffer empty interrupt is inhibited by disabling SPI transmit buffer empty interrupt (SPCR.SPTIE = 0b) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI detects an overrun error without copying data from the shift register to the receive buffer (as described in **7.5.3.10 Error Detection**). To prevent overrun of received data, read received data before the next serial transfer ends.

Transmit buffer state and receive buffer state can be monitored by an SPI transmit buffer empty interrupt and an SPI receive buffer full interrupt or a corresponding interrupt flag or by the SPTEF and SPRF flags.

7.5.3.8 Idle Interrupt

The idle interrupt during master mode operation is when the SPCP[2:0] of the SPSSR register becomes 000b (start of sequence control), the IDLNF flag in the SPSR register is set to 1b and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0b.

7.5.3.8.1 In the Motorola-SPI case

Figure 7.5-35 shows an example of idle interrupt operation during normal operation.

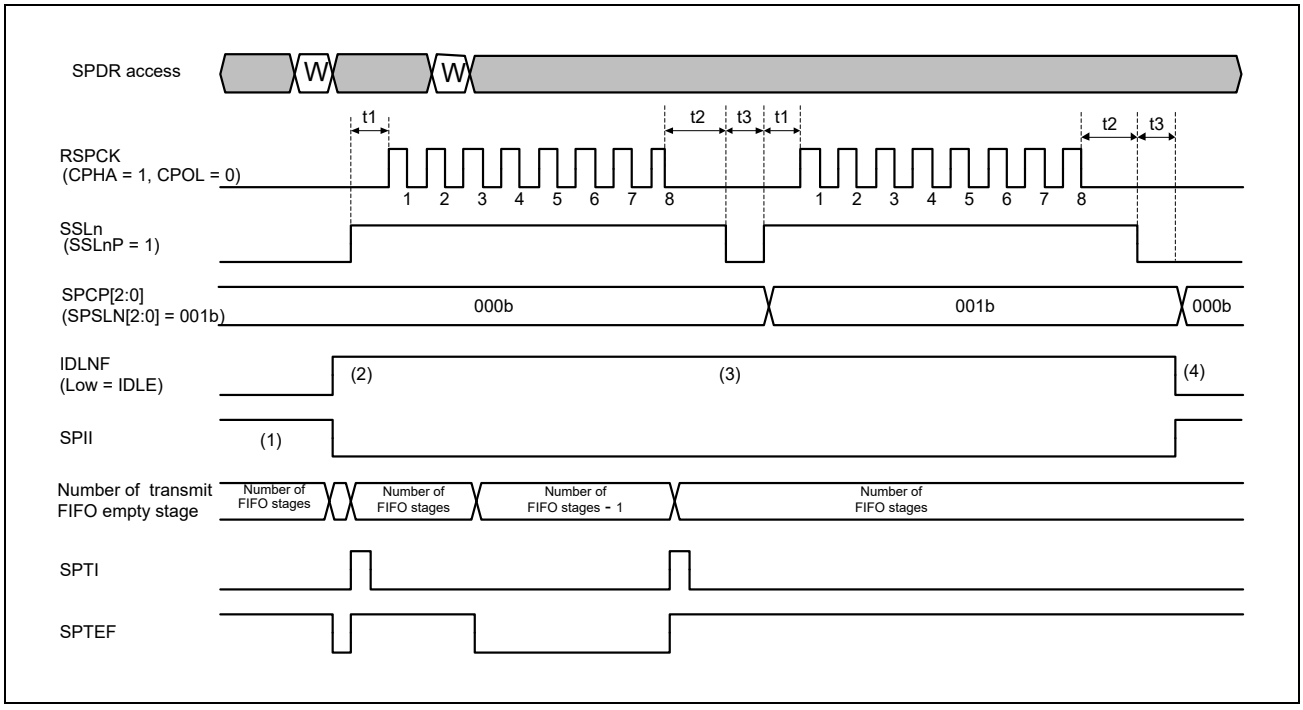

Figure 7.5-35 Example of Idle Interrupt Operation (Master Mode/Motorola-SPI)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1b before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0b before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1b (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1b currently, an SPII interrupt is output.

7.5.3.8.2 In the TI-SSP case

Figure 7.5-36 shows an example of idle interrupt operation during normal operation.

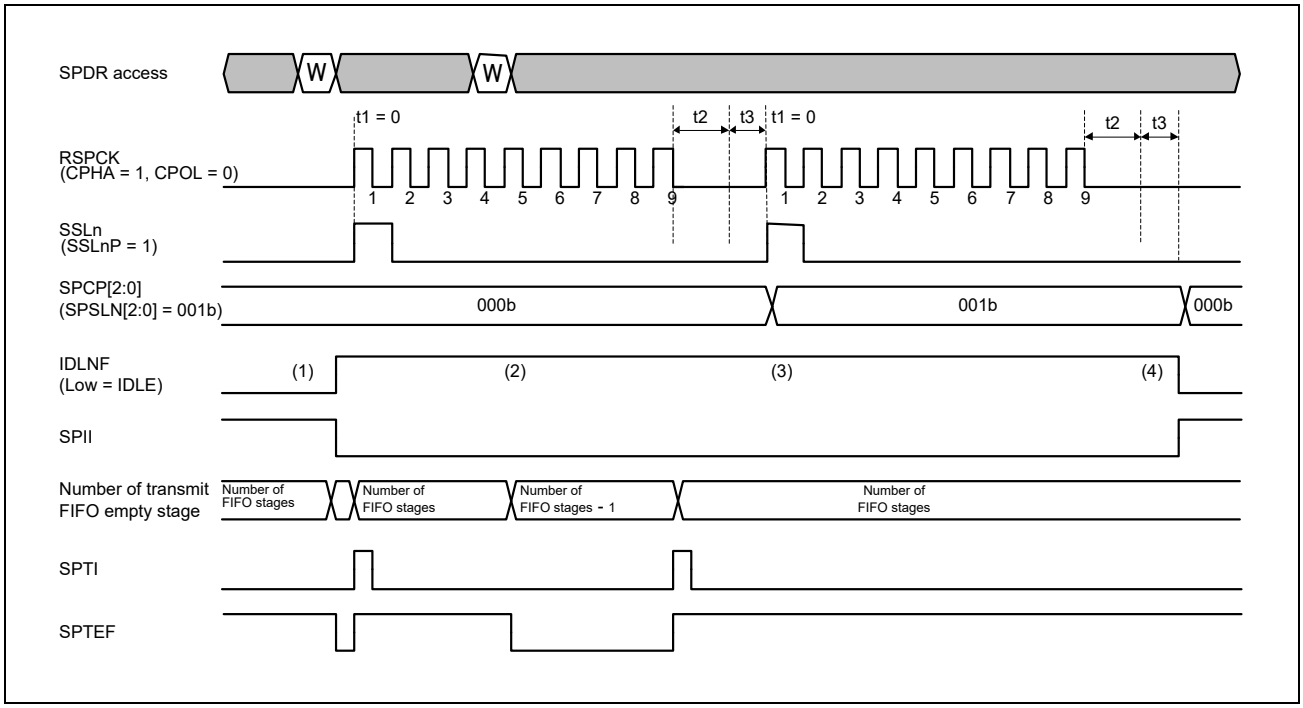

Figure 7.5-36 Example of Idle Interrupt Operation (Master Mode/TI-SSP)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0b (IDLE). Writing transmit data makes sets the IDLNF flag to 1b (BUSY). When the SPCR.SPIIE bit is set to 1b before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0b before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1b (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0b (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When SPCR.SPIIE = 1b currently, an SPII interrupt is output.

7.5.3.9 Communication End Interrupt

7.5.3.9.1 Transmit-receive/transmit-only in master mode

Refer to the description of the CENDF bit in **7.5.2.2.19 SPI Transfer FIFO Status Register (RSPIm_SPTFSR)** and **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)** for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

(1) In the Motorola-SPI case

Figure 7.5-37 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

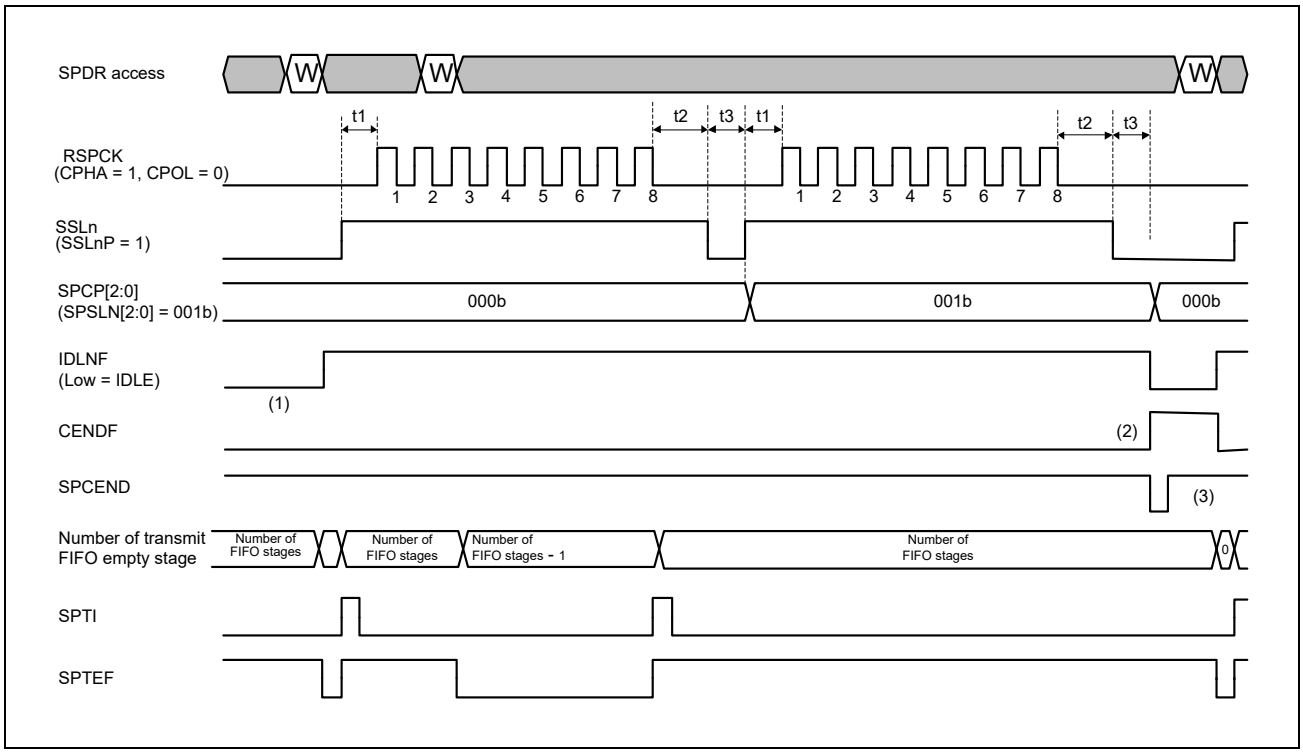

Figure 7.5-37 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Master Mode/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 7.5-38 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

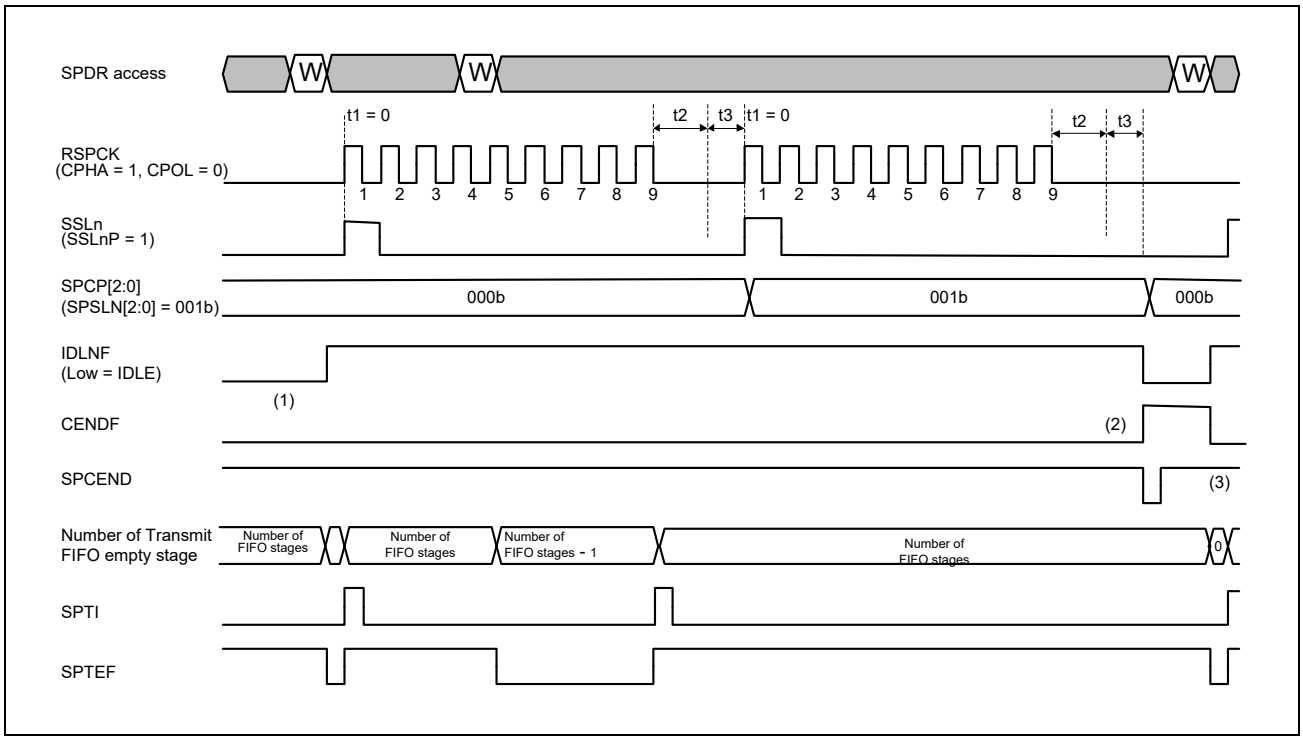

Figure 7.5-38 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Master Mode/TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1b (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.2 Receive-only in master mode

Refer to the description of the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)** for the setting/clearing conditions of the communication completion flag during Receive-only in Master Mode.

Figure 7.5-39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 00h.

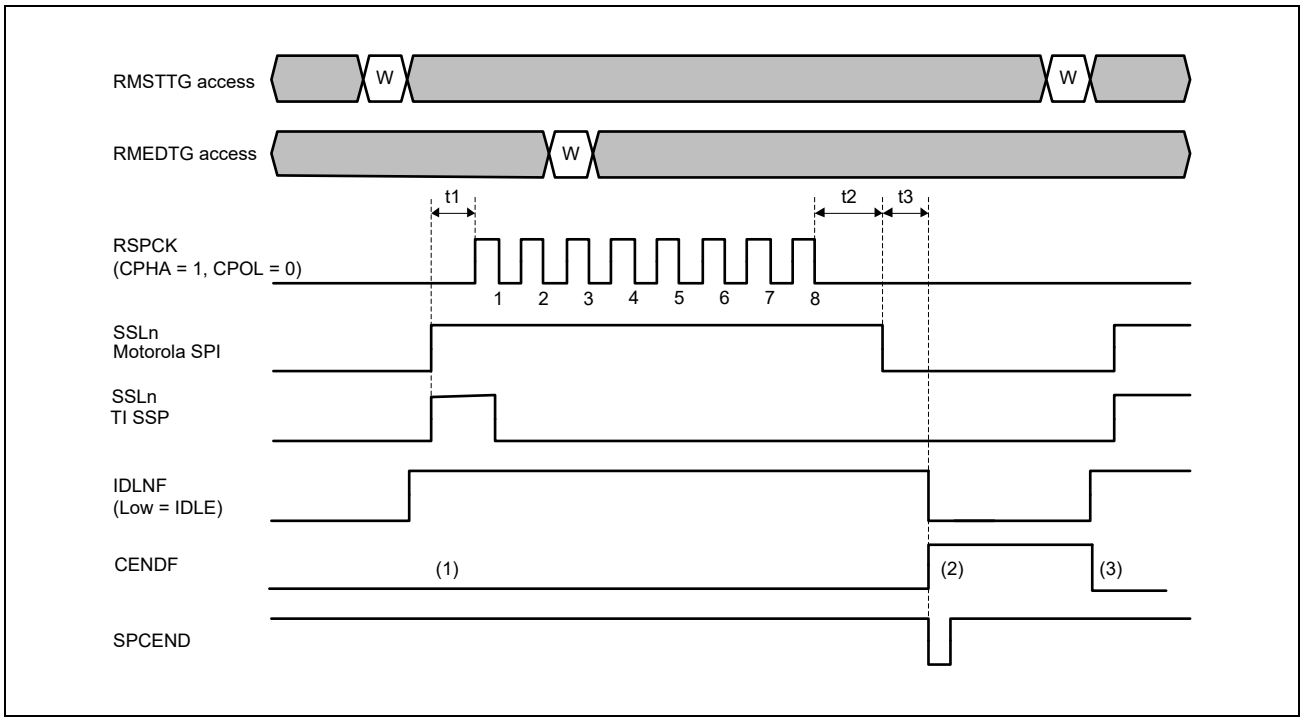

Figure 7.5-39 Example of Communication End Interrupt Operation (Receive-Only Master Mode/Motorola-SPI) at RMFM[4:0] = 00h

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, by writing 1 to RMEDTG during the communication frame. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when writing 1b to RMSTTG, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 7.5-40 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 00h.

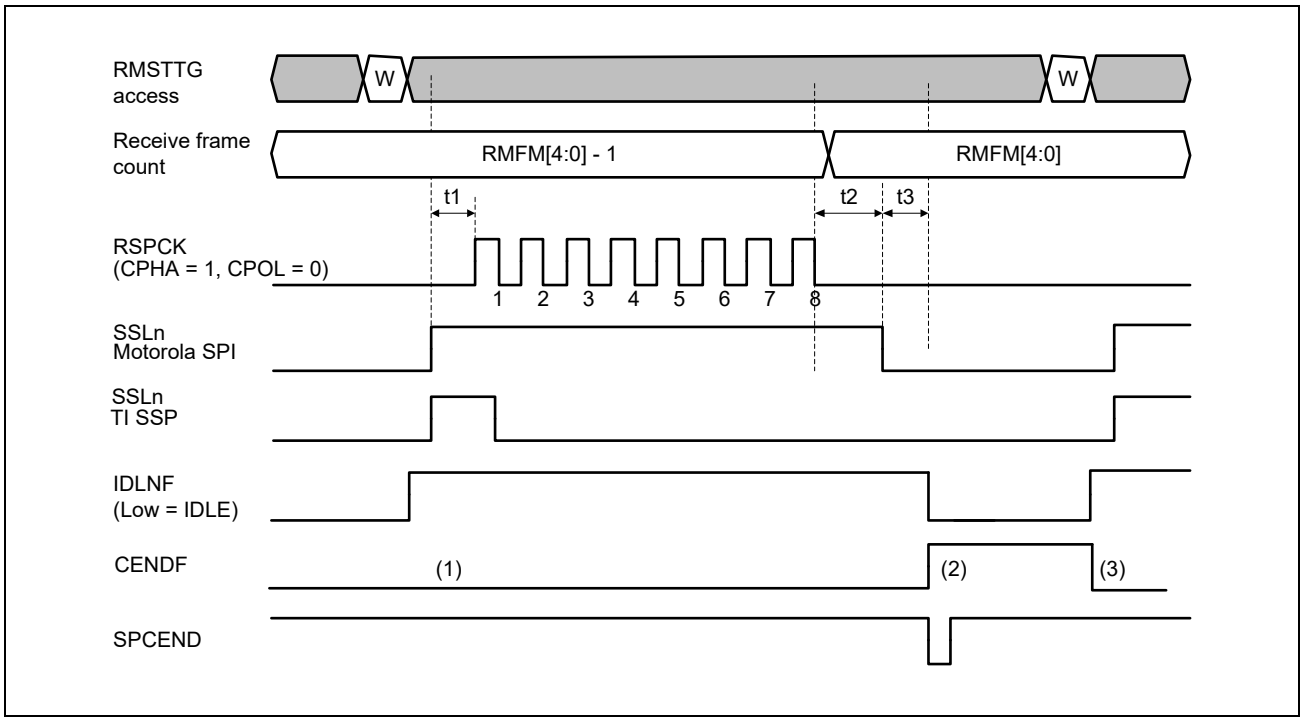

Figure 7.5-40 Example of Communication End Interrupt Operation (Receive-Only Master Mode/Motorola-SPI) at RMFM[4:0] ≠ 00h

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, after receiving the number of frames set by RMFM[4:0]. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared when writing 1b to RMSTTG, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is dependent on the value of the SPCR.SPMS bit (SPI mode select bit). The clear timing of the communication end interrupt is dependent on the communication mode (transmit-receive or transmit-only or receive-only).

7.5.3.9.3 Transmit-receive/transmit-only in slave mode on SPI operation (4-wire)

See the description for the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)** for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 7.5-41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

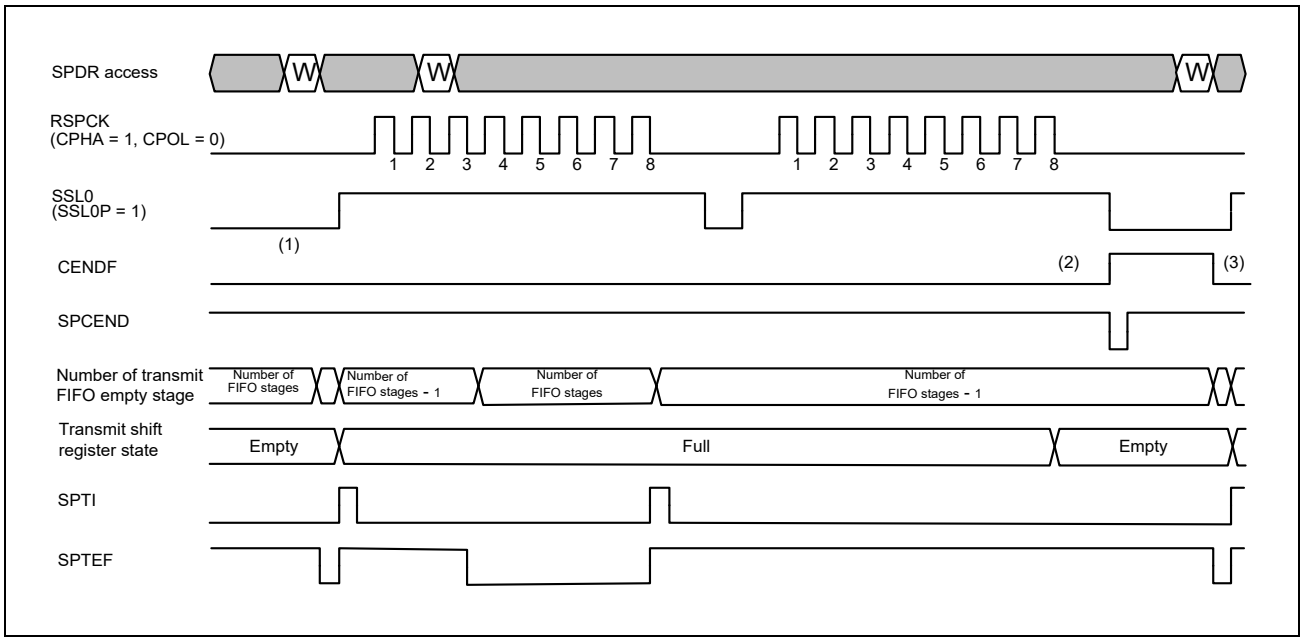

Figure 7.5-41 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Slave Mode on SPI Operation/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the timing of SSL0 negate, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 7.5-42 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

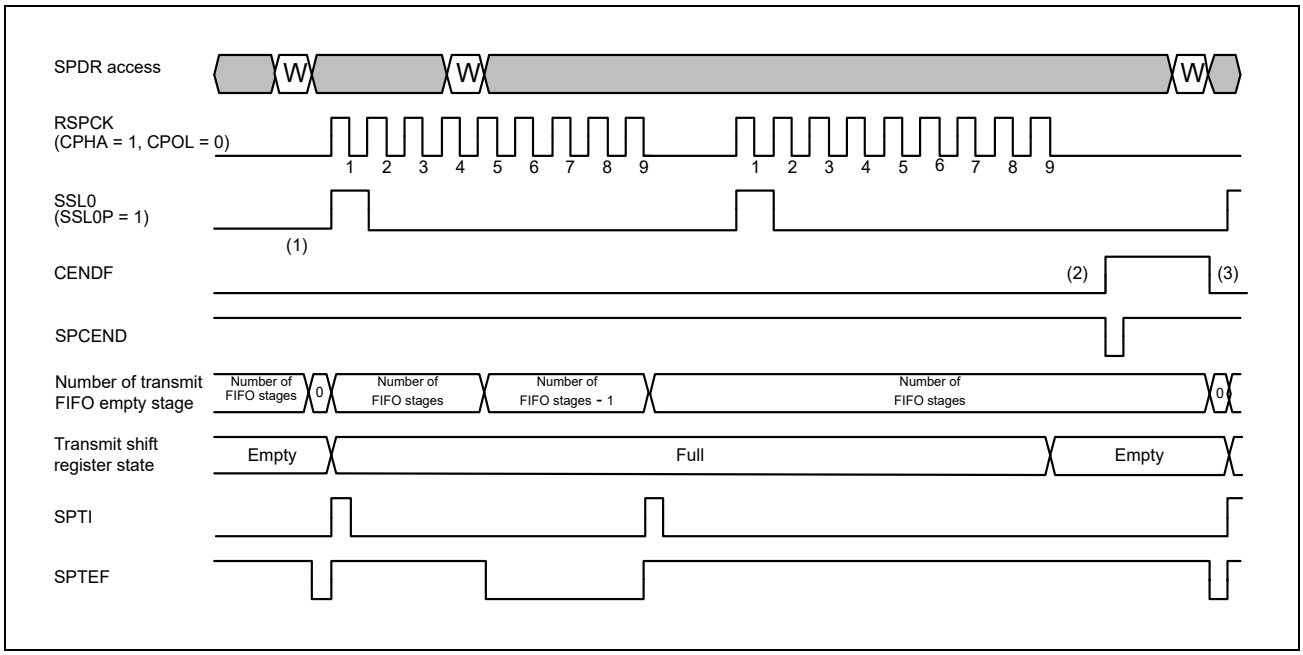

Figure 7.5-42 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Slave Mode on SPI Operation/TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1 (communication end) at the RSPCK last data bit sampling, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.4 Receive only in slave mode on SPI operation (4-wire)

Refer to the description of the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)** for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 7.5-43 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

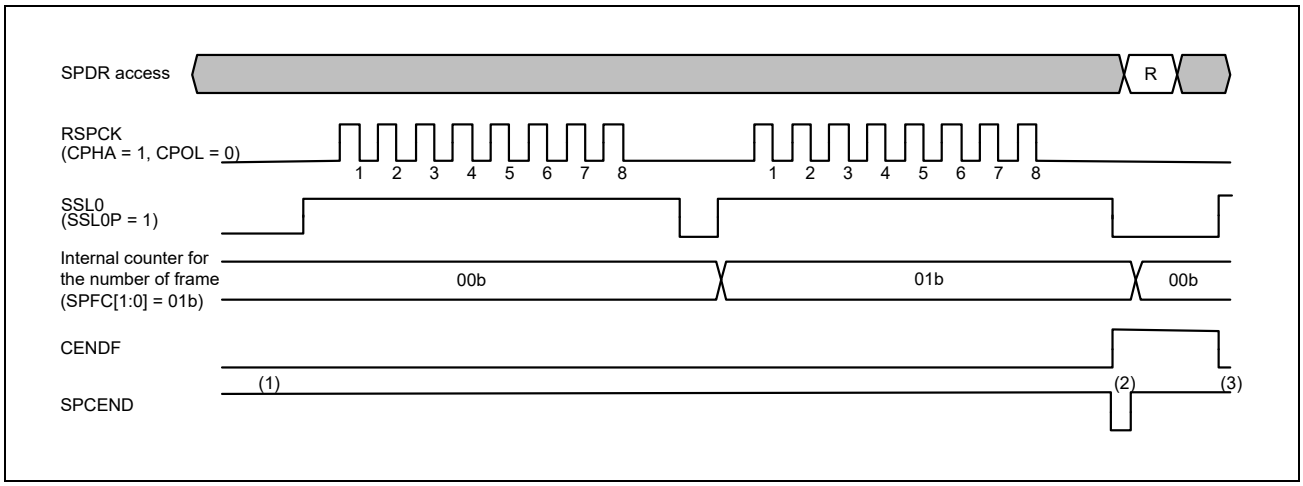

Figure 7.5-43 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on SPI Operation/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication start, and these have kept during communication.

(2) After store the frames for the SPDCR.SPFC register set value in the receive buffer, the CENDF flag becomes 1b (communication completed) at the timing of SSL0 negation. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 7.5-44 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

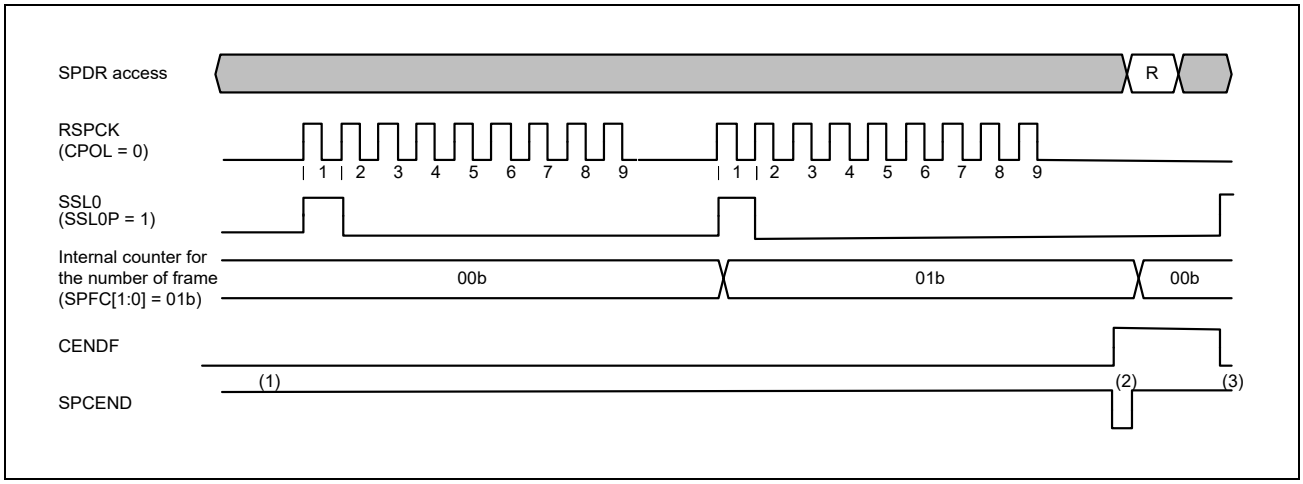

Figure 7.5-44 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on SPI Operation/TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1b (communication end) at the RSPCK last data bit sampling, when the last frame transmission ends. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.5 Transmit-receive/transmit-only in slave mode on clock synchronous operation (3-wire)

Refer to the description of the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)** for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

Figure 7.5-45 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

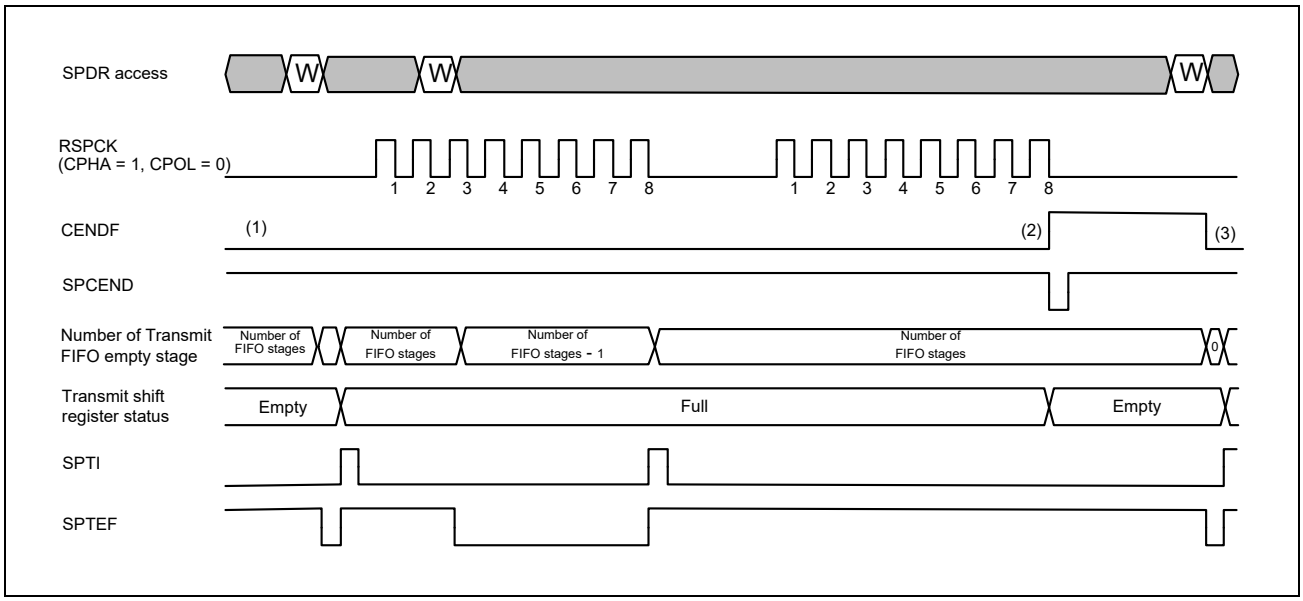

Figure 7.5-45 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on SPI Operation/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication start, and these have kept during communication.

(2) When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, the SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.6 Receive only in slave mode on clock synchronous operation (3-wire)

Refer to the description of the CENDF bit in **7.5.2.2.19 SPI Transfer FIFO Status Register (RSPIm_SPTFSR)** and **7.5.2.2.18 SPI Status Register (RSPIm_SPSR)** for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode on Clock Synchronous (3-wire).

Figure 7.5-46 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

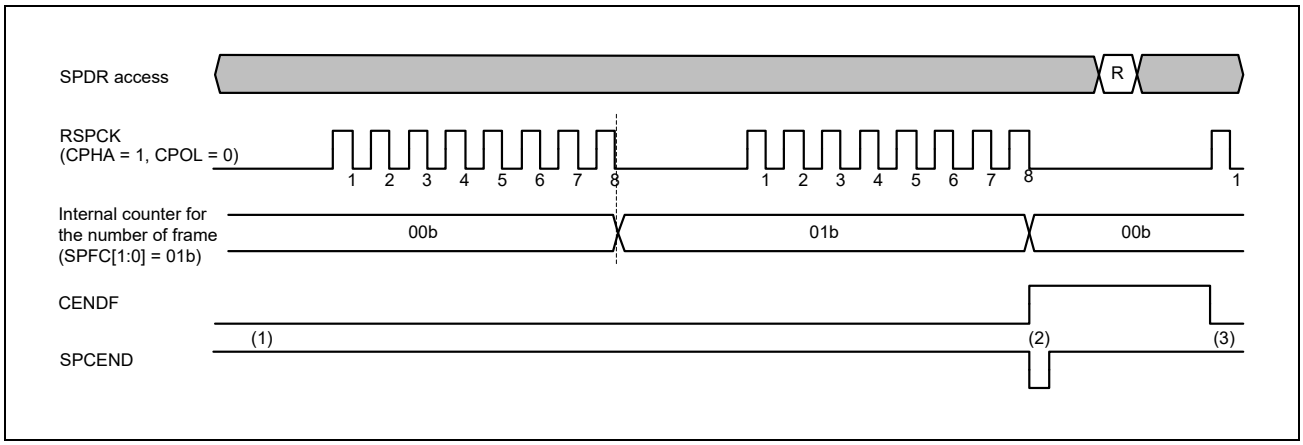

Figure 7.5-46 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on Clock Synchronous Operation)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is set to 1 (communication completed) at the timing of the last data bit sampling of RSPCK in the last frame communication when the last frame of the SPDCR.SPFC bit set value is received. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the first edge of RSPCK for the next transmission, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.7 Common operation

In this Section, the operation common to each mode communication in **7.5.3.9.1 Transmit-receive/transmit-only in master mode** to **7.5.3.9.6 Receive only in slave mode on clock synchronous operation (3-wire)** is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

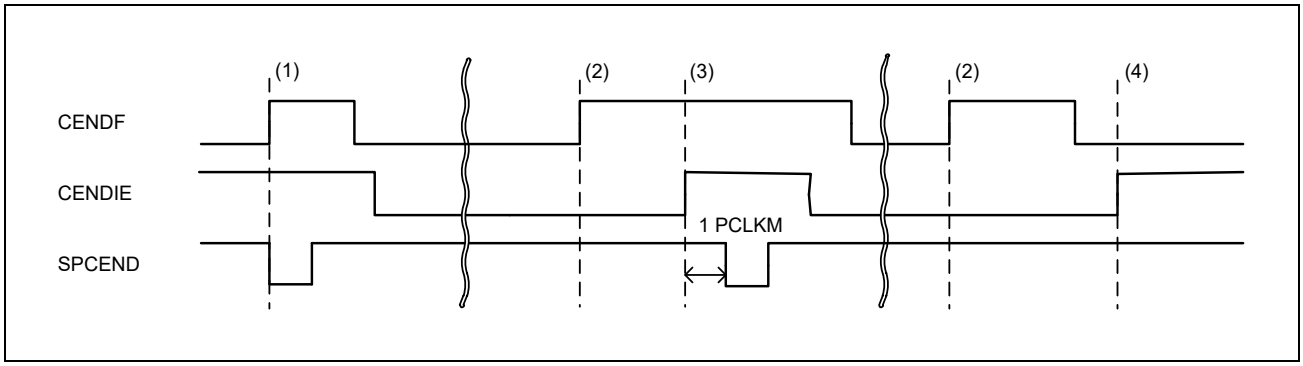

Figure 7.5-47 Example of Communication End Interrupt Operation (Enable Control)

(1) When the enable of SPI communication end interrupt (CENDIE) is 1b, at the time of communication completion, the following two are the same timing
— a flag of communication end (CENDF)
— the communication end interrupt

(2) When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following occurs, but no interrupt.
— a flag of communication end (CENDF)

(3) After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKM.

(4) After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

7.5.3.10 Error Detection

In normal serial transfer of SPI, data written to the transmit buffer in the SPDR register is transmitted in serial and received serial data can be read from the SPDR's receive buffer. Depending on the transmit buffer or receive buffer status when SPDR is accessed and the SPI status at the start or end of serial transfer, abnormal transfer is performed.

When some abnormal transfer operation takes place, the SPI detects it as an underrun error, overrun error, parity error, or mode fault error. **Table 7.5-11** shows the relationship between abnormal transfer operation and the SPI's error detection function.

Table 7.5-11 Abnormal Transfer Occurrence Conditions and Error Detection Function of SPI (1/2)

	Transfer Occurrence Condition	SPI Operation	Error Detection
1	SPDR is written when while no empty stages in the transmit FIFO.	• Transmit buffer data is retained. • No write data is present.	None
2	SPDR is read while no data stored in receive FIFO.	Received data and previously received serial data are read.	None
3	Serial transfer starts in transmit slave mode or transmit-only slave mode, before transmit data output is ready.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Receive FIFO data is retained. • No serial receive data is present.	Overrun error
5	Incorrect parity bit has been received with the parity function enabled in following mode. • Transmit/receive master mode • Receive-only master mode • Transmit/receive slave mode • Receive-only slave mode	The parity error flag is asserted.	Parity error
6	The SSL0 input signal is asserted when the serial transfer is idle state in multi-master mode.	• Driving of the RSPCK, MOSI, SSL1 to SSL3 output signals is stopped. • SPI function is disabled.	Mode fault error
7	The SSL0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCK, MOSI, SSL1 to SSL3 output signals is stopped. • SPI function is disabled.	Mode fault error
8	[In the Motorola-SPI case] The SSL0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error

Table 7.5-11 Abnormal Transfer Occurrence Conditions and Error Detection Function of SPI (2/2)

	Transfer Occurrence Condition	SPI Operation	Error Detection
9	[In the TI-SSP case] The SSL0 input signal is asserted during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error

The SPI does not detect any error for the operation shown in No.1 in **Table 7.5-11**. To prevent missing of data during SPDR writing, write data to SPDR upon a transmit buffer empty interrupt request or while the SPSR.SPTEF flag is 1b.

The SPI does not detect any error also for the operation shown in No.2 in **Table 7.5-11**. To prevent reading of unnecessary data, read data from SPDR upon a receive buffer full interrupt request or while the SPSR.SPRF flag is 1b.

The underrun error shown in No.3 in **Table 7.5-11** is described in **7.5.3.10.4 Underrun error**.

The overrun error shown in No.4 in **Table 7.5-11** is described in **7.5.3.10.1 Overrun error**.

The parity error shown in No.5 in **Table 7.5-11** is described in **7.5.3.10.2 Parity error**.

The mode fault error shown in No.6 to No.9 in **Table 7.5-11** is described in **7.5.3.10.3 Mode fault error**.

For transmission and reception interrupts, see **7.5.3.7 Transmission buffer empty/receive buffer full interrupt**.

7.5.3.10.1 Overrun error

When serial transfer ends while the receive buffer in the SPDR register is full, the SPI detects an overrun error and sets the OVRF flag in SPSR to 1b. While the OVRF flag is 1b, the SPI does not copy shift register data to the receive buffer. Therefore, data before an error occurs is retained in the receive buffer. To clear the OVRF flag in SPSR to 0b, issue a system reset or 1b is written to the SPSRC.OVRFC bit.

Figure 7.5-48 shows operation of the SPRF flag and the OVRF flag in SPSR. “SPSR access” and “SPDR access” described in **Figure 7.5-48** show an access to SPSR and SPDR respectively. “W” shows a write cycle and “R” shows a read cycle. In the example in **Figure 7.5-48**, the SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1b and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

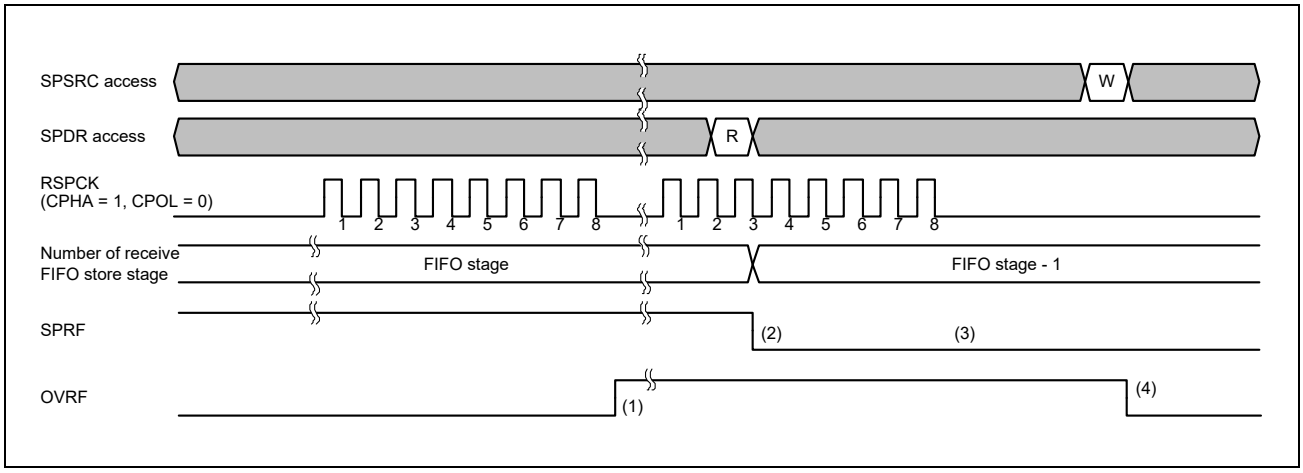

Figure 7.5-48 Example of Operation of SPRF and OVRF Flags

The following describes operation of flags at timings (1) to (4) in the figure above.

(1) When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1b. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a parity error even when SPPE = 1b. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits.

(2) The SPI can read receive buffer data by reading SPDR. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DMAC.

(3) When serial transfer ends while the OVRF flag is 1b (overrun error), the SPI does not copy shift register data to the receive buffer (SPRF flag remains 0) and no SPI receive buffer full interrupt is generated. The SPI does not detect a parity error even when SPPE = 1b. In master mode, the SPI does not update the SPSSR.SPECM[2:0] bits. When the SPI does not copy received data from the shift register to receive buffer while an overrun error is present, the SPI also determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(4) When 1 is written to the SPSRC.OVRFC bit.

Whether an overrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To perform serial transfer without using an SPI error interrupt, read SPDR and then immediately read SPSR to quickly detect an overrun error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM bits. When an overrun error occurs and the OVRF flag is set to 1, successful reception is disabled until the OVRF flag is cleared to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. **Figure 7.5-49** and **Figure 7.5-50** show the clock stop waveform when a serial transfer continues while the reception buffer is full in master mode.

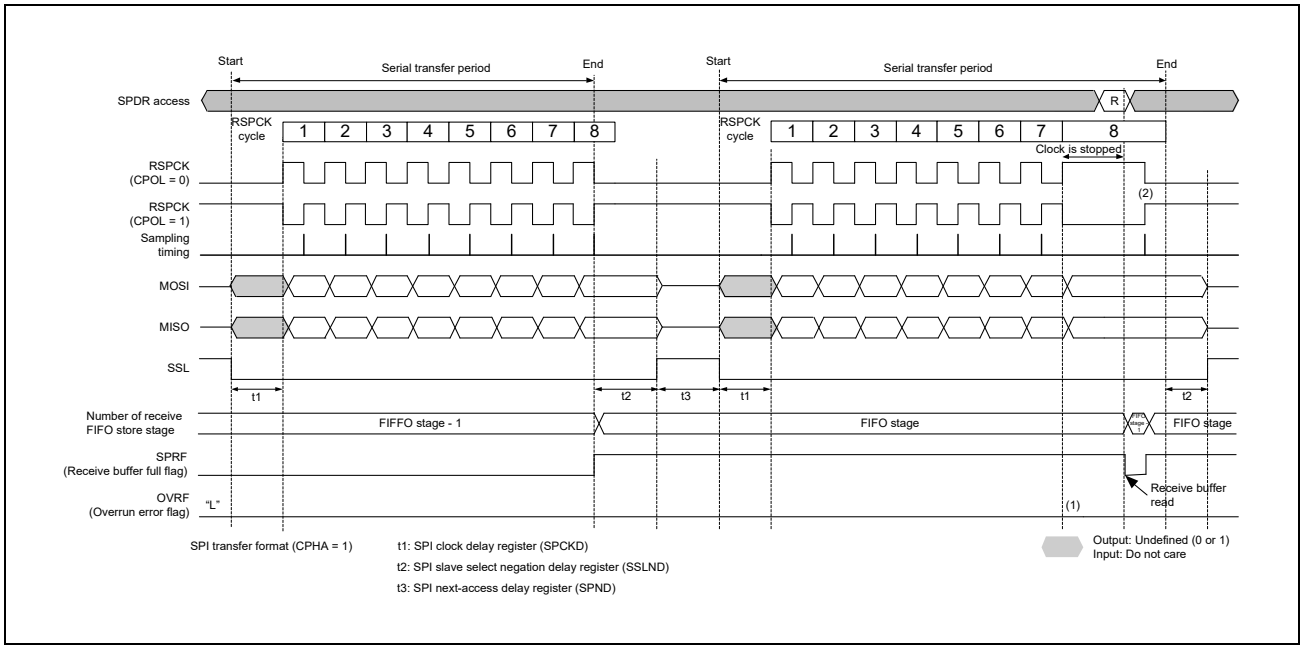

Figure 7.5-49 Clock Stop Waveform when Serial Transfer Continues with Data is Stored for the Number of FIFO Stages in Master Mode (CPHA = 1b)

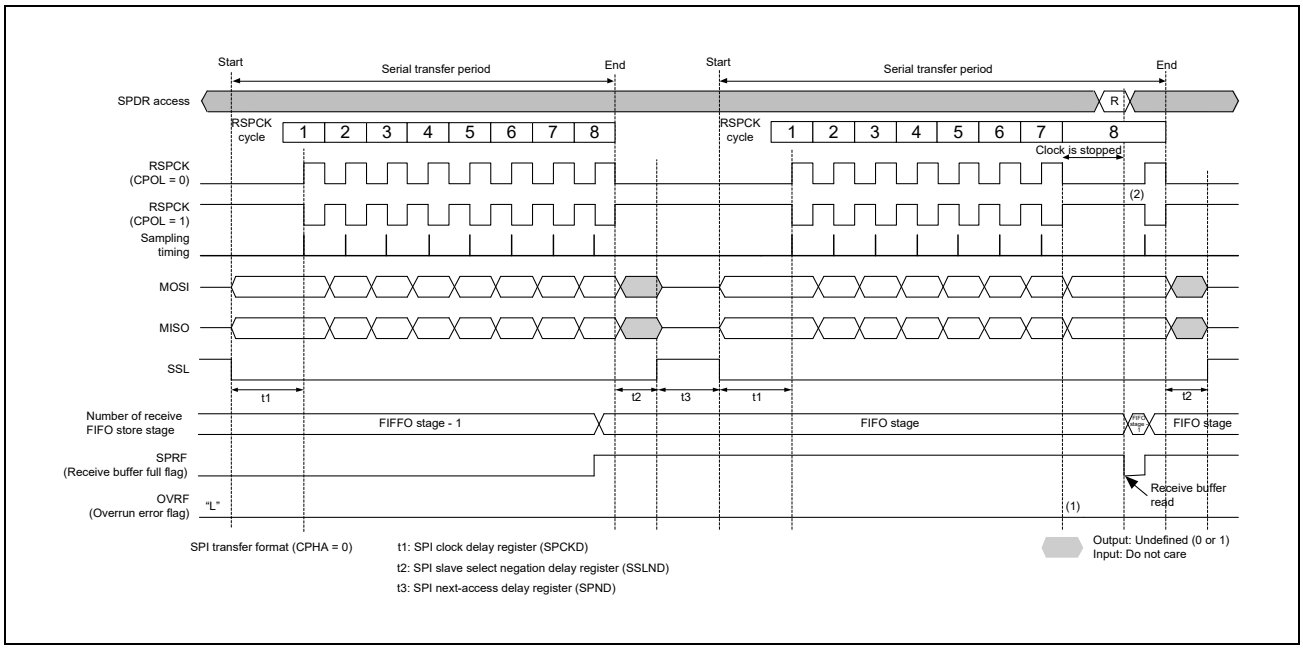

Figure 7.5-50 Clock Stop Waveform when Serial Transfer Continues with Data is Stored for the Number of FIFO Stages in Master Mode (CPHA = 0b)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. The **Figure 7.5-51** and the **Figure 7.5-52** show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

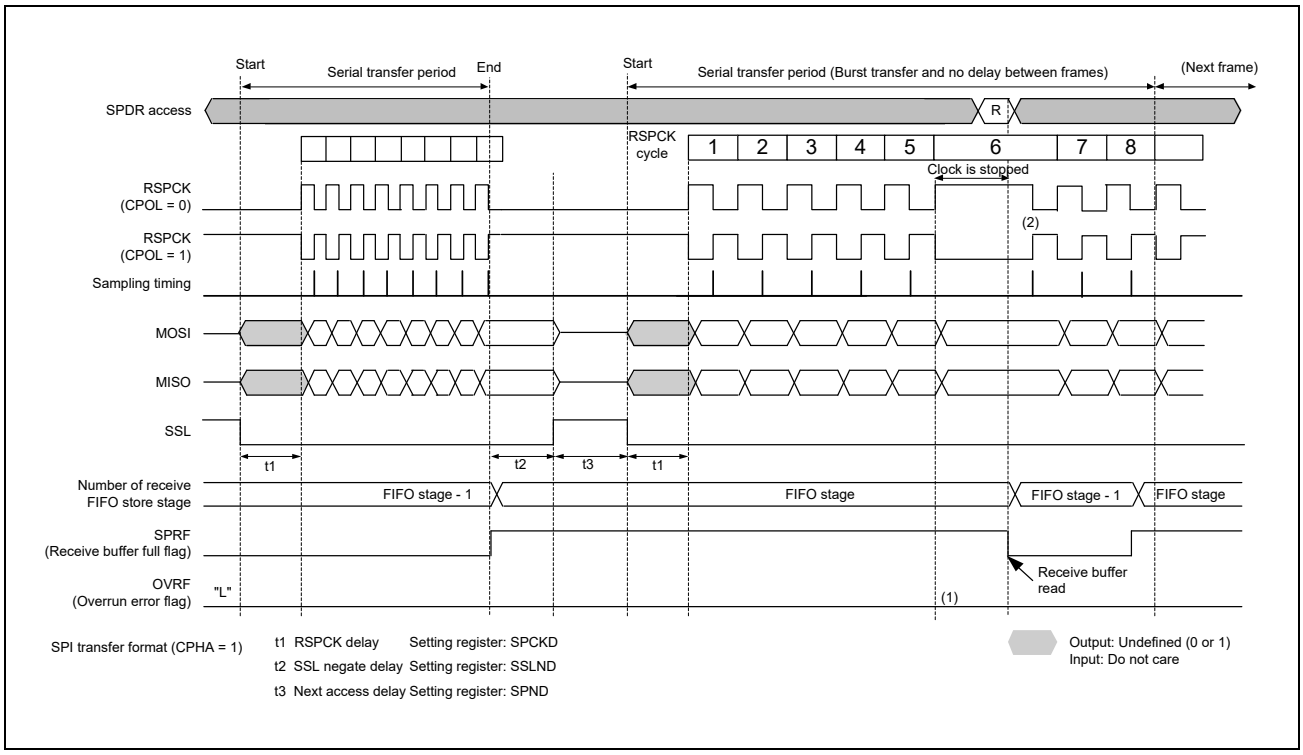

Figure 7.5-51 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full with Data is Stored for the Number of FIFO Stages in Master Mode (at Burst Transfer and No Delay between Frames CPHA = 1b)

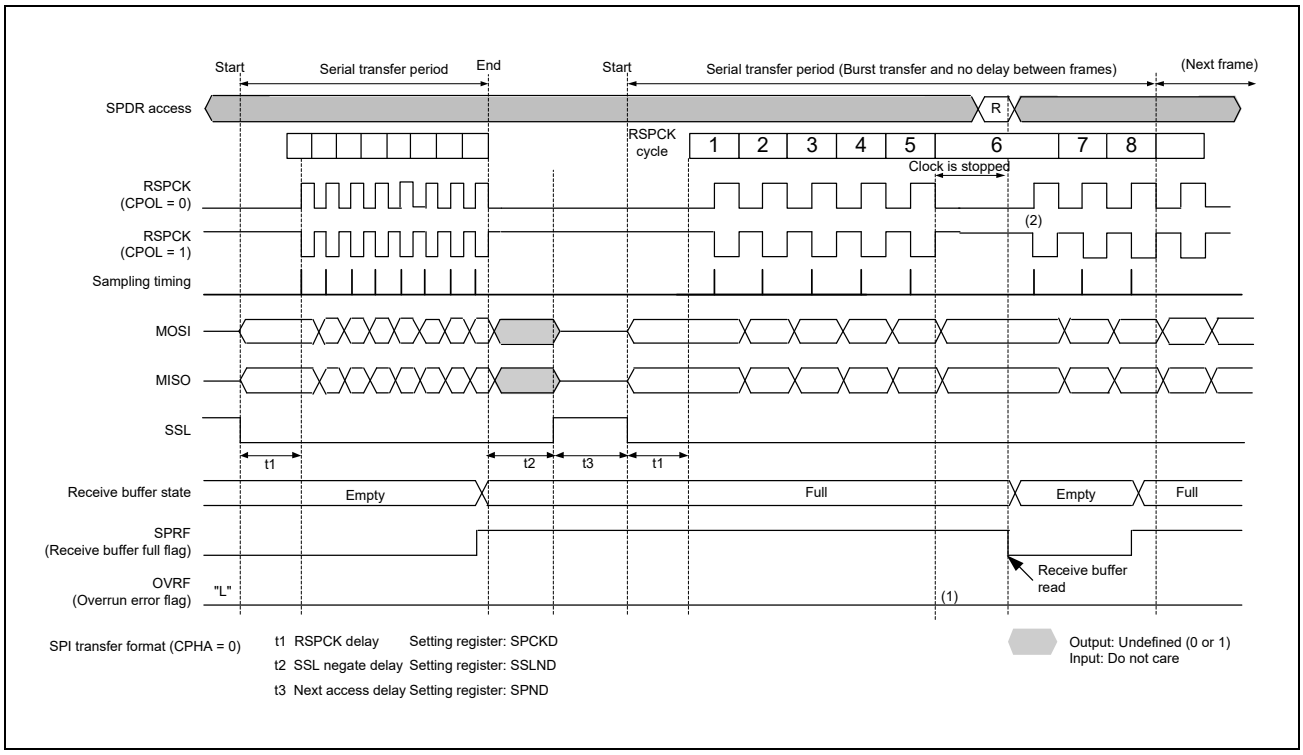

Figure 7.5-52 Clock Stop Waveform when Serial Transfer Continues with Data is Stored for the Number of FIFO Stages in Master Mode (at Burst Transfer and No Delay between Frames CPHA = 0b)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

7.5.3.10.2 Parity error

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPCR.SPPE = 1b, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPSR register is set to 1b. While the OVRF flag is 1b, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0b, issue a system reset or write 1b to the SPSRC.PERFC bit.

Figure 7.5-53 shows operation of the OVRF and PERF flags in SPSR. “SPSR access” described in **Figure 7.5-53** shows an access to SPSR. “W” shows a write cycle and “R” shows a read cycle. In the example in **Figure 7.5-53**, the SPI performs transmit-receive serial communication while SPCR.SPPE = 1b. The SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1b and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

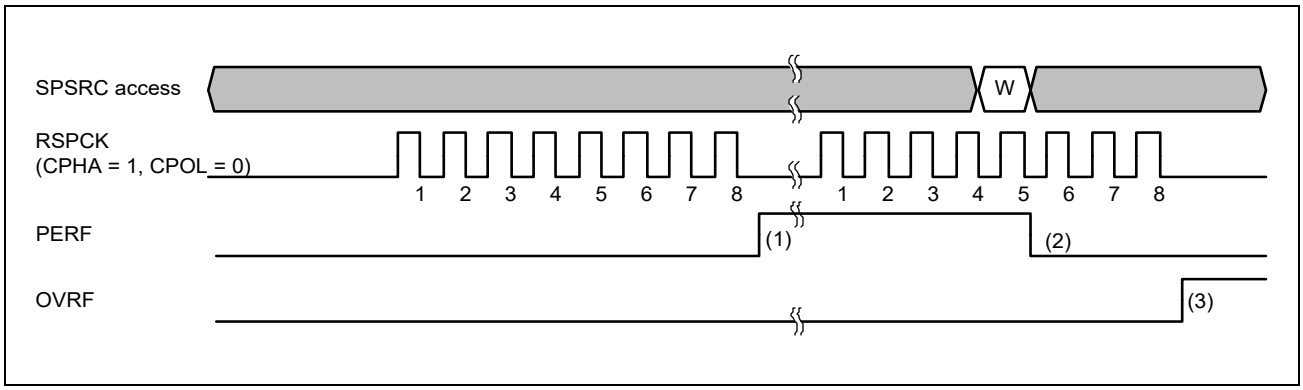

Figure 7.5-53 Example of Operation of OVRF and PERF Flags

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1b. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPCM [2:0] bits.

(2) When 1 is written to the SPSRC.PERFC bit.

(3) When the SPI detects an overrun error and terminates the serial transfer, the SPI does not copy shift register data to the receive buffer and does not detect a parity error.

Whether a parity error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To use an SPI error interrupt, set the SPCR.SPEIE bit to 1b. To perform serial transfer without using an SPI error interrupt, read SPDR to quickly detect a parity error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

7.5.3.10.3 Mode fault error

When the SPCR.MSTR = 1b, SPCR.SPMS = 0b, and SPCR.MODFEN = 1b, the SPI operates in multi-master mode. When an active level is input to the SSL0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of serial transfer status and sets the MODF flag in the SPSR register to 1. When a mode fault error is detected, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits. The SSL0 signal active level depends on the SSL0P bit in the SSLP register.

While SPCR.MSTR = 0b, the SPI operates in slave mode. When SPCR.SPMS = 0b and SPCR.MODFEN = 1b in slave mode, if the SSL0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error while any of the following 2 conditions is met.

(1) In the Motorola-SPI case

When the SSL0 input signal is negated while serial data transfer.

(2) In the TI-SSP case

When the SSL0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSL0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPCR.SPE bit.

When the SPE bit is cleared, the SPI function is disabled (as described in **7.5.3.12 SPI Initialization**). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the SPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

While the MODF flag = 1b, the SPI ignores writing 1b to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0b without fail.

7.5.3.10.4 Underrun error

While the SPI is operating in slave mode (SPCR.MSTR = 0b) and the communication mode select SPCR.TXMD[1:0] bits are set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1b (SPI function enabled), the SPI detects an underrun error and sets the MODF and UDRF flags in the SPSR register to 1b.

When the SPI detects an underrun error, it stops driving output signals and clears the SPE bit to 0b. When the SPE bit is cleared, the SPI function is disabled (as described in **7.5.3.12 SPI Initialization**)

Whether an underrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect an underrun error without using an SPI error interrupt, poll SPSR.

While the MODF flag = 1b, the SPI ignores writing 1b to the SPE bit. To enable the SPI function after an underrun error is detected, clear the MODF flag to 0 without fail.

7.5.3.11 Received Data Ready Detection

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPDRCR.SPDRC[7:0] ≠ 00h, after receiving data in the receive FIFO during communication (SPE = 1), SPDR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs ≤ the threshold value and the value set in SPDRCR.SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt can be selected as SPRI or SPEI with the SPCR.SPDRES bit. **Figure 7.5-54** shows an example of reception data ready detection operation.

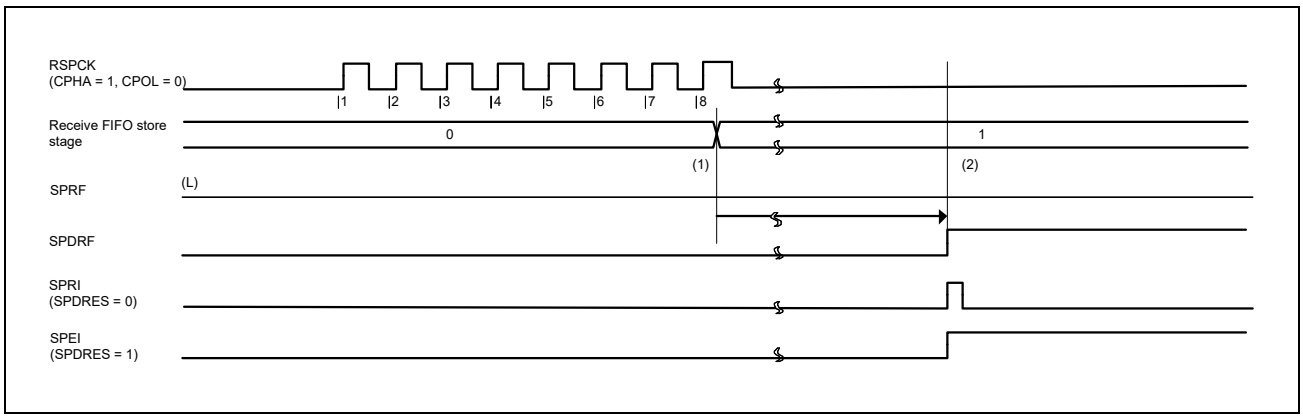

Figure 7.5-54 Received Data Ready

The following describes operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0b, because receive FIFO store stage ≤ RTRG.

(2) Set SPDRF and assert SPRI or SPEI because there is no writing to the receive FIFO for the amount of SPDRC[7:0] set from (1).

7.5.3.12 SPI Initialization

When 0b is written to the SPCR.SPE bit or when the SPI clears the SPE bit to 0b after it detects a mode fault error or an underrun error, the SPI disables the SPI function and initializes a part of module functions. Furthermore, the SPI initializes all module functions when a system reset occurs. The following describes initialization by clearing the SPCR.SPE bit and by using a system reset.

7.5.3.12.1 Initialization by clearing the SPE bit

When the SPCR.SPE bit is cleared to 0b, the SPI performs the following initialization:

- Suspends the ongoing serial transfer.
- Stops driving output signals (Hi-Z) in slave mode.
- Resets the internal SPI state.
- SPSR.SPTEF flag = 1b.

In initialization by clearing the SPE bit, control bits in SPI are not initialized. For this reason, re-setting the SPE bit to 1b activates the SPI with the pre-initialization transfer mode.

Values of the CENDF flag, the SPRF flag, OVRF flag, MODF flag, PERF flag, and UDRF flag in SPSR are not initialized. The SPSSR register value is not initialized either. For this reason, it is possible to read receive buffer data and check the communication completion status and the error status during SPI transfer also after the SPI is initialized.

SPSR.SPTEF flag is initialized to 1b. Therefore, if the SPCR.SPTIE bit is set to 1 after the SPI is initialized, an SPI transmit buffer empty interrupt is generated. When the CPU initializes the SPI, write 0b to the SPE bit and the SPTIE bit to disable an SPI transmit buffer empty interrupt.

7.5.3.12.2 System reset

In initialization by using a system reset, all SPI control bits, status bits, and data register are initialized in addition to the initialization described in **7.5.3.12.1 Initialization by clearing the SPE bit** to completely initialize the SPI.

7.5.3.13 SPI Operation

7.5.3.13.1 Master mode operation

Single master mode operation and multi-master mode operation are different from each other only in mode fault error detection (see **7.5.3.10 Error Detection**). The SPI in single master mode (SPI) detects no mode fault error.

The SPI in multi-master mode detects a mode fault error. The following describes operations common to single master mode and multi-master mode.

(1) Starting a serial transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 15) data in SPDR.

While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. The SSL output signal polarity depends on the set SSLP register value.

(2) Terminating a serial transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.
The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer.
- When writing SPCRRM.RMEDTG = 1b during the serial transfer period, the SPI terminates the serial transfer.

When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

(3) Sequence control

The transfer format in master mode is determined as follows.

The transfer format in master mode is determined by the SPSCR register, SPCMDm (m = 0 to 7) register, SPBR register, SPCKD register, SSLND register, and SPND register.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. The SSL output signal value, MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7.

A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPE bit in the SPCR register is set to 1 to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

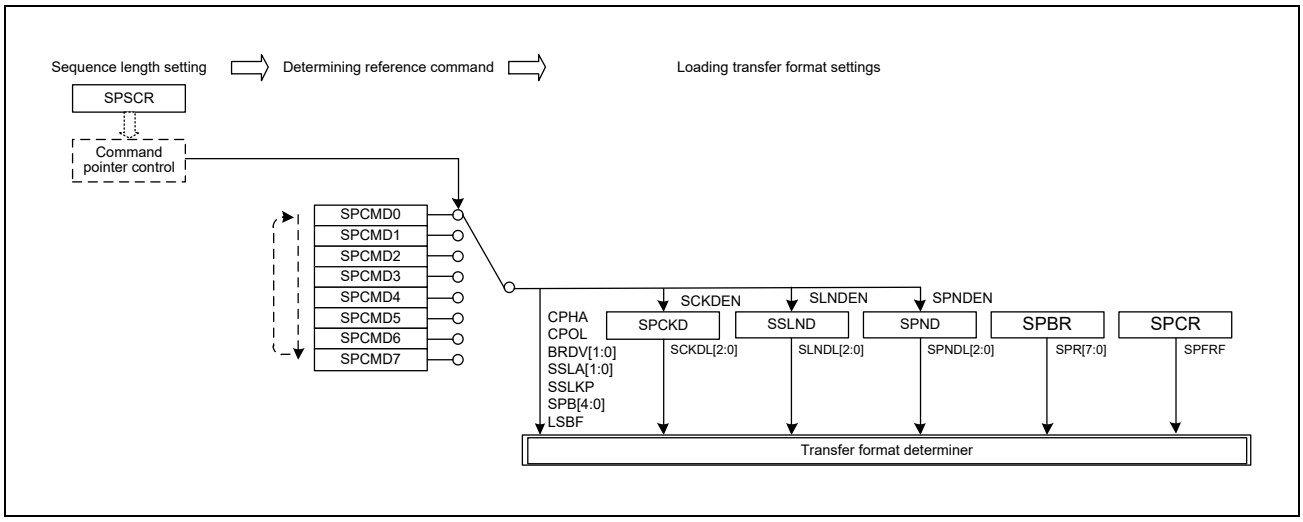

Figure 7.5-55 Determining Serial Transfer Method in Master Mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm).

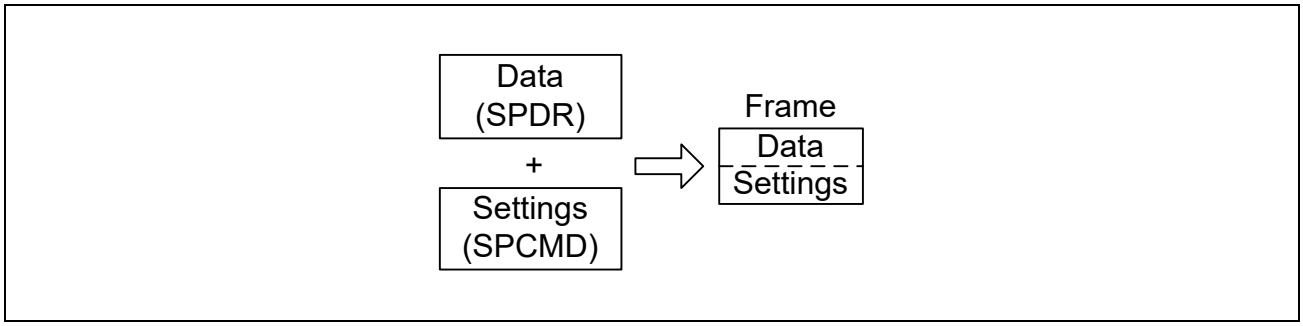

Figure 7.5-56 Conceptual Diagram of Frame

Figure 7.5-57 shows the correspondence between the SPI command register and transmit buffer (SPTXn, n = 0 to 15)/receive buffer (SPRXn, n = 0 to 15) in the sequence operation.

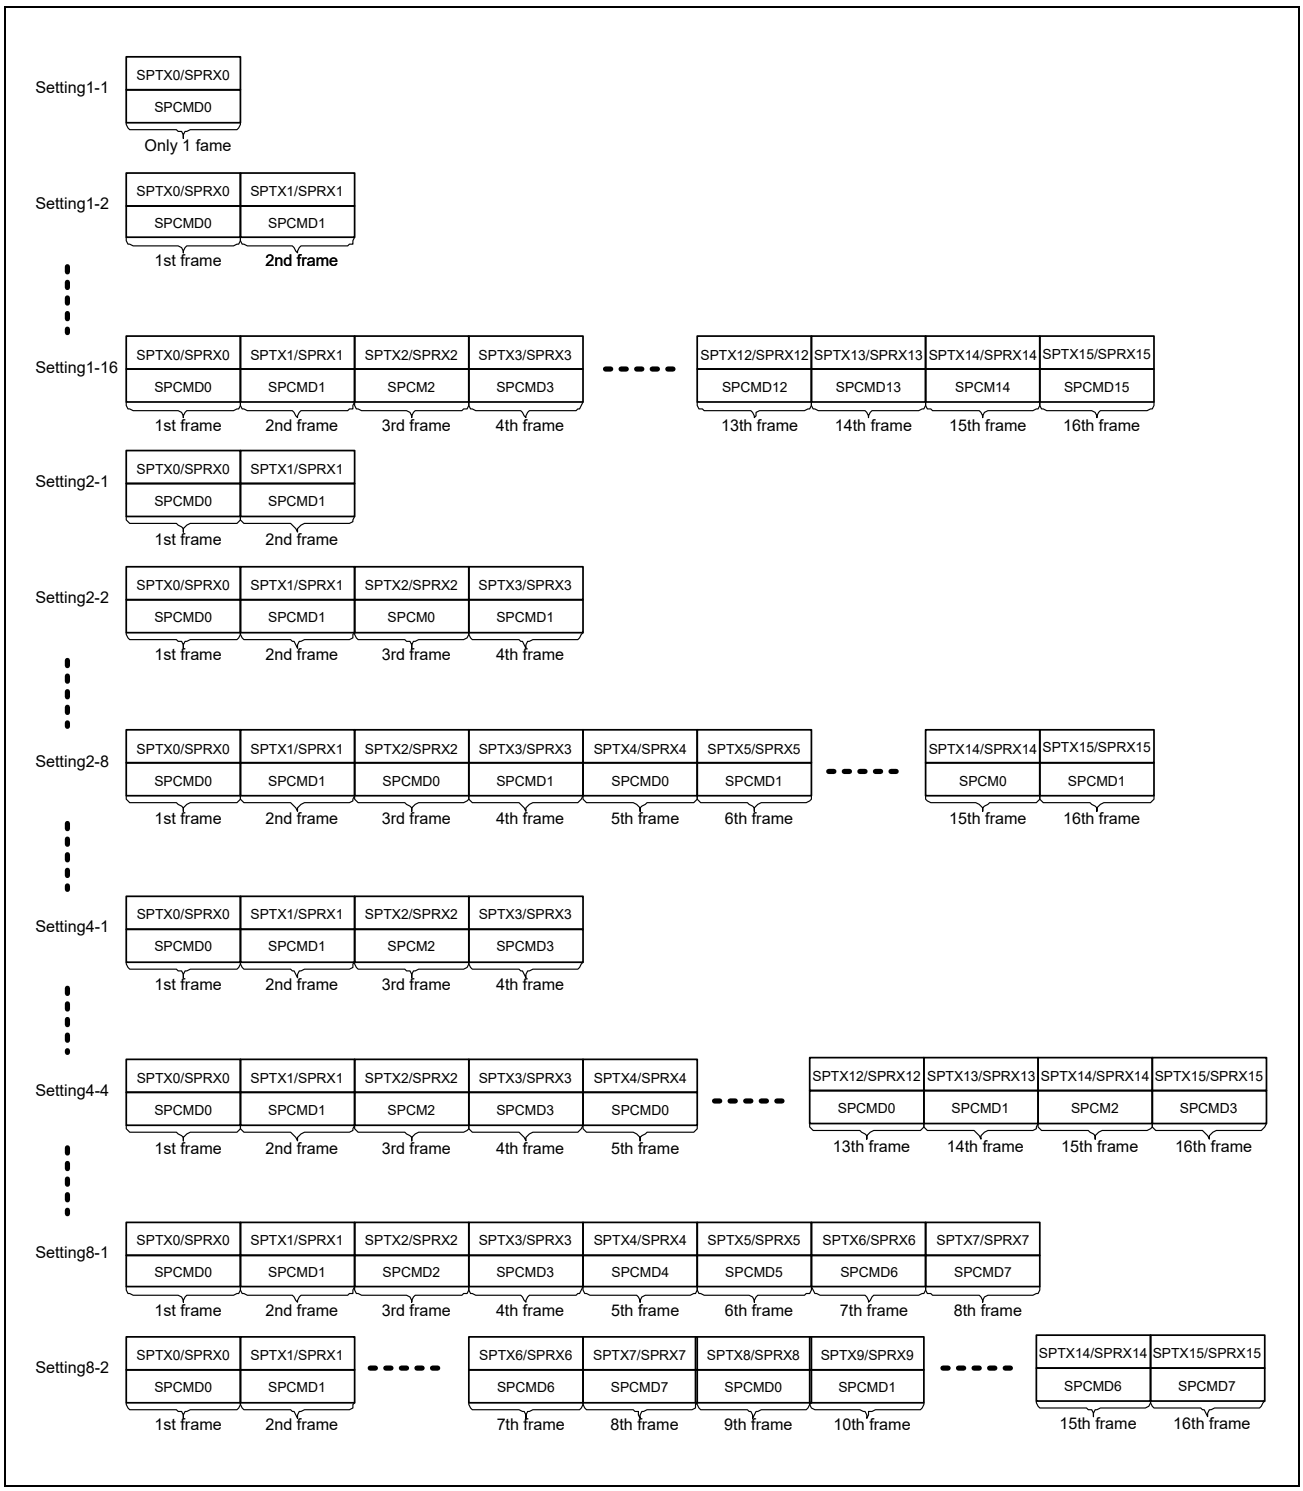

Figure 7.5-57 Correspondence between SPI Command Register and Transmit/Receive Buffers in Sequence Operation

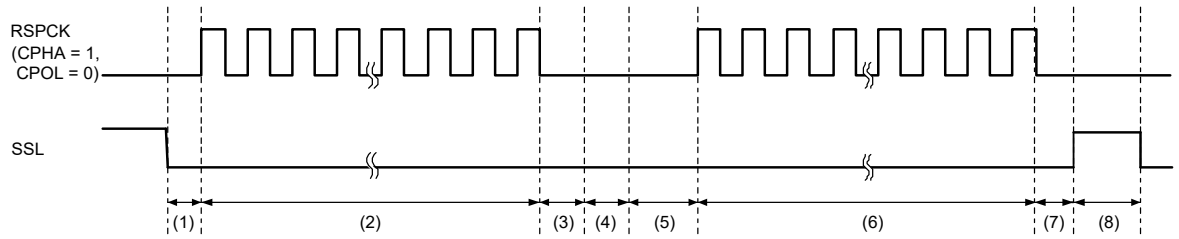
(4) Burst transfer



This section describes burst transfer during transmit-receive/transmit-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1b, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(a) SPCR.BFDS = 0b

Figure 7.5-58 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in **Figure 7.5-58**. The SSL output signal polarity depends on the set the SSLP register.

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1b. This period additionally continues for 5 RSPI_n_TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0. When the shift register is empty after the minimum period has passed, this period continues until transmit data for the next transfer is stored in the shift register.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

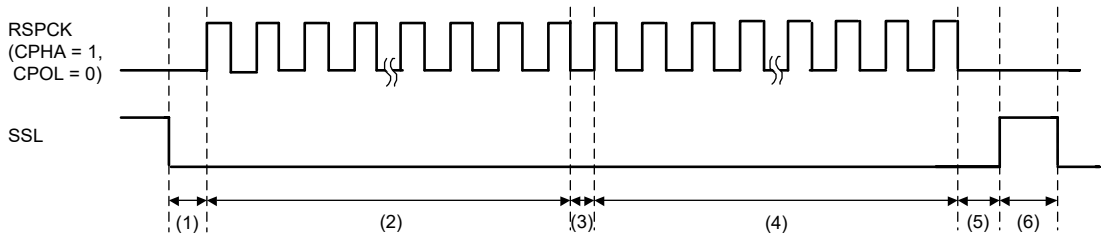


Figure 7.5-58 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0b, SPFRF = 0b)

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0b, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See **7.5.3.13 SPI Operation**.)

(b) SPCR.BFDS = 1

Figure 7.5-59 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in **Figure 7.5-59**. The SSL output signal polarity depends on the set SSSLP register value.

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

(2) Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.

(3) The value of SSL signal according to SPCMD0 was hold, because SPCMD0.SSLKP = 1b. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

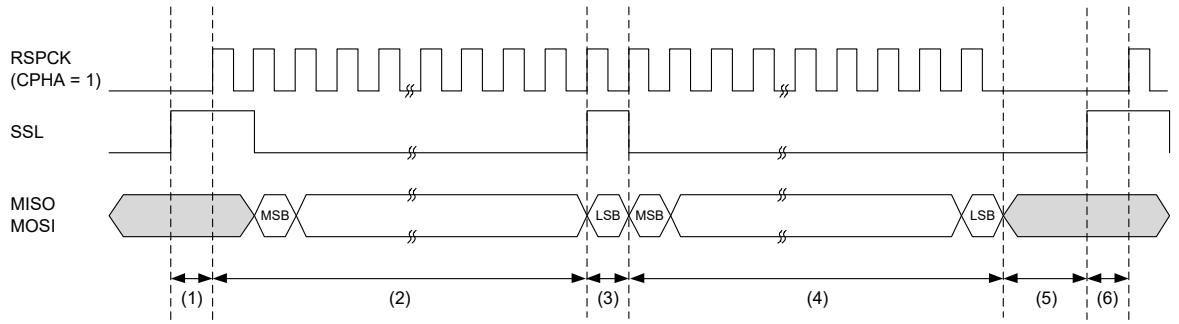

Figure 7.5-59 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1b, SPFRF = 0b)

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.
Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(c) SPCMD.SSLKP = 1b and SPCR.BFDS = 1b

SPCMD0 to SPCMD1 are shown in **Figure 7.5-60**. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

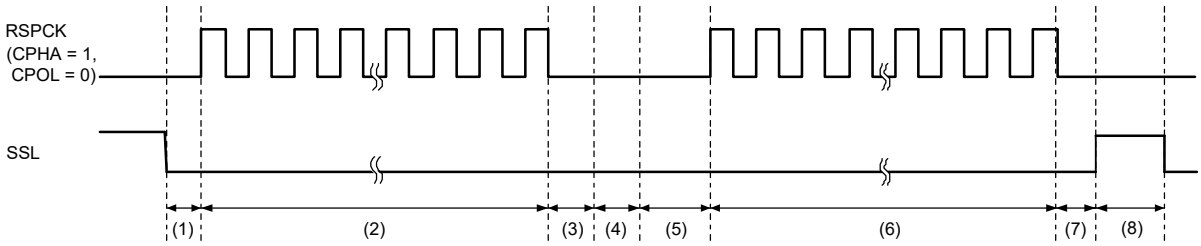
(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because the SPCMD1.SSLKP = 0b.

Figure 7.5-60 Example of Burst Transfer Operation (SPFRF = 1b)

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.



This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(d) SPCR.BFDS = 0b

Figure 7.5-61 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in **Figure 7.5-61**. The SSL output signal polarity depends on the set SSLP register value.

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1b. This period additionally continues for 5 RSPI_n_TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

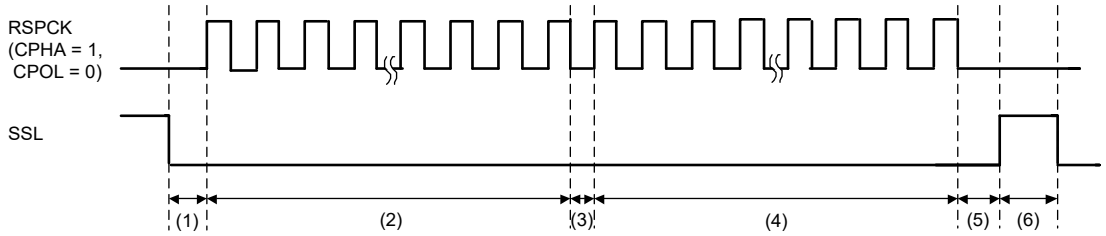


Figure 7.5-61 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0b, SPFRF = 0b)

If the SSL signal output setting and the SSL signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0b, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See **7.5.3.13, SPI Operation**.)

(e) SPCR.BFDS = 1b

Figure 7.5-62 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in **Figure 7.5-62**. The SSL output signal polarity depends on the set SSLP register value.

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Since it is not the last frame, the SSL signal value at SPCMD0 is retained. RSPCK negation between frames is 0.5 RSPCK for the next frame.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last time.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 00h
Or, a frame in which SPCRRM.RMEDTG = 1b has been accepted.

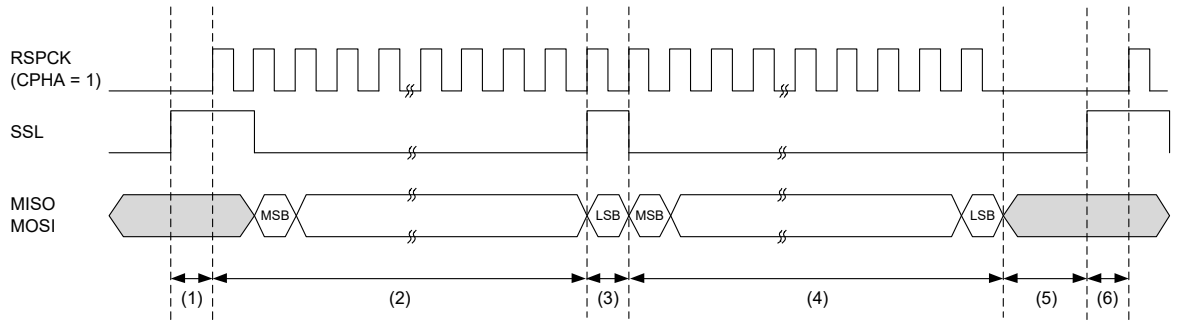

Figure 7.5-62 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.
Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(f) SPCMD.SSLKP = 1b and SPCR.BFDS = 1b

SPCMD0 to SPCMD1 are shown in **Figure 7.5-63**. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SSLP register value.

(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously.

(4) Perform serial transfer according to SPCMD1.

(5) Insert Output disable delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0b.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 00h
Or, a frame in which SPCRRM.RMEDTG = 1b has been accepted.

Figure 7.5-63 Example of Burst Transfer Operation (SPFRF = 0b)

If the SSL signal output setting between the SPCMDs used for burst transfer differs from the SSL signal output setting, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the settings of the SPCMD.SCKDEN and SPCKD.SCKDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SCKDEN bit and SPCKD.SCKDL[2:0] bits as shown in **Table 7.5-12**. For the definition of RSPCK delay, see **7.5.3.5 Transfer Format (Frame Format)**.

RSPCK delay insert to only the first frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1b, SPCR.BFDS = 1b).

Table 7.5-12 Relationship between SCKDEN/SPCKD and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the settings of the SPCMD.SLNDEN bit and SSLND.SLNDL[2:0]. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the SSL negation delay value for serial transfer by using the selected SPCMD.SLNDEN and SSLND.SLNDL[2:0] as shown in **Table 7.5-13**. For the definition of SSL negation delay, see **7.5.3.5 Transfer Format (Frame Format)**.

SSL negate delay insert to only the last frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay” (SPCMD.SSLKP = 1b, SPCR.BFDS = 1b).

Table 7.5-13 Relationship between SSLND and SSL Negation Delay Value

SLNDEN	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000b to 111b	1 RSPCK cycle
1	000b	1 RSPCK cycle
	001b	2 RSPCK cycle
	010b	3 RSPCK cycle
	011b	4 RSPCK cycle
	100b	5 RSPCK cycle
	101b	6 RSPCK cycle
	110b	7 RSPCK cycle
	111b	8 RSPCK cycle

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the settings of the SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits as shown in **Table 7.5-14**. For the definition of next-access delay, see **7.5.3.5 Transfer Format (Frame Format)**.

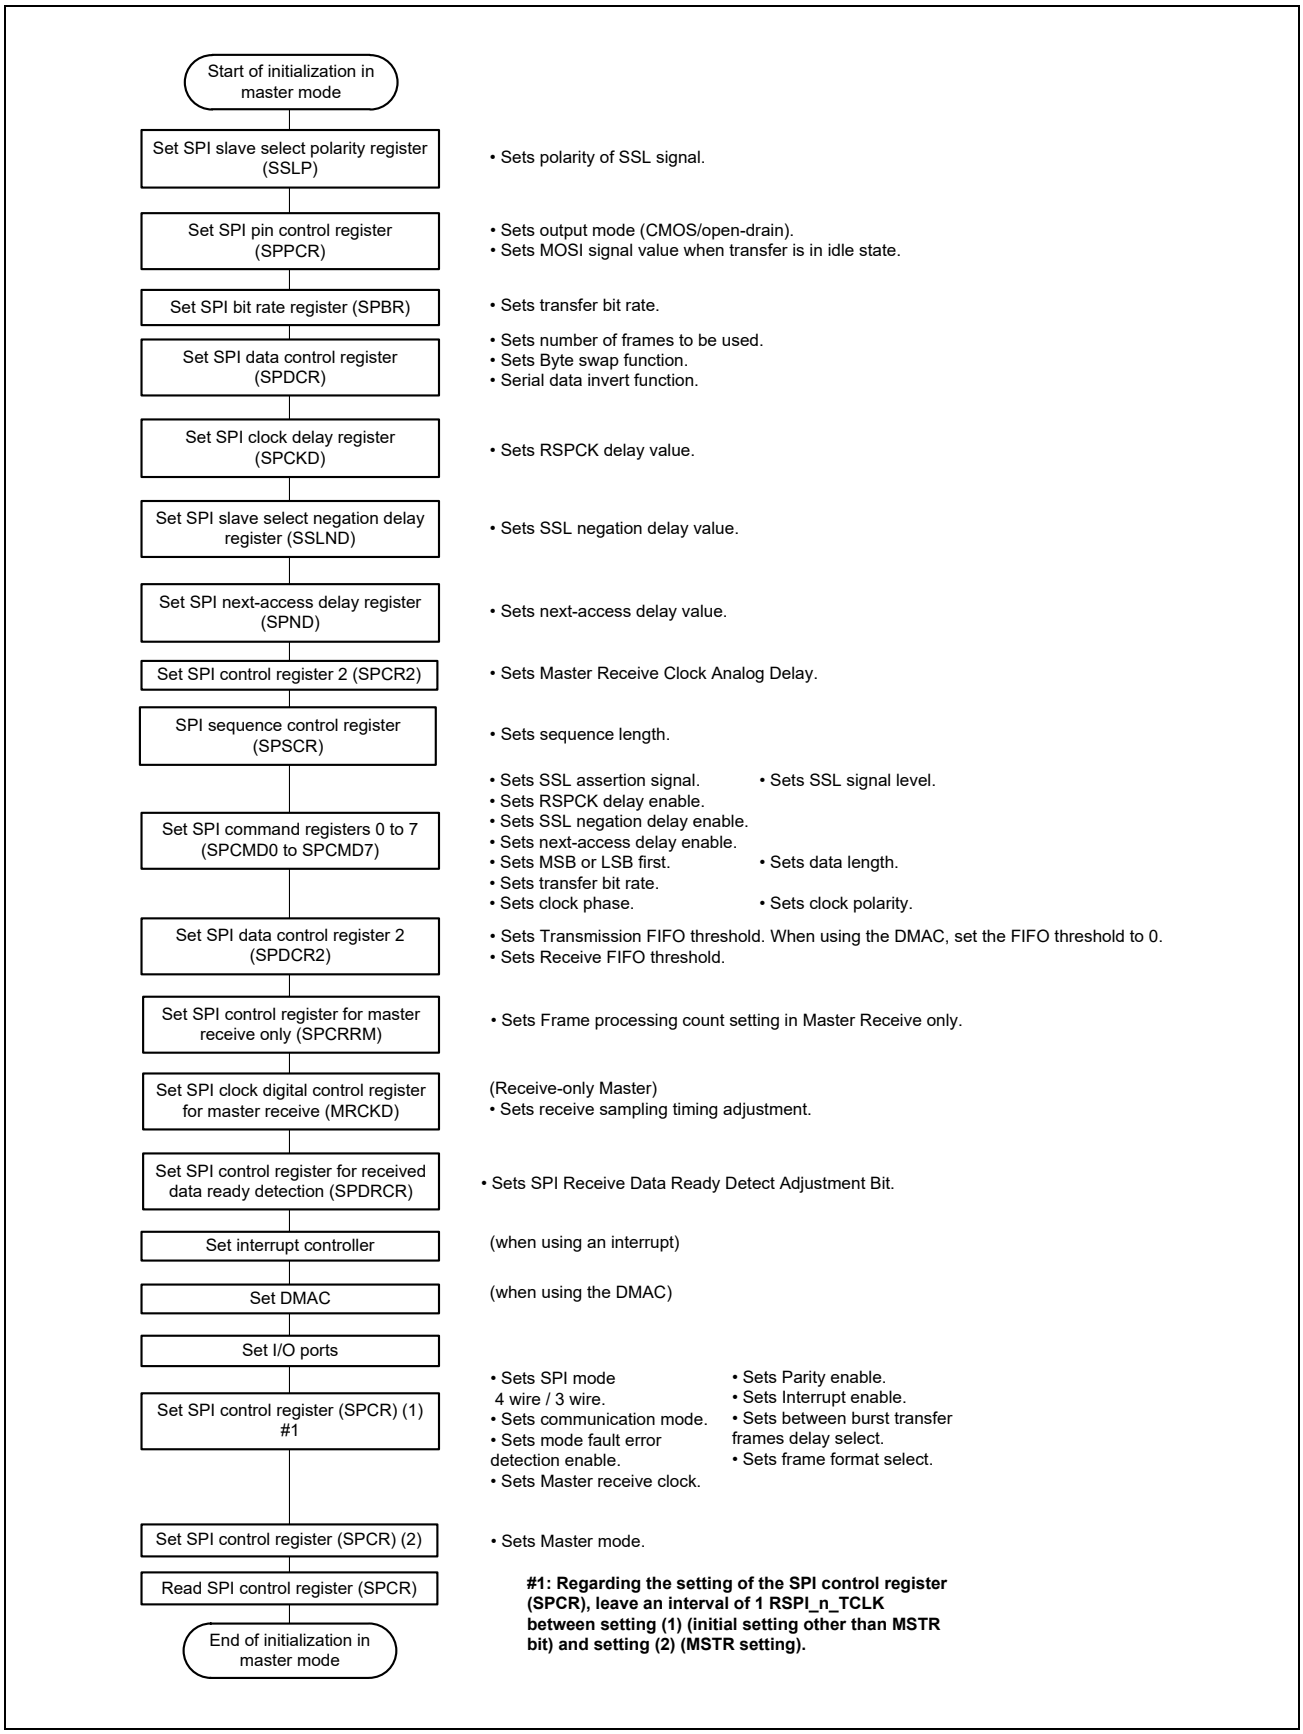
Next-Access delay insert to only the last frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay” (SPCMD.SSLKP = 1b, SPCR.BFDS = 1b).

Table 7.5-14 Relationship between SPNDEN Bit, SPND Bits, and Next-Access Delay Value

SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 5 RSPI_n_TCLK cycles
1	000b	1 RSPCK + 5 RSPI_n_TCLK cycles
	001b	2 RSPCK + 5 RSPI_n_TCLK cycles
	010b	3 RSPCK + 5 RSPI_n_TCLK cycles
	011b	4 RSPCK + 5 RSPI_n_TCLK cycles
	100b	5 RSPCK + 5 RSPI_n_TCLK cycles
	101b	6 RSPCK + 5 RSPI_n_TCLK cycles
	110b	7 RSPCK + 5 RSPI_n_TCLK cycles
	111b	8 RSPCK + 5 RSPI_n_TCLK cycles

(8) Initialization flowchart

Figure 7.5-64 shows an example of initialization flow when using the SPI in master-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.



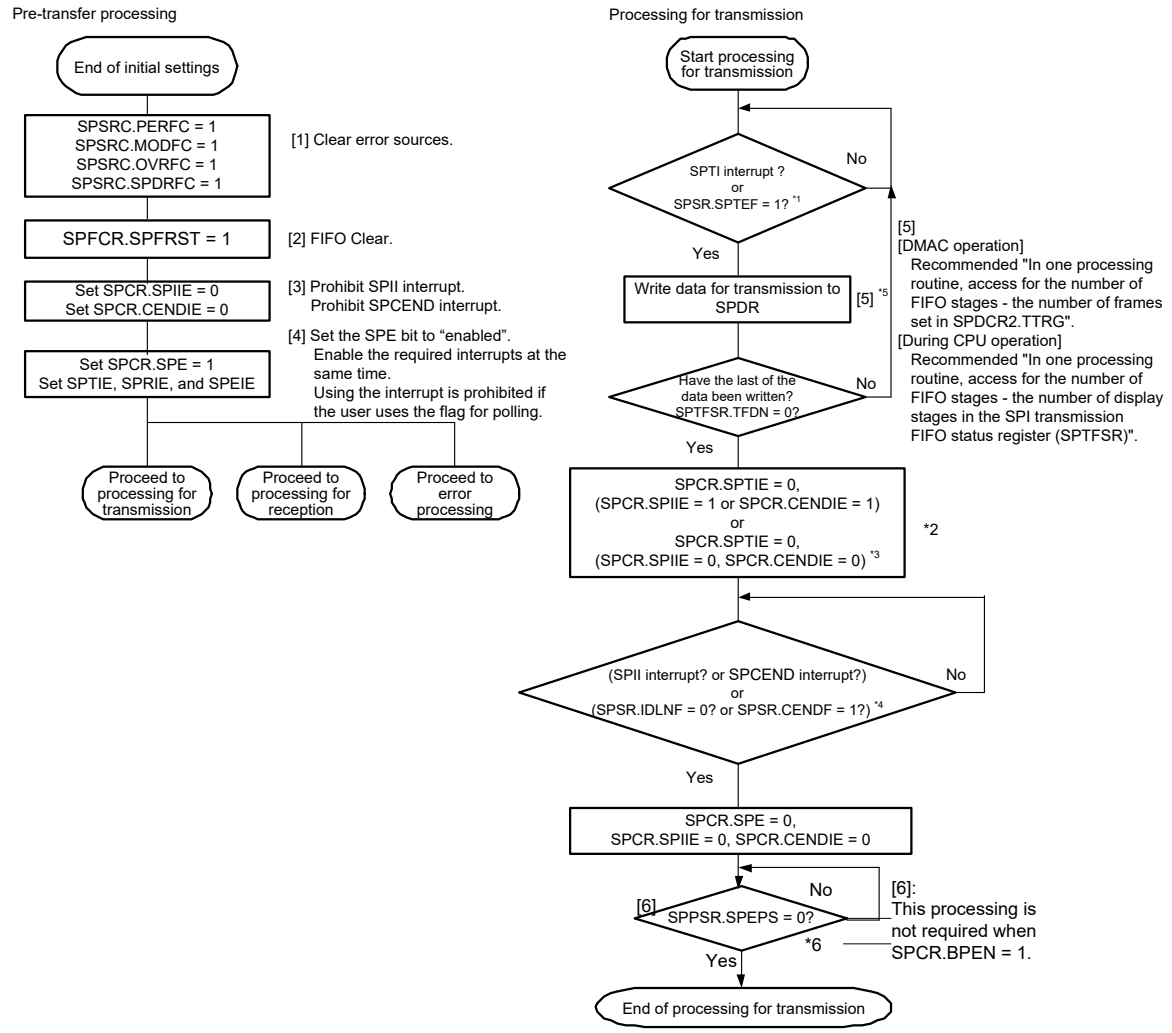


Figure 7.5-64 Example of Initialization Flowchart in Master Mode (SPI Operation)

(9) Software processing flow

Figure 7.5-65 to **Figure 7.5-68** show examples of the flow of software processing.

(a) Transmit processing flow

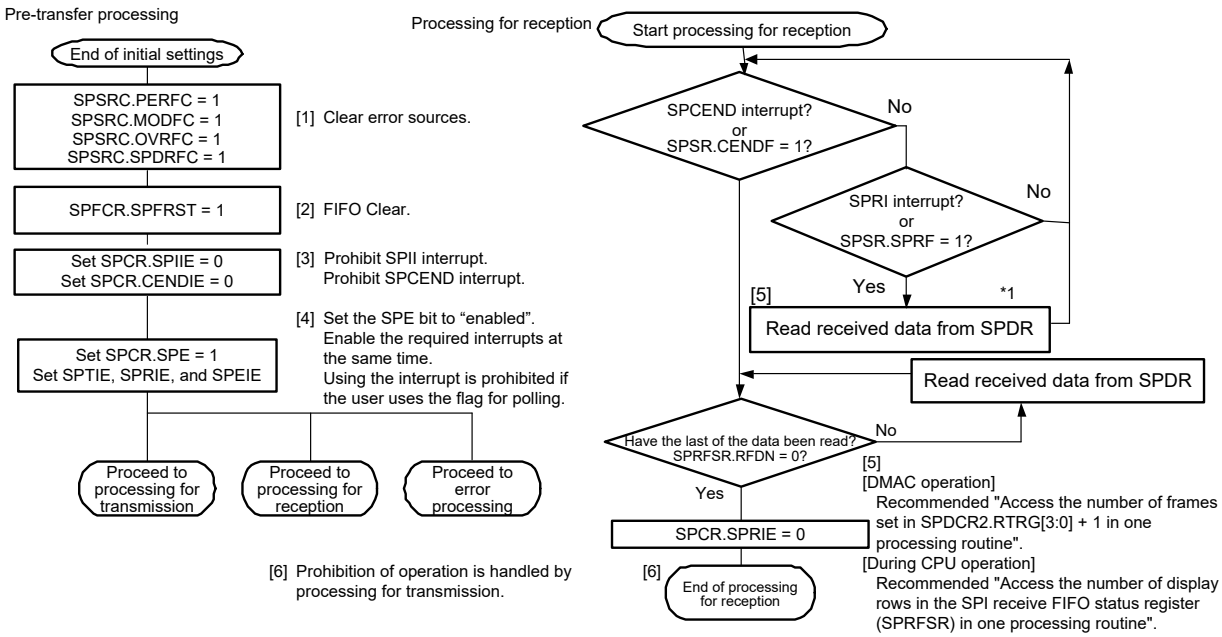
Enabling an SPII or SPCEND interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.

Note: SPII: Idle interrupt
SPTI: Transmission buffer empty interrupt

Note 1. Proceed to process of writing data for transmission after reading SPSR.SPTEF flag is 1b, if the user uses the flag for polling.

Note 2. The user can know the communication end by SPII interrupt (IDLNF flag) or SPCEND interrupt (CENDF flag). Please use either SPII interrupt (IDLNF flag) or SPCEND interrupt (CENDF flag).

Note 3. Set SPII interrupt prohibited (SPCR.SPIIE = 0b) and SPCEND interrupt prohibited (SPCR.CENDIE = 0b), if the user uses the flag for polling.



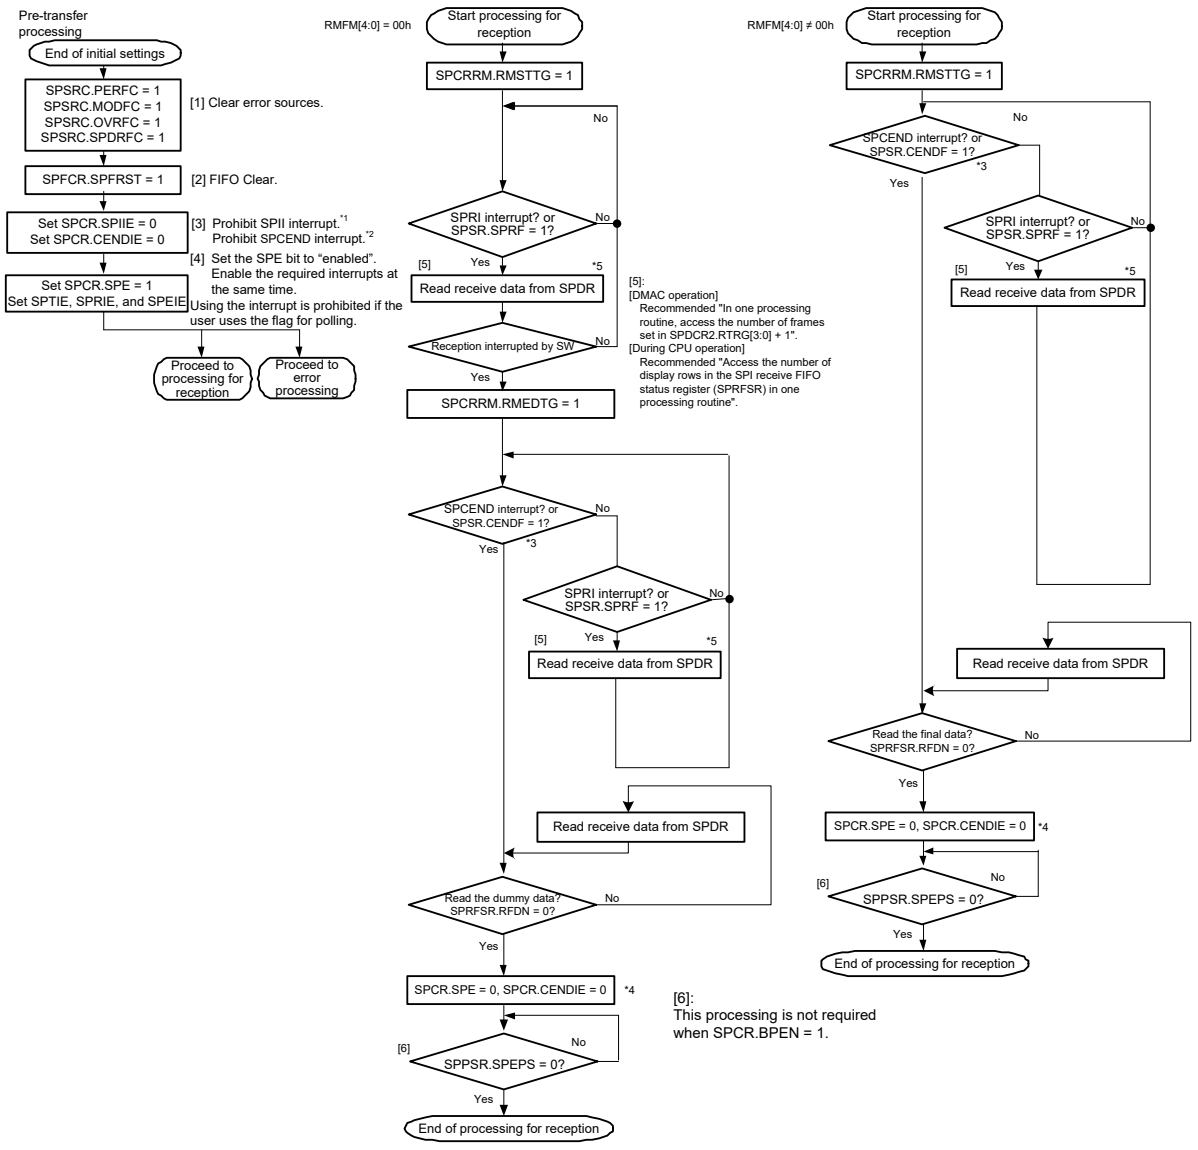
Note 4. Wait more than 1 PCLKM, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF, if the user uses the flag for polling.

Note 5. During CPU operation, "Write 1b to SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine."

Note 6. When setting to 0b in slave mode and SPCR.BPEN = 0b, check that SPPSR.SPEPS has become 0b. (Not required when BPEN = 1b.)

Figure 7.5-65 Software Processing Flowchart in Master Mode (Transmission)

(b) Reception processing flow



Note: SPII: Idle interrupt
SPRI: Reception buffer full interrupt

Note 1. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPRFC) after one processing routine.

Figure 7.5-66 Software Processing Flowchart in Master Mode (Reception)

(c) Master reception-only processing flow

Note 1. The end of communication can be determined by the SPCEND interrupt (CENDF flag). Use the SPCEND interrupt (CENDF flag).

Note 2. Disable SPCEND interrupt (SPCR.CENDIE = 0b) during flag polling.

Note 3. A communication completion interrupt at reception only operation (Master) occurs at a predetermined timing under any of the following conditions.
- Frame number processing set by RMFM completed (RMFM[4:0] ≠ 00h)
- RMEDTG = 1b, when processing of the number of frames set by RMFM is not completed (including RMFM[4:0] = 00h)

Note 4. Internal trigger is also cleared.

Note 5. During CPU operation, write 1b to the SPI receive buffer full flag clear bit (SPSRC.SPRFC) after one processing routine.

Figure 7.5-67 Software Processing Flowchart in Master Mode (Reception-Only)

(d) Error processing flow

When a mode fault error occurs, the SPE bit is automatically cleared to stop transmission and reception operations.

However, other error sources do not clear the SPE bit or stop transmission and reception operations. For this reason, if an error occurs due to another source different from the source of the error occurred first, the SPECM[2:0] value is updated. Therefore, we recommend that you clear the SPE bit to stop the ongoing operation.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.

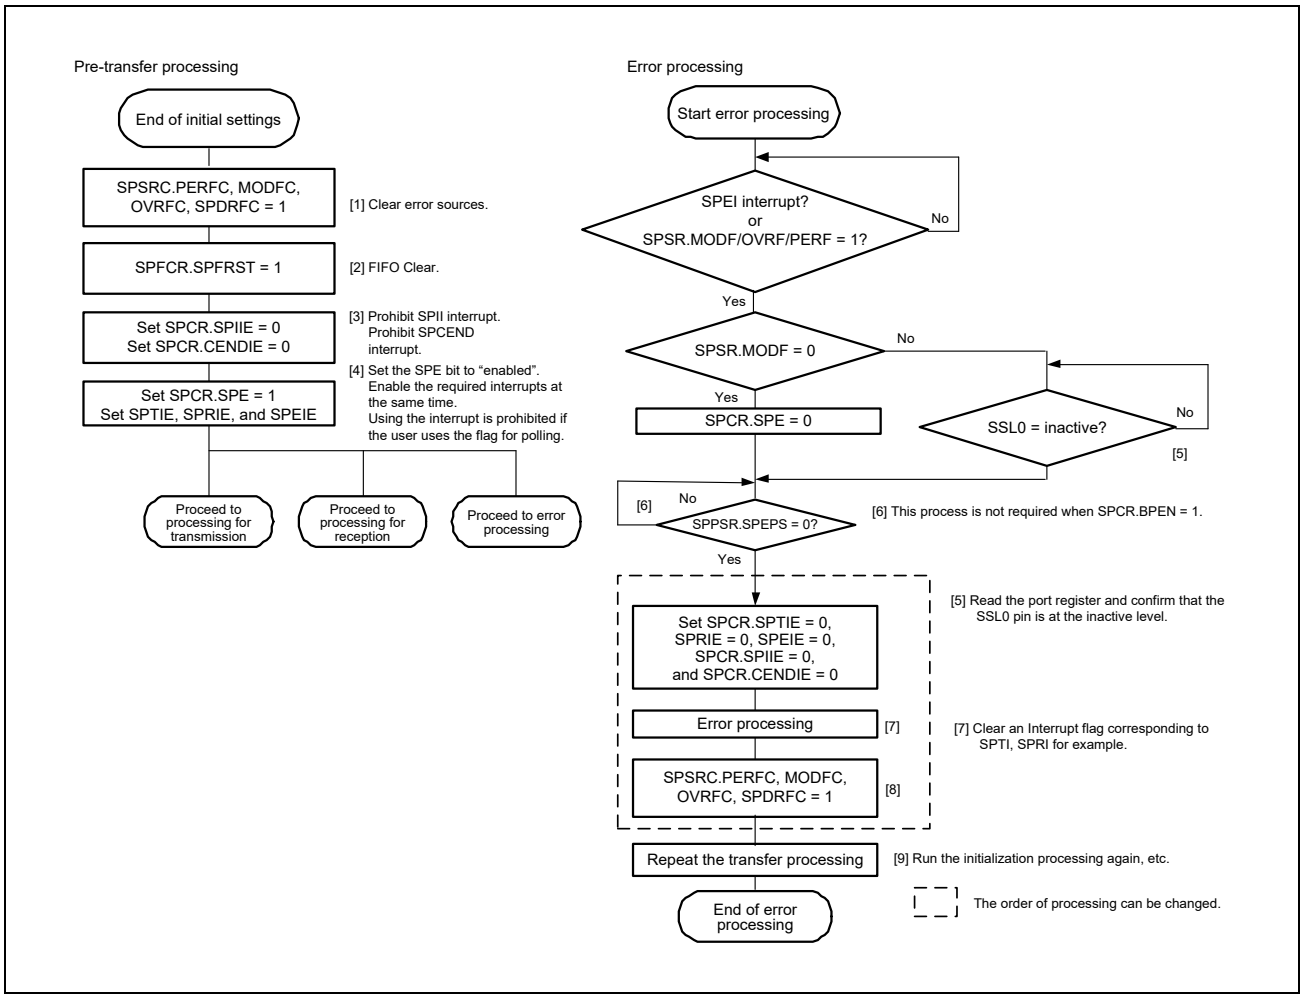


Figure 7.5-68 Flowchart for Master Mode (Error Processing)

7.5.3.13.2 Slave mode operation

(1) Starting a serial transfer

When the SPI detects SSL0 input signal assertion while SPCMD0.CPHA = 0, valid data drive to the MISO output signal must be started. For this reason, the SSL0 input signal assertion becomes a trigger to start serial transfer.

While SPCMD0.CPHA = 1b, when the SPI detects the first RSPCK edge with the SSL0 input signal asserted, valid data drive to the MISO output signal must be started. For this reason, the first RSPCK edge in the SSL0 signal assertion state becomes a trigger to start serial transfer when SPCMD0.CPHA = 1b.

The SPI starts driving the MISO output signal at the SSL0 signal assertion timing independently of the CPHA bit setting. Data that the SPI outputs is enabled or disabled depending on the set CPHA bit value.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. The SSL0 input signal polarity depends on the set SSL0P bit value in the SSLP register.

(2) Terminating a serial transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing regardless of the value of SPCMD0.CPHA bit, the SPI terminates serial transfer. When the number of data stored in the receive FIFO is smaller than the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. When the SPI detects SSL0 input signal negation during a period from serial transfer start to the end of serial transfer, a mode fault error occurs. (See **7.5.3.10 Error Detection**.)

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. The SSL0 input signal polarity depends on the set value of SSLP.SSL0P bit. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

(3) Notes on single-slave operations

[In the Motorola-SPI case]

Upon detecting the SSL0 input signal assertion edge while SPCMD0.CPHA = 0b, the SPI starts serial transfer. When using the SPI in single slave mode in a configuration as shown in the example in **Figure 7.5-9**, the SPI cannot start serial transfer correctly while CPHA is set to 0b because the SSL0 input signal is always active. To correctly perform transmission and reception of the SPI in slave mode in a configuration where the SSL0 input signal is fixed to active state, set the CPHA bit to 1b. If the CPHA bit needs to be set to 0b, do not fix the SSL0 input signal.

[In the TI-SSP case]

When TI SSP is set, when SPI is used as a single slave in the configuration shown in the example of **Figure 7.5-9**, the SSL0 input signal is always fixed to the inactive state, SPI cannot start serial transfer correctly.

When using a single slave, use the configuration shown in the example in **Figure 7.5-8**.

(4) Burst transfer

[In the Motorola-SPI case]

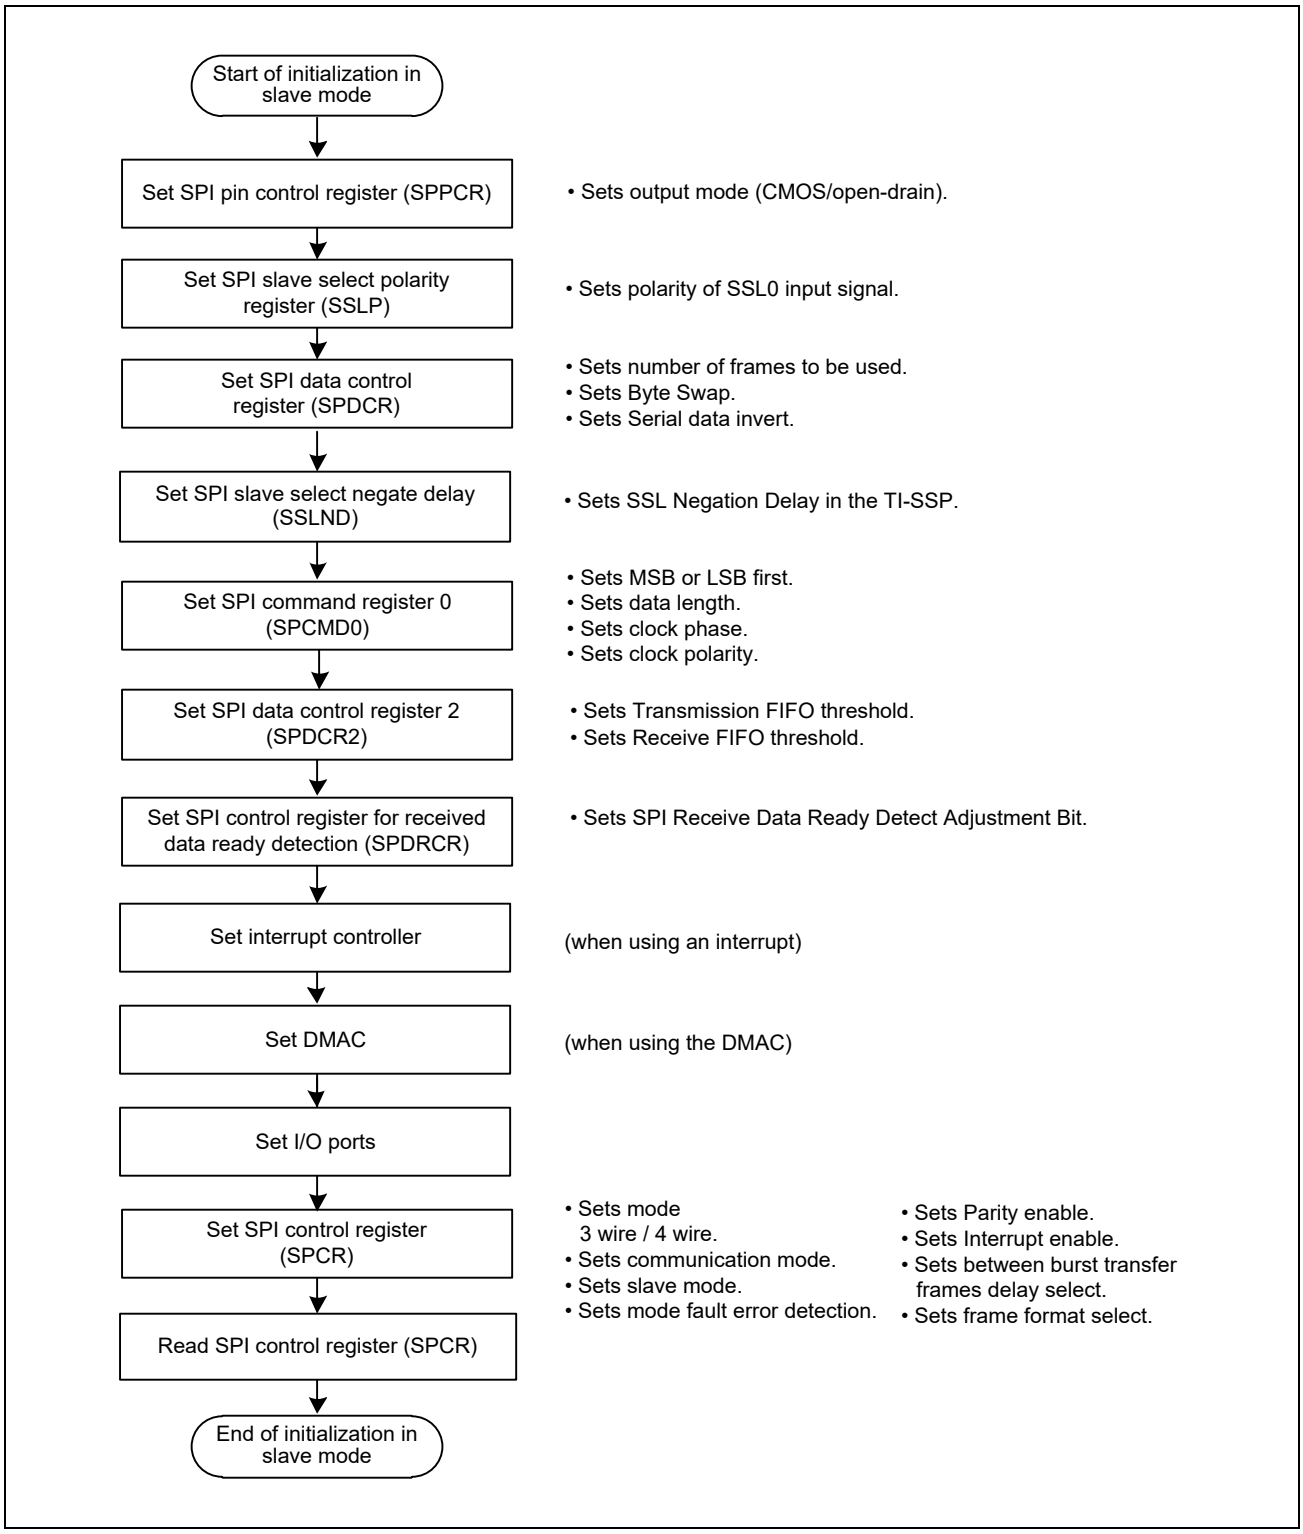
When SPCMD0.CPHA = 1b, continuous serial transfer (burst transfer) is possible while maintaining the SSL0 input signal assertion state. When SPCMD0.CPHA = 1b, the period (from the first RSPCK edge in the SSL0 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSL0 input signal is always at the active level, start of an access can be detected, which allows burst transfer.
When SPCMD0.CPHA = 0b, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSL input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL input signal, SSL must be asserted between frames.

(5) Initialization flowchart

Figure 7.5-69 shows an example of initialization flow when using the SPI in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.



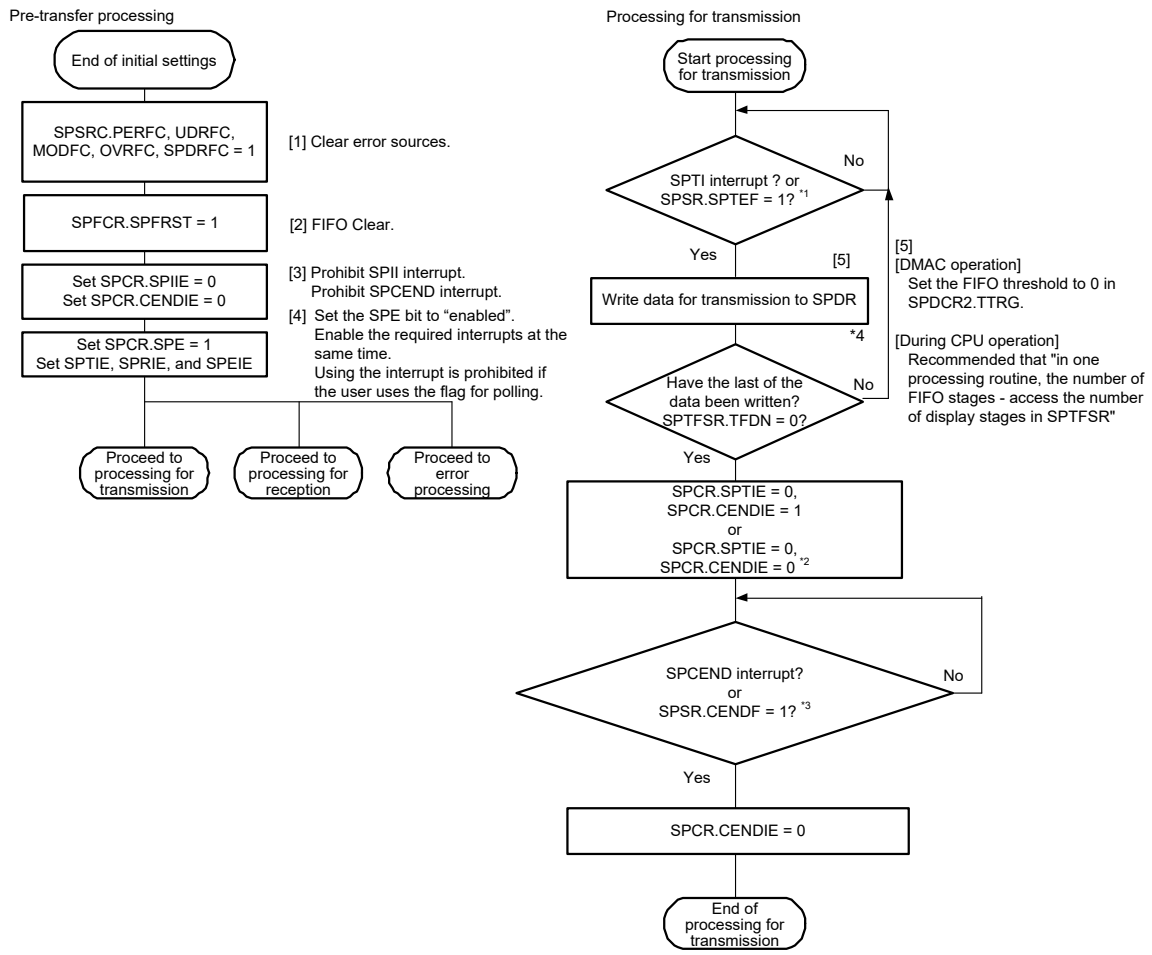


Figure 7.5-69 Example of Initialization Flow in Slave Mode

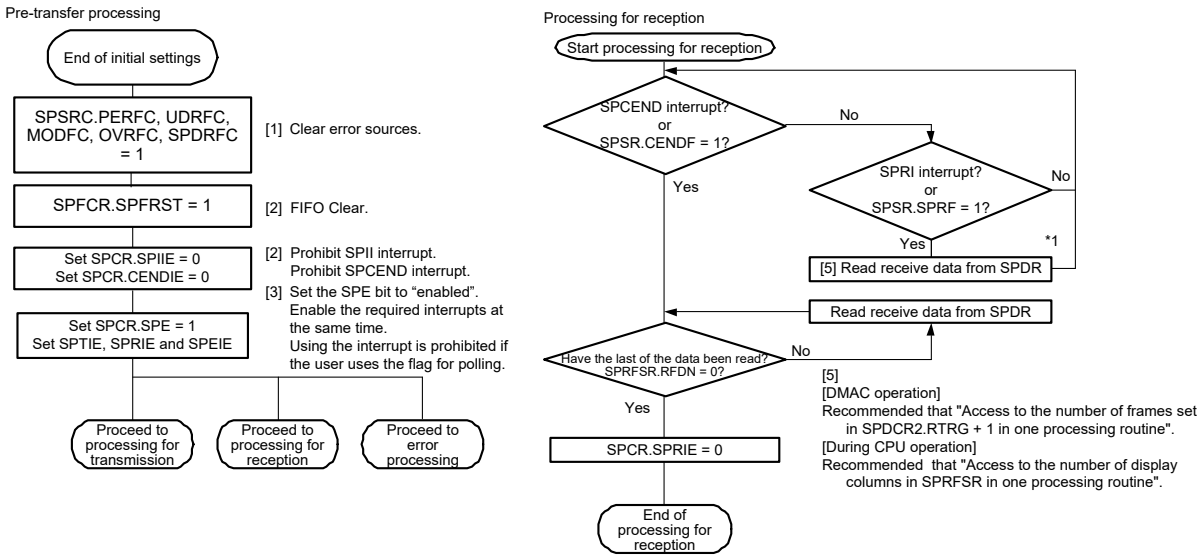
(6) Software processing flow

Figure 7.5-70 to **Figure 7.5-73** show examples of the flow of software processing.

(a) Transmit processing flow

Note: SPII: Idle interrupt

Note 1. Proceed to process of writing data for transmission after reading SPSR.SPTEF flag is 1b, if the user uses the flag for polling.



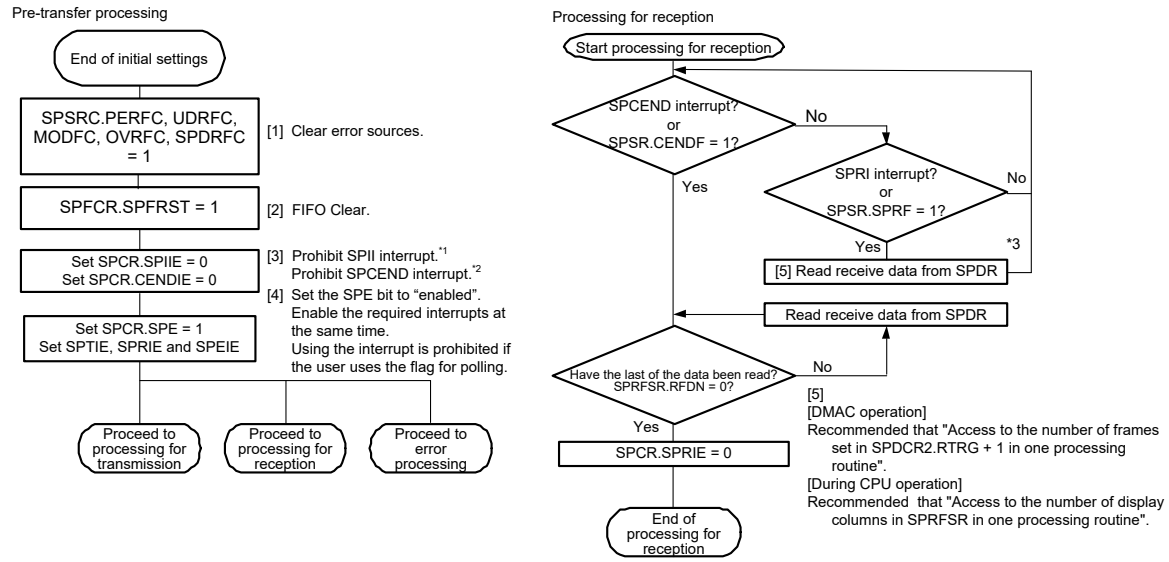
Note 2. Set SPCEND interrupt prohibited (SPCR.CENDIE = 0b), if the user uses the flag for polling.

Note 3. Wait more than 1 PCLKM, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF , if the user uses the flag for polling.

Note 4. During CPU operation, write 1b to the SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 7.5-70 Software Processing Flowchart in Slave Mode (Transmission)

(b) Reception processing flow



Note: SPII: Idle interrupt

Note 1. During CPU operation, "Write 1b to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine."

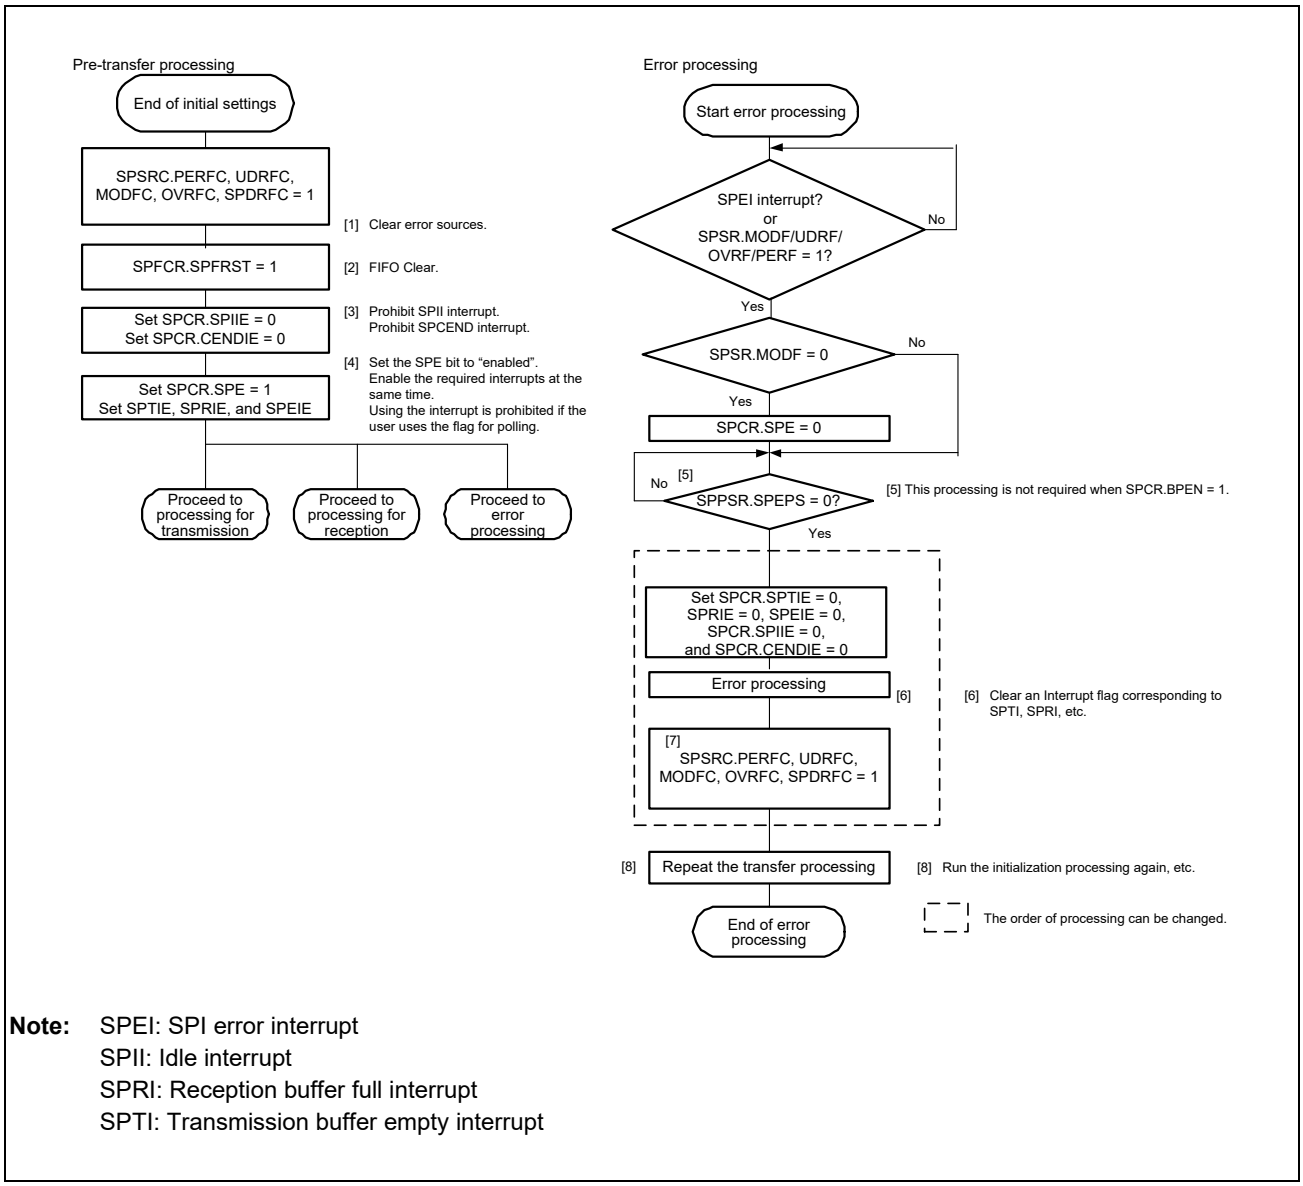
Figure 7.5-71 Flowchart in Slave Mode (Reception)

(c) Master reception-only processing flow

Note: SPII: Idle interrupt

Note 1. The end of communication can be determined by the SPCEND interrupt (CENDF flag). Use the SPCEND interrupt (CENDF flag).

Note 2. Disable the SPCEND interrupt (SPCR.CENDIE = 0b) during flag polling.



Note 3. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 7.5-72 Software Processing Flowchart in Slave Mode (Reception-Only)

(d) Error processing flow

In slave mode operation, the MODF flag can be cleared regardless of the SSL0 pin status even when a mode fault error is present.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.

Note: SPEI: SPI error interrupt
SPII: Idle interrupt
SPRI: Reception buffer full interrupt
SPTI: Transmission buffer empty interrupt

Figure 7.5-73 Software Processing Flowchart in Slave Mode (Error Processing)

7.5.3.14 Clock Synchronous Operation

When SPCR.SPMS bit = 1b, the SPI operates in synchronization with clock. Clock synchronous operation enables communication by using three pins RSPCK, MOSI, and MISO without using SSL pins. SSL pins can be used as I/O ports.

Clock synchronous operation does not use SSL pins for communication, but the module operates internally in the similar manner to SPI operation. In master mode operation and slave mode operation, communication is possible according to the flow similar to SPI operation, but no mode fault error is detected because SSL pins are not used.

In clock synchronous operation, if the SPCMD.CPHA bit is set to 0b in slave mode (SPCR.MSTR = 0b), subsequent operation is not guaranteed.

7.5.3.14.1 Master mode operation

(1) Starting a serial transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 15) data in SPDR. While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(2) Terminating a serial transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(3) Sequence control

The transfer format in master mode is determined by the SPSCR, SPCMDm (m = 0 to 7), SPBR, SPCKD, SSLND, and SPND registers. These settings are valid though SSL signals are not output in clock synchronous operation.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7. A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1b to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer when the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

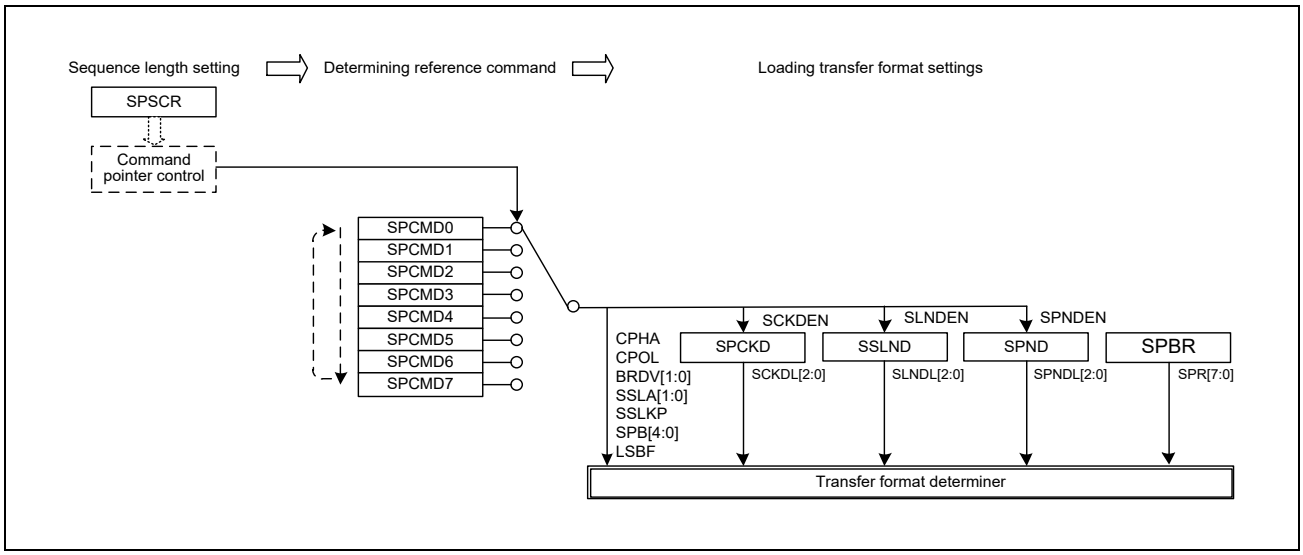


Figure 7.5-74 Determining Serial Transfer Method in Master Mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm (m = 0 to 7)).

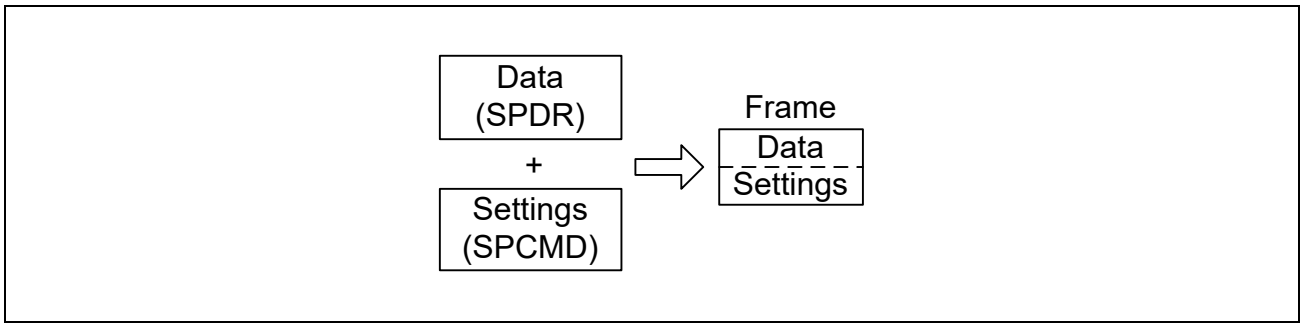

Figure 7.5-75 Conceptual Diagram of Frame

Figure 7.5-76 shows the correspondence between the command in the sequence operation performed and the transmit buffer/receive buffer.

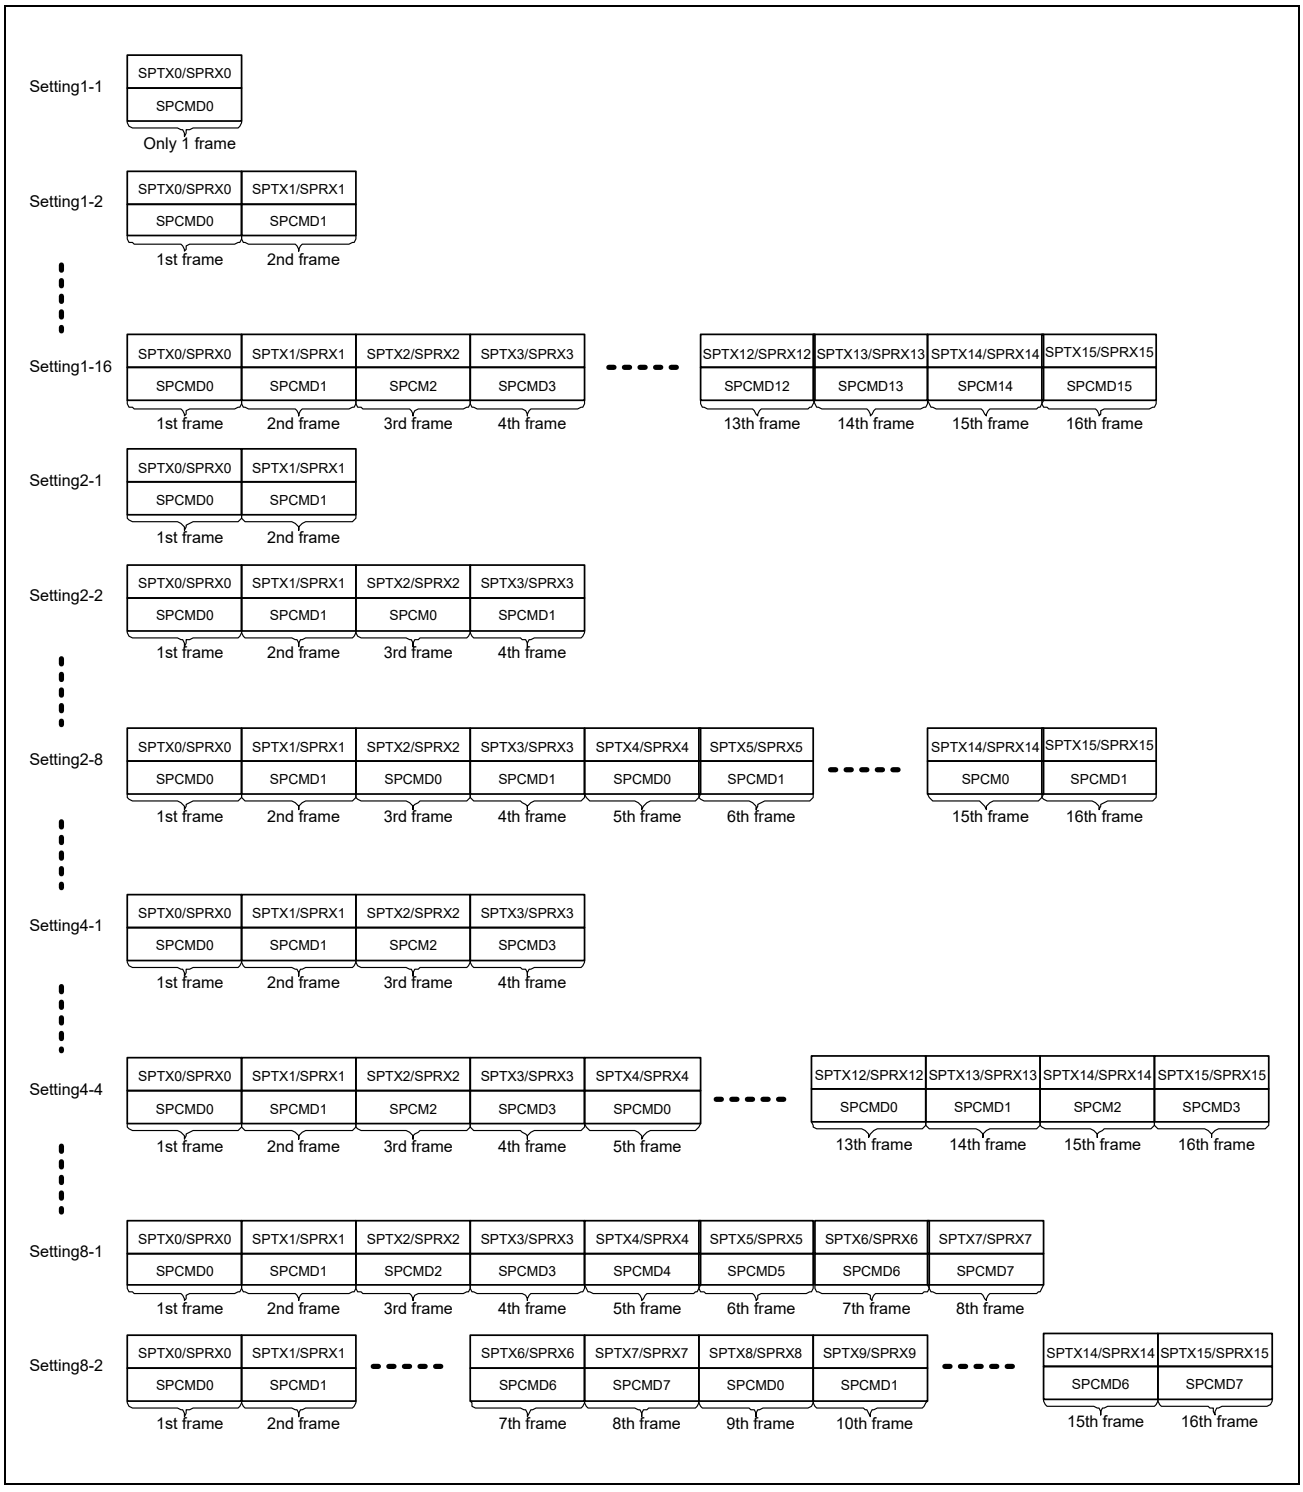

Figure 7.5-76 Correspondence between SPI Command Register and Transmit/Receive Buffers in Sequence Operation

(4) Initialization flow

Figure 7.5-77 shows an example of initialization flow when using the SPI in master-mode clock synchronous operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

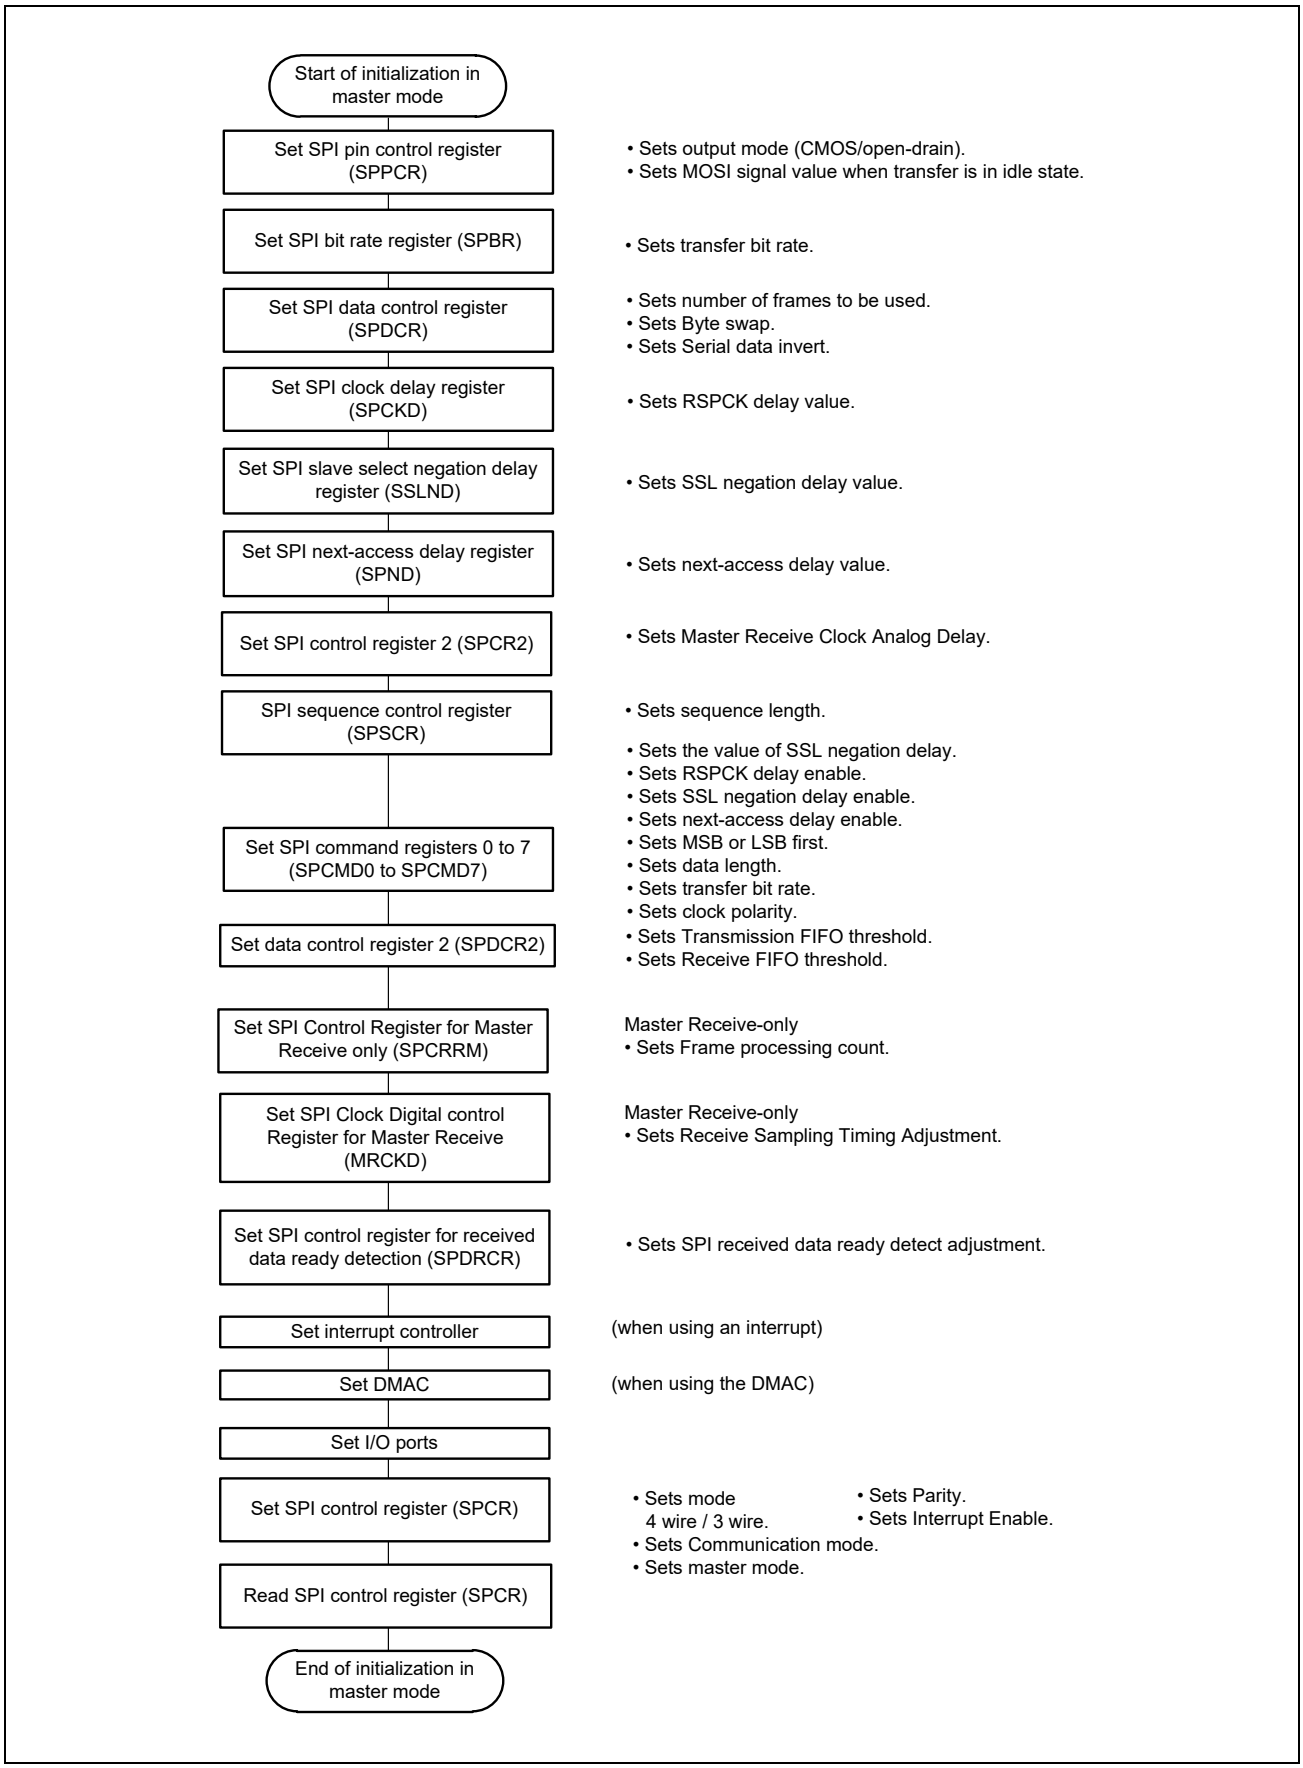

Figure 7.5-77 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of software processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

7.5.3.14.2 Slave mode operation

(1) Starting a serial transfer

When SPCR.SPMS = 1b, the first RSPCK edge becomes a trigger to start serial transfer of the SPI.

While SPCR.SPMS = 1b, the SPI always drives the MISO output signal.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. In clock synchronous operation, however, the SSL0 input signal is not used.

(2) Terminating a serial transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

(3) Initialization flowchart

Figure 7.5-78 shows an example of initialization flow when using the SPI in slave-mode clock synchronous operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

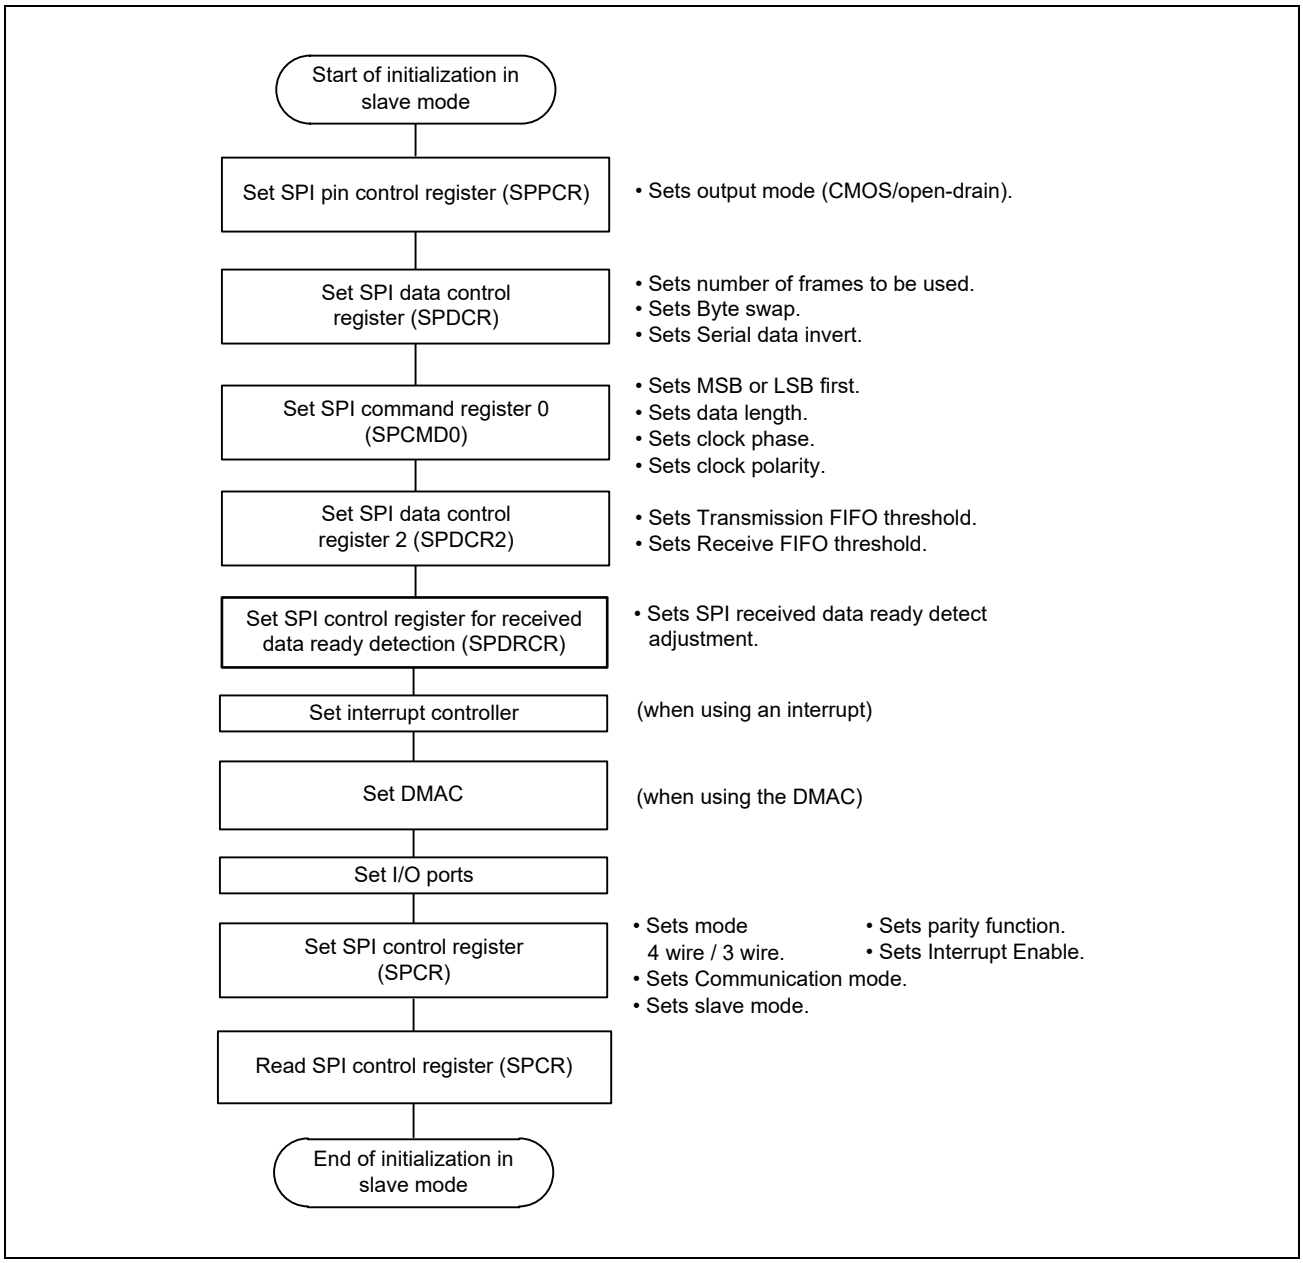

Figure 7.5-78 Example of Initialization Flow in Slave Mode

(4) Flow of software processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

7.5.3.15 Loopback Mode

When 1b is written to the SPPCR.SPLP bit or SPPCR.SPLP2 bit, the SPI disconnects the path between MISO pin and shift register (when SPCR.MSTR = 1b) or between MOSI pin and shift register (when SPCR.MSTR = 0b), and then connects the shift register input path to the output path. When SPCR.MSTR = 1, the SPI does not disconnect the path between MOSI pin and shift register. When SPCR.MSTR = 0b, the SPI does not disconnect the path between MISO pin and shift register.

When serial transfer is performed in loopback mode, transmit data or inverted transmit data of the SPI becomes received data of the SPI.

Figure 7.5-79 shows the relationship between settings of the SPLP2 and SPLP bits and received data.

Table 7.5-15 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0b	0b	Input data from the MOSI pin or MISO pin
0b	1b	Inversed transmit data
1b	0b	Transmit data
1b	1b	Transmit data

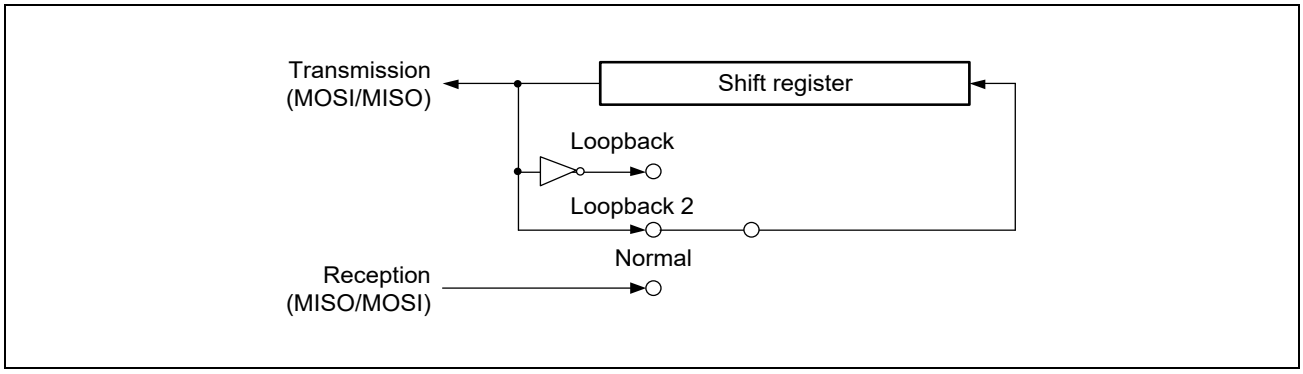

Figure 7.5-79 Configuration of Shift Register I/O Paths in Loopback Mode

7.5.3.16 Self-Diagnosis of Parity Function

The parity circuit consists of a section to add a parity bit to transmit data and a section to detect an error in receive data.

To detect a failure of these sections of the parity circuit, self-diagnosis of the parity circuit is performed according to the flow in **Figure 7.5-80**.

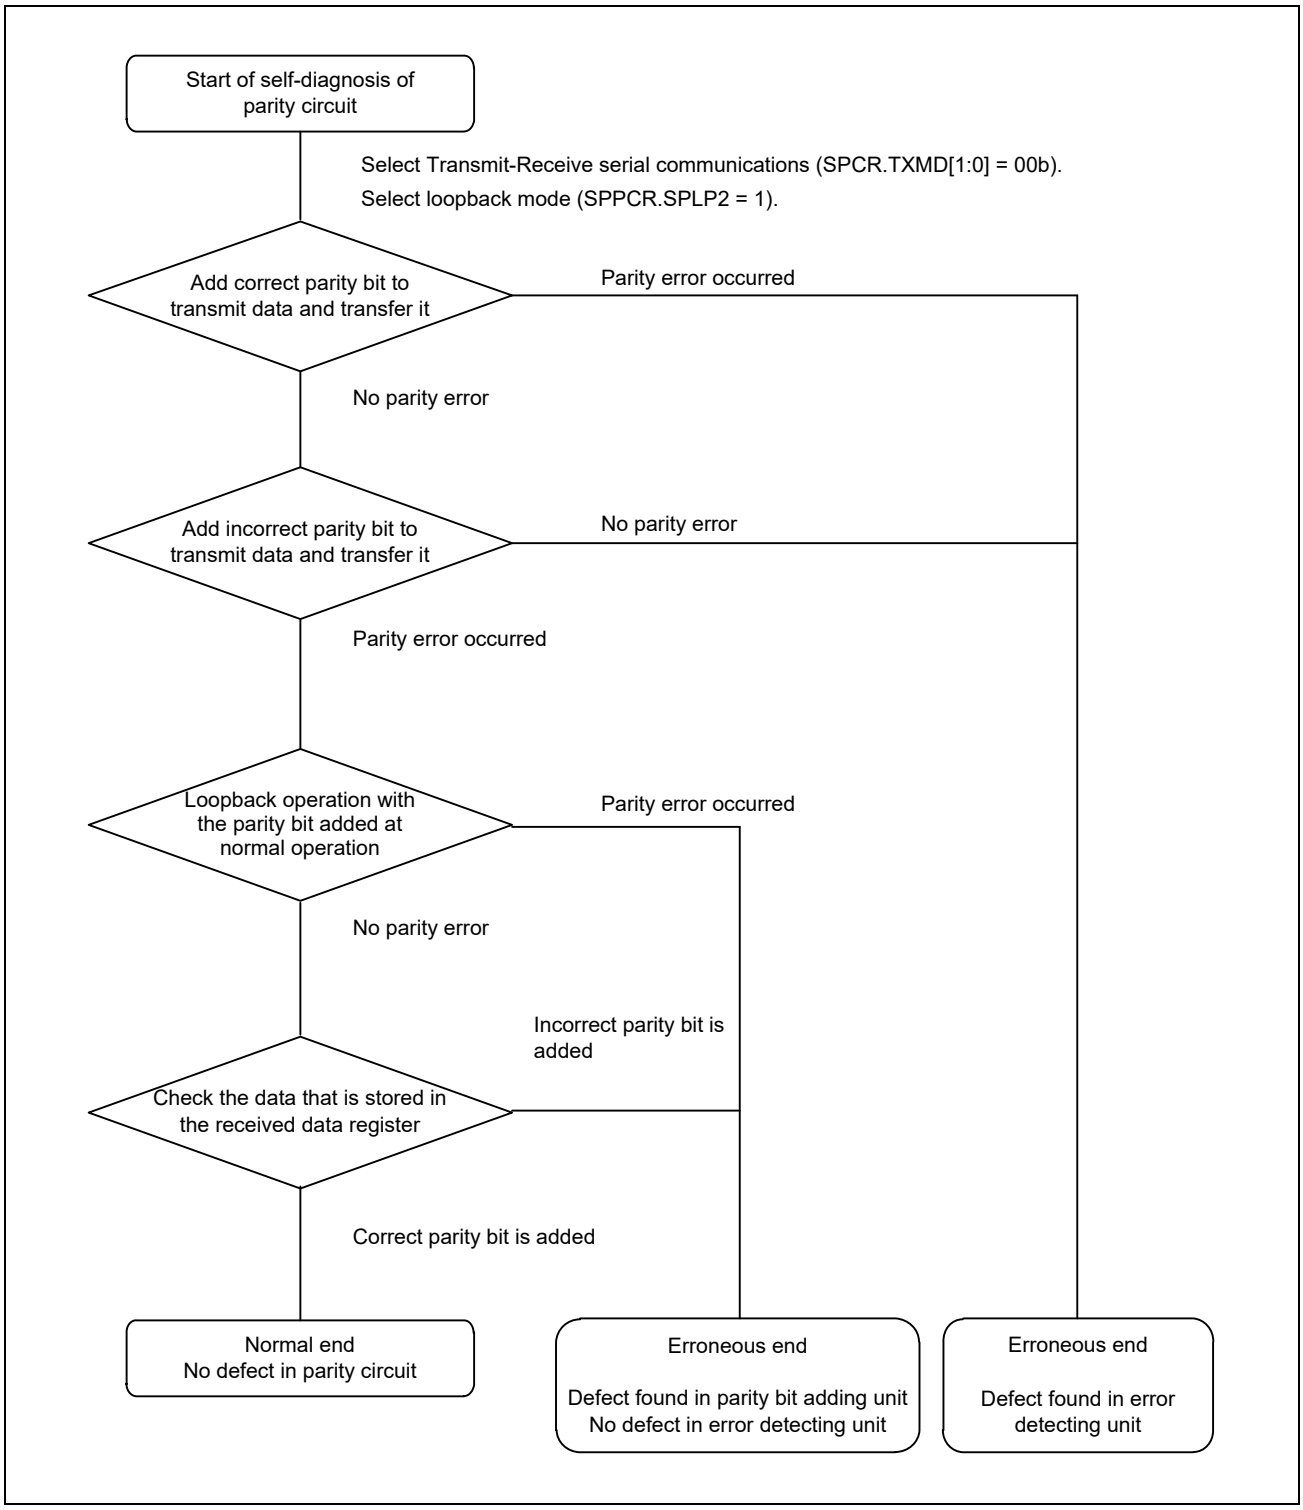

Figure 7.5-80 Parity Circuit Self-Diagnosis Flow

7.5.3.17 Interrupt Requests

The SPI has the following interrupt sources: receive buffer full, transmit buffer empty, mode fault, underrun, overrun, parity error, SPI idle, communication end, and received data ready. Furthermore, the DMAC can be activated by a receive buffer full interrupt request and a transmit buffer empty interrupt request to start data transfer.

Mode fault, underrun, overrun, parity error, and received data ready (SPCR.SPDRES = 1b) interrupt requests are allocated to vector addresses in SPEI. Therefore, identify these interrupt sources by reading respective flags. **Table 7.5-16** lists SPI's interrupt sources. When each interrupt condition in **Table 7.5-16** is met, an interrupt is generated. Clear the receive buffer full and transmit buffer empty interrupt sources by performing data transfer.

When starting transmission or reception by using the DMAC, configure the DMAC to enable it, and then configure the SPI.

Even when the transmit buffer empty interrupt or receive buffer full interrupt condition is met while an Interrupt flag is 1, an interrupt request is not output to ICU but is internally retained. (Only one request per source can be internally retained.) When an Interrupt flag is cleared to 0, the retained interrupt request is output to ICU and then automatically cleared. An internally retained interrupt request can also be cleared by setting the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0b.

Table 7.5-16 Interrupt Sources of SPI

Interrupt Source	Symbol	ICU Input Name	Interrupt Condition	DMAC Activation
Reception buffer full	SPRI	RSPI_CHn_sp_rxintpls_n	SPRIE = 1b and (receive buffer full (SPRF = 1b) | (SPDRES = 0b and Receive data ready (SPDRF = 1b)))	Activated
Transmission buffer empty	SPTI	RSPI_CHn_sp_txintpls_n	SPTIE = 1b and transmit buffer empty (SPTEF = 1b)	Activated
SPI errors (mode fault, underrun, overrun, and parity error, received data ready)	SPEI	RSPI_CHn_sp_errint_n	SPEIE = 1b and (MODF = 1b | UDRF = 1b | OVRF = 1b | PERF = 1b | (SPDRES = 1b and SPDRF = 1b))	—
SPI idle	SPII	RSPI_CHn_sp_idint_n	SPIIE = 1b and IDLNF = 0b	—
Communication end*1	SPCEND	RSPI_CHn_sp_ceintpls_n	CENDIE = 1b and CENDF = 1b	—

Note 1. See **7.5.3.9.7 Common operation** for details on the communication completion interrupt output conditions.

Note: n = 0 to 2

7.5.4 Usage Notes

7.5.4.1 Notes on Communication Start

When an Interrupt flag is 1 at the beginning of communication, perform the following procedure to clear an interrupt request before enabling operation (setting the SPCR.SPE bit to 1b).

1. Confirm that communication is not going (SPCR.SPE = 0b).
2. Set the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0b.
3. Read the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that it is 0b.
4. Set the Interrupt flag to 0.

7.5.4.2 Notes on the Module-Stop Function

To stop this module using the power consumption reducing function, be sure to set the SPE bit in SPCR to 0b to terminate communication and then use the power consumption reducing function.

7.5.4.3 Notes on SPRF and SPTEF Flags

When using the SPRF and SPTEF flags in SPSR by polling them, set the SPRIE and SPTIE bits in SPCR to 0b.

7.5.4.4 Notes on Receive Sampling Function

When using the receive sampling function (sampling receive data with MRIOCLK or MRCLK), set the SSLND register considering the delay of the receive data sampling clock (MRIOCLK or MRCLK) from RSPCK. Please see **7.5.2.2.3 SPI Slave Select Negation Delay Register (RSPIm_SSLND)**.

7.5.4.5 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between SPCMD with the SSLKP bit set to 1b and SPCMD used in the next transfer is prohibited.

1. SSL Signal Assertion setting (SSLA[1:0] bits)
2. RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

7.5.4.6 Notes on TI-SSP in Slave Mode

In the slave TI SSP mode, the delay between frames must observe the following intervals.

Secure the following intervals on the master side.

[Master side: interval from RSPCK edge of last bit to RSPCK edge of next SSL] > [Slave side: Output enable delay time = RSPI_n_TCLK × (1 to 2) + SLNDL[2:0] setting value]

7.5.4.7 Notes at SPE = 1b

(1) When SPCR.SPE = 1b, if the following register bits are rewritten, subsequent operations are not guaranteed.

Table 7.5-17 Communication End Event Generating Conditions (Receive Only Slave Mode) (1/2)

Register Name	Bit Name

Note 1. Rewriting prohibited in slave mode. In master mode, this is possible only when there is no next transfer data in the transmit FIFO.

(2) After rewriting from SPE = 1b to 0b when SPCR.BPEN = 0b, or when SPSR.MODF is set to 1b, check that the SPPSR.SPEPS bit is set to 0b, then do the next operation.

SECTION 7 LOW-SPEED INTERFACE

7.7 I²C Bus Interface

This section gives an overall description of the I²C bus interface (RIIC).

The first section describes the features specific to this LSI, including the number of units and the register base addresses. The subsequent sections describe the RIIC's functions and registers.

7.7.1 Features

7.7.1.1 Channels

This LSI has the following number of channels of the I²C bus interface (RIIC).

Table 7.7-1 Channels of RIIC

Item	Description
Number of channels	4
Name	RIICn (n = 0 to 3)

Table 7.7-2 Index

Index	Description
n	Throughout this section, the individual channels of the I²C bus interface are identified by the index "n" (n = 0 to 3); for example, RIICnCR1 for the I²C bus control register 1.

7.7.1.2 Register Base Addresses

The base address <RIICn_base> of each RIICn is listed in the following table.

All RIICn register addresses are given as values obtained by adding offsets to the register base address <RIICn_base> for each channel.

Table 7.7-3 Register Base Address

Channel	Base Address Name	Base Address
RIIC0	<RIIC0_base>	H'0_100A_E000 (Cortex-A55 Address Space)
RIIC1	<RIIC1_base>	H'0_1009_0400 (Cortex-A55 Address Space)
RIIC2	<RIIC2_base>	H'0_1009_0800 (Cortex-A55 Address Space)
RIIC3	<RIIC3_base>	H'0_1009_0C00 (Cortex-A55 Address Space)
RIIC0	<RIIC0_base>	H'400A_E000 (Cortex-M33 Address Space Secure)
RIIC1	<RIIC1_base>	H'4009_0400 (Cortex-M33 Address Space Secure)
RIIC2	<RIIC2_base>	H'4009_0800 (Cortex-M33 Address Space Secure)
RIIC3	<RIIC3_base>	H'4009_0C00 (Cortex-M33 Address Space Secure)
RIIC0	<RIIC0_base>	H'500A_E000 (Cortex-M33 Address Space Non-Secure)
RIIC1	<RIIC1_base>	H'5009_0400 (Cortex-M33 Address Space Non-Secure)
RIIC2	<RIIC2_base>	H'5009_0800 (Cortex-M33 Address Space Non-Secure)
RIIC3	<RIIC3_base>	H'5009_0C00 (Cortex-M33 Address Space Non-Secure)

7.7.1.3 External I/O Signals

The following table shows the external I/O signals of the RIIC.

Table 7.7-4 RIICn Pin Configuration

Channel Number	Pin Name	Signal Name in This Section	Input/Output	Functional Description
0	RIIC0_SCL	RIICnSCL	I/O	I2C serial clock Input/Output pin
	RIIC0_SDA	RIICnSDA		I2C serial data Input/Output pin
1	RIIC1_SCL	RIICnSCL		I2C serial clock Input/Output pin
	RIIC1_SDA	RIICnSDA		I2C serial data Input/Output pin
2	RIIC2_SCL	RIICnSCL		I2C serial clock Input/Output pin
	RIIC2_SDA	RIICnSDA		I2C serial data Input/Output pin
3	RIIC3_SCL	RIICnSCL		I2C serial clock Input/Output pin
	RIIC3_SDA	RIICnSDA		I2C serial data Input/Output pin

Note: n = 0 to 3

Note: RIIC0 to RIIC3 are low level drive only LVTTL buffer.

7.7.2 Overview

7.7.2.1 Functional Overview

Communications format

- I^2C bus format or SMBus format
- Master mode or slave mode selectable
- Automatic securing of the various set-up times, hold times, and bus-free times for the transfer rate

Transfer rate

Up to 1 Mbps

SCL clock

For master operation, the duty cycle of the SCL clock is selectable in the following range. 4% < Duty cycle < 96%.

Issuing and detecting conditions

- Start, restart, and stop conditions are automatically generated.
- Start conditions (including restart conditions) and stop conditions are detected.

Slave address

- Up to three slave-address settings can be made.
- Seven- and ten-bit address formats are supported (along with the use of both at once).
- General call addresses, device ID addresses, and SMBus host addresses are detected.

Acknowledgement

- For transmission, the acknowledge bit is automatically loaded
  - Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit.
- For reception, the acknowledge bit is automatically transmitted
  - If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.

Wait function

- In reception, the following periods of waiting can be obtained by holding the clock signal (SCL) at the low level:
  - Waiting between the eighth and ninth clock cycles
  - Waiting between the ninth clock cycle and the first clock cycle of the next transfer (WAIT function)

SDA output delay function

Timing of the output of transmitted data, including the acknowledge bit, can be delayed.

Arbitration

- For multi-master operation
  - Operation to synchronize the SCL (clock) signal in cases of conflict with the SCL signal from another master is possible.
  - When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line.
  - In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line.
- Loss of arbitration due to detection of the start condition while the bus is busy is detectable (to prevent the issuing of double start conditions).
- Loss of arbitration in transfer of a not-acknowledge bit due to the internal signal for the SDA line and the level on the SDA line not matching is detectable.
- Loss of arbitration due to non-matching of internal and line levels for data is detectable in slave transmission.

Timeout function

The internal time-out function is capable of detecting long-interval stop of the SCL (clock signal).

Noise removal

The interface incorporates analog noise filters and digital noise filters for input on the RIICnSCL and RIICnSDA pins, and the width for noise cancellation by the digital noise filters is adjustable by software.

Interrupt sources

- Eight sources:
  - Transmission complete
  - Receive-data-full
  - Transmit-data-empty
  - Detection of a stop condition
  - Detection of a start condition
  - Reception of a NACK
  - Arbitration lost
  - Timeout

Low power consumption function

Module-stop state can be set.

7.7.2.2 Block Diagram

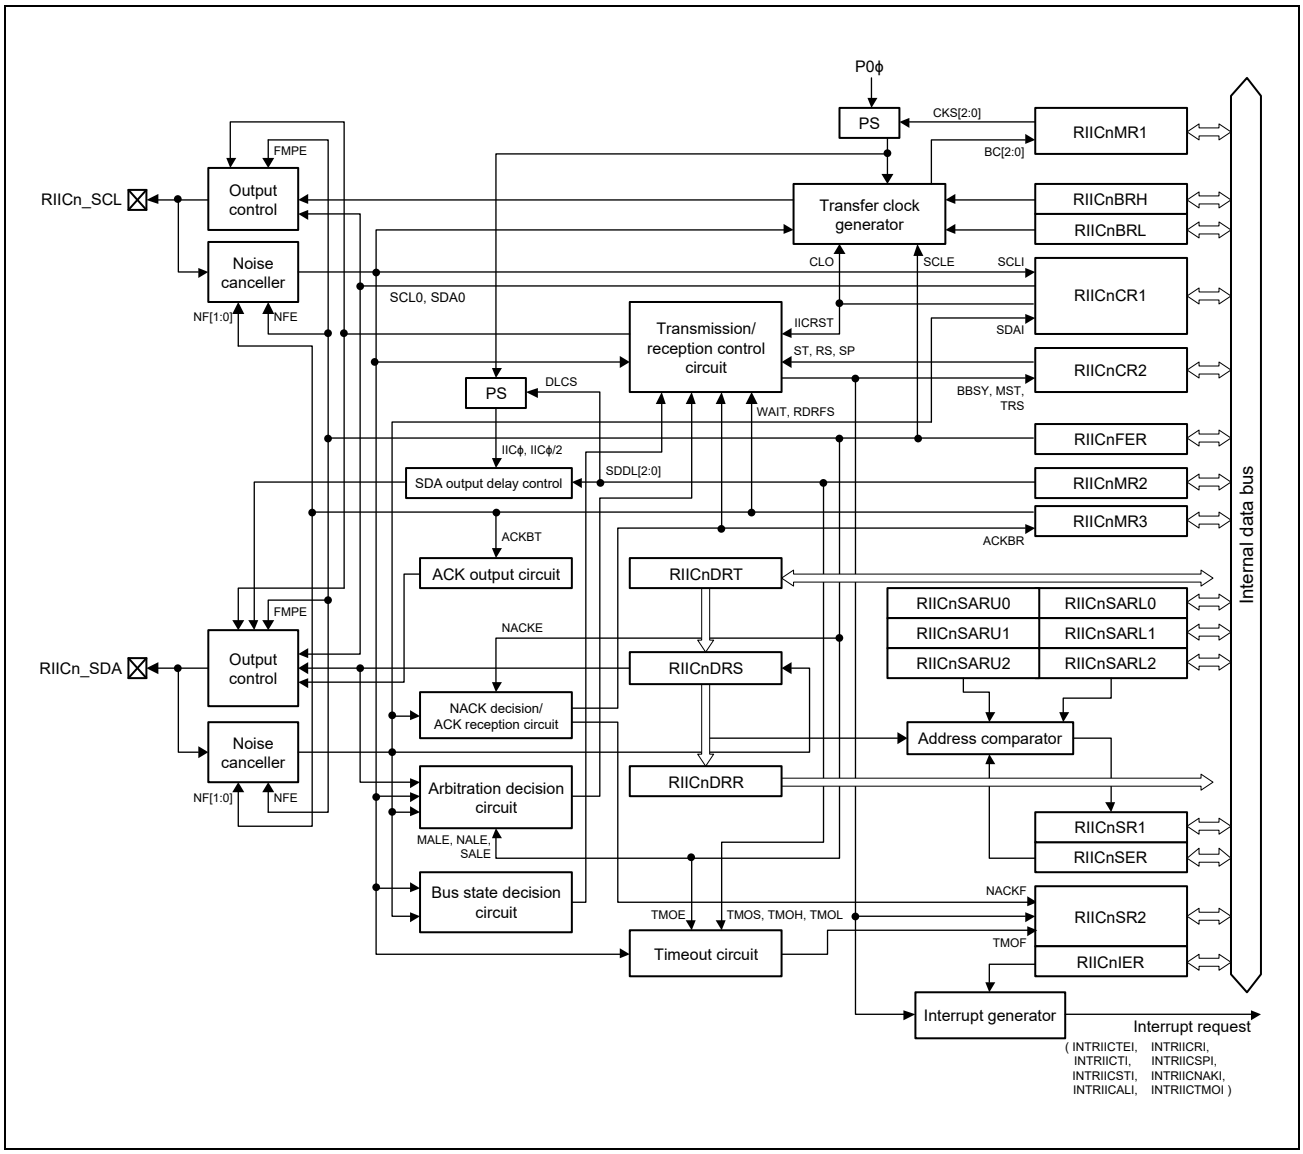

Figure 7.7-1 Block Diagram of RIIC

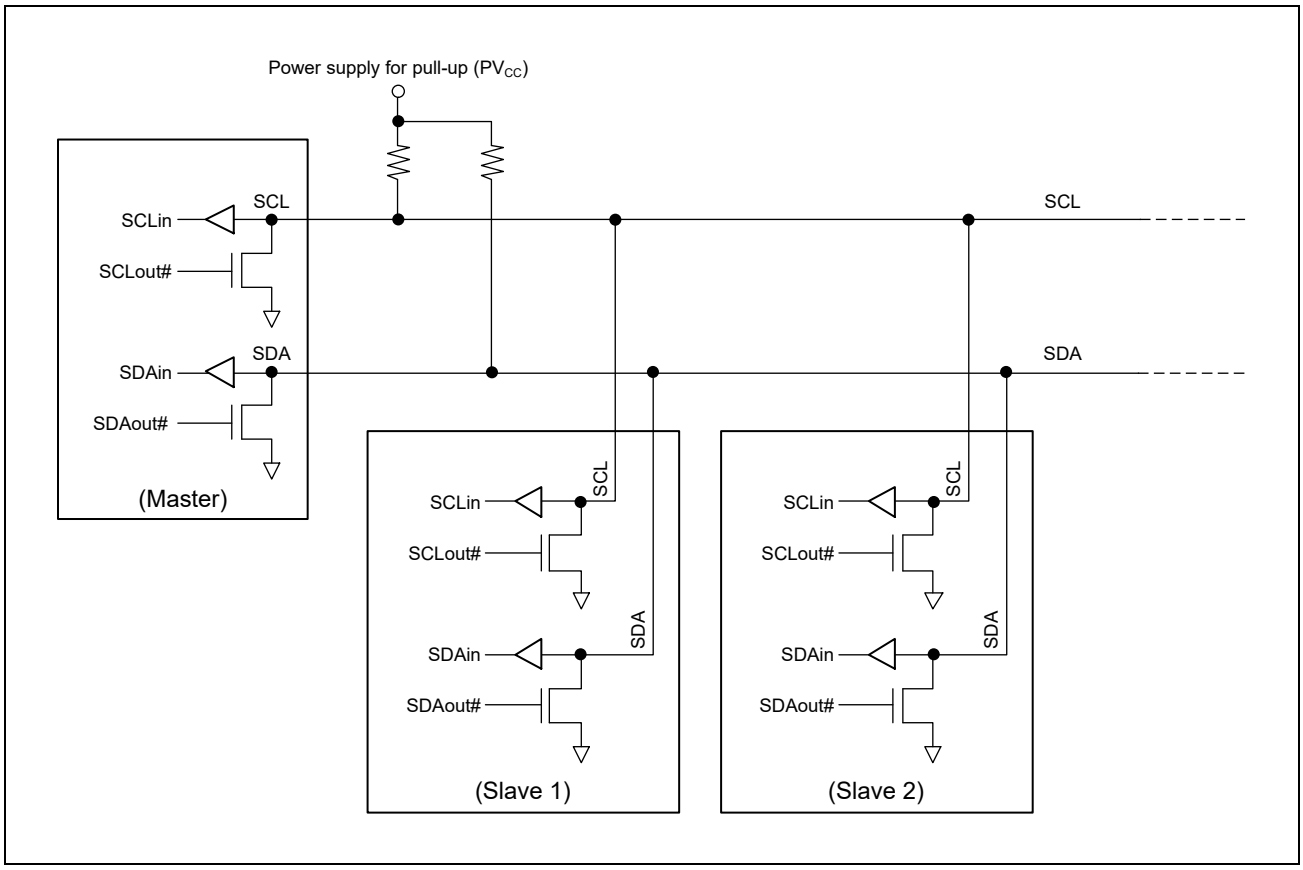

Figure 7.7-2 Connections to the External Circuit by the I/O Pins (I^2C Bus Configuration Example)

RIICnSCL and RIICnSDA are Schmitt input/open-drain output pins for both master and slave operations. Because the output is open drain, an external pull-up resistor is required.

7.7.3 Registers

Table 7.7-5 RIICn (n = 0 to 3) Register Configuration

Channel	Register Name	Abbreviation	Offset Address	Access Size
RIICn	I^2C bus control register 1	ICCR1	H'00	8
(n = 0 to 3)	I^2C bus control register 2	ICCR2	H'01	8
	I^2C bus mode register 1	ICMR1	H'02	8

	I^2C bus receive data register	ICDRR	H'13	8
	I^2C bus shift register	ICDRS	—	—

7.7.3.1 I²C Bus Control Register 1 (RIICnCR1)

Access Size: RIICnCR1 is a 8-bit readable/writable register.

Address(es): RIICnCR1: <RIICn_base> + H'0000

Initial Value: H'1F. This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Initial Value	0	0	0	1	1	1	1	1
R/W	R/W	R/W	R/W	W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	ICE	0	R/W	I²C Bus Interface Enable 0: Output to the RIICnSCL and RIICnSDA pins is disabled. (Input to the RIICnSCL and RIICnSDA pins is enabled.) 1: Enabled (RIICnSCL and RIICnSDA pins are in the driving state) (An RIIC reset or an internal reset is selected according to the combination of this bit and IICRST bit settings.)
6	IICRST	0	R/W	I²C Bus Interface Internal Reset 0: Clears the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCL/SDA output latch)
5	CLO	0	R/W	Extra SCL Clock Cycle Output 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (The CLO bit is cleared automatically after one clock cycle is output.)
4	SOWP*2	1	W	SCLO/SDAO Write Protect 0: Allows the SCLO and SDAO bits to be rewritten. 1: Bits SCLO and SDAO are protected. (This bit is read as 1.)
3	SCLO*1, *2	1	R/W	SCL Output Control • Read: 0: RIICnSCL pin output is at a low level. 1: RIICnSCL pin is in a high-impedance state. • Write: 0: Changes the RIICnSCL pin output to a low level. 1: Changes the RIICnSCL pin in a high-impedance state. (High level output is achieved through an external pull-up resistor.)
2	SDAO*1,*2	1	R/W	SDA Output Control • Read: 0: RIICnSDA pin output is at a low level. 1: RIICnSDA pin is in a high-impedance state. • Write: 0: Changes the RIICnSDA pin output to a low level. 1: Changes the RIICnSDA pin in a high-impedance state. (High level output is achieved through an external pull-up resistor.)
1	SCLI	1	R	SCL Bus Input Monitor 0: RIICnSCL pin input is at a low level. 1: RIICnSCL pin input is at a high level.
0	SDAI	1	R	SDA Bus Input Monitor 0: RIICnSDA pin input is at a low level. 1: RIICnSDA pin input is at a high level.

Note 1. Do not write to these bits during communication. Changing a value during communication may cause a transmission or reception failure or an AL error.

Note 1. To change the SDAO and SCLO bits, set the SOWP bit to 0 at the same timing to set the SDAO and SCLO bits to 0.

SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the SDAn and SCLn signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit. The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

When reading these bits, the state of signals output from the RIIC can be read.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see **7.7.13.2 Extra SCL Clock Cycle Output Function**.

IICRST Bit (I^2C Bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC. Setting this bit to 1 initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. **Table 7.7-6** lists the resets of the RIIC.

The RIIC reset resets all registers including the RIICnCR2.BBSY flag (except ICE and IICRST) and internal states of the RIIC, and the internal reset resets the bit counter (RIICnMR1.BC[2:0] bits), the I^2C bus shift register (RIICnDRS), and the I^2C bus status registers (RIICnSR1 and RIICnSR2) as well as the internal states of the RIIC. For the reset conditions for each register, see **7.7.15 Reset Function of RIIC**.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.

If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the RIICnSCL pin and RIICnSDA pin at a high impedance.

Remark If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCL line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 7.7-6 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers (except ICE and IICRST) and internal states of the RIIC.
	1	Internal reset	Reset the RIICnMR1.BC[2:0] bits, and the RIICnSR1, RIICnSR2, RIICnDRS registers and the internal states of the RIIC.

ICE Bit (I^2C Bus Interface Enable)

The ICE bit selects driving or non-driving of the RIICnSCL and RIICnSDA pins. Moreover, this bit can perform two types of reset in combination with the IICRST bit. For the types of reset, see **Table 7.7-6**.

Set the ICE bit to 1 when using RIIC. Setting the ICE bit to 1 selects driving of the RIICnSCL and RIICnSDA pins. Set the ICE bit to 0 when RIIC is not to be used. Clearing the ICE bit to 0 disables output from the RIICnSCL and RIICnSDA pins.

7.7.3.2 I²C Bus Control Register 2 (RIICnCR2)

Access Size: RIICnCR2 is a 8-bit readable/writable register.

Address(es): RIICnCR2: <RIICn_base> + H'0001

Initial Value: H'00 This register is initialized by any reset.

R/W	R	R/W*1	R/W*1	R	R/W	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
7	BBSY	0	R	Bus Busy Detection Flag 0: The I²C bus is released (bus free state). 1: The I²C bus is occupied (bus busy state or in the bus free state).
6	MST	0	R/W*1	Master/Slave Mode 0: Slave mode 1: Master mode
5	TRS	0	R/W*1	Transmit/Receive Mode 0: Receive mode 1: Transmit mode
4	—	0	R	Reserved This bit is read as 0. The write value should be 0.
3	SP	0	R/W	Stop Condition Issuance Request 0: Does not request to issue a stop condition. 1: Requests to issue a stop condition.
2	RS	0	R/W	Restart Condition Issuance Request 0: Does not request to issue a restart condition. 1: Requests to issue a restart condition.
1	ST	0	R/W	Start Condition Issuance Request 0: Does not request to issue a start condition. 1: Requests to issue a start condition.
0	—	0	R	Reserved This bit is read as 0. The write value should be 0.

Note 1. Set RIICnMR1.MTWP bit before writing MST and TRS bits.

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free).

For details on the start condition issuance, see **7.7.12 Start Condition/Restart Condition/Stop Condition Issuing Function**.

[Setting condition]

When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been issued

- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Remark Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free).
Note that arbitration may be lost if the ST bit is set to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy).

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.

When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the restart condition issuance, see **7.7.12 Start Condition/Restart Condition/Stop Condition Issuing Function**.

[Setting condition]

When 1 is written to the RS bit with the RIICnCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been issued or a start condition is detected
- When a stop condition is detected
- When the RIICnCR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Remark 1. Do not set the RS bit to 1 while issuing a stop condition.

Remark 2. It is commended to issue a restart condition in master transmit mode. If the RS bit is set to 1 (restart condition issuance request) in mode other than master mode, the restart condition is not issued in this mode but the restart condition issuance request bit remains set. If the operating mode changes to master mode with the bit not being cleared, the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.

When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the stop condition issuance, see **7.7.12 Start Condition/Restart Condition/Stop Condition Issuing Function**.

[Setting condition]

When 1 is written to the SP bit with both the RIICnCR2.BBSY flag and the RIICnCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been issued or a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected

- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Remark 1. Wring to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free).

Remark 2. Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a start condition and setting or clearing of the R/W# bit. Although writing to the TRS bit is possible when the MTWP bit in RIICnMR1 is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in RIICnSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in RIICnMR1 set to 1

[Clearing conditions]

- When a stop condition is detected
- The RIICnSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in RIICnSER when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave transmit mode, a restart condition is detected (a restart condition is detected with RIICnCR2.BBSY = 1 and RIICnCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in RIICnMR1 set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.

The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit is automatically changed to 1 for master mode or 0 for slave mode by issuing of a start condition and issuing of detection, or of a stop condition, etc. Although writing to the MST bit is possible when the RIICnMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the RIICnMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 0 is written to the MST bit with the RIICnMR1.MTWP bit to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy) or released (bus free).

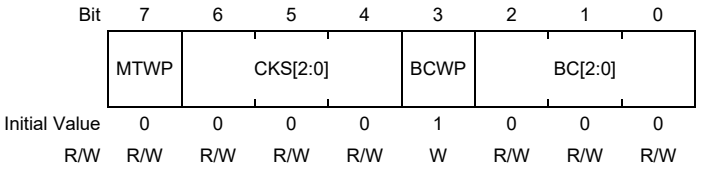
This bit is set to 1 when the SDA line changes from high to low under the condition of SCL = high, assuming that a start condition has been issued.

When the SDA line changes from low to high under the condition of SCL = high, this bit is cleared to 0 after the bus free time (specified in RIICnBRL) start condition is not detected, assuming that a stop condition has been issued.

[Setting condition]

- When a start condition is detected

[Clearing conditions]



- When the bus free time (specified in RIICnBRL) start condition is not detected after detecting a stop condition
- When 1 is written to the RIICnCR1.IICRST bit with the RIICnCR1.ICE bit set to 0 (RIIC reset)

7.7.3.3 I²C Bus Mode Register 1 (RIICnMR1)

Access Size: RIICnMR1 is a 8-bit readable/writable register.

Address(es): RIICnMR1: <RIICn_base> + H'0002

Initial Value: H'08 This register is initialized by any reset.

Bit	Bit Name	Initial Value	R/W	Description
7	MTWP	0	R/W	MST/TRS Write Protect 0: Disables writing to the MST and TRS bits in ICCR2. 1: Enables writing to the MST and TRS bits in ICCR2.
6 to 4	CKS[2:0]	000	R/W	Internal Reference Clock (IICϕ) Selection b6 b4 0 0 0: IICϕ = P0ϕ/1 0 0 1: IICϕ = P0ϕ/2 0 1 0: IICϕ = P0ϕ/4 0 1 1: IICϕ = P0ϕ/8 1 0 0: IICϕ = P0ϕ/16 1 0 1: IICϕ = P0ϕ/32 1 1 0: IICϕ = P0ϕ/64 1 1 1: IICϕ = P0ϕ/128
3	BCWP*1	1	W	BC Write Protect 0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.)
2 to 0	BC[2:0]	000	R/W	Bit Counter b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits

Note 1. When rewriting the BC[2:0] bits, write 0 to the BCWP bit simultaneously.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred frames when the SCL line is at a low level.

The values of the BC[2:0] bits return to 000b at the end of a data transfer including the acknowledge bit or when a start condition including a restart condition is detected.

7.7.3.4 I²C Bus Mode Register 2 (RIICnMR2)

Access Size: RIICnMR2 is a 8-bit readable/writable register.

Address(es): RIICnMR2: <RIICn_base> + H'0003

Initial Value: H'06 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Initial Value	0	0	0	0	0	1	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	DLCS	0	R/W	SDA Output Delay Clock Source Selection 0: The internal reference clock (IICϕ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICϕ/2) is selected as the clock source of the SDA output delay counter.*1
6 to 4	SDDL[2:0]	000	R/W	SDA Output Delay Counter • When RIICnMR2.DLCS = 0 (IICϕ) b6 b4 0 0: No output delay 0 1: 1 IICϕ cycle 1 0: 2 IICϕ cycles 1 1: 3 IICϕ cycles 0 0: 4 IICϕ cycles 0 1: 5 IICϕ cycles 1 0: 6 IICϕ cycles 1 1: 7 IICϕ cycles • When RIICnMR2.DLCS = 1 (IICϕ/2) b6 b4 0 0: No output delay 0 1: 1 or 2 IICϕ cycles 1 0: 3 or 4 IICϕ cycles 1 1: 5 or 6 IICϕ cycles 0 0: 7 or 8 IICϕ cycles 0 1: 9 or 10 IICϕ cycles 1 0: 11 or 12 IICϕ cycles 1 1: 13 or 14 IICϕ cycles
3	—	0	R/W	Reserved This bit is read as 0. The write value should be 0.
2	TMOH	1	R/W	Timeout H Count Control 0: Count is disabled while the SCL line is at a high level. 1: Count is enabled while the SCL line is at a high level.
1	TMOL	1	R/W	Timeout L Count Control 0: Count is disabled while the SCL line is at a low level. 1: Count is enabled while the SCL line is at a low level.
0	TMOS	0	R/W	Timeout Detection Time Selection 0: Long mode is selected. 1: Short mode is selected.

Note 1. The setting DLCS = 1 (IICϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting DLCS = 1 becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS Bit (Timeout Detection Time Selection)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (RIICnFER.TMOE bit = 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit-counter. While the SCL line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source.

For details on the timeout function, see **7.7.13.1 Timeout Function**.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held low when the timeout function is enabled (RIICnFER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held high when the timeout function is enabled (RIICnFER.TMOE bit = 1).

SDDL[2:0] Bits (SDA Output Delay Setup Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

For details on this function, see **7.7.7 Facility for Delaying SDA Output**.

Remark Set the SDA output delay time to meet the I^2C bus standard (within the data enable time/acknowledge enable time*1) or the SMBus standard (within the data hold time: 300 [ns] or more, and SCL-clock low-level period - the data setup time: 250 [ns]). Note that, if a value outside the standard is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

Note 1. Data enable time/acknowledge enable time
- 3,450 [ns] (0 to 100 [kbps]: standard mode (Sm))
- 900 [ns] (0 to 400 [kbps]: fast mode (Fm))
- 450 [ns] (0 to 1 [Mbps]: fast mode plus (Fm+))

7.7.3.5 I²C Bus Mode Register 3 (RIICnMR3)

Access Size: RIICnMR3 is a 8-bit readable/writable register.

Address(es): RIICnMR3: <RIICn_base> + H'0004

Initial Value: H'00 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	SMBS	0	R/W	SMBus/I²C Bus Selection 0: I²C bus is selected. 1: SMBus is selected.
6	WAIT*2	0	R/W	WAIT 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading RIICnDRR.
5	RDRFS*2	0	R/W	RDRF Flag Set Timing Selection 0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCL line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKBT bit.
4	ACKWP*1	0	R/W	ACKBT Write Protect 0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.
3	ACKBT*1	0	R/W	Transmit Acknowledge 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).
2	ACKBR	0	R	Receive Acknowledge 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).
1, 0	NF[1:0]	00	R/W	Noise Filter Stage Selection b1 b0 0 0: Noise of up to one IICϕ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICϕ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICϕ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICϕ cycles is filtered out (4-stage filter).

Note 1. If it is attempted to write 1 to both ACKWP and ACKBT bits, the ACKBT bit cannot be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Noise Filter Stage Selection)

These bits are used to select the width of noise that can be removed from the signals input to RIICnSCL or RIICnSDA pin.

For details on the digital noise filter function, refer to **7.7.8 Digital Noise-Filter Circuits**.

Remark Set the noise range to be filtered out by the noise filter within a range less than the SCLn line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or low-level period, whichever is shorter) − [1.5 internal reference clock (IICϕ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise by the noise filter function of the RIIC, which may prevent the RIIC from operating normally.

ACKBR Bit (Receive knowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in receive mode.

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

Remark The ACKBT bit must be written to while the ACKWP bit is 1. If the ACKBT bit is written to with the ACKWP bit cleared to 0, writing to the ACKBT bit is disabled.

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Selection)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL line low at the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCL line is released by writing a value to the ACKBT bit.

After data is received with this setting, the SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (RIICnDRR) is completely read each time single-byte data is received in receive mode. When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL line is held low from the falling edge of the ninth clock cycle until the RIICnDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Remark When the value of the WAIT bit is to be read, be sure to read the RIICnDRR beforehand.

SMBS Bit (SMBus/I^{2}C Selection)

Setting this bit to 1 selects the SMBus and enables the RIICnSER.HOAE bit.

7.7.3.6 I²C Bus Function Enable Register (RIICnFER)

Access Size: RIICnFER is a 8-bit readable/writable register.

Address(es): RIICnFER: <RIICn_base> + H'0005

Initial Value: H'72 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	FMPE	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Initial Value	0	1	1	1	0	0	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	FMPE*1	0	R/W	Fast-mode Plus Enable 0: No Fm+ slope control circuit is used for the SCLn pin and SDAn pin 1: An Fm+ slope control circuit is used for the SCLn pin and SDAn pin
6	SCLE	1	R/W	SCL Synchronous Circuit Enable 0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used.
5	NFE	1	R/W	Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.
4	NACKE	1	R/W	NACK Reception Transfer Suspension Enable 0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).
3	SALE	0	R/W	Slave Arbitration-Lost Detection Enable 0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.
2	NALE	0	R/W	NACK Transmission Arbitration-Lost Detection Enable 0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.
1	MALE	1	R/W	Master Arbitration-Lost Detection Enable 0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the RIICnCR2.MST and RIICnCR2.TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the RIICnCR2.MST and RIICnCR2.TRS bits automatically when arbitration is lost.)
0	TMOE	0	R/W	Timeout Function Enable 0: The timeout function is disabled. 1: The timeout function is enabled.

Note 1. The fast-mode plus enable bit (FMPE) is only supported by RIIC0. In RIIC2, bit 7 is reserved.

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, see **7.7.13.1 Timeout Function**.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content. For details on the NACK reception transfer suspension function, refer to **7.7.10.2 NACK Reception Transfer Suspension Function**.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is cleared to 0 (SCL synchronous circuit not used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in RIICnBRH and RIICnBRL regardless of the SCL line state.

For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output.

When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.

This bit must not be cleared to 0 except for checking the output of the transfer rate.

FMPE Bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [Fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control standard (tof) of the I^2C bus is selected. When this bit is cleared to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast- mode [Fm] slope control standard (tof) of the I^2C bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus[Fm+]) of the I^2C bus standard. Clear this bit to 0 when using the transmission rate at other rates (up to 100 kbps[Sm], up to 400 kbps[Fm]) or for SMBus (10 to 100 kbps).

7.7.3.7 I²C Bus Status Enable Register (RIICnSER)

Access Size: RIICnSER is a 8-bit readable/writable register.

Address(es): RIICnSER: <RIICn_base> + H'0006

Initial Value: H'09 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	HOAE	—	DIDE	—	GCE	SAR2E	SAR1E	SAR0E
Initial Value	0	0	0	0	1	0	0	1
R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	HOAE	0	R/W	Host Address Enable 0: Host address detection is disabled. 1: Host address detection is enabled.
6	—	0	R	Reserved This bit is read as 0. The write value should be 0.
5	DIDE	0	R/W	Device-ID Address Detection Enable 0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.
4	—	0	R	Reserved This bit is read as 0. The write value should be 0.
3	GCE	1	R/W	General Call Address Enable 0: General call address detection is disabled. 1: General call address detection is enabled.
2	SAR2E	0	R/W	Slave Address Register 2 Enable 0: Slave address in RIICnSARL2 and RIICnSARU2 are disabled. 1: Slave address in RIICnSARL2 and RIICnSARU2 are enabled.
1	SAR1E	0	R/W	Slave Address Register 1 Enable 0: Slave address in RIICnSARL1 and RIICnSARU1 are disabled. 1: Slave address in RIICnSARL1 and RIICnSARU1 are enabled.
0	SAR0E	1	R/W	Slave Address Register 0 Enable 0: Slave address in RIICnSARL0 and RIICnSARU0 are disabled. 1: Slave address in RIICnSARL0 and RIICnSARU0 are enabled.

SARyE Bit (Slave Address Register y Enable) (y = 0 to 2)

This bits are used to enable or disable the received slave address and the slave address set in RIICnSAR(L,U)y.

When these bits are set to 1, the slave address set in RIICnSAR(L,U)y are enabled and are compared with the received slave address. When these bits are cleared to 0, the slave address set in RIICnSAR(L,U)y are disabled and are ignored even if it match the received slave address.

GCE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000_000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in RIICnSAR(L,U)y (y = 0 to 2) and performs data receive operation.

When this bit is cleared to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111_100b) is received in the first frame after a start condition or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the RIIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 [W], the RIIC recognizes the second and the following frames as slave addresses and continues the receive operation.

When this bit is cleared to 0, the RIIC ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.

For details on the device-ID address detection, see **7.7.9.3 Device-ID Address Detection**.

HOAE Bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001_000b) when the RIICnMR3.SMBS bit is 1.

When this bit is set to 1 while the RIICnMR3.SMBS bit is 1, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in RIICnSAR(L,U)y (y = 0 to 2) and performs the receive operation.

When the RIICnMR3.SMBS bit or the HOAE bit is cleared to 0, the received slave address is ignored even if it matches the host address.

7.7.3.8 I²C Bus Interrupt Enable Register (RIICnIER)

Access Size: RIICnIER is a 8-bit readable/writable register.

Address(es): RIICnIER: <RIICn_base> + H'0007

Initial Value: H'00 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	Transmit Data Empty Interrupt Enable 0: Transmit data empty interrupt request (INTRIICTI) is disabled. 1: Transmit data empty interrupt request (INTRIICTI) is enabled.
6	TEIE	0	R/W	Transmit End Interrupt Enable 0: Transmit end interrupt request (INTRIICTEI) is disabled. 1: Transmit end interrupt request (INTRIICTEI) is enabled.
5	RIE	0	R/W	Receive Data Full Interrupt Enable 0: Receive data full interrupt request (INTRIICRI) is disabled. 1: Receive data full interrupt request (INTRIICRI) is enabled.
4	NAKIE	0	R/W	NACK Reception Interrupt Enable 0: NACK reception interrupt request (INTRIICNAKI) is disabled. 1: NACK reception interrupt request (INTRIICNAKI) is enabled.
3	SPIE	0	R/W	Stop Condition Detection Interrupt Enable 0: Stop condition detection interrupt request (INTRIICSPI) is disabled. 1: Stop condition detection interrupt request (INTRIICSPI) is enabled.
2	STIE	0	R/W	Start Condition Detection Interrupt Enable 0: Start condition detection interrupt request (IINTRIICSTI) is disabled. 1: Start condition detection interrupt request (INTRIICSTI) is enabled.
1	ALIE	0	R/W	Arbitration-Lost Interrupt Enable 0: Arbitration-lost interrupt request (INTRIICALI) is disabled. 1: Arbitration-lost interrupt request (INTRIICALI) is enabled.
0	TMOIE	0	R/W	Timeout Interrupt Enable 0: Timeout interrupt request (INTRIICTMOI) is disabled. 1: Timeout interrupt request (INTRIICTMOI) is enabled.

TMOIE Bit (Timeout Interrupt Enable)

This bit is used to enable or disable timeout interrupt requests (INTRIICTMOI) when the RIICnSR2.TMOF flag is set to 1. An INTRIICTMOI interrupt request is canceled by clearing the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Enable)

This bit is used to enable or disable arbitration-lost interrupt requests (INTRIICALI) when the RIICnSR2.AL flag is set to 1. An INTRIICALI interrupt request is canceled by clearing the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Enable)

This bit is used to enable or disable start condition detection interrupt requests (INTRIICSTI) when the RIICnSR2.START flag is set to 1. An INTRIICSTI interrupt request is canceled by clearing the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Enable)

This bit is used to enable or disable stop condition detection interrupt requests (INTRIICSPI) when the RIICnSR2.STOP flag is set to 1. An INTRIICSPI interrupt request is canceled by clearing the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Enable)

This bit is used to enable or disable NACK reception interrupt requests (INTRIICNAKI) when the RIICnSR2.NACKF flag is set to 1. An INTRIICNAKI interrupt request is canceled by clearing the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Data Full Interrupt Enable)

This bit is used to enable or disable receive data full interrupt requests (INTRIICRI) when the RIICnSR2.RDRF flag in ICSR2 is set to 1. An INTRIICRI interrupt request is canceled by clearing the RDRF flag or the RIE bit to 0.

TEIE Bit (Transmit End Interrupt Enable)

This bit is used to enable or disable transmit end interrupts (INTRIICTEI) when the RIICnSR2.TEND flag is set to 1. An INTRIICTEI interrupt request is canceled by clearing the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit is used to enable or disable transmit data empty interrupts (INTRIICTI) when the RIICnSR2.TDRE flag is set to 1.

7.7.3.9 I²C Bus Status Register 1 (RIICnSR1)

Access Size: RIICnSR1 is a 8-bit readable/writable register

Address(es): RIICnSR1: <RIICn_base> + H'0008

Initial Value: H'00 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Initial Value	0	0	0	0	0	0	0	0
R/W	R(/W)*1	R	R(/W)*1	R	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1

Bit	Bit Name	Initial Value	R/W	Description
7	HOA	0	R(/W)*1	Host Address Detection Flag 0: Host address is not detected. 1: Host address is detected.
6	—	0	R	Reserved This bit is read as 0. The write value should be 0.
5	DID	0	R(/W)*1	Device-ID Address Detection Flag 0: Device-ID command is not detected. 1: Device-ID command is detected.
4	—	0	R	Reserved This bit is read as 0. The write value should be 0.
3	GCA	0	R(/W)*1	General Call Address Detection Flag 0: General call address is not detected. 1: General call address is detected.
2	AAS2	0	R(/W)*1	Slave Address 2 Detection Flag 0: Slave address 2 is not detected. 1: Slave address 2 is detected.
1	AAS1	0	R(/W)*1	Slave Address 1 Detection Flag 0: Slave address 1 is not detected. 1: Slave address 1 is detected.
0	AAS0	0	R(/W)*1	Slave Address 0 Detection Flag 0: Slave address 0 is not detected. 1: Slave address 0 is detected.

Note 1. Only 0 can be written to this bit.

AASy Flag (Slave Address y Detection) (y = 0 to 2)

[Setting conditions]

<For 7-bit address format: RIICnSARUy.FS = 0>

- When the received slave address matches the RIICnSARLy.SVA[7:1] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)

  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARUy.FS = 1>

- When the received slave address matches a value of (1111_0b + RIICnSARUy.SVA[9:8]) and the following address matches the RIICnSARLy.SVA[7:0] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled) This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy bit after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

<For 7-bit address format: RIICnSARUy.FS = 0>

- When the received slave address does not match the RIICnSARLy.SVA[7:1] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARUy.FS = 1>

- When the received slave address does not match a value of (1111_0b + RIICnSARUy.SVA[9:8]) with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (1111_0b + RIICnSARUy.SVA[9:8]) and the following address does not match the RIICnSARLy.SVA[7:0] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

GCA Flag (General Call Address Detection)

[Setting condition]

- When the received slave address matches the general call address (0000_000b + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA bit after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000_000b + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection)

[Setting condition]

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID (1111_100b) + 0 [W]) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled) This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.
- When a restart condition is detected after a match with the device ID address and the device ID address (1111_100b) + 1 [R] has matched with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID bit after reading DID = 1
- When a stop condition is detected

- When the first frame received immediately after a start condition or restart condition is detected does not match a value of (device ID (1111_100b)) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled) This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID (1111_100b) + 0 [W]) and the second frame does not match any of slave addresses 0 to 2 with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

HOA Flag (Host Address Detection)

[Setting condition]

- When the received slave address matches the host address (0001_000b) while the RIICnMR3.SMBS bit and RIICnSER.HOAE bit are set to 1 (host address detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA bit after reading HOA = 1
- When a stop condition is detected
- When 0 is written to the RIICnMR3.SMBS bit in ICMR3 or the RIICnSER.HOAE bit
- When the received slave address does not match the host address (0001_000b) with the RIICnSER.HOAE bit set to 1 (host address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit 1 to apply an RIIC reset or an internal reset

7.7.3.10 I²C Bus Status Register 2 (RIICnSR2)

Access Size: RIICnSR2 is a 8-bit readable/writable register

Address(es): RIICnSR2: <RIICn_base> + H'0009

Initial Value: H'00 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	0	R	Transmit Data Empty Flag 0: RIICnDRT contains transmit data. 1: RIICnDRT contains no transmit data.
6	TEND	0	R(/W)*1	Transmit End Flag 0: Data is being transmitted. 1: Data has been transmitted.
5	RDRF	0	R(/W)*1	Receive Data Full Flag 0: RIICnDRR contains no receive data. 1: RIICnDRR contains receive data.
4	NACKF	0	R(/W)*1	NACK Reception Flag 0: NACK is not received. 1: NACK is received.
3	STOP	0	R(/W)*1	Stop Condition Detection Flag 0: Stop condition is not detected. 1: Stop condition is detected.
2	START	0	R(/W)*1	Start Condition Detection Flag 0: Start condition is not detected. 1: Start condition is detected.
1	AL	0	R(/W)*1	Arbitration-Lost Flag 0: Arbitration is not lost. 1: Arbitration is lost.
0	TMOF	0	R(/W)*1	Timeout Flag 0: No timeout has occurred. 1: Timeout has occurred.

Note 1. Only 0 can be written to this bit.

TMOF Flag (Timeout Flag)

This flag is set to 1 when the RIIC recognizes timeout after the SCL line state remains unchanged for a certain period.

[Setting condition]

The timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is held low or high during the following conditions:

- The bus is busy (RIICnCR2.BBSY = 1) in master mode (RIICnCR2.MST = 1).
- The slave address matches that of this module (RIICnSR1 register is not H'00) and the bus is busy (RIICnCR2.BBSY = 1) in slave mode (RIICnCR2.MST = 0).
- Issuing of a start condition is being requested (RIICnCR2.ST = 1) and the bus is free (RIICnCR2.BBSY = 0).

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost Flag)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDA line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL bit to 1 to indicate that the bus is occupied by another device.

The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

<When master arbitration-lost detection is enabled: RIICnFER.MALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high-impedance state))
- When a start condition is detected while the RIICnCR2.ST bit is 1 (start condition issuance request) or the internal SDA output state does not match the SDA line level
- When the RIICnCR2.ST bit is set to 1 (start condition issuance request) with the RIICnCR2.BBSY flag set to 1.

<When NACK arbitration-lost detection is enabled: RIICnFER.NALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode

<When slave arbitration-lost detection is enabled: RIICnFER.SALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL bit after reading AL = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 7.7-7 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

RIICnFER			RIICnSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	x	x	1	Start condition issuance error	When internal SDA output state does not match SDA line level when a start condition is detected while the RIICnCR2.ST bit is 1
					When RIICnCR2.ST is set to 1 with RIICnCR2.BBSY set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
x	1	x	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master receive mode or slave receive mode
x	x	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

Note: x: Don't care

START Flag (Start Condition Detection Flag)

[Setting condition]

- When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection Flag)

[Setting condition]

- When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Reception Flag)

[Setting condition]

- When acknowledge is not received (NACK is received) from the receive device in transmit mode with the RIICnFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Remark When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to RIICnDRT in transmit mode or reading from RIICnDRR in receive mode with the NACKF flag set to 1 does not enable data transmit/ receive operation. To restart data transmission/reception, clear the NACKF flag to 0.

RDRF Flag (Receive Data Full Flag)

[Setting conditions]

- Slave receive mode
  - When the received slave address matches and the RIICnCR2.TRS bit is cleared to 0 after a start condition (or a restart condition) is detected
  - At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit) after receive data is transferred from RIICnDRS to RIICnDRR
- Master receive mode
  - When the slave address and the data direction are transmitted and the receive mode is entered (the RIICnCR2.TRS bit is set to 1) after a start condition (or a restart condition) is issued
  - At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit) after receive data is transferred from RIICnDRS to RIICnDRR

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from RIICnDRR
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmit End Flag)

[Setting condition]

At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to RIICnDRT
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

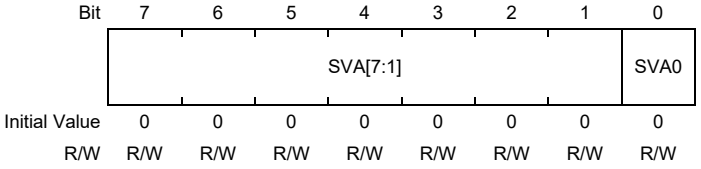
TDRE Flag (Transmit Data Empty Flag)

[Setting conditions]

- When data has been transferred from RIICnDRT to RIICnDRS and RIICnDRT becomes empty
- When the RIICnCR2.TRS bit is set to 1
  - When the RIICnCR2.MST bit is set to 1 after a start condition (or a restart condition) is detected
  - When the RIIC enters transmit mode from receive mode
- When the received slave address matches while the TRS bit is 1

[Clearing conditions]

- When data is written to RIICnDRT
- When the RIICnCR2.TRS bit is cleared to 0
  - When a stop condition is detected
  - When the RIIC enters receive mode from transmit mode
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset



Remark When the NACKF flag is set to 1 while the RIICnFER.NACKE bit is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the RIICnDRS register and the RIICnDRT register becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

7.7.3.11 I²C Slave Address Register Lower y (y = 0 to 2) (RIICnSARLy)

Access Size: RIICnSARLy is a 8-bit readable/writable register.

Address(es): RIICnSARL0: <RIICn_base> + H'000A
RIICnSARL1: <RIICn_base> + H'000C
RIICnSARL2: <RIICn_base> + H'000E

Initial Value: H'00 This register is initialized by any reset.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	SVA[7:1]	All 0	R/W	7-Bit Address Bits [6:0]/10-Bit Address Lower Bits [7:1] A slave address is set.
0	SVA0	0	R/W	10-Bit Address LSB A slave address is set.

SVA0 Bit (10-Bit Address LSB [0])

When the 10-bit address format is selected (RIICnSARUy.FS = 1), this bit functions as the LSB of a 10-bit address and forms the lower 8 bits of a 10-bit address in combination with the SVA[7:1] bits.

When the RIICnSER.SARyE bit is set to 1 (RIICnSARLy and RIICnSARUy enabled) and the RIICnSARUy.FS bit is 1, this bit is valid.

While the RIICnSARUy.FS bit or the RIICnSER.SARyE bit is 0, the setting of this bit is ignored.

SVA[7:1] Bits (7-Bit Address Bits[6:0]/10-Bit Address Lower Bits [7:1])

When the 7-bit address format is selected (RIICnSARUy.FS = 0), these bits function as a 7-bit address. When the 10-bit address format is selected (RIICnSARUy.FS = 1), these bits function as the lower 8 bits of a 10-bit address in combination with the SVA0 bit.

While the RIICnSER.SARyE bit is 0, the setting of these bits is ignored

7.7.3.12 I²C Slave Address Register Upper y (y = 0 to 2) (RIICnSARUy)

Access Size: RIICnSARy is a 8 bit readable/writable register.

Address(es): RIICnSARU0: <RIICn_base> + H'000B
RIICnSARU1: <RIICn_base> + H'000D
RIICnSARU2: <RIICn_base> + H'000F

Initial Value: H'00 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	SVA[9:8]		FS
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
2, 1	SVA[9:8]	00	R/W	10-Bit Address Upper Bits [9:8] A slave address is set.
0	FS	0	R/W	7-Bit/10-Bit Address Format Selection 0: The 7-bit address format is selected. 1: The 10-bit address format is selected.

FS Bit (7-Bit/10-Bit Address Format Selection)

This bit is used to select 7-bit address or 10-bit address for slave address y (in SARLy and SARUy).

When the RIICnSER.SARyE bit is set to 1 (RIICnSARLy and RIICnSARUy enabled) and the RIICnSARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[7:1] setting in RIICnSARLy is valid, and the settings of the SVA[9:8] bits and the SVA0 bit in RIICnSARLy are ignored.

When the RIICnSER.SARyE bit is set to 1 (RIICnSARLy and RIICnSARUy enabled) and the RIICnSARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[9:8] bits and RIICnSARLy are valid.

While the RIICnSER.SARyE bit is 0 (RIICnSARLy and RIICnSARUy disabled), the setting of the RIICnSARUy.FS bit is invalid.

SVA[9:8] Bits (10-Bit Address Upper Bits [9:8])

When the 10-bit address format is selected (FS = 1), these bits function as the upper 2 bits of a 10-bit address.

When the RIICnSER. SARyE bit is set to 1 (RIICnSARLy and RIICnSARUy enabled) and the RIICnSARUy.FS bit is 1, these bits are valid.

While the RIICnSARUy.FS bit or RIICnSER.SARyE bit is 0, the setting of these bits is ignored.

7.7.3.13 I²C Bus Bit Rate Low-Level Register (RIICnBRL)

Access Size: RIICnBRL is a 8 bit readable/writable register.

Address(es): RIICnBRL: <RIICn_base> + H'0010

Initial Value: H' FF This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	BRL[4:0]				
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	111	R/W	Reserved These bits are read as 1. The write value should be 1.
4 to 0	BRL[4:0]	H'1F	R/W	Bit Rate Low-Level Period Low-level period of SCL clock

The RIICnBRL register is a 5-bit register that is used to set the width at low level for the SCL clock.

It also works to generate the data setup time for automatic SCL low-hold operation (see **7.7.10 Automatic Low-Hold Function for SCL**); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time*[1].

RIICnBRL counts the low-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

If the digital noise filter is enabled (the RIICnFER.NFE bit is 1), set the RIICnBRL register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the RIICnMR3.NF[1:0] bits.

Note 1. Data setup time (t_{SU}: DAT)
- 250 [ns] (0 to 100 [kbps]: standard mode (Sm))
- 100 [ns] (0 to 400 [kbps]: fast mode (Fm))
- 50 [ns] (0 to 1 [Mbps]: fast mode plus (Fm+))

7.7.3.14 I²C Bus Bit Rate High-Level Register (RIICnBRH)

Access Size: RIICnBRH is a 8 bit readable/writable register..

Address(es): RIICnBRH: <RIICn_base> + H'0011

Initial Value: H' FF This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	BRH[4:0]				
Initial Value	1	1	1	1	1	1	1	1
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	111	R	Reserved These bits are read as 1. The write value should be 1.
4 to 0	BRH[4:0]	H'1F	R/W	Bit Rate High-Level Period High-level period of SCL clock

RIICnBRH is a 5-bit register to set the high-level period of SCL clock. RIICnBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high-level period.

RIICnBRH counts the high-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the RIICnFER.NFE bit is 1), set the RIICnBRH register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the RIICnMR3.NF[1:0] bits.

The I²C transfer rate and the SCL clock duty cycles are calculated using one of the following expressions (1) to (5) according to the register settings.

Remark The minimum value that can be specified in RIICnBRL and RIICnBRH is determined according to the values of the SCLE and NFE bits in RIICnFER and the NF bit in RIICnMR3. For details of the minimum specifiable value, see **Table 7.7-8**.

(1) When SCLE = 0

Transfer rate = 1 / {[(BRH + 1) + (BRL + 1)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 1) / IICϕ} / {tr + tf + [(BRH + 1) + (BRL + 1)] / IICϕ}

(2) When SCLE = 1, NFE = 0, CKS = 000 (IICϕ = P0ϕ)

Transfer rate = 1 / {[(BRH + 3) + (BRL + 3)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 3) / IICϕ} / {tr + tf + [(BRH + 3) + (BRL + 3)] / IICϕ}

(3) When SCLE = 1, NFE = 1, CKS = 000 (IICϕ = P0ϕ)

Transfer rate = 1 / {[(BRH + 3 + nf) + (BRL + 3 + nf)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 3 + nf) / IICϕ} / {tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)] / IICϕ}

(4) When SCLE = 1, NFE = 0, CKS ≠ 000 (IICϕ < P0ϕ)

Transfer rate = 1 / {[(BRH + 2) + (BRL + 2)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 2) / IICϕ} / {tr + tf + [(BRH + 2) + (BRL + 2)] / IICϕ}

(5) When SCLE = 1, NFE = 1, CKS ≠ 000 (IICϕ < P0ϕ)

Transfer rate = 1 / {[(BRH + 2 + nf) + (BRL + 2 + nf)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 2 + nf) / IICϕ} / {tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)] / IICϕ}

[Symbols in the expressions]

SCLE: RIICnFER.SCLE bit

BRH: RIICnBRH.BRH[4:0] bits

BRL: RIICnBRL.BRL[4:0] bits

CKS: RIICnMR1.CKS bits

NFE: RIICnFER.NFE bit

IICϕ: Internal reference clock selected by the CKS bits*1

tf: SCL signal falling time [s]*2

tr: SCL signal rising time [s]*2

nf: Number of digital noise filter stages specified in the RIICnMR3.NF[1:0] bits*3

Note 1. IICϕ = PCLK × Division ratio

Note 2. The SCLn line rising time [tr] and SCLn line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C bus standard from NXP Semiconductors.

Note 3. nf = Number of digital noise filter selected by ICMR3.NF bit.

Table 7.7-8 Minimum Specifiable Value for RIICnBRL and RIICnBRH

SCLE	NFE	nf	Minimum Pulse Width that Passes through Digital Filter	Minimum Specifiable Value for BRH and BRL	Pulse Width when Minimum Value is Specified
0	0	—	1 × IICϕ	1	2 × IICϕ
0	1	1	2 × IICϕ	2	3 × IICϕ
0	1	2	3 × IICϕ	3	4 × IICϕ
0	1	3	4 × IICϕ	4	5 × IICϕ
0	1	4	5 × IICϕ	5	6 × IICϕ
IICϕ cycle > P0ϕ cycle (CKS ≠ 000)					
1	0	—	1 × IICϕ	0	2 × IICϕ
1	1	1	2 × IICϕ	1	4 × IICϕ
1	1	2	3 × IICϕ	2	6 × IICϕ
1	1	3	4 × IICϕ	3	8 × IICϕ
1	1	4	5 × IICϕ	4	10 × IICϕ
IICϕ cycle = P0ϕ cycle (CKS = 000)					
1	0	—	2 × P0ϕ	0	3 × IICϕ
1	1	1	3 × P0ϕ	1	5 × IICϕ
1	1	2	4 × P0ϕ	2	7 × IICϕ
1	1	3	5 × P0ϕ	3	9 × IICϕ
1	1	4	6 × P0ϕ	4	11 × IICϕ

Table 7.7-9 and **Table 7.7-10** list examples of RIICnBRH/RIICnBRL settings.

Table 7.7-9 Examples of RIICnBRH/RIICnBRL Settings for Transfer Rate (when RIICnFER.SCLE = 1 and RIICnFER.NFE= 0)

Transfer Rate [kbps]	Peripheral Clock Operating Frequency P0ϕ [MHz]			
	100			
	RIICnMR1.CKS[2:0]	RIICnBRH.BRH	RIICnBRL.BRL	Actual transfer rate [kbps]
12	111b	30 (H'FE)	31 (H'FF)	12
50	101b	28 (H'FC)	30 (H'FE)	50.4
100	100b	28 (H'FC)	31 (H'FF)	99.2
400	010b	29 (H'FD)	30 (H'FE)	396.8
1000	001b	20 (H'F4)	25 (H'F9)	1020.4

Table 7.7-10 Examples of RIICnBRH/RIICnBRL Settings for Transfer Rate (when RIICnFER.SCLE = 1, RIICnFER.NFE= 1, and Number of NF Stages = 4)

Transfer Rate [kbps]	Peripheral Clock Operating Frequency P0ϕ [MHz]			
	100			
	RIICnMR1.CKS[2:0]	RIICnBRH.BRH	RIICnBRL.BRL	Actual transfer rate [kbps]
12	111b	25 (H'F9)	28 (H'FC)	12
50	101b	23 (H'F7)	28 (H'FC)	49.6
100	100b	24 (H'F8)	27 (H'FB)	99.2
400	010b	25 (H'F9)	26 (H'FA)	396.8
1000	001b	14 (H'EE)	24 (H'F8)	1000

7.7.3.15 I²C Bus Transmit Data Register (RIICnDRT)

Access Size: RIICnDRT is a 8 bit readable/writable register.

Address(es): RIICnDRT: <RIICn_base> + H'0012

Initial Value: H'FF This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	DRT[7:0]							
Initial Value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When RIICnDRT detects a space in the I²C bus shift register (RIICnDRS), it transfers the transmit data that has been written to RIICnDRT to RIICnDRS and starts transmitting data in transmit mode.

The double-buffer structure of RIICnDRT and RIICnDRS allows continuous transmit operation if the next transmit data has been written to RIICnDRT while the RIICnDRS data is being transmitted.

RIICnDRT can always be read and written. Write transmit data to RIICnDRT once when a transmit data empty interrupt (INTRIICTI) request is generated.

7.7.3.16 I²C Bus Receive Data Register (RIICnDRR)

Access Size: RIICnDRR is a 8 bit readable/writable register.

Address(es): RIICnDRR: <RIICn_base> + H'0013

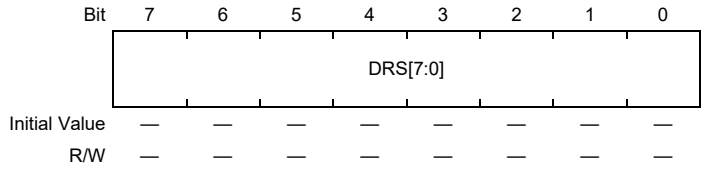
Initial Value: H'00 This register is initialized by any reset.

Bit	7	6	5	4	3	2	1	0
	DRR[7:0]							
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

When 1 byte of data has been received, the received data is transferred from the I²C bus shift register (RIICnDRS) to RIICnDRR to enable the next data to be received.

The double-buffer structure of RIICnDRS and RIICnDRR allows continuous receive operation if the received data has been read from RIICnDRR while RIICnDRS is receiving data.

RIICnDRR cannot be written. Read data from RIICnDRR once when a receive data full interrupt (INTRIICRI) request is generated.



If RIICnDRR.DRR[7:0] receives the next receive data before the current data is read from RIICnDRR (while the RIICnSR2.RDRF flag is 1), the RIIC automatically holds the SCL clock low one cycle before the RIICnSR2.RDRF flag is set to 1 next.

7.7.3.17 I²C Bus Shift Register (RIICnDRS)

Access Size: This register is not accessible.

Address(es): —

Initial Value: —

RIICnDRS is an 8-bit shift register to transmit and receive data.

During transmission, transmit data is transferred from RIICnDRT to RIICnDRS and is sent from the SDAn pin. During reception, data is transferred from RIICnDRS to RIICnDRR after 1 byte of data has been received.

RIICnDRS cannot be accessed directly.

7.7.4 Interrupt Sources

The RIIC issues eight types of interrupt request: transmit end, receive data full, transmit data empty, stop condition detection, start condition detection, NACK reception, arbitration-lost, and timeout.

Table 7.7-11 lists details of the several interrupt requests. The receive data full and transmit data empty sources are both capable of launching data transfer by the DMAC.

Table 7.7-11 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DMAC Launching	Priority*1	Interrupt Condition
INTRIICRI	Receive-data-full	RDRF	Possible	High	RDRF = 1 • RIE = 1
INTRIICTI	Transmit-data-empty	TDRE	Possible	↑	TDRE = 1 • TIE = 1
INTRIICTEI	Transmission complete	TEND	Not possible		TEND = 1 • TEIE = 1
INTRIICNAKI	Reception of a NACK	NACKF	Not possible		NACKF = 1 • NAKIE = 1
INTRIICSPI	Detection of a stop condition	STOP	Not possible		STOP = 1 • SPIE = 1
INTRIICSTI	Detection of a start condition	START	Not possible		START = 1 • STIE = 1
INTRIICALI	Arbitration lost	AL	Not possible		AL = 1 • ALIE = 1
INTRIICTMOI	Timeout	TMOF	Not possible	Low	TMOF = 1 • TMOIE = 1

Note 1. When the interrupt priority register (ICDIPRn) setting is the same

Clear or mask each flag during interrupt handling.

CAUTIONS

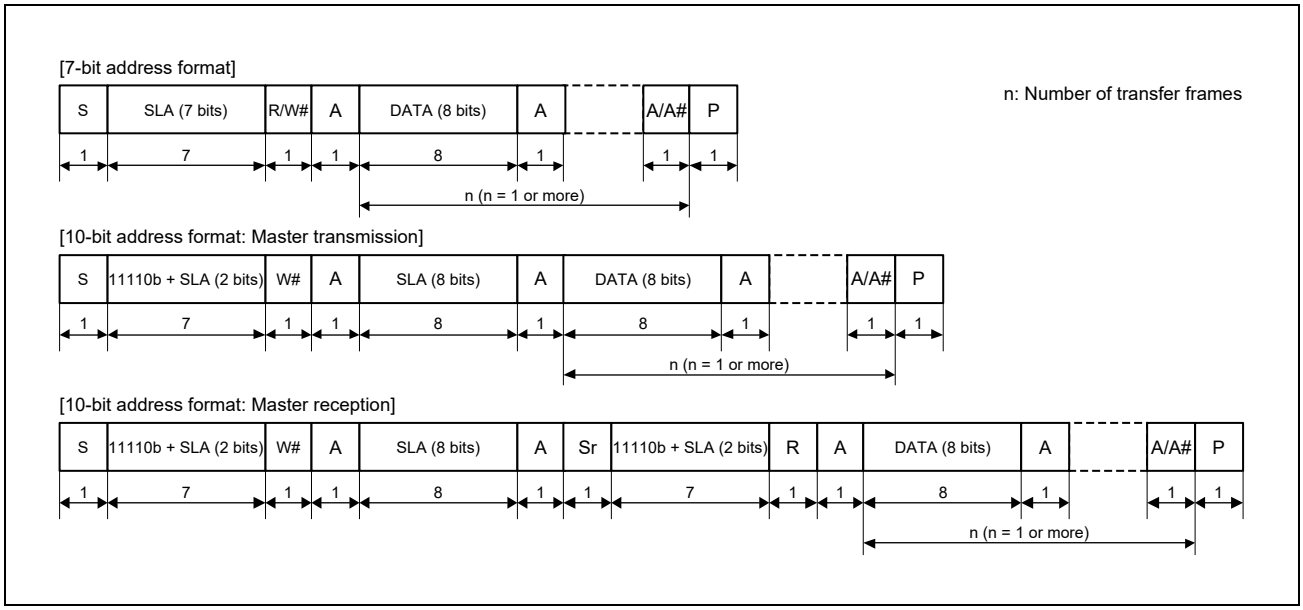
1. There is a latency (delay) between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt processing. Returning from interrupt processing without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.
2. Since INTRIICRI and INTRIICTI are edge-detected interrupts, they do not require clearing.
3. When using the INTRIICTEI interrupt, clear the RIICnSR2.TEND flag in the INTRIICTEI interrupt processing.
4. When using the INTRIICSPI interrupt, clear the RIICnSR2.STOP flag in the INTRIICSPI interrupt processing.
5. When using the INTRIICSTI interrupt, clear the RIICnSR2.START flag in the INTRIICSTI interrupt processing.
6. When using the INTRIICNAKI interrupt, clear the RIICnSR2.NACKF flag in the INTRIICNAKI interrupt processing.
7. When using the INTRIICALI interrupt, clear the RIICnSR2.AL flag in the INTRIICALI interrupt processing.
8. When using the INTRIICTMOI interrupt, clear the RIICnSR2.TMOF flag in the INTRIICTMOI interrupt processing.

7.7.5 Operation

7.7.5.1 Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge (one frame). After a start condition or restart condition is issued, the master device sends the slave address and data direction in the first frame. The specified slave is valid until a stop condition is issued or a new slave is specified by a restart condition.

Figure 7.7-3 shows the I²C bus format, and **Figure 7.7-4** shows the I²C bus timing.



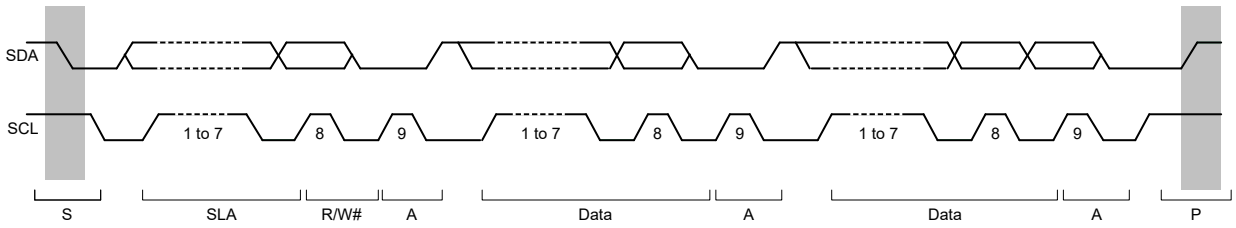


Figure 7.7-3 I²C Bus Format

S: Start condition. The master device drives the SDA line low from high level while the SCL line is at a high level.

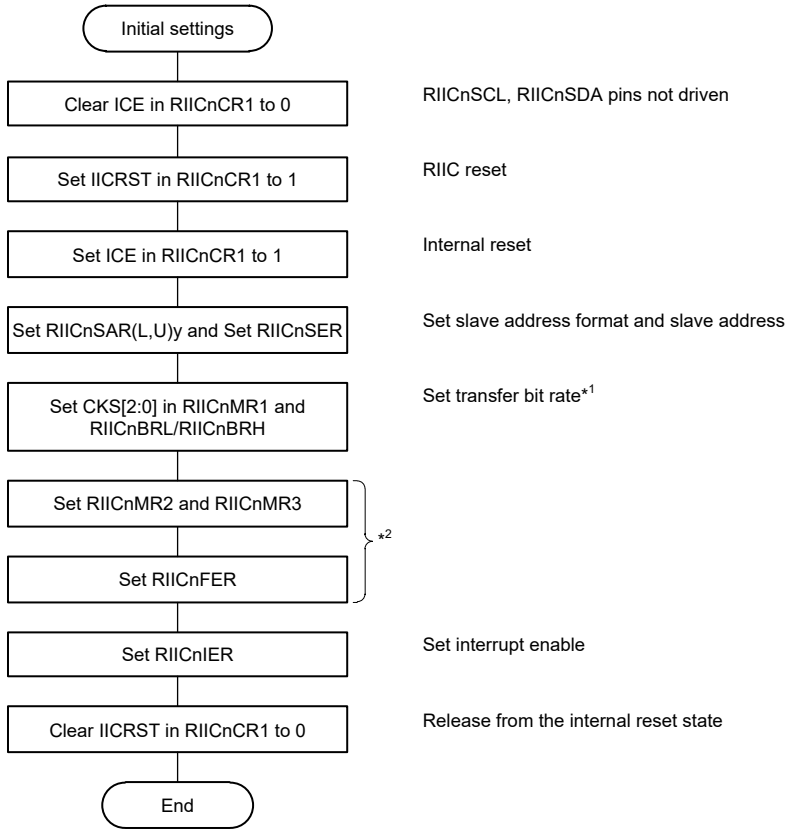
SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives the SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not-acknowledge. The receiving device has not returned a response or is not present so the SDA line has remained at the high level.

Sr: Restart condition. The master device drives the SDA line low from the high level after the setup time has elapsed with the SCL line at the high level.



DATA: Transmitted or received data

P: Stop condition. The master device drives the SDA line high from low level while the SCL line is at a high level.

Figure 7.7-4 I^2C Bus Timing (SLA = 7 Bits)

7.7.5.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in **Figure 7.7-5**.

Note: y = 0 to 2

Note 1. When the RIIC is used only in slave mode, set the RIICnBRL register to a value at least the same as the data setup time.

Note 2. Set these registers, as necessary.

Figure 7.7-5 Example of RIIC Initialization Flowchart

7.7.5.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL (clock) and transmitted data signals as the master device, and the slave device returns acknowledgements. **Figure 7.7-6** shows an example of usage of master transmission and **Figure 7.7-7** to **Figure 7.7-9** show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

(1) Set the RIICnCR1.IICRST bit 1 to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSAR(L,U)y, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see **Figure 7.7-5**). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.

Since the RIICnSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the RIICnSR2.STOP bit and then write 1 to the RIICnCR2.SP bit to issue a stop condition.

For data transmission with an address in the 10-bit format, start by writing 1111_0b, the two higher-order bits of the slave address, and W# to RIICnDRT as the first address transmission. Then, as the second address transmission, write the eight lower-order bits of the slave address to RIICnDRT.

(4) After confirming that the RIICnSR2.TDRE flag is 1, write the data for transmission to the RIICnDRT register. The RIIC automatically holds the SCL line low until the data for transmission are ready or a stop condition is issued.

(5) After the last byte of the data to be transmitted is written to the RIICnDRT register, wait until the value of the RIICnSR2.TEND flag returns to 1, after that write 1 to the RIICnSR2.STOP bit and then set the RIICnCR2.SP bit to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.

(6) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00b and enters slave receive mode. Furthermore, it automatically clears the RIICnSR2.TDRE and TEND flags to 0, and sets the RIICnSR2.STOP flag in to 1.

(7) After checking that the RIICnSR2.STOP flag is 1, set the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

CAUTION

Operations for transfer start if the RIICnSR2.NACKF flag is cleared to 0 before RIICnSR2.STOP is set to 1. Be sure to confirm that RIICnSR2.STOP is set to 1 before clearing RIICnSR2.NACKF to 0. In particular, when the NACK receive interrupt (INTRIICNAKI) is in use, take care not to clear the NACKF flag to 0 before the STOP flag is set to 1 during interrupt processing.

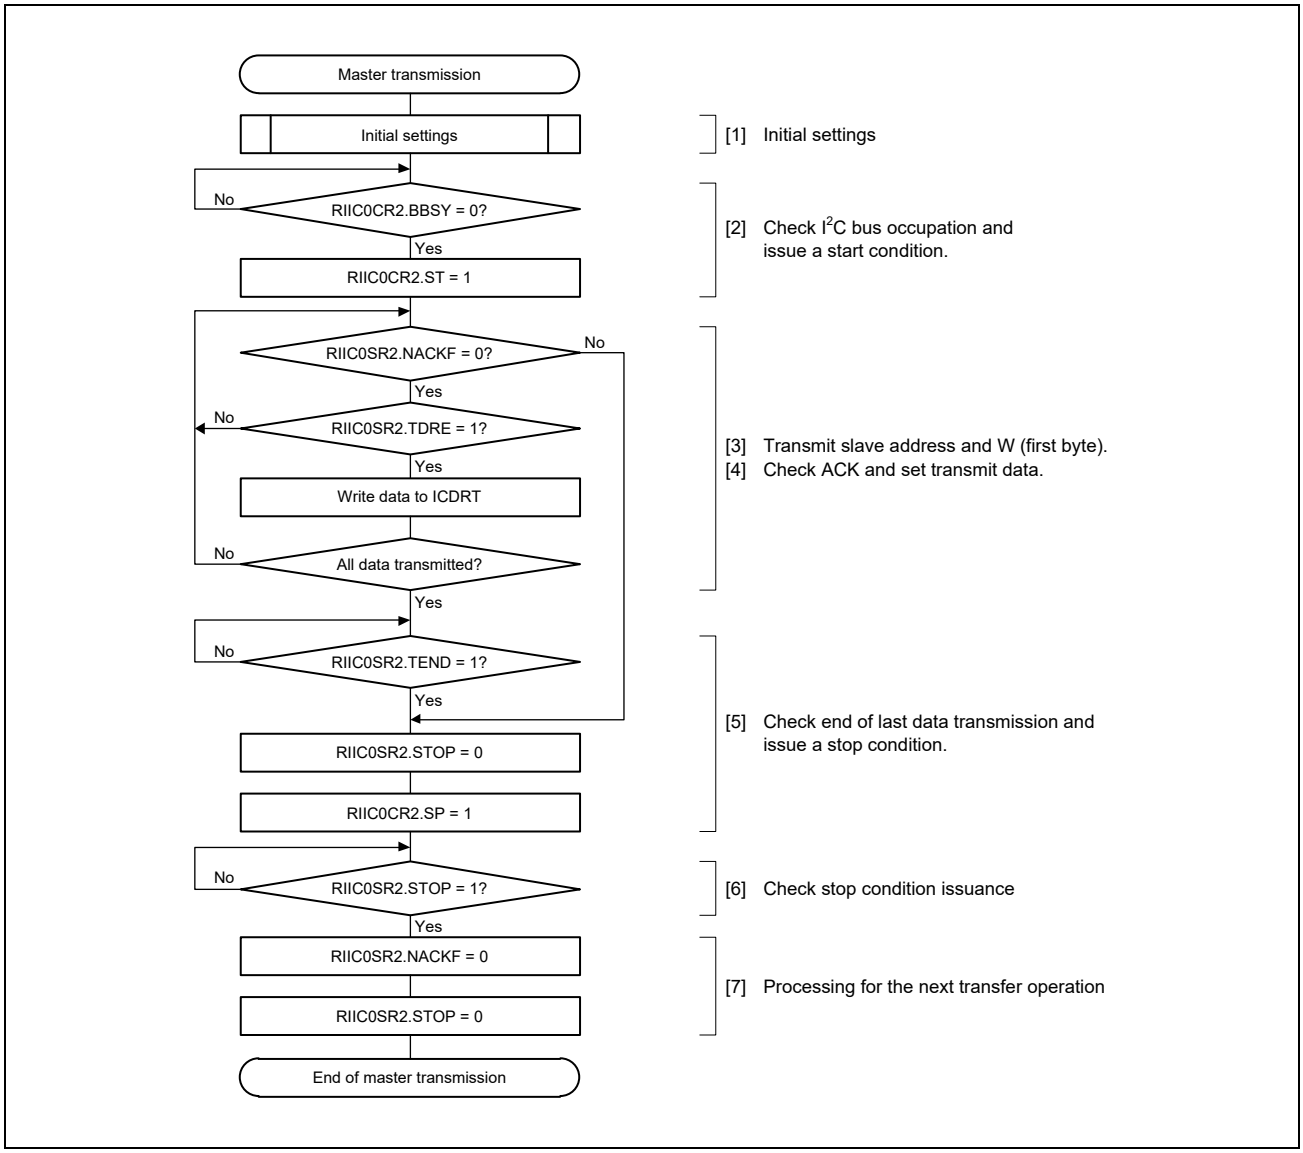


Figure 7.7-6 Example of Master Transmission Flowchart

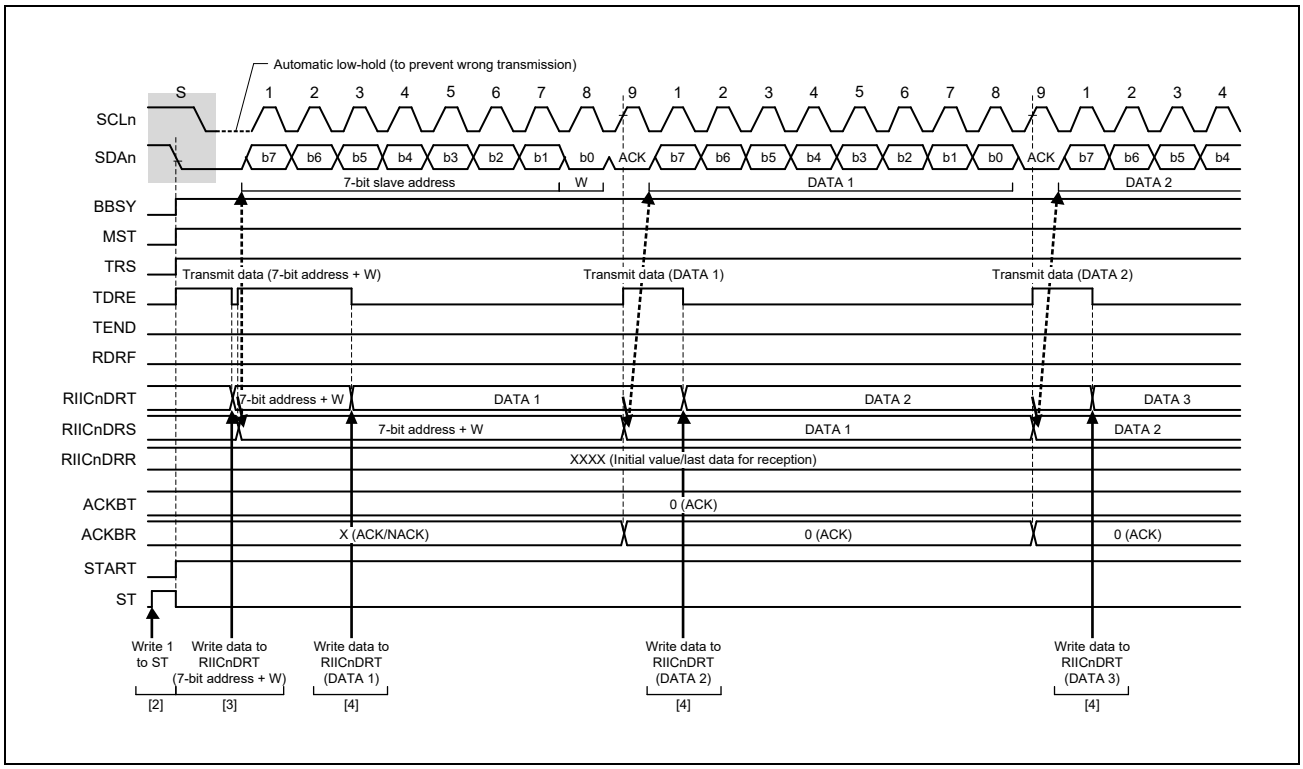

Figure 7.7-7 Master Transmit Operation Timing (1) (7-Bit Address Format)

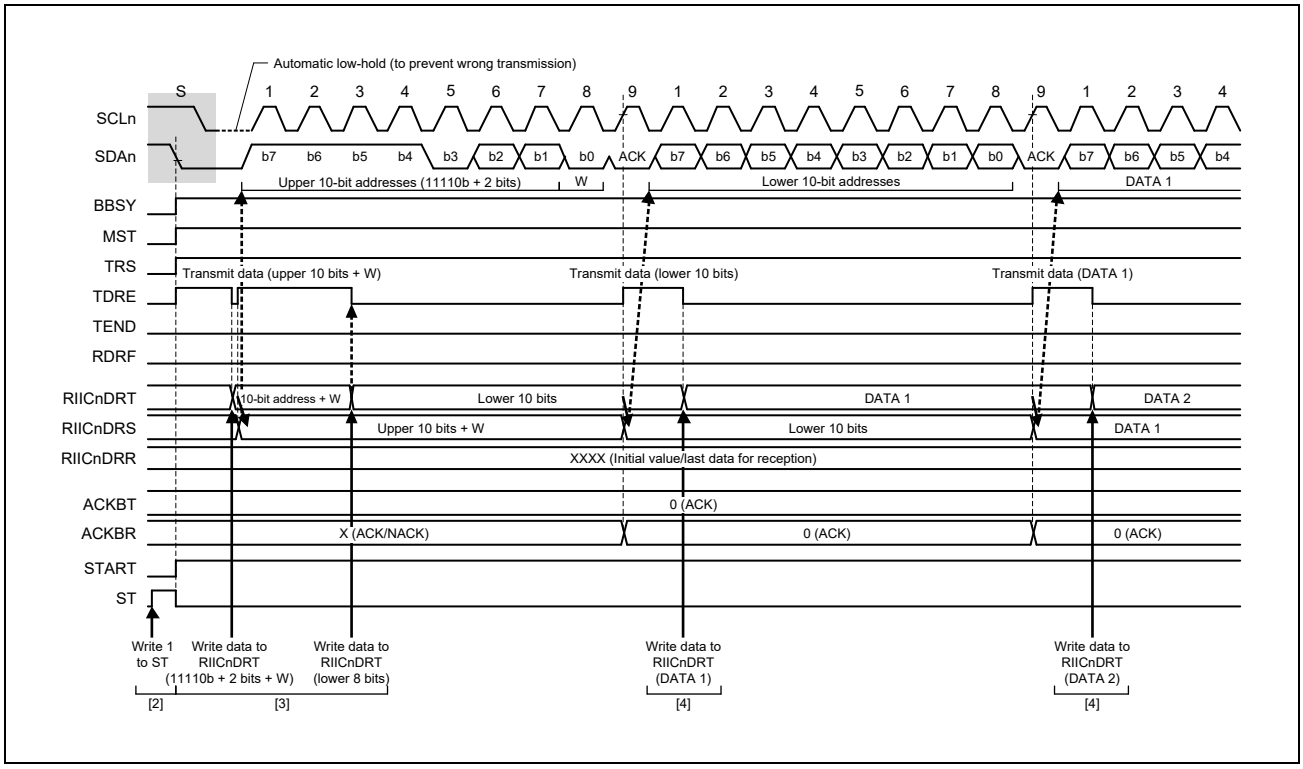

Figure 7.7-8 Master Transmit Operation Timing (2) (10-Bit Address Format)

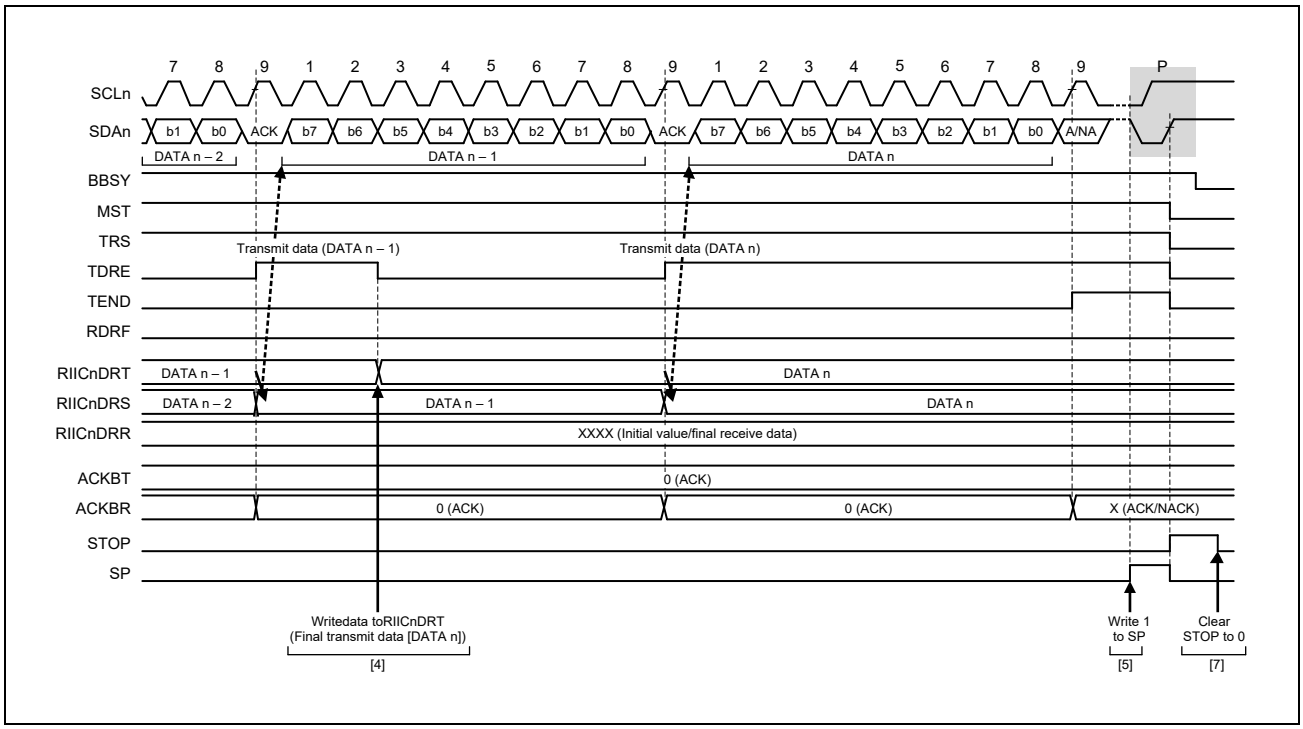

Figure 7.7-9 Master Transmit Operation Timing (3)

7.7.5.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL (clock) signal, receives data from the slave device, and returns acknowledgements. Since the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 7.7-10 shows an example of usage for the master reception of 3 or more bytes (7-bit address format), **Figure 7.7-14** shows an example of usage for the master reception of 1 or 2 bytes (7-bit address format), and **Figure 7.7-11** to **Figure 7.7-13** show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

(1) Set the RIICnCR1.IICRST bit to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSAR(L,U)y, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see **Figure 7.7-5**). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the RIICnCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the RIICnCR2.TRS bit is cleared to 0 on the rising edge of the ninth cycle of SCL (the clock signal), placing the RIIC in master receive mode. At this time, the TDRE flag is automatically cleared to 0 and the RIICnSR2.RDRF flag is automatically set to 1.

Since the RIICnSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.

For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111_0b, the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

(4) Dummy read RIICnDRR after confirming that the RIICnSR2.RDRF flag is 1; this makes the RIIC start output of the SCL (clock) signal and start data reception.

(5) After 1 byte of data has been received, the RIICnSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the RIICnMR3.RDRFS bit. Reading out RIICnDRR at this time will produce the received data, and the RDRF flag is automatically cleared to 0 at the same time. Furthermore, the value of the acknowledgement field received during the ninth cycle of SCL clock is returned as the value set in the RIICnMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the RIICnMR3.WAIT bit to 1 (for wait insertion) before reading the RIICnDRR (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the RIICnMR3.ACKBT bit

to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.

(6) When the RIICnMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the RIICnMR3.ACKBT bit to 1 (NACK).

(7) After reading out the byte before last from the RIICnDRR register, if the value of the RIICnSR2.RDRF flag is confirmed to be 1, write 1 to the RIICnSR2.STOP bit and then write 1 to the RIICnCR2.SP bit (stop condition issuance request) and then read the last byte from RIICnDRR. When RIICnDRR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCL line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00b and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the RIICnSR2.STOP flag to 1.

(9) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

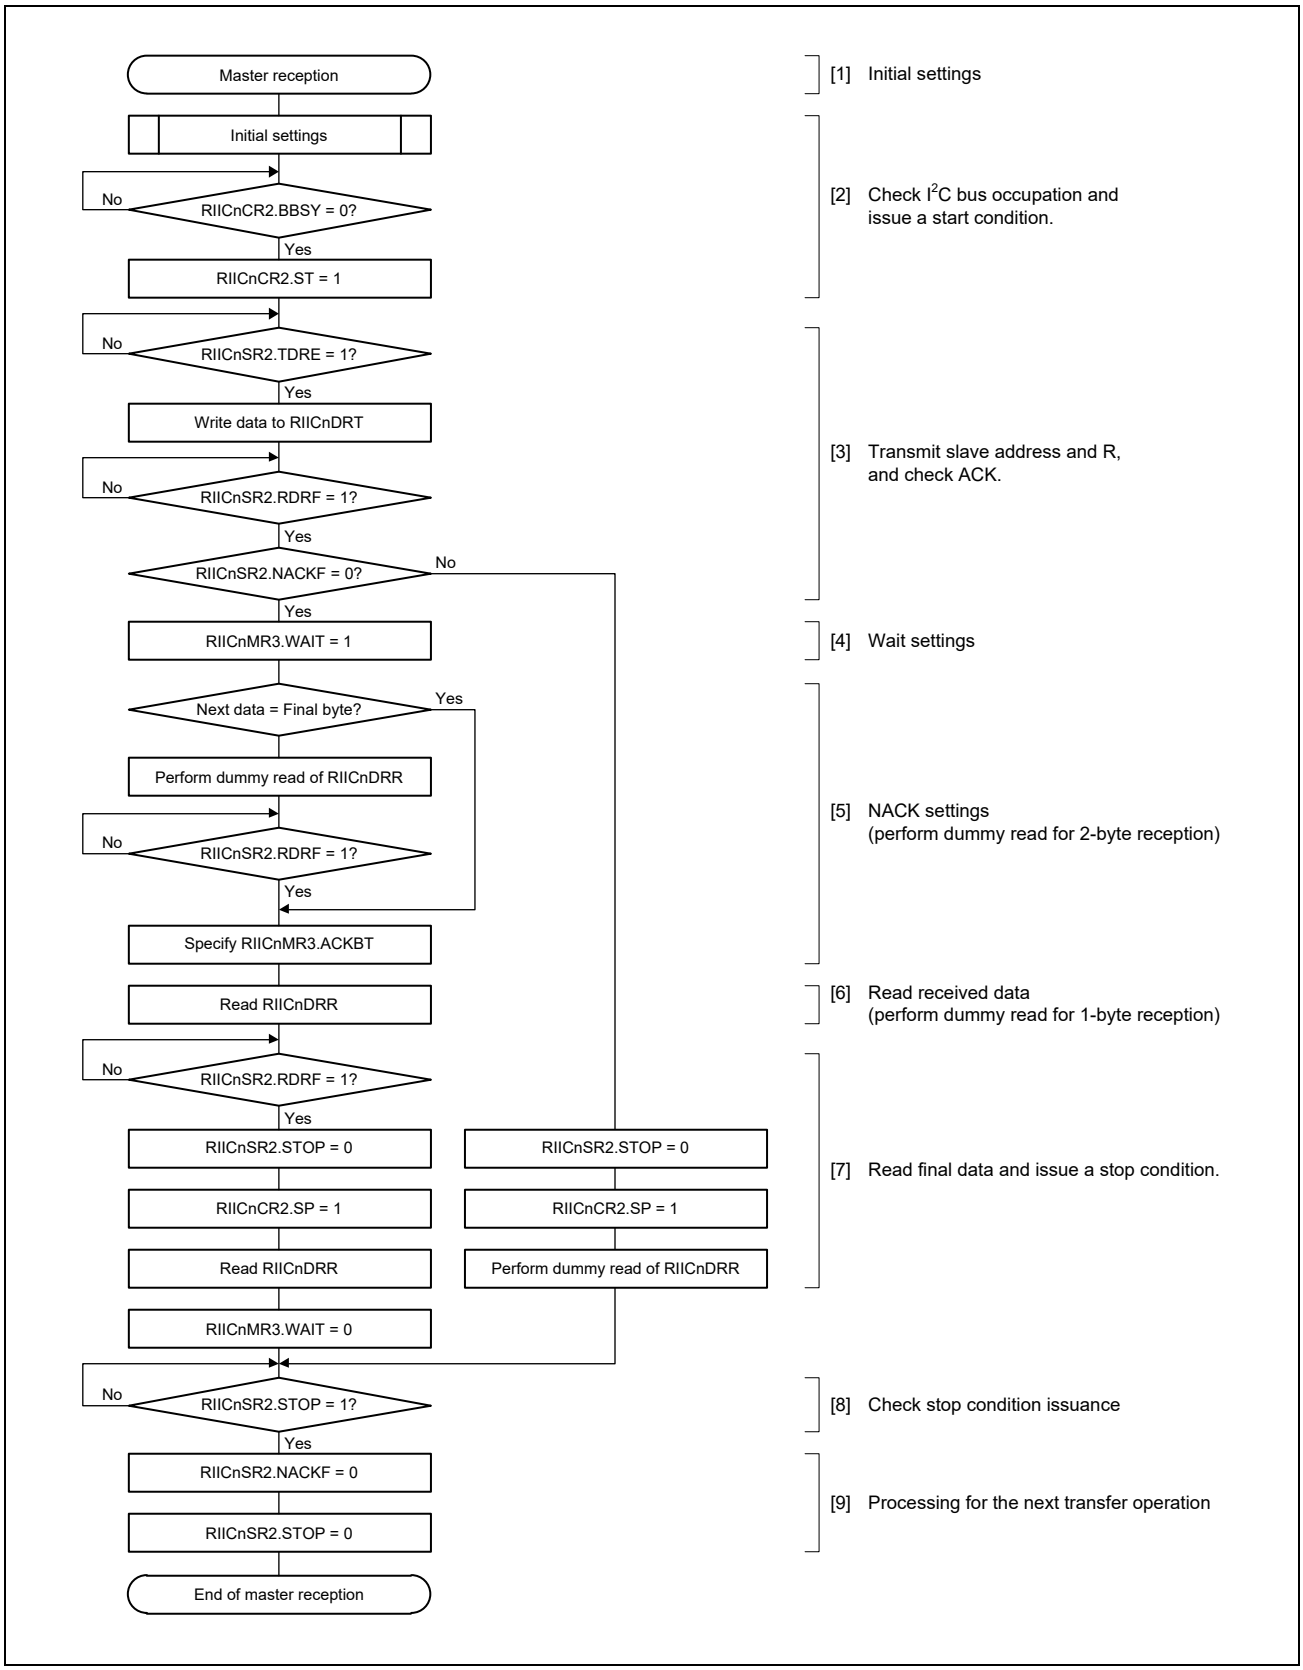

Figure 7.7-14 Example Flowchart for the Master Reception of 1 or 2 Bytes (7-Bit Address Format)

7.7.5.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL (clock) signal, the RIIC transmits data as a slave device, and the master device returns acknowledgements.

Figure 7.7-15 shows an example of usage of slave transmission and **Figure 7.7-16** and **Figure 7.7-17** show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

(1) Follow the procedure in **Figure 7.7-5** to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the RIICnCR2.TRS bit and the RIICnSR2.TDRE flag to 1.

(3) After the RIICnSR2.TEND flag is confirmed to be 1, write the data for transmission to the RIICnDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the RIICnFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait unit the RIICnSR2.TEND flag is set to 1 while the RIICnSR2.TDRE flag is 1, after the RIICnSR2.NACKF flag is set to 1 or the last byte for transmission is written to the RIICnDRT register. When the RIICnSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL line low on the ninth falling edge of SCL clock.

(5) When the RIICnSR2.NACKF flag or the RIICnSR2.TEND flag is 1, dummy read RIICnDRR to complete the processing. This releases the SCL line.

(6) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2), flags RIICnSR2.TDRE and TEND, and the RIICnCR2.TRS bit to 0, and enters slave receive mode.

(7) After checking that the RIICnSR2.STOP flag is 1, set the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

CAUTION

Operations for transfer start if the RIICnSR2.NACKF flag is cleared to 0 before RIICnSR2.STOP is set to 1. Be sure to confirm that RIICnSR2.STOP is set to 1 before clearing RIICnSR2.NACKF to 0. In particular, when the NACK receive interrupt (INTRIICNAKI) is in use, take care not to clear the NACKF flag to 0 before the STOP flag is set to 1 during interrupt processing.

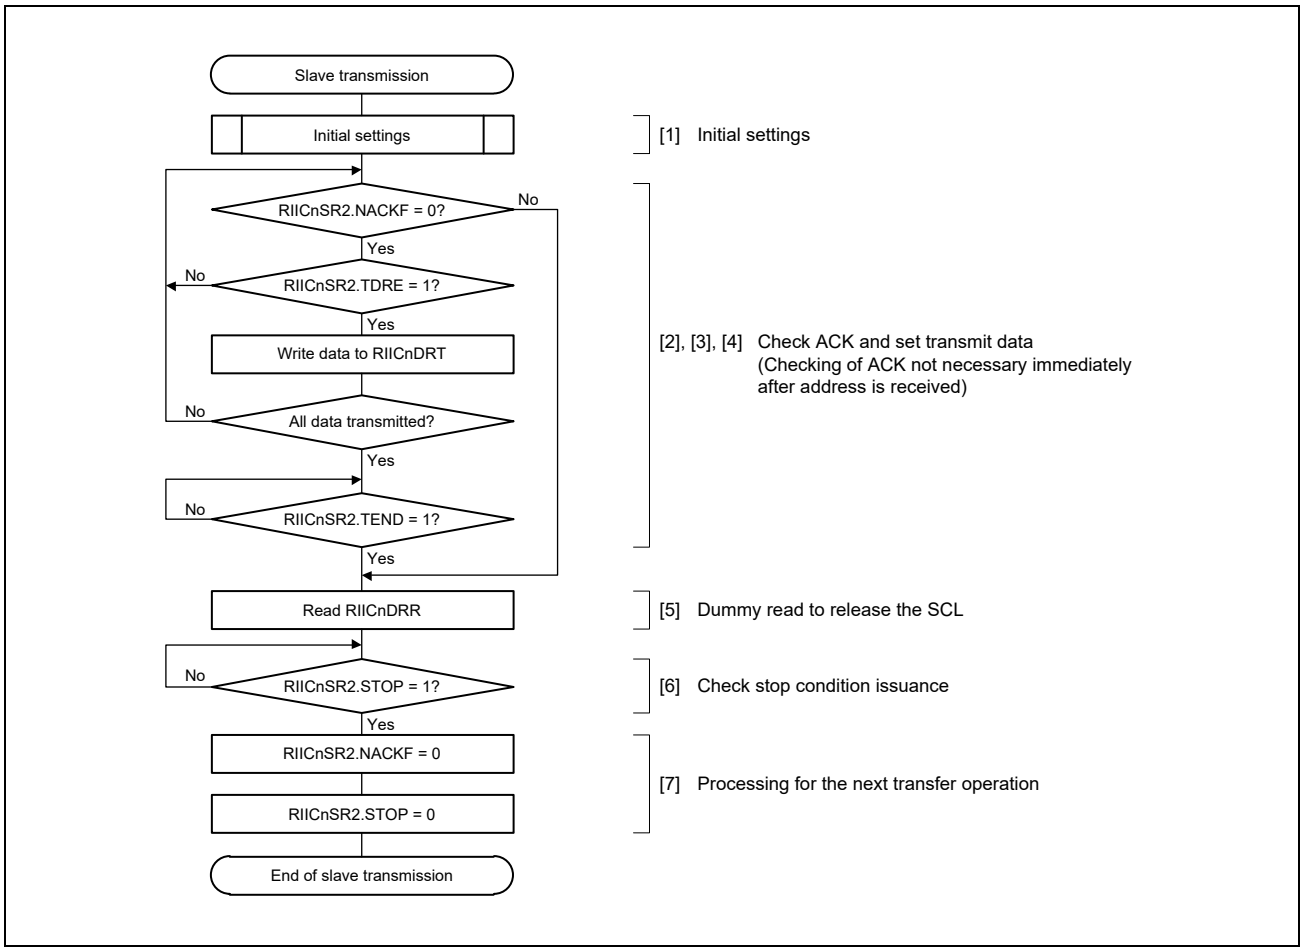

Figure 7.7-15 Example of Slave Transmission Flowchart

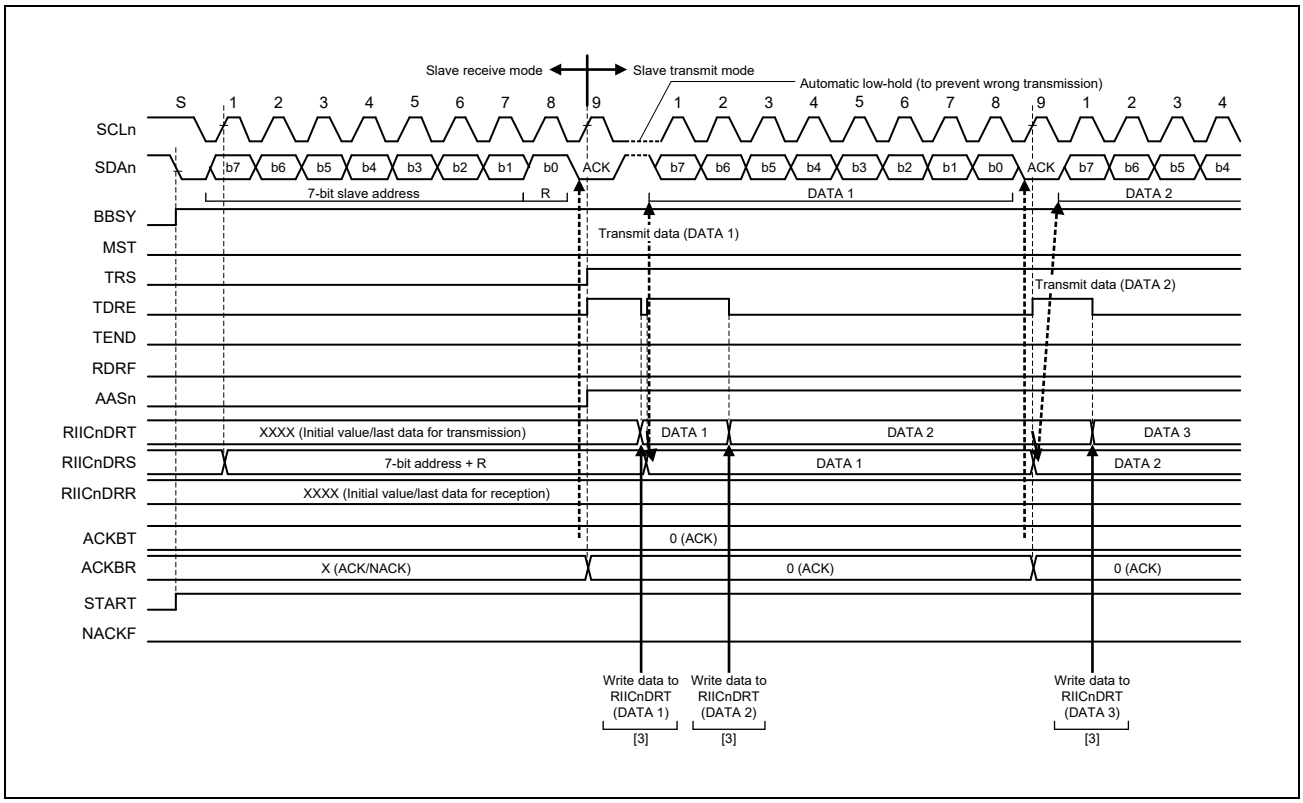

Figure 7.7-16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

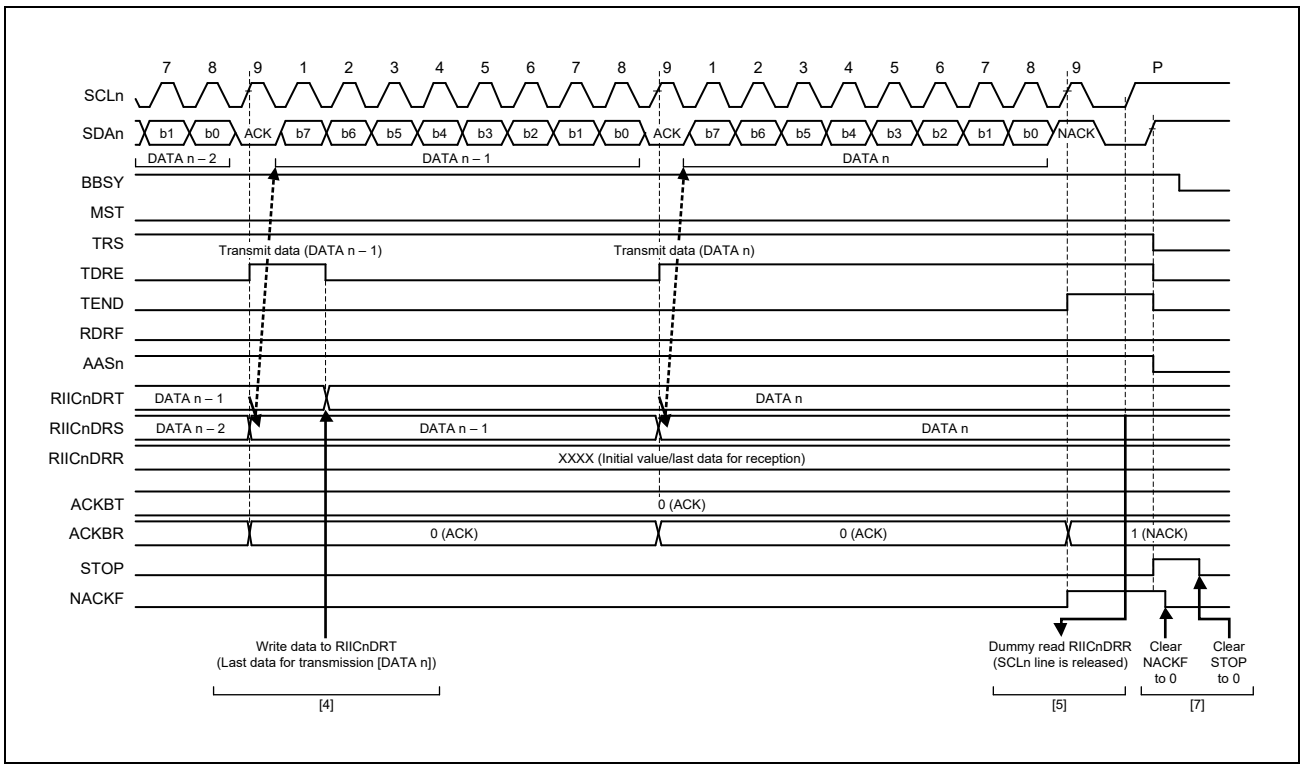

Figure 7.7-17 Slave Transmit Operation Timing (2)

7.7.5.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgements as a slave device.

Figure 7.7-18 shows an example of usage of slave reception and **Figure 7.7-19** and **Figure 7.7-20** show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Follow the procedure in **Figure 7.7-5** to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the RIICnSR2.RDRF flag to 1.

(3) After the RIICnSR2.STOP flag is confirmed to be 0 and the RIICnSR2.RDRF flag to be 1, dummy read RIICnDRR (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower eight bits when the 10-bit address format is selected).

(4) When RIICnDRR is read, the RIIC automatically clears the RIICnSR2.RDRF flag to 0. If reading of RIICnDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading RIICnDRR releases the SCL line from being held at the low level.

When the RIICnSR2.STOP flag is 1 and the RIICnSR2.RDRF flag is also 1, read RIICnDRR until all the data is completely received.

(5) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 0.

(6) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.STOP flag to 0 for the next transfer operation.

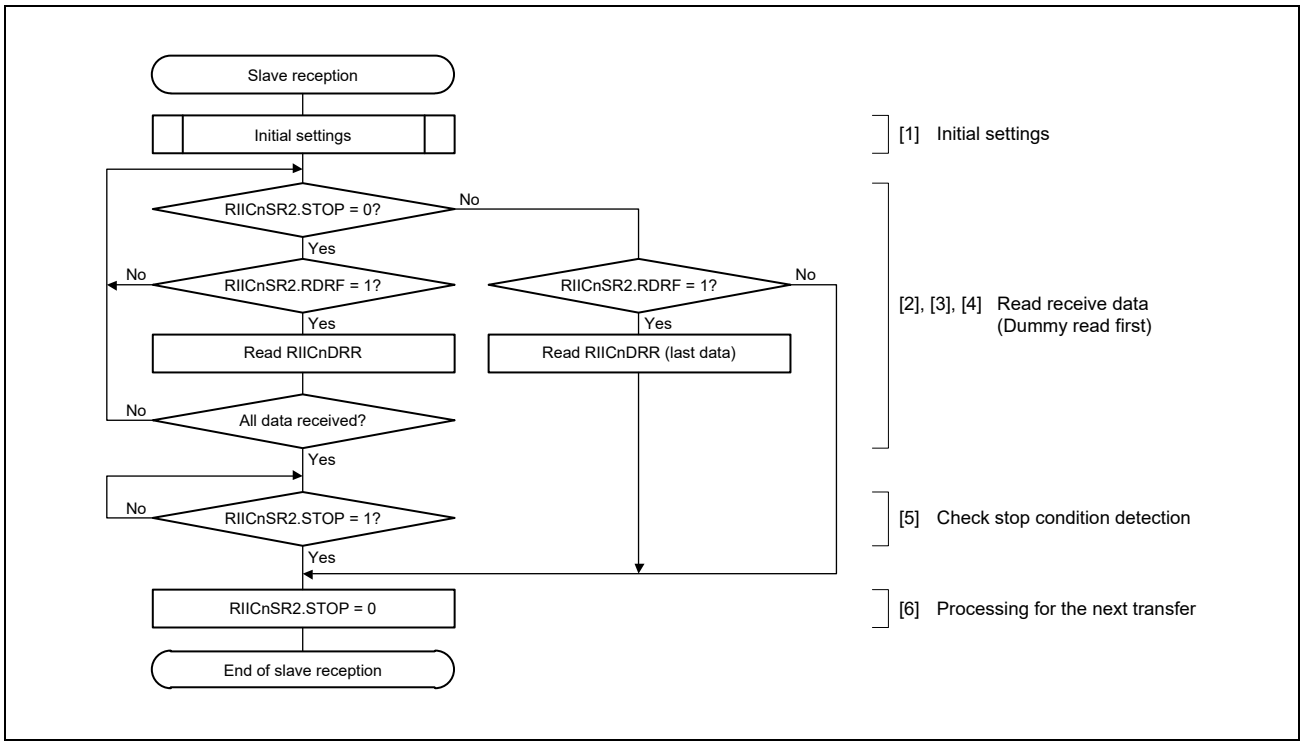

Figure 7.7-18 Example of Slave Reception Flowchart

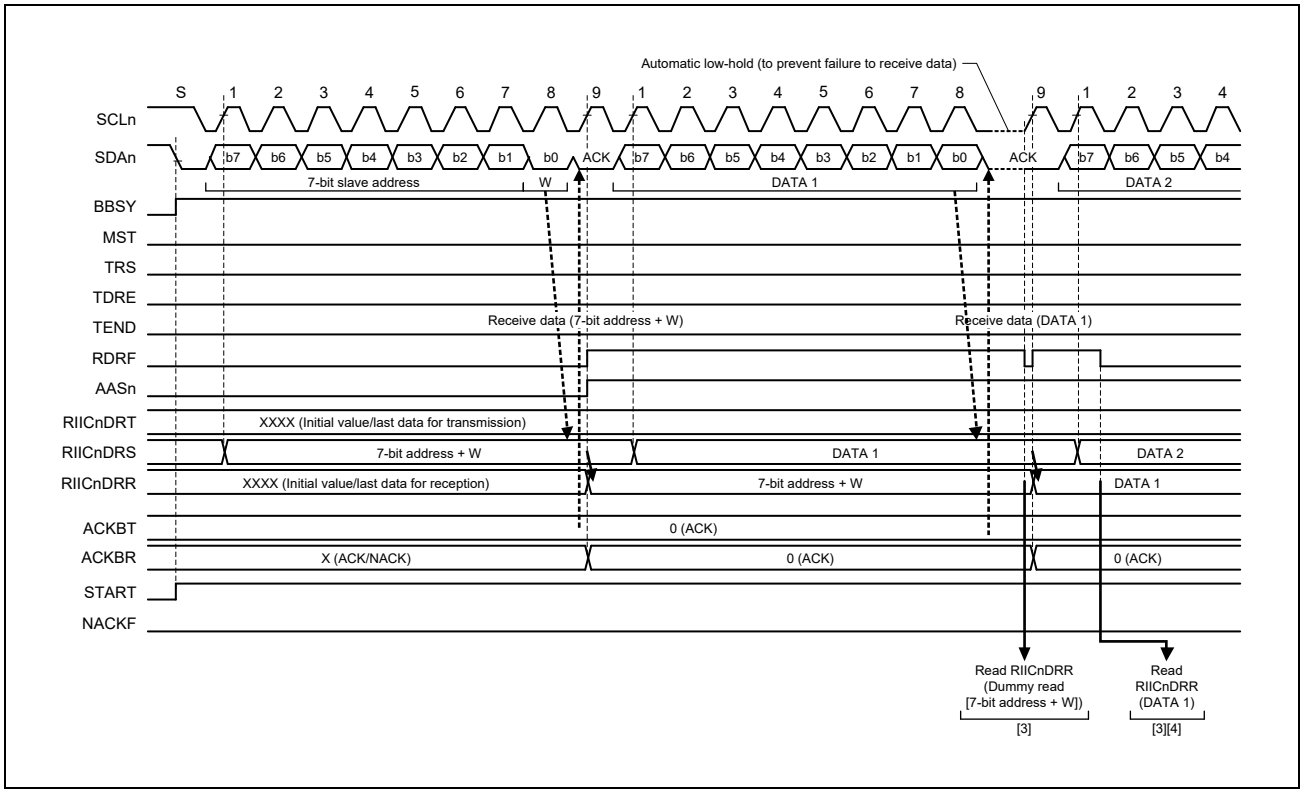

Figure 7.7-19 Slave Receive Operation Timing (1) (7-Bit Address Format, when RDRFS = 0)

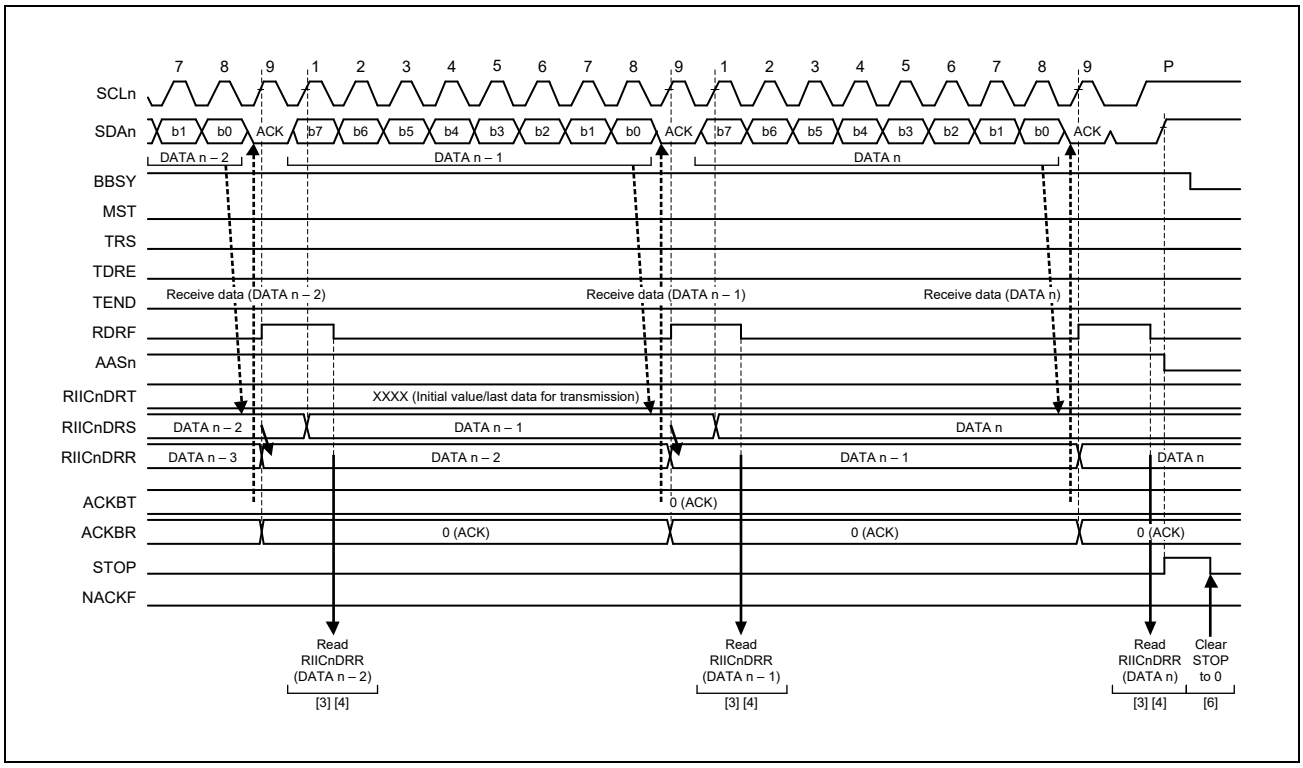

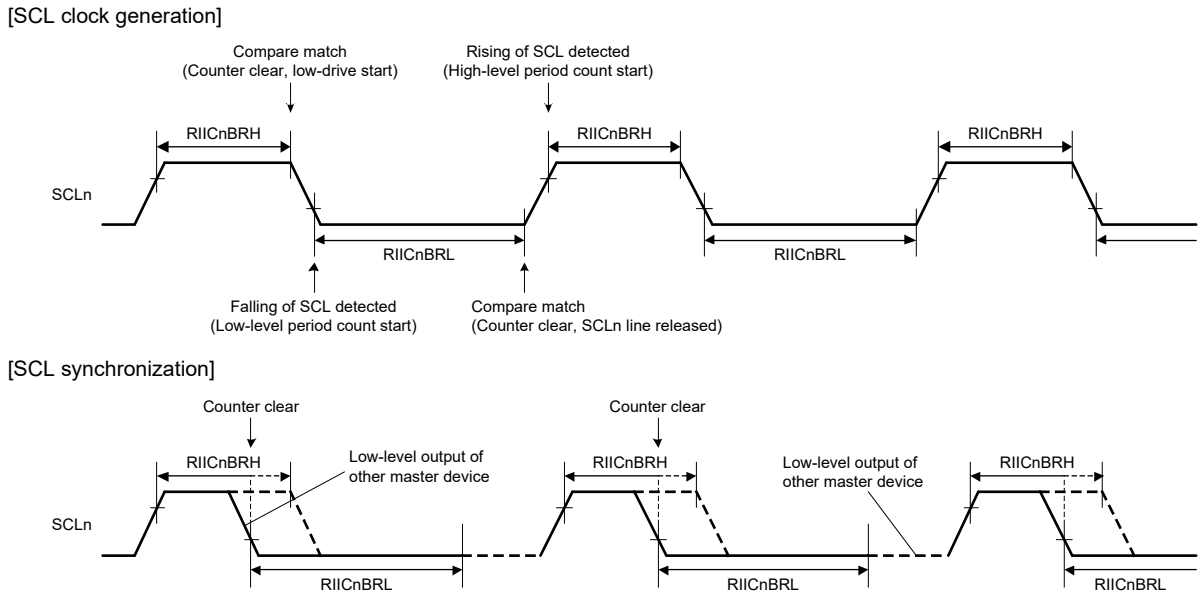

Figure 7.7-20 Slave Receive Operation Timing (2) (when RDRFS = 0)

7.7.6 SCL Synchronization Circuit

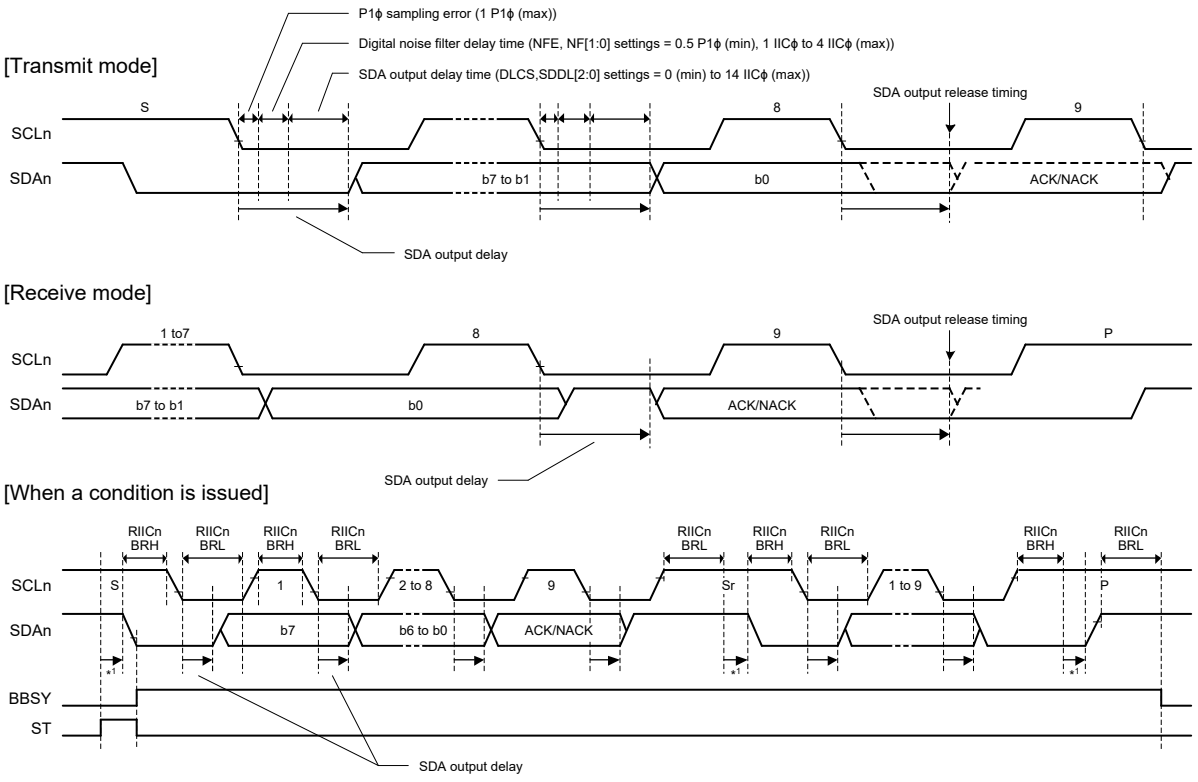
In generation of the SCL (clock) signal, the RIIC starts counting out the value for width at high level specified in RIICnBRH when it detects a rising edge on the SCL line and drives the SCL line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL line, it starts counting out the width at low level period specified in RIICnBRL, and then stops driving the SCL line (releases the line) once counting of the width at low level is complete. The SCL (clock) signal is thus generated.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL line while in master mode.

When the RIIC has detected a rising edge on the SCL line and thus started counting out the width at high level specified in RIICnBRH, and the level on the SCL line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL line low, and starts counting out the width at low level specified in RIICnBRL. When the RIIC finishes counting out the width at low level, it stops driving the SCL line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL line has been released. When the RIIC finishes outputting the low-level period of the SCL clock, the SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the RIICnFER.SCLE bit is set to 1.

Note: RIICnBRH: I^2C bus bit rate high-level register (SCL clock high-level period counter)
RIICnBRL: I^2C bus bit rate low-level register (SCL clock low-level period counter)

Figure 7.7-21 Generation and Synchronization of the SCL Signal from the RIIC



7.7.7 Facility for Delaying SDA Output

The RIIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL (clock) signal is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300-ns (min.) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the RIICnMR2.SDDL[2:0] bits to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (i.e. while the SDDL[2:0] bits in RIICnMR2 are set to any value other than 000b), the RIICnMR2.DLCS bit selects the clock source for counting by the SDA output delay counter as the internal base clock (IICϕ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in RIICnMR2. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

Note 1. The output is delayed by the number of cycles set by the SDDL [2:0] bits when a start (S), restart (Sr), or stop (P) condition is issued.

Figure 7.7-22 SDA Output Delay Facility

7.7.8 Digital Noise-Filter Circuits

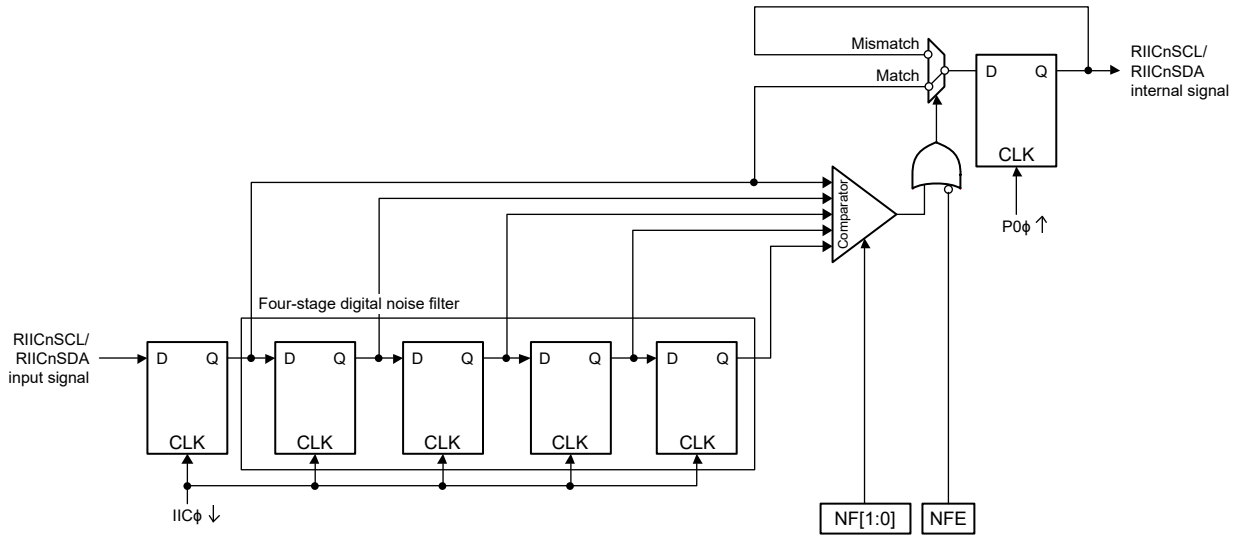


Figure 7.7-23 is a block diagram of the digital noise-filter circuit. When the NFE bit in the RIICnFER register is set to 1, input to the RIICnSCL and RIICnSDA pins are conveyed to the internal circuitry through digital noise-filter circuits.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match- detection circuit.

The number of effective stages in the digital noise filter is selected by the RIICnMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the RIICnSCL pin (or RIICnSDA pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the RIICnMR3.NF[1:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between P0ϕ and IICϕ is small when the RIICnMR1.CKS[2:0] bits are set to 000b, note that the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.

Note: NFE: Digital noise filter circuit enable bit
NF[1:0]: Digital noise filter stage selection bits

Figure 7.7-23 Block Diagram of Digital Noise Filter Circuit

7.7.9 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10-bit slave addresses.

7.7.9.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the RIICnSER.SARyE bit (y = 0 to 2) is set to 1, the slave addresses set in RIICnSAR(L,U)y (y = 0 to 2) can be detected. When the RIIC detects a match of the set slave address, the corresponding RIICnSR1.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the RIICnSR2.RDRF flag or the RIICnSR2.TDRE flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (INTRIICRI) or transmit data empty interrupt (INTRIICTI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 7.7-24 to **Figure 7.7-26** show the AASy flag set timing in three cases.

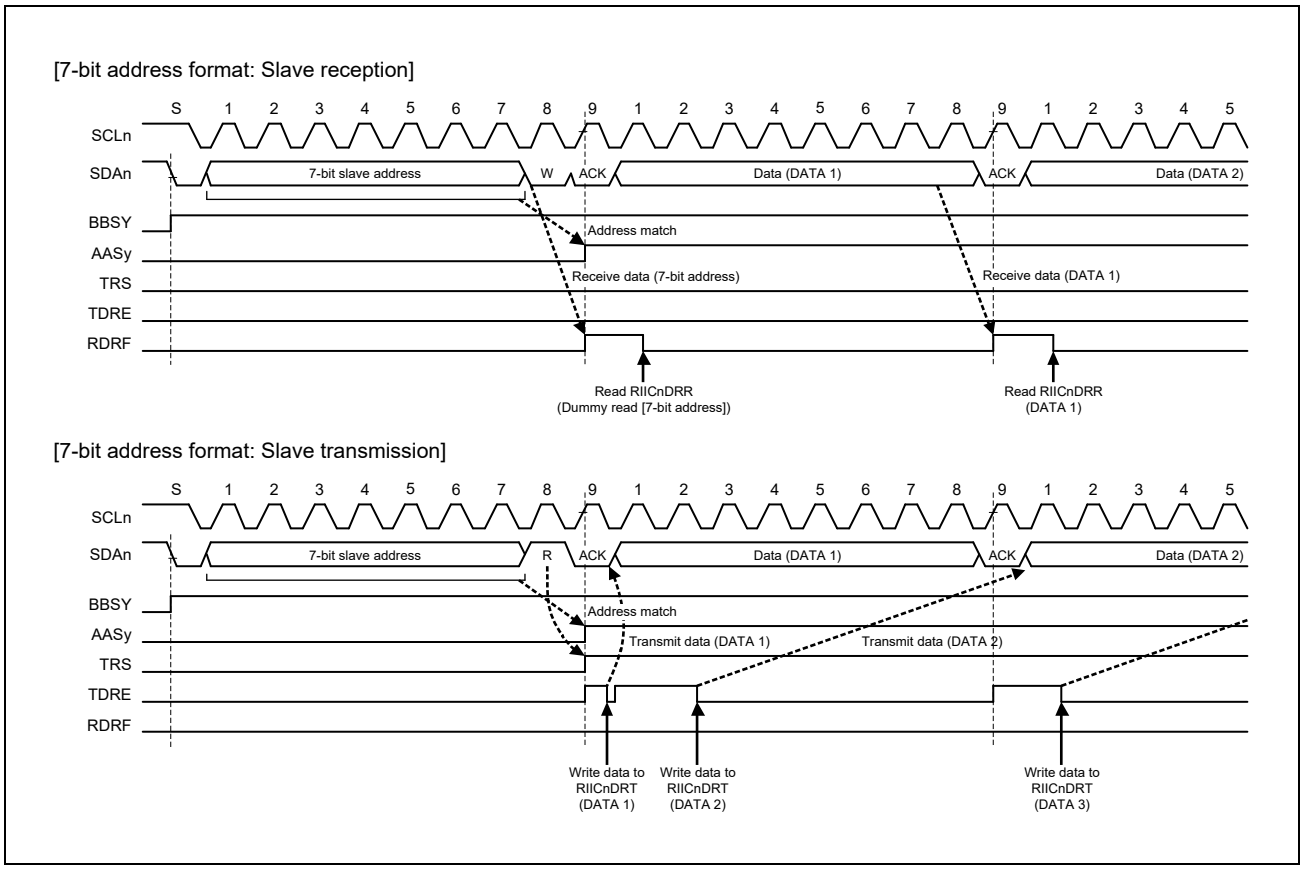

Figure 7.7-24 AASy Flag Set Timing with 7-Bit Address Format Selected

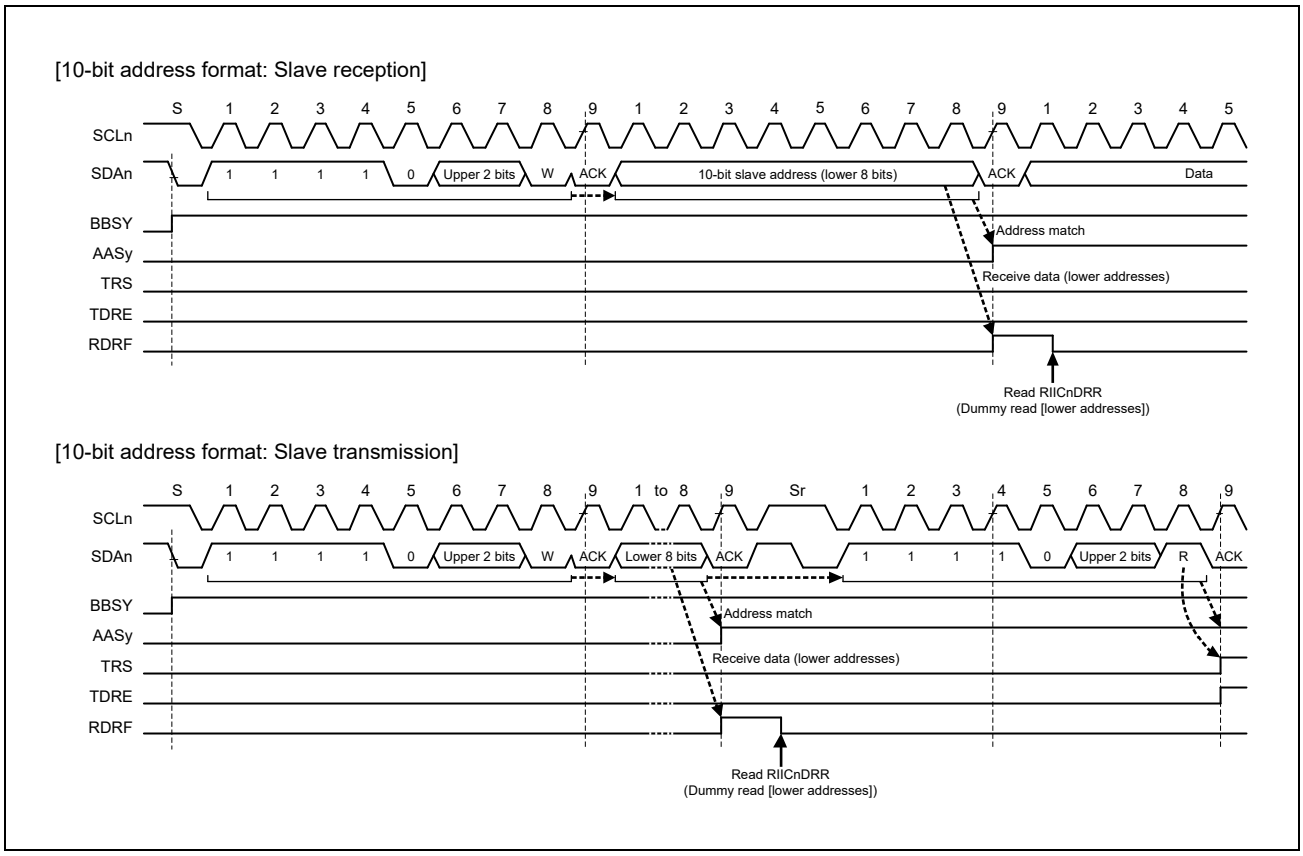

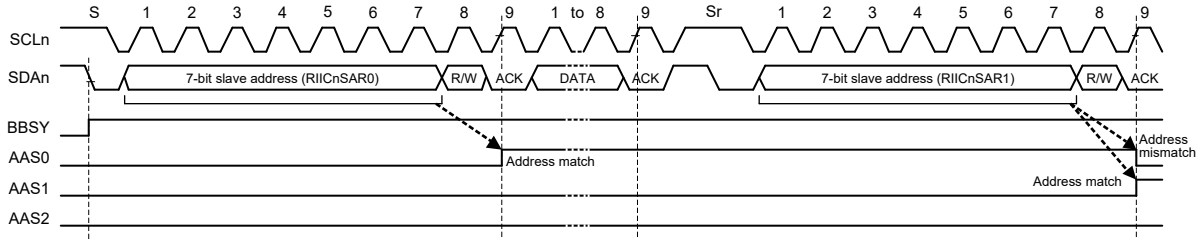

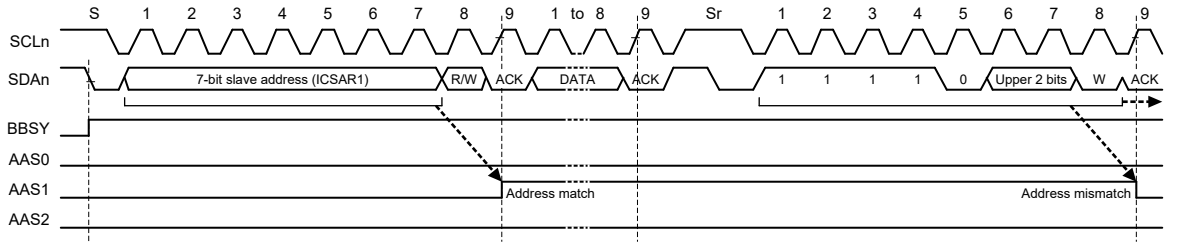

Figure 7.7-25 AASy Flag Set Timing with 10-Bit Address Format Selected

Figure 7.7-26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

7.7.9.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address (0000_000b + 0 [W]). This is enabled by setting the RIICnSER.GCE bit to 1.

If the address received after a start or restart condition is issued is 0000_000b + 1[R] (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the RIICnSR1.GCA flag and the RIICnSR2.RDRF flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (INTRIICRI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

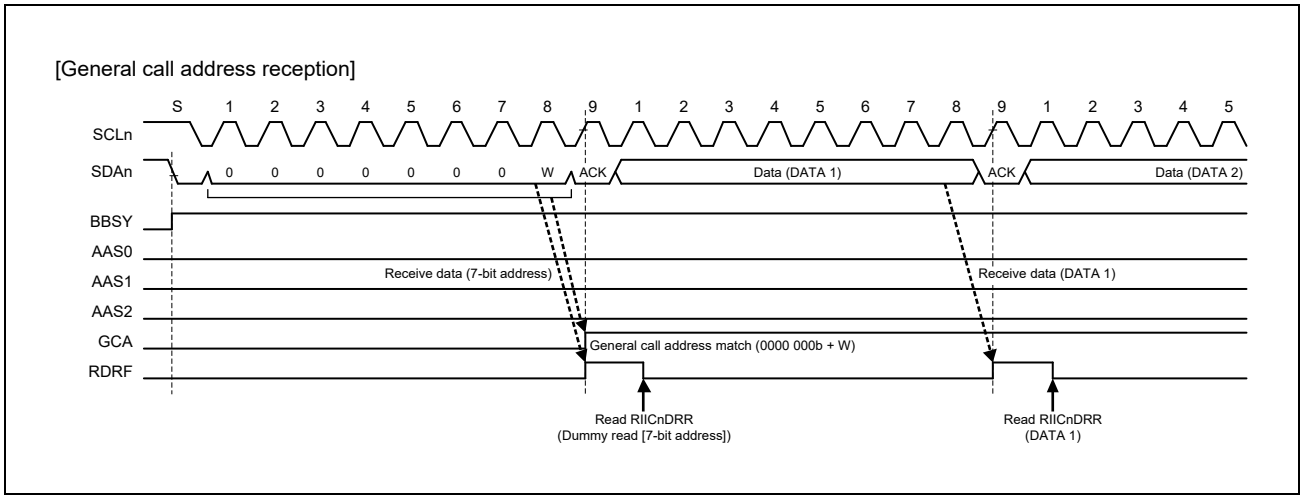

Figure 7.7-27 Timing of GCA Flag Setting during Reception of General Call Address

7.7.9.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conformant with the I²C bus specification (Rev. 03). When the RIIC receives 1111_100b as the first byte after a start condition or restart condition was issued with the RIICnSER.DIDE bit set to 1, the RIIC recognizes the address as a device ID, sets the RIICnSR1.DID flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding RIICnSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111_100b) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the RIICnSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC clears the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111_100b) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details, see I²C Bus Standard from NXP Semiconductors.

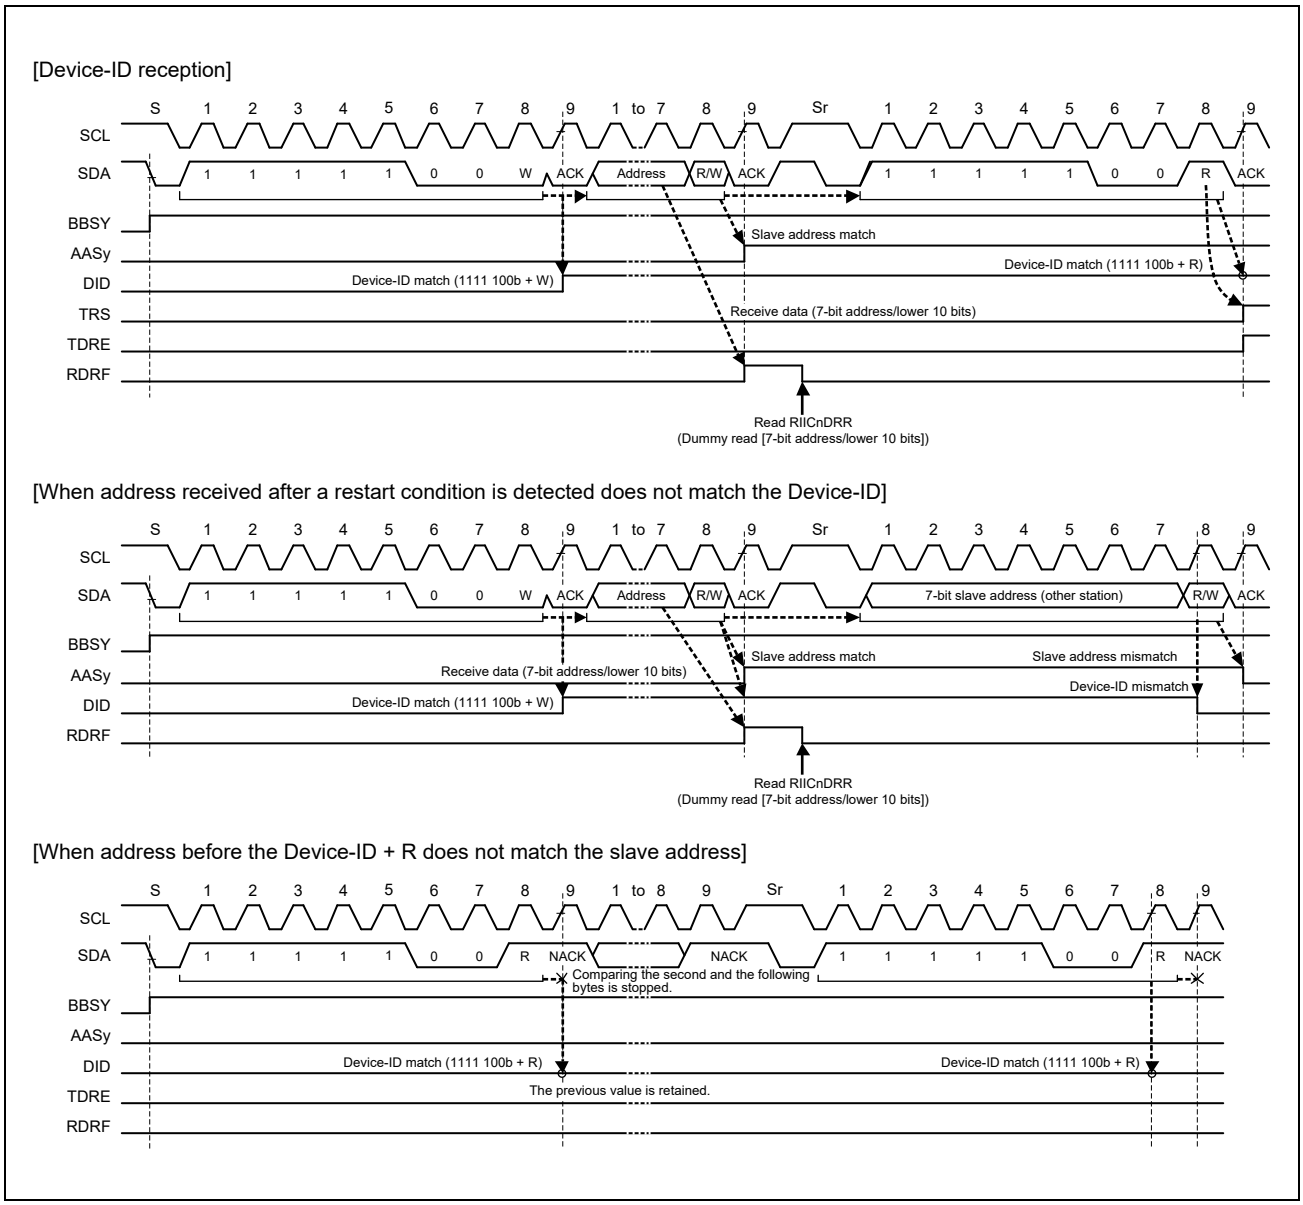

Figure 7.7-28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

7.7.9.4 Host Address Detection

The RIIC has a function to detect the host address while the SMBus is operating. When the RIICnSER.HOAE bit is set to 1 while the RIICnMR3.SMBS bit is 1, the RIIC can detect the host address (0001_000b) in slave receive mode (RIICnCR2.MST and TRS bits = 00b).

When the RIIC detects the host address, the RIICnSR1.HOA flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the RIICnSR2.RDRF flag is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (INTRIICRI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001_000b) is an Rd bit (R/W# bit = 1), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as normal slave operation.

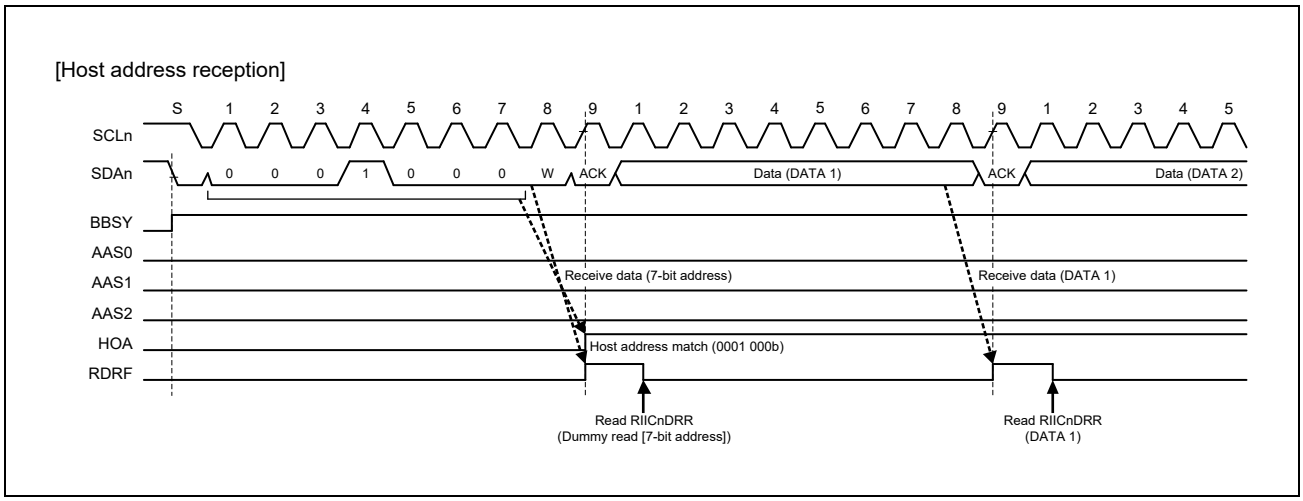

Figure 7.7-29 HOA Flag Set Timing during Reception of Host Address

7.7.10 Automatic Low-Hold Function for SCL

7.7.10.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (RIICnDRS) is empty when data have not been written to the transmit data register (RIICnDRT) with the RIIC in transmission mode (RIICnCR2.TRS bit = 1), the SCL signal is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

<Master transmit mode>

- Low-level interval after a start condition or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

<Slave transmit mode>

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

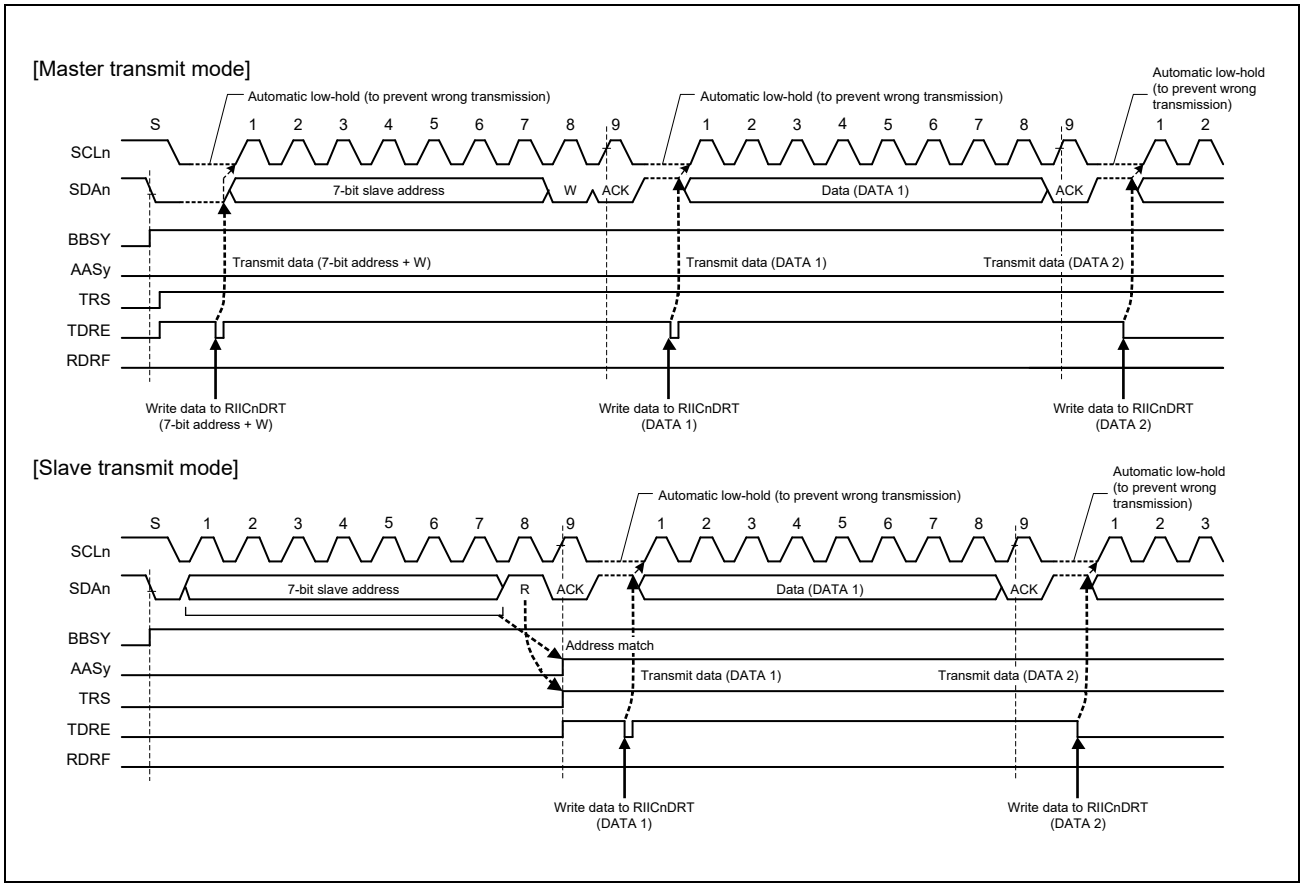

Figure 7.7-30 Automatic Low-Hold Operation in Transmit Mode

7.7.10.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (RIICnCR2.TRS bit = 1). This function is enabled when the RIICnFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (RIICnSR2.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (RIICnSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to clear the NACKF flag to 0. In master transmit mode, clear the NACKF flag to 0 after issuing a restart condition or clear the NACKF and STOP flags to 0 after confirming that a stop condition has been issued, and then issue a start condition.

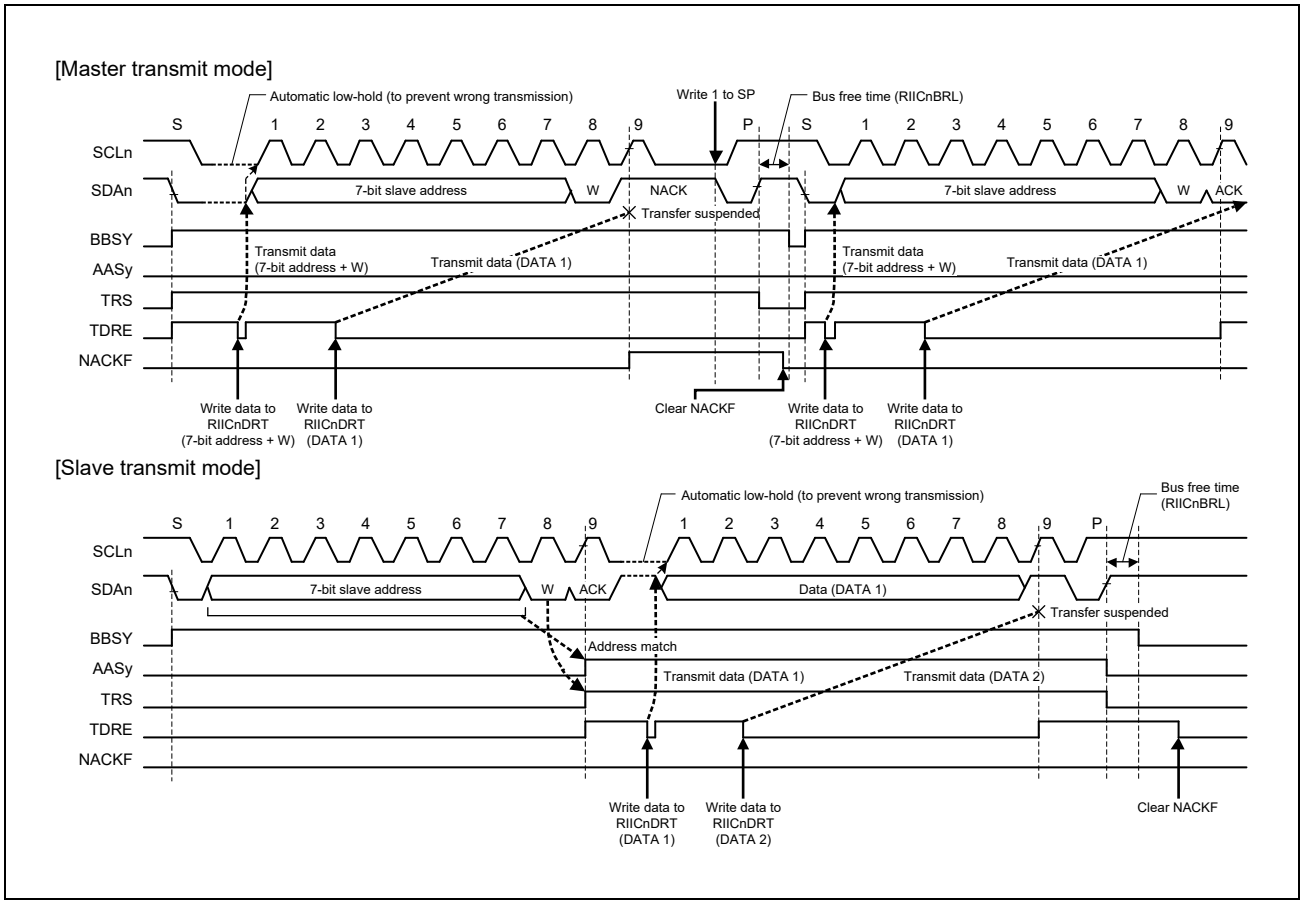

Figure 7.7-31 Suspension of Data Transfer when NACK is Received (NACKE = 1)

7.7.10.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (RIICnDRR) read is delayed for a period of one transfer frame or more with receive data full (RIICnSR2.RDRF flag = 1) in receive mode (RIICnCR2.TRS = 0), the RIIC holds the SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCL line low when a mismatch with its own slave address occurs after a stop condition is issued.

Sections in which the SCL line is held low can be selected with a combination of the RIICnMR3.WAIT and RDRFS bits.

(1) One-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the RIICnMR3.WAIT bit is set to 1, the RIIC performs one-byte receive operation using the WAIT bit function. Furthermore, when the RIICnMR3.RDRFS bit is 0, the RIIC automatically sends the RIICnMR3.ACKBT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCL line low at the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from RIICnDRR, which enables bytewise receive operation.

The WAIT bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) One-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the RIICnMR3.RDRFS bit is set to 1, the RIIC performs one-byte receive operation using the RDRFS bit function. When the RIICnSR2.RDRFS bit is set to 1, the RDRF flag (receive data full) in RIICnSR2 is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This low hold is released by writing a value to the RIICnMR3.ACKBT bit, but cannot be released by reading data from RIICnDRR, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

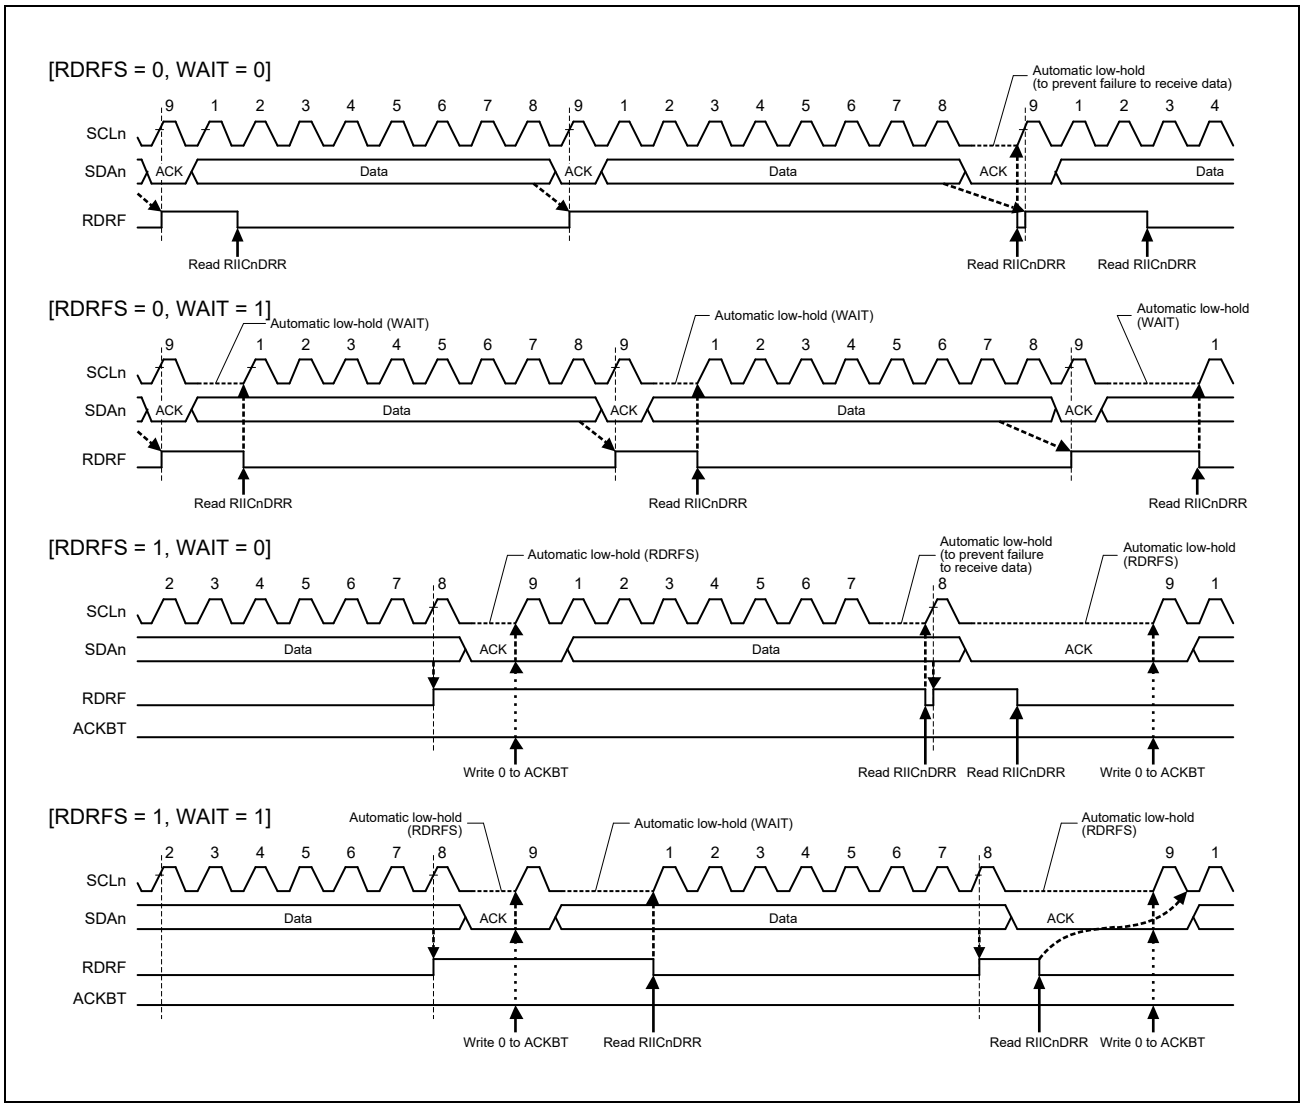

Figure 7.7-32 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

7.7.11 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I^2C bus standard, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

7.7.11.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA line low to issue a start condition. However, if the SDA line has already been driven low by another master device issuing a start condition, the RIIC regards its own issuing of a start condition as an error and considers this a loss in arbitration, so priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the RIICnCR2.ST bit to 1 while the bus is busy (RIICnCR2.BBSY flag = 1), the RIIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration, thus preventing a failure of transfer due to issuing of a start condition while transfer is in progress.

When a start condition is issued successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line, the RIIC loses in arbitration.

After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the RIICnFER.MALE bit is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDA line after a start condition was issued by setting the RIICnCR2.ST bit to 1 while the RIICnCR2.BBSY flag was cleared to 0 (erroneous issuing of a start condition)
- Setting of the RIICnCR2.ST bit to 1 (start condition double-issue error) while the RIICnCR2.BBSY flag is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in master transmit mode (RIICnCR2.MST and TRS bits = 11b)

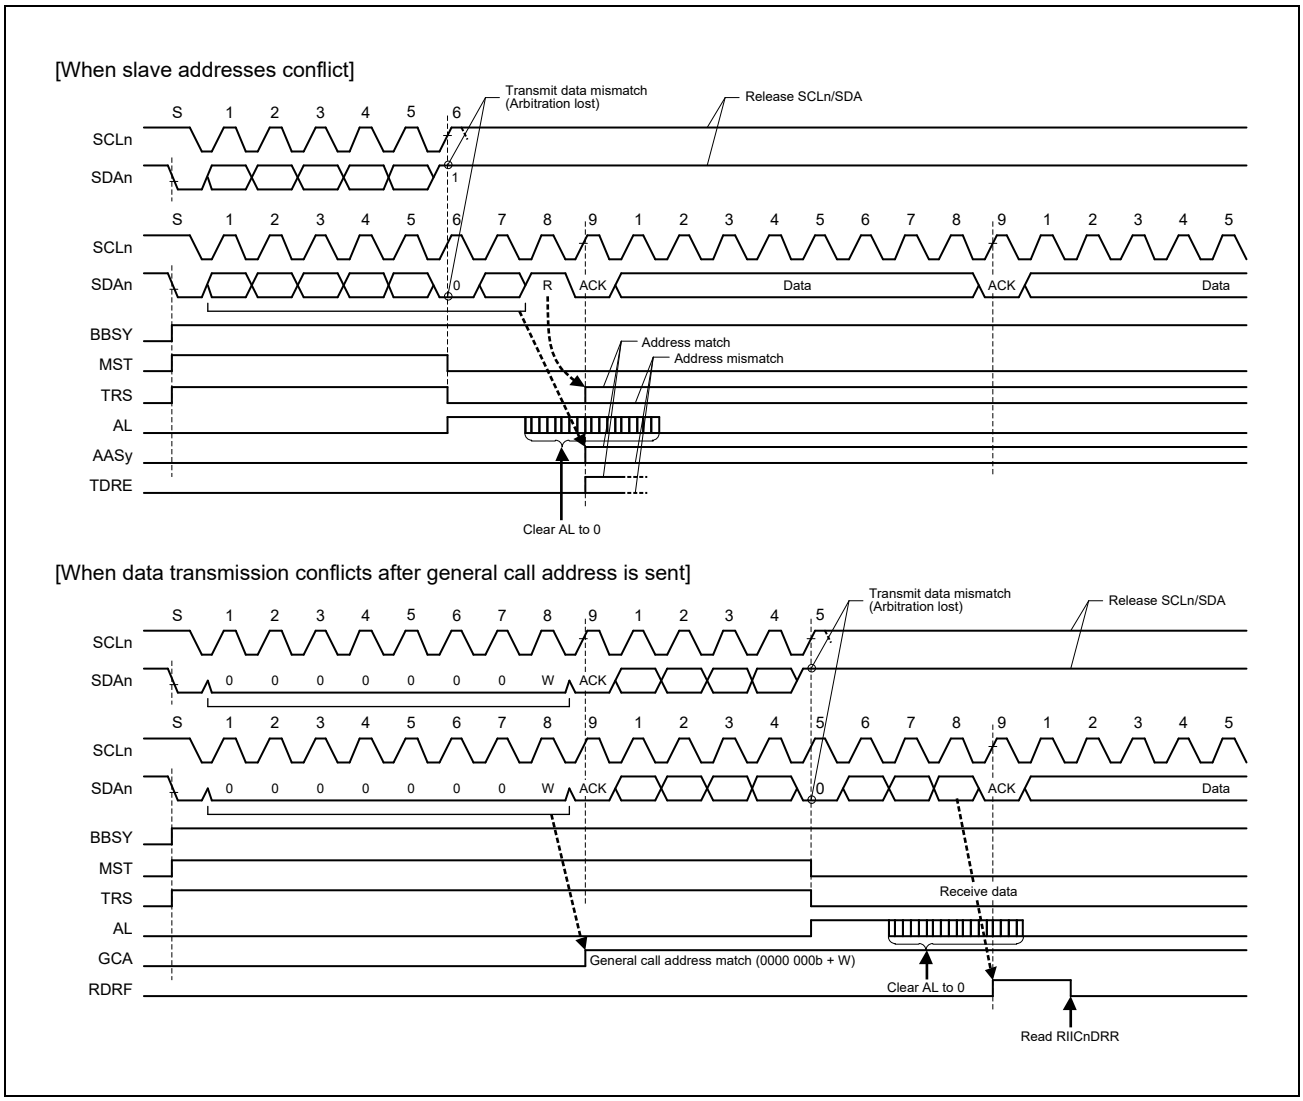

Figure 7.7-33 Examples of Master Arbitration-Lost Detection (MALE = 1)

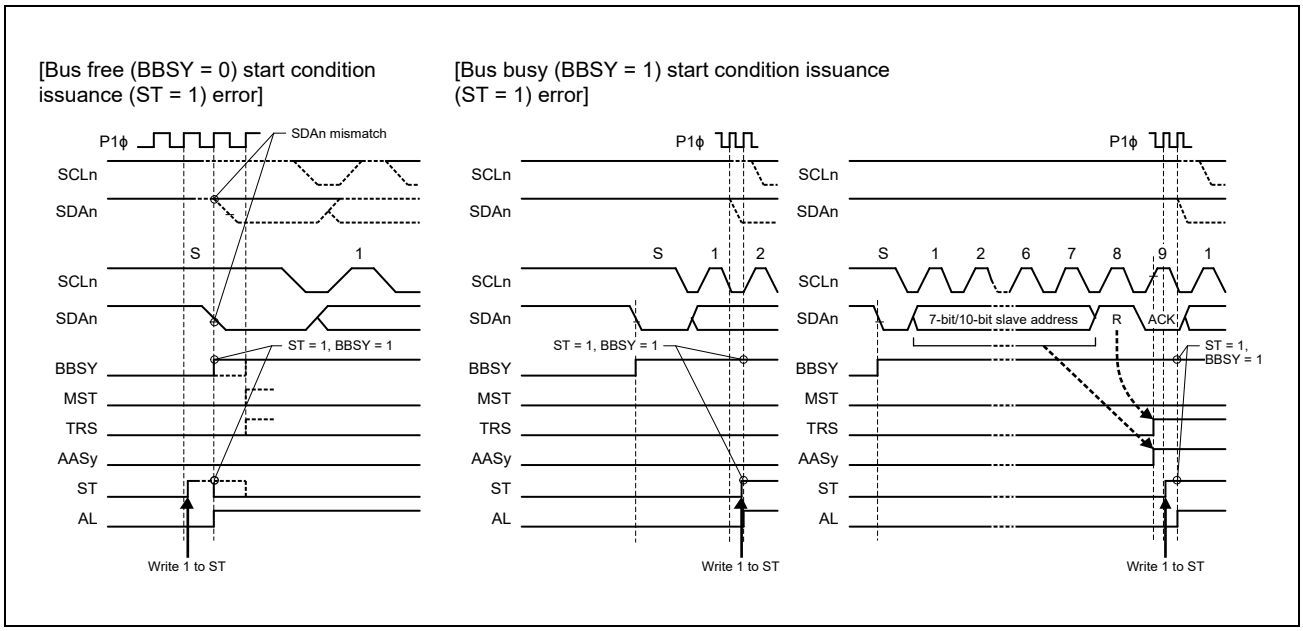

Figure 7.7-34 Arbitration-Lost when a Start Condition is Issued (MALE = 1)

7.7.11.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA line (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. **Figure 7.7-35** shows an example of arbitration-lost detection during transmission of NACK.

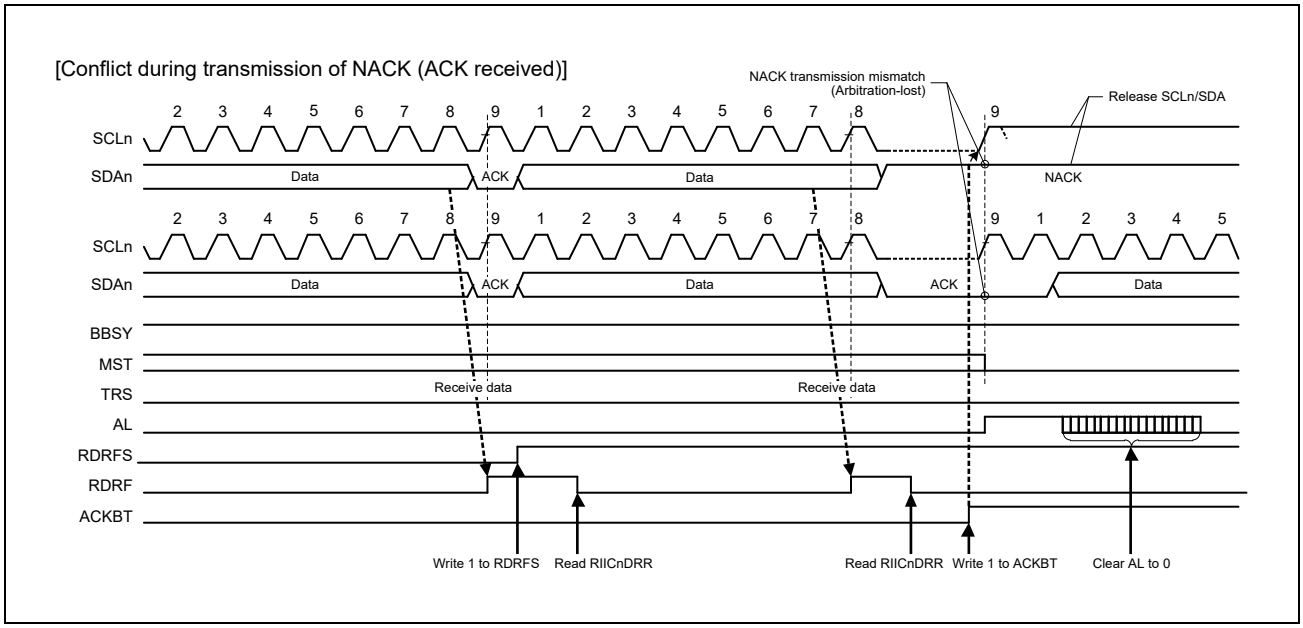

Figure 7.7-35 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received two final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as H'FF transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign address command.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the RIICnFER.NALE bit set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

When the internal SDA output level does not match the SDA line (ACK is received) during transmission of NACK (RIICnMR3.ACKBT bit = 1).

7.7.11.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When it loses slave arbitration, the RIIC enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing (processing for the transmission of H'FF).

The RIIC detects slave arbitration-lost when the following condition is met with the RIICnFER.SALE bit set to 1 (slave arbitration-lost detection enabled). [Condition for slave arbitration-lost]

When transmit data excluding acknowledge (internal SDA output level) does not match the SDA line in slave transmit mode (RIICnCR2.MST and TRS bits = 01b)

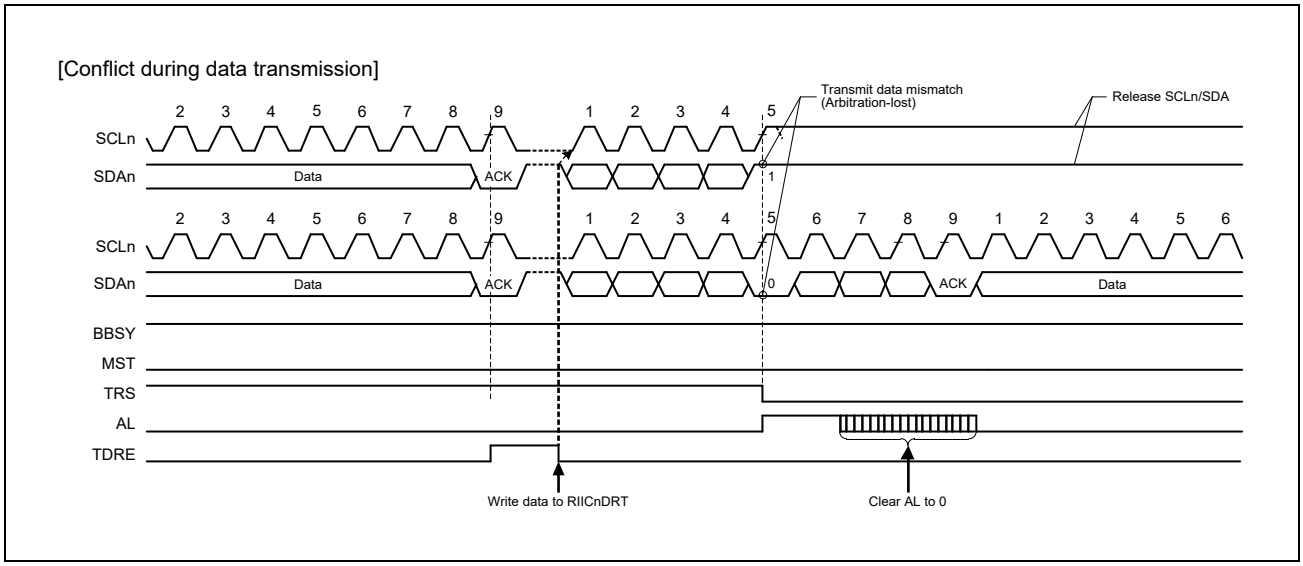

Figure 7.7-36 Example of Slave Arbitration-Lost Detection (SALE = 1)

7.7.12 Start Condition/Restart Condition/Stop Condition Issuing Function

7.7.12.1 Issuing a Start Condition

The RIIC issues a start condition when the RIICnCR2.ST bit is set to 1.

When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the RIICnCR2.BBSY flag is 0 (bus free). When a start condition is issued normally, the RIIC automatically shifts to the master transmit mode.

A start condition is issued in the following sequence.

[Start condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the start condition hold time.
- Drive the SCL line low (high level to low level).
- Detect low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

7.7.12.2 Issuing a Restart Condition

The RIIC issues a restart condition when the RIICnCR2.RS bit is set to 1.

When the RS bit is set to 1, a restart condition issuance request is made and the RIIC issues a restart condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A restart condition is issued in the following sequence.

[Restart condition issuance]

- Release the SDA line.
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRL and the restart condition setup time.
- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the restart condition hold time.
- Drive the SCL line low (high level to low level).
- Detect a low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

CAUTION

To issue a restart condition request, set RIICnSR2.RS to 1 after setting RIICnSR2.START to 0. After checking that RIICnSR2.START is 1, set RIICnSR2.START to 0, and then write the slave address to RIICnDRT.

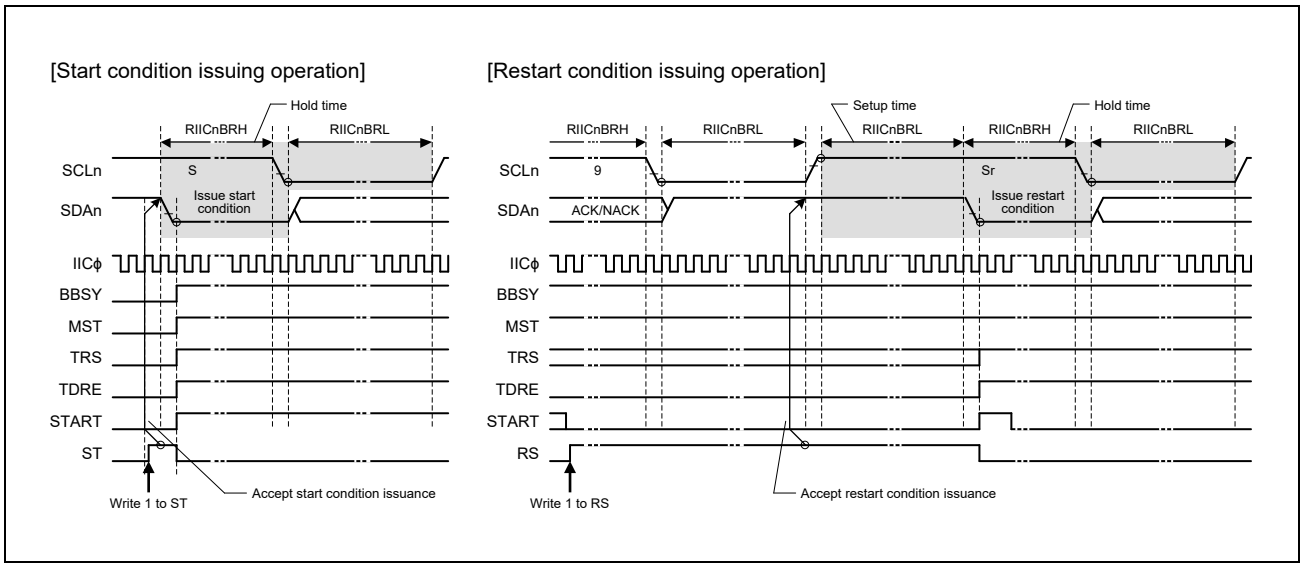

Figure 7.7-37 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

7.7.12.3 Issuing a Stop Condition

The RIIC issues a stop condition when the RIICnCR2.SP bit is set to 1.

When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A stop condition is issued in the following sequence.

[Stop condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRH and the stop condition setup time.
- Release the SDA line (low level to high level).
- Ensure the time set in RIICnBRL and the bus free time.
- Clear the BBSY flag to 0 (to release the bus mastership).

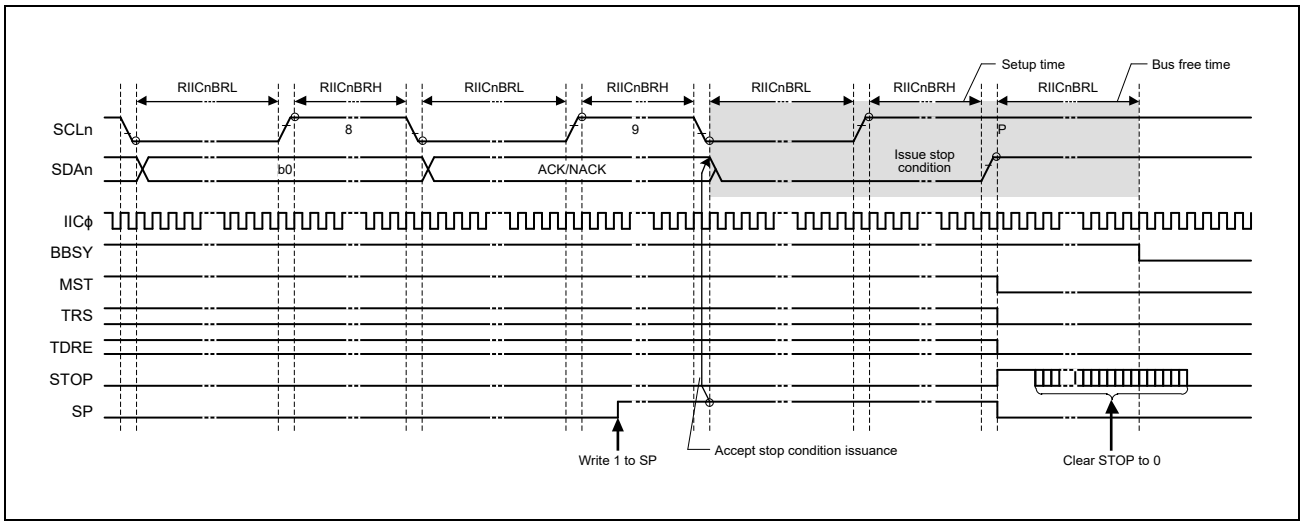

Figure 7.7-38 Stop Condition Issue Timing (SP Bit)

7.7.13 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I^2C bus might hang with a fixed level on the SCL line and/or SDA line.

As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, and the RIIC/internal reset function.

By checking the RIICnCR1.SCLO, SDAO, SCLI, and SDAI bits, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL or SDA lines.

7.7.13.1 Timeout Function

The RIIC has the timeout function to detect an abnormality that the SCL line is held for a certain period of time. The RIIC can detect an abnormal bus state by monitoring that the SCL line is held low or high for a predetermined time. The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, the RIIC can detect the timeout and report the bus abnormality.

This timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state in which the SCL line is held low or high in the following cases.

1. When the bus is busy (RIICnCR2.BBSY = 1) in master mode (RIICnCR2.MST = 1)
2. When the bus is busy (RIICnCR2.BBSY = 1) and the RIIC's own slave address matches (RIICnSR1 is not H'00) in slave mode (RIICnCR2.MST = 0)
3. While the bus is free (RIICnCR2.BBSY = 0) and issuing of a start condition is being requested (RIICnCR2.ST = 1).

The internal counter of the timeout function works using the internal reference clock (IICϕ) set by the RIICnMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (RIICnMR2.TMOS bit = 0) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCL line level (low/high or both levels) during which this counter is activated can be selected by the setting of the RIICnMR2.TMOH and TMOL bits. If both TMOL and TMOH bits are cleared to 0, the internal counter does not work.

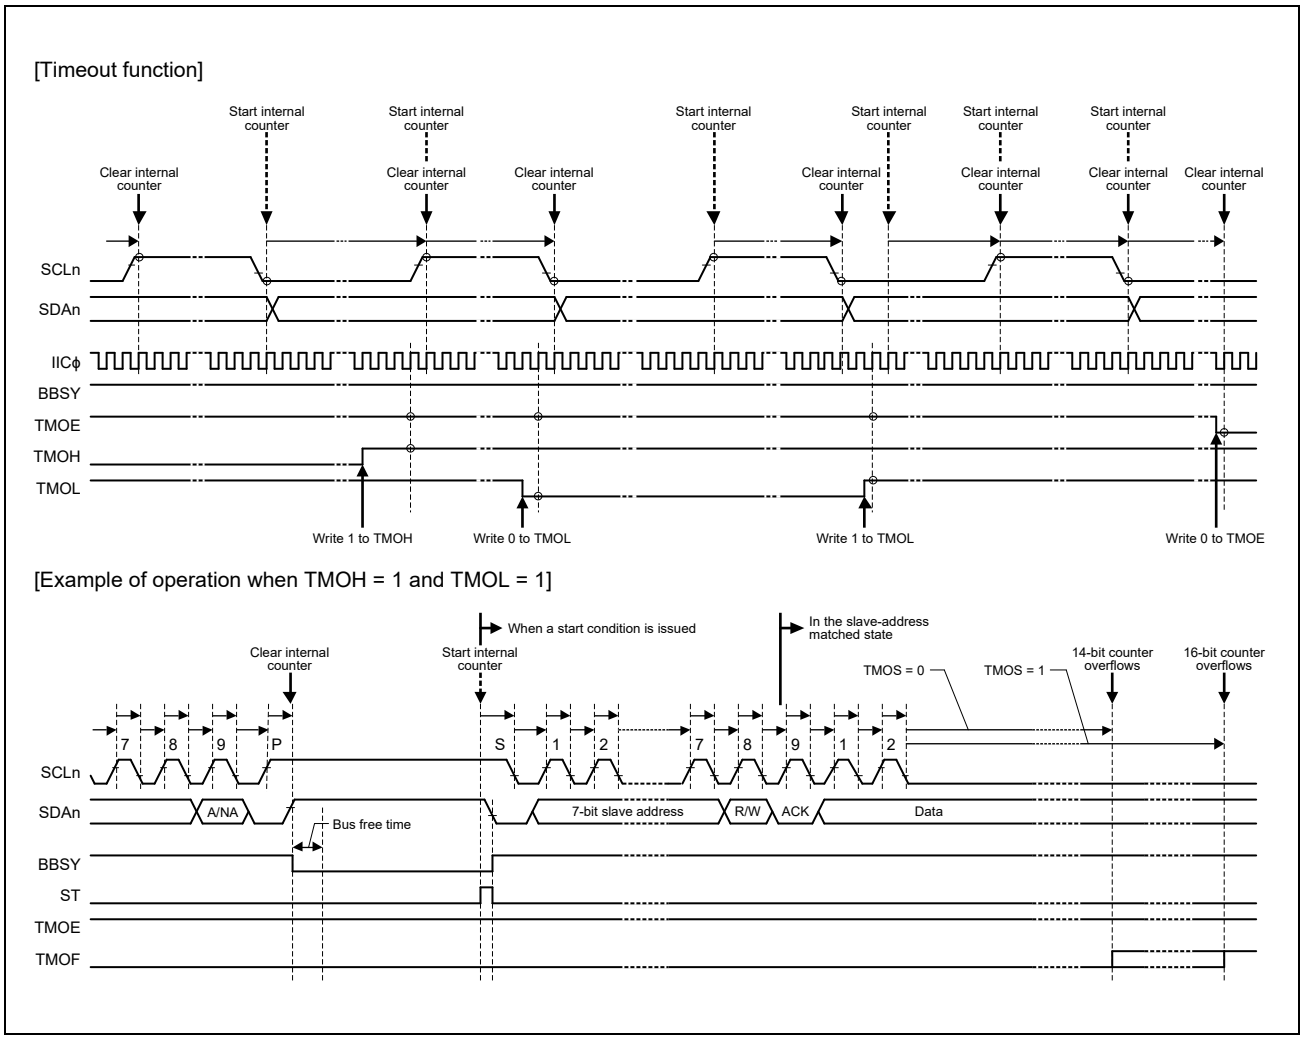

Figure 7.7-39 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits)

7.7.13.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL (clock) cycles to release the SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL (clock) signal as the unit in the case of a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the RIICnCR1.CLO bit is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the RIICnMR1.CKS[2:0] bits, and of the RIICnBRH and RIICnBRL registers) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically cleared to 0. At this point, the SCL pin output is held at a low level if the BBSY flag is 1, or the SCL pin outputs at high level if the BBSY flag is 0. Further clock cycles can consecutively be output by writing 1 to the CLO bit after having read CLO is 0 by software.

When the RIIC module is in master mode and the slave device is holding the SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL (clock) signal can be used to output extra cycles of SCL one by one to make the slave device release the SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDA line by the slave device can be monitored by reading the RIICnCR1.SDAI bit. After confirming release of the SDA line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the RIICnCR1.CLO bit]

- When the bus is free (RIICnCR2.BBSY flag = 0) or in master mode (RIICnCR2.MST bit = 1 and BBSY flag = 1)
- When the communication device does not hold the SCL line low

Figure 7.7-40 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

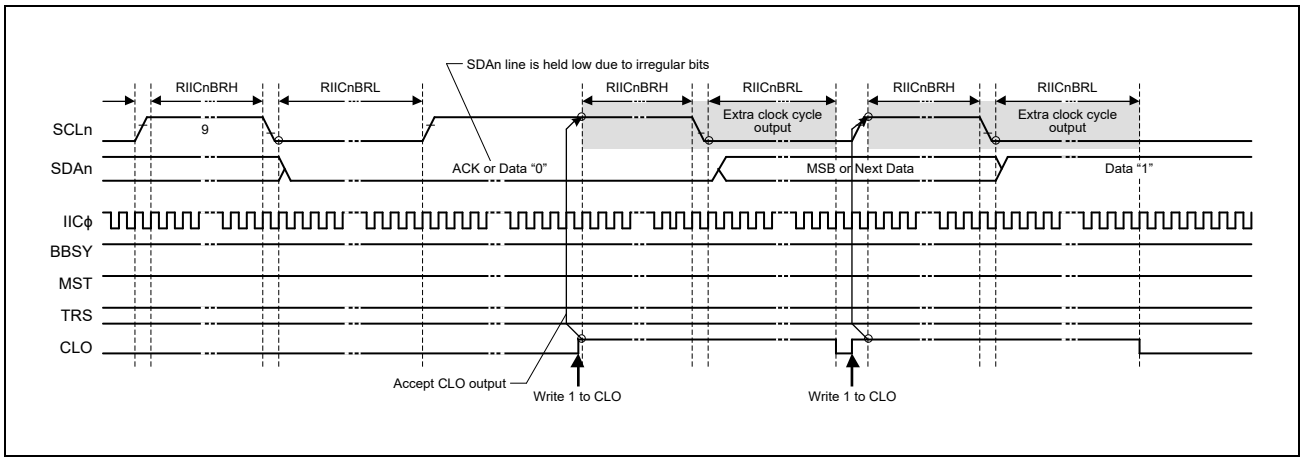

Figure 7.7-40 Extra SCL Clock Cycle Output Function (CLO Bit)

7.7.13.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the RIICnCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings. After issuing a reset, be sure to clear the RIICnCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states since both restore the output state of the SCL and SDA pins to the high impedance state.

Issuing a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoided this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (RIICnCR1.ICE and IICRST bits = 01b).

For a detailed description of the RIIC and internal resets, see **7.7.15 Reset Function of RIIC**.

7.7.14 SMBus Operation

The RIIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the RIICnMR3.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the RIICnMR1.CKS[2:0] bits, RIICnCBRH, and RIICnBRL. In addition, determine the values of the RIICnMR2.DLCS bit and the RIICnMR2.SDDL[2:0] bits to meet the data hold time specification of 300 ns or more. If the RIIC is used only as a slave device, the transfer rate setting is not necessary. When the RIIC is used only as a slave device, the transfer rate setting is not necessary, whereas the RIICnBRL needs to be set to a value at least the same as the data setup time (250 ns).

For the SMBus device default address (1100_001b), use one of the slave address registers L0 to L2 (RIICnSARL0, RIICnSARL1, and RIICnSARL2), and set the corresponding RIICnSARUy.FS bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the RIICnFER.SALE bit to 1 to enable the slave arbitration lost detection function.

7.7.14.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From start condition to stop condition

  To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the internal timer using a start condition detection interrupt (INTRIICSTI) and stop condition detection interrupt (INTRIICSPI) of the RIIC. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus standard.

  If the time measured with the internal timer exceeds the clock low-level detection timeout TTIMEOUT: 25 ms (min.) of the SMBus standard, the slave device must release the bus by writing 1 to the RIICnCR1.IICRST bit to issue an internal reset of the RIIC. When an internal reset is issued, the RIIC stops driving the bus for the SCL pin and SDA pin and make the SCL/SDA pin outputs high impedance, which releases the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition

To measure timeout for master devices, measure these periods with the internal timer using a start condition detection interrupt (INTRIICSTI), stop condition detection interrupt (INTRIICSPI), and transmit end interrupt (INTRIICTEI) or receive data full interrupt (INTRIICRI) of the RIIC. The measured timeout period must be within the total clock low-level extended period [master device] $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus standard, and the total of all $T_{LOW:MEXT}$ from start condition to stop condition must be within $T_{LOW:SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SMBCLK clock cycle), monitor the RIICnSR2.TEND flag in master transmit mode (master transmitter) and the RIICnSR2.RDRF flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the RIICnMR3.RDRFS bit 0 until the byte just before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SMBCLK clock cycle.

If the period measured with the internal timer exceeds the total clock low-level extended period [master device] $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout TTIMEOUT: 25 ms (min.) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to RIICnDRT).

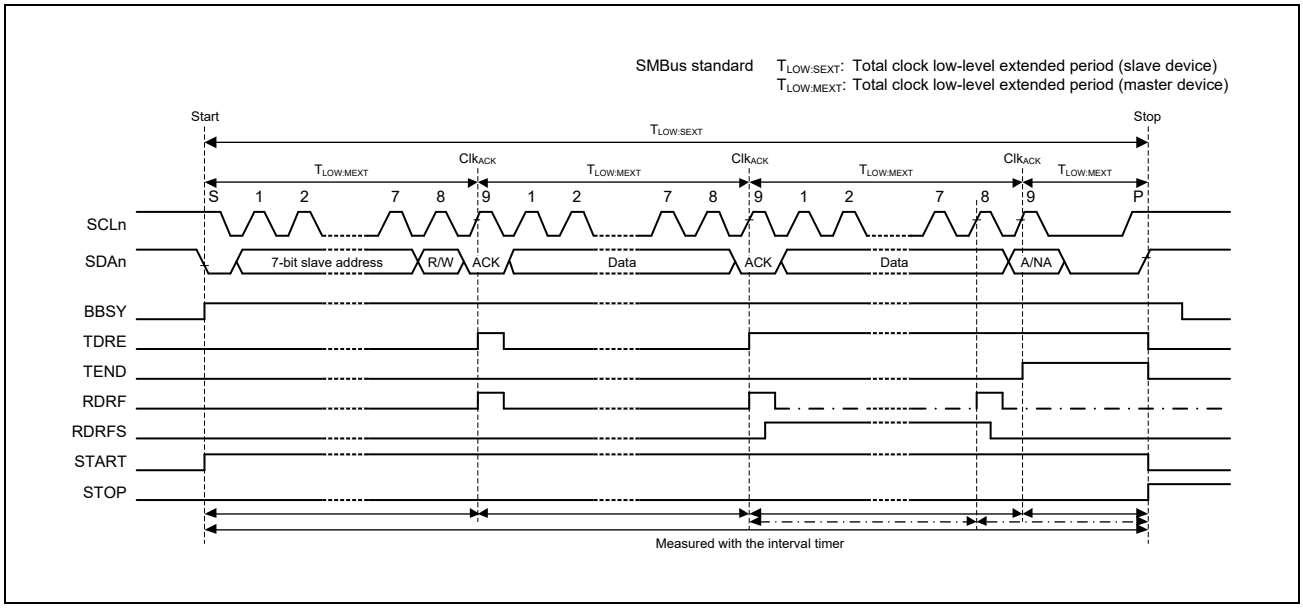

Figure 7.7-41 SMBus Timeout Measurement

7.7.14.2 SMBus Host Notification Protocol/Notify ARP Master

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of (or request the SMBus host for) its own slave address or to request its own slave address from the SMBus host.

For this LSI to operate as an SMBus host (or ARP master), the host address (0001_000b) sent from the slave device must be detected as a slave address, so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the RIICnMR3.SMBS bit and the RIICnSER.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

7.7.15 Reset Function of RIIC

The RIIC has chip reset, RIIC reset, and internal reset functions. **Table 7.7-12** lists the scope of each reset and reset conditions.

Table 7.7-12 RIIC Reset Functions (1/2)

Register		RIIC Reset (ICE = 0, IICRST = 1)	Internal Reset (ICE = 1, IICRST = 1)	Start Condition/Restart Condition Detection	Stop Condition Detection

Note 1. When an internal reset is applied while the bus is free after detection of a stop condition, the setting of the BBSY flag is 0 while the bus is free following de-assertion of the internal reset signal.
When an internal reset is applied while the bus is not free, the BBSY flag is not cleared.

SECTION 7 LOW-SPEED INTERFACE

7.8 I3C Bus Interface (I3C)

NOTE

This LSI does not support High-speed mode (Hs-mode) for I2C mode.
Related descriptions of the Hs-mode in this section should be ignored.

7.8.1 Overview

7.8.1.1 Functional Overview

The I3C bus interface (I3C) has 1 channel. The I3C module conform with and provide a subset of the NXP I^2C (Inter-Integrated Circuit) bus interface functions and a subset of the MIPI I3C.

Table 7.8-1 lists the I^2C specifications, and **Table 7.8-2** lists the I3C specifications.

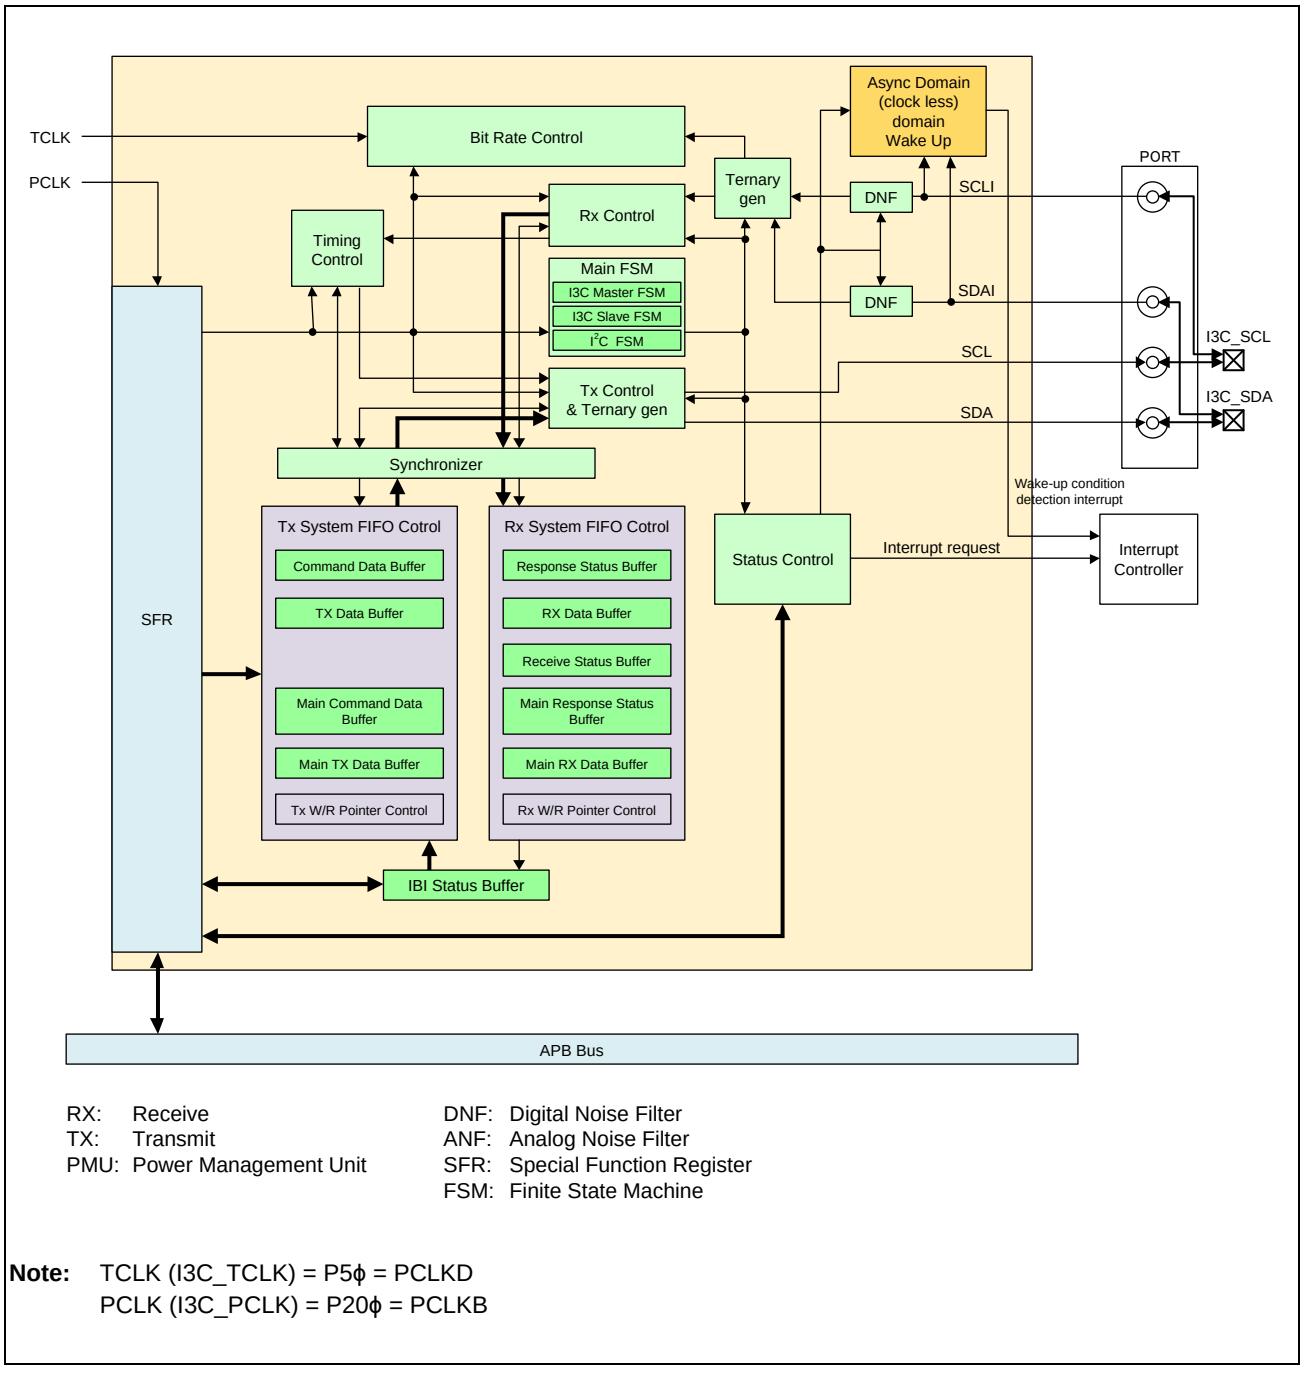
Table 7.8-1 I^2C Specifications (1/2)

Item	Description
Operation mode	Master mode and slave mode selectable
Data handler	Single buffer transfer
Communication protocol	• I^2C bus format – Standard-mode (Sm): Up to 100 kbps – Fast-mode (Fm): Up to 400 kbps – Fast-mode Plus (Fm+): Up to 1 Mbps
Address format	• 7-bit address • 10-bit address
Address detection	• Slave address (static address) (max. 3 address) • General call address • Device ID • Host address • 10-bit slave addressing
Clock stretching	Clock stretching capability
Noise-filter	• Analog noise-filter • Digital noise-filter
Interrupt source	• Rx data buffer full • Tx data buffer empty • START condition detection • STOP condition detection • Transmit end • NACK detection • Arbitration lost • Timeout detection • Wake-up condition detection

Table 7.8-1 I^2C Specifications (2/2)

Item	Description
Error detection	• NACK received • Arbitration lost error • Timeout error
Wake-Up Source	• Address detection of Slave Address

Table 7.8-2 I3C Specifications



Item	Description
Operation mode	Master (main master/secondary master) mode and slave mode selectable.
Data handler	• Master: Normal FIFO buffer transfer • Slave: Normal FIFO buffer transfer
Communication protocol	• SDR (I3C single data rate) mode – Private message – Broadcast message (common command code) – Direct message (common command code) • Legacy I^2C message – Fast-mode (Fm): up to 400 kbps – Fast-mode Plus (Fm+): up to 1 Mbps
In-band interrupt	• Slave interrupt request • Master ship request (secondary master only) • Hot-join event
Address format	7-bit address
Address detection	• Slave address (static address or dynamic address) • Broadcast address (H'7E)
Clock stalling	Clock stalling capability
Timing Control	• Synchronous Timing Control – Sync Mode: Synchronous Basic Mode • Asynchronous Timing Control – Async Mode 0: Asynchronous Basic Mode – Async Mode 1: Asynchronous Advanced Mode
Interrupt source	• Non-recoverable internal error • Transfer error • Transfer abort • Response queue full • Command queue empty • IBI status queue full • Receive data buffer full • Transmit data buffer empty • Receive status queue full • START condition detection • STOP condition detection • Timeout detection • Wake-up condition detection
Error detection	• Non-recoverable internal error • CRC error • Parity error • Frame error • Address header error • Address NACKed or dynamic address assignment NACKed • Receive overflow or transfer underflow error. • Aborted • NACK received for the I^2C write data transfer. • Timeout error
Wake-Up Source	[Master] SDA assert of IBI (START condition detection) [Slave] Address detection of Broadcast Address (H'7E) and Slave Address

Table 7.8-3 I3C I/O Pins

Pin Name	Signal Name in This Section	Input/Output	Functional Description
I3C_SCL	SCL	I/O	Input/output pins for clock
I3C_SDA	SDA	I/O	Input/output pins for data

7.8.1.2 Block Diagram [I²C/I3C common]

Figure 7.8-1 shows the main components of this I3C.

RX: Receive
TX: Transmit
PMU: Power Management Unit

DNF: Digital Noise Filter
ANF: Analog Noise Filter
SFR: Special Function Register

6 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	INCBA	0b	RW	Include I3C Broadcast Address*1 0: Do not include I3C broadcast address for private transfers 1: Include I3C broadcast address for private transfers

Note 1. This bit supports for I3C master mode and I3C secondary master mode.

Note 2. This bit supports for all I3C mode.

INCBA bit (Include I3C Broadcast Address)

This bit controls whether the I3C broadcast address (H’7E) is included for private transfers.

If the I3C broadcast address is not included for private transfers, then IBIs driven from Slaves might not win the arbitration, potentially delaying acceptance of the IBIs.

HJACKCTL bit (Hot-Join Acknowledge Control)

This bit acts as global control to either ACK (0) or NACK (1) all Hot-Join Requests arriving from the Devices on the I3C Bus. If set to NACK (1), then the NACK will be followed by the broadcast CCC to disable Hot-Join.

ABT bit (Abort)

When set to 1, this bit allows I3C to relinquish control of the I3C Bus before completing the currently issued transfer.

In response to an ABORT request, I3C issues the STOP condition on the I3C Bus after the complete data byte is transferred or received.

The Driver shall clear the ABT bit to allow operation on the Bus.

If BCTL.ABT is set and ABORT processing is performed, please ignore ERR_STATUS of Response Descriptor.

RSM bit (Resume)

This bit is used to resume I3C operation following the Halt state.

I3C enters the Halt state (as indicated in register PRSTDBG) as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in register NRSPQP, NRSQP and NIBIQP).

After I3C has entered the Halt state, the application must write the value 1 to the RSM bit to resume I3C operation. I3C shall auto clear the RSM bit once it has resumed making transfers (it has initiated the next Command).

BUSE bit (Bus Enable)

Enables or disables the operation on the I3C Bus by I3C.

Set the BUSE bit to 1 when using I3C. The SCL and SDA pins are placed in the active state when the BUSE bit is set to 1. Set the BUSE bit to 0 when I3C is not to be used. The SCL and SDA pins are placed in the inactive state when the BUSE bit is set to 0.

If the software sets this bit, then it also confirms that initialization is done, and that I3C can use the programmed register values (For example, generation of SCL on IBI detection, etc.). If this bit is not set, then I3C shall not generate SCL for incoming IBI.

Software may disable I3C bus operation while it is active, however:

- If a disabled request occurs while receiving IBI, the actual disabling will not occur until reception of the IBI is complete.
- When the software reads the value 0 from this field, this indicates that I3C bus operation disable operation has completed.
  If commands remain in the command queue, do not set BUSE = 0.

7.8.2.4 Master Device Address Register (MSDVAD)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MDYADV	—	—	—	—	—	—	—	—	MDYAD[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	MDYADV	0b	R/W	Master Dynamic Address Valid 0: The master dynamic address field is not valid. 1: The master dynamic address field is valid.
30 to 23	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
22 to 16	MDYAD[6:0]	All 0	R/W	Master Dynamic Address
15 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

MDYAD[6:0] bits (Master Dynamic Address)

This field is used to program I3C master dynamic address. I3C uses this address to respond to master transactions in I3C interface mode (slave or secondary master role).

In I3C main master mode, the software shall program the dynamic address as it self-assigns its dynamic address.

MDYADV bit (Master Dynamic Address Valid)

This bit indicates whether or not the value in the MDYAD field is valid.

In I3C main master mode, the user sets this bit to 1 as it self-assigns its dynamic address.

NOTE

After setting MSDVAD and setting BCTL. BUSE = 1, the device will act as main master.
Without setting MSDVAD, setting SVDCT.TBCR[7:6] = 00b (Device Role Slave), and setting BCTL.BUSE = 1, the device will act as slave.
Without setting MSDVAD, setting MSDCTm.RBCR[7:6] = 01b (Device Role Master), and setting BCTL.BUSE = 1, the device will act as slave.

7.8.2.5 Reset Control Register (RSTCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTLRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RSQRST	IBIQRST	RDBRST	TDBRST	RSPQRST	CMDQRST	RI3CRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
16	INTLRST	0b	R/W	Internal Software Reset 0: Releases of some registers and internal state. 1: Resets of some registers and internal state.
15 to 13	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
12 to 9	—	All 0	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
8, 7	—	00b	R	Reserved These bits are read as 0. The write value should be 0.
6	RSQRST	0b	R/W	Receive Status Queue Software Reset*2 0: The Receive Status Queue in I3C is not flushed. 1: The Receive Status Queue in I3C is flushed.
5	IBIQRST	0b	R/W	IBI Queue Software Reset*1 0: The IBI Queues in I3C is not flushed. 1: The IBI Queues in I3C is flushed.
4	RDBRST	0b	R/W	Receive Data Buffer Software Reset*1 0: The Receive Queues in I3C is not flushed. 1: The Receive Queues in I3C is flushed.
3	TDBRST	0b	R/W	Transmit Data Buffer Software Reset*1 0: The Transmit Queues in I3C is not flushed. 1: The Transmit Queues in I3C is flushed.
2	RSPQRST	0b	R/W	Response Queue Software Reset*1 0: The Response Queues in I3C is not flushed. 1: The Response Queues in I3C is flushed.
1	CMDQRST	0b	R/W	Command Queue Software Reset*1 0: The Command Queues in I3C is not flushed. 1: The Command Queues in I3C is flushed.
0	RI3CRST	0b	R/W	I3C Software Reset 0: Release I3C reset. 1: Initiate I3C reset.

Note 1. This bit supports for all I3C mode.

Note 2. This bit supports for I3C secondary master mode and I3C slave mode.

For details on reset for each register, refer to **7.8.5 Reset Descriptions**.

RI3CRST bit (I3C Software Reset)

On Driver setting this bit to 1, I3C shall be reset and disabled.

All registers shall return to their reset values, and the software shall re-initialize I3C.

This field is cleared automatically upon I3C reset completion. This field also resets all Queues in I3C.

CMDQRST bit (Command Queue Software Reset)

On software setting this bit to 1, the Command Queues in I3C shall be flushed.

This field shall be cleared automatically upon Command Queue reset completion.

RSPQRST bit (Response Queue Software Reset)

On software setting this bit to 1, the Response Queues in I3C shall be flushed.

This field shall be cleared automatically upon Response Queue reset completion.

TDBRST bit (Transmit Data Buffer Software Reset)

On software setting this bit to 1, the Transmit Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon Transmit Data Buffer reset completion.

RDBRST bit (Receive Data Buffer Software Reset)

On software setting this bit to 1, the Receive Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon completion of Receive Data Buffer reset.

IBIQRST bit (IBI Queue Software Reset)

On software setting this bit to 1, the IBI Queues in I3C shall be flushed.

This field shall be cleared automatically upon completion of IBI Queue reset.

RSQRST bit (Receive Status Queue Software Reset)

On software setting this bit to 1, the Receive Status Queues in I3C shall be flushed. This field shall be cleared automatically upon Receive Status Queue reset completion.

INTLRST bit (Internal Software Reset)

When set to 1, some of registers is reset. For details on the registers to be reset, refer to **7.8.5 Reset Descriptions**.

NOTE

Programming this field while it contains a value of 1 may result in undefined behavior.

7.8.2.6 Present State Register (PRSST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	PRSSTWP	—	—	TRMD	—	CRMS	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	R	R	R	R	R/W*1	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
7	PRSSTWP	0b	W	Present State Write Protect*2 0: CRMS bit is protected. 1: CRMS bit can be written when writing simultaneously with the value of the target bit.
6, 5	—	00b	R	Reserved These bits are read as 0. The write value should be 0.
4	TRMD	0b	R	Transmit/Receive Mode*3 0: Receive mode 1: Transmit mode
3	—	0b	R	Reserved These bits are read as 0. The write value should be 0.
2	CRMS	0b	R/W*1	Current Master*2 0: The Master is not the Current Master and must request and acquire bus ownership before initiating any transfer. 1: The Master is the Current Master, and as a result can initiate transfers.
1, 0	—	00b	R	Reserved These bits are read as 0. The write value should be 0.

Note 1. When the PRSSTWP bit is set to 1, the CRMS bit can be written to.

Note 2. This bit supports for I^2C, I3C master, and I3C secondary master mode.

Note 3. This bit supports for I^2C mode.

CRMS bit (Current Master)

Indicates the set condition and reset condition of each operation mode.

Operation Mode [I^2C/I3C common]

[Clearing conditions]

- When 1 written to the RSTCTL.RI3CRST by the software.
- When 1 written to the RSTCTL.INTLRST by the software.
- When 0 written to the PRSST.CRMS by the software.
- When STOP is issued.
- When Master Arbitration-Lost.

[Setting conditions]

- When 1 written to the PRSST.CRMS by the software.
- When START is issued.

Operation Mode [I3C Main Master]

[Clearing conditions]

- When 0 written to the MSDVAD.MDYADV by the software.
- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Secondary Master.

[Setting conditions]

- When 1 written to the MSDVAD.MDYADV by the software.
- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Secondary Master.

Operation Mode [I3C Secondary Master]

[Clearing condition]

- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Non-Current Master.

[Setting condition]

- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Current Master.

The PRSST register returns I3C current state.

State has two parts: this register, which is mandatory, and an additional optional PRSST_DEBUG register intended for debug purposes (see the Debug Capability Registers in the Extended Capabilities list).

TRMD bit (Transmit/Receive Mode*3)

This bit indicates transmit or receive mode.

I3C is in receive mode when the TRMD bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the CRMS bit indicates the operating mode of I3C.

The value of TRMD bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is issued normally according to the START condition issuance request (when a START condition is detected with the CNDCTL.STCND bit set to 1).
- When a Repeated START condition is issued normally according to the Repeated START condition issuance request (when a Repeated START condition is detected with the CNDCTL.SRCND bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in SVCTL, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- The ALF (arbitration-lost) flag in BST being set to 1.

- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.
- In slave mode, a match between the received address and the address enabled in SVCTL when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a Repeated START condition is detected (a Repeated START condition is detected with BCST.BFREF = 0 and CRMS = 0).

PRSSTWP bit (Present State Write Protect)

PRSSTWP is always 0 when reading.

When writing to PRSST, writing 1 to this bit at the same time enables writing to CRMS bit.

7.8.2.7 Internal Status Register (INST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	INEF	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W*1	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
10	INEF	0b	R/W*1	Internal Error Flag 0: I3C Internal Error has not detected. 1: I3C Internal Error has detected.
9 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

Note: This register supports for all I3C mode.

Note 1. Clearing (to 0) condition: Writing 0 after the 1 state is read.

The Interrupt Status register reflects the status of outstanding interrupt (s).

The status fields are either RW0C (write 0 to clear), or else are cleared based on queue operations.

INEF bit (Internal Error Flag)

When this bit is 1, it indicates that I3C Internal Error has detected.

When this bit is 0, it indicates that I3C Internal Error has not detected.

[Setting conditions]

- The following 1 is satisfied and any of the following 2 to 9 are satisfied.

1. The INSTE.INEE bit = 1
2. When transmit data is written to the Transmit Data Buffer that is completely full.
3. When received data is read from the Receive Data Buffer that is completely empty.
4. When Command Descriptor is written to the Command Queue that is completely full.
5. When Response Descriptor is read from the Response Status Queue that is completely empty.
6. When Receive Status Descriptor is read from the Receive Status Queue that is completely empty.
7. When IBI Status Descriptor is read from the IBI Queue under the condition that the IBI Queue is completely empty and PRSST.CRMS = 1.
8. When IBI Data is written to the IBI Queue under the condition that the IBI Queue is completely full and PRSST.CRMS = 0.
9. When the Response Status Queue, IBI Status Queue or Receive Status Queue overflows.

[Clearing condition]

- When 0 is written to the INEF bit after reading INEF bit = 1.

7.8.2.8 Internal Status Enable Register (INSTE)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	INEE	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
10	INEE	0b	R/W	Internal Error Enable 0: Disable INST.INEF 1: Enable INST.INEF
9 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

Note: This register supports for all I3C mode.

INEE bit (Internal Error Enable)

- When this bit set to 1, it enables detection of I3C Internal Error.
- When this bit set to 0, it disables detection of I3C Internal Error.

7.8.2.9 Internal Interrupt Enable Register (INIE)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	INEIE	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
10	INEIE	0b	R/W	Internal Error Interrupt Enable 0: Disables Non-recoverable Internal Error Interrupt Signal. 1: Enables Non-recoverable Internal Error Interrupt Signal.
9 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

Note: This register supports for all I3C mode.

INEIE bit (Internal Error Interrupt Enable)

When set to 1 and register INEF is set, the hardware Controller asserts an interrupt to the Host.

7.8.2.10 Internal Status Force Register (INSTFC)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	INEFC	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
10	INEFC	0b	W	Internal Error Force 0: Not force a specific interrupt 1: Force a specific interrupt
9 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

Note: This register supports for all I3C mode.

INEFC bit (Internal Error Force)

For debug, helps to force this interrupt.

7.8.2.11 Device Characteristic Table Register (DVCT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	IDX[4:0]					—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are read as 0.
23 to 19	IDX[4:0]	All 0	R	DCT Table Index Current index of the DCT, which is used as the starting index for the I3C ENTDAA CCC.
18 to 0	—	All 0	R	Reserved These bits are read as 0.

Note: This register supports for I3C master mode and I3C secondary master mode.

IDX[4:0] bits (DCT Table Index)

Once the complete characteristics of device that won the arbitration are written to the DCT (during ENTDAA using Address Assignment Command) this index is incremented by 1.

Notes: How to check the progress of ENTDAA using this bit:

1. Read the value of this bit before setting the Command Descriptor for issuing the ENTDAA command.
2. After starting the ENTDAA command, until the value of this bit is updated (that is, it changes from the value read in advance), it indicates that the Dynamic Address is being assigned to the device specified by the first index value (value set in DEV_INDEX [4:0] of Command Descriptor).
3. After the value of this bit is updated, it indicates that Dynamic Address is being assigned according to the value set in DEV_INDEX [4:0] and DEV_COUNT [3:0] of Command Descriptor to the device of the first index value or later.

7.8.2.12 IBI Notify Control Register (IBINCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	NRSIRCTL	—	NRMRCTL	NRHJCTL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
3	NRSIRCTL	0b	R/W	Notify Rejected Slave Interrupt Request Control 0: Do not pass rejected IBI Status to the IBI Queue/Rings, if the incoming SIR is NACKed and is auto disabled based on DVSIRRJ field in relevant DAT entry. 1: Pass rejected IBI Status to the IBI Queue/Rings, if the incoming SIR is NACKed and is auto disabled based on DVSIRRJ field in relevant DAT entry.
2	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
1	NRMRCTL	0b	R/W	Notify Rejected Master Request Control 0: Do not pass rejected IBI Status to IBI Queue/Ring, if the incoming Master Request is NACKed and is auto disabled based on DVMRRJ field in relevant DAT entry. 1: Pass rejected IBI Status to the IBI Queue, if the incoming Master Request is NACKed and is autodisabled based on DVMRRJ field in relevant DAT entry.
0	NRHJCTL	0b	R/W	Notify Rejected Hot-Join Control 0: Do not pass rejected IBI Status to IBI Queue, if the incoming HotJoin request is NACKed and is autodisabled based on field HJACKCTL of BCTL. 1: Pass rejected IBI Status to the IBI Queue, if the incoming Hot Join request is NACKed and is autodisabled based on field HJACKCTL of BCTL.

Note: This register supports for I3C master mode and I3C secondary master mode.

NRHJCTL bit (Notify Rejected Hot-Join Control)

Enables or disables reporting rejection of individual Hot Join requests.

NRMRCTL bit (Notify Rejected Master Request Control)

Enables or disables reporting rejection of individual Master Requests.

NRSIRCTL bit (Notify Rejected Slave Interrupt Request Control)

Enables or disables reporting rejection of individual Slave Interrupt Requests (SIR).

7.8.2.13 Bus Function Control Register (BFCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	HSME	FMPE	—	—	—	—	—	SCSYNE	—	—	—	—	—	SALE	NALE	MALE
Initial Value	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W	R/W	R/W	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15	HSME	0b	R/W	High Speed Mode Enable*1 0: Disable High Speed Mode. 1: Enable High Speed Mode.
14	FMPE	0b	R/W	Fast-mode Plus Enable*1 0: No Fm+ slope control circuit uses for the SCLn pin and SDAn pin. (n = 0) 1: An Fm+ slope control circuit uses for the SCLn pin and SDAn pin. (n = 0)
13	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
12	—	0b	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
11 to 9	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
8	SCSYNE	1b	R/W	SCL Synchronous Circuit Enable*1 0: No SCL synchronous circuit uses. 1: An SCL synchronous circuit uses.
7 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2	SALE	0b	R/W	Slave Arbitration-Lost Detection Enable*1 0: Slave arbitration-lost detection disables. 1: Slave arbitration-lost detection enables.
1	NALE	0b	R/W	NACK Transmission Arbitration-Lost Detection Enable*1 0: NACK transmission arbitration-lost detection disables. 1: NACK transmission arbitration-lost detection enables.
0	MALE	1b	R/W	Master Arbitration-Lost Detection Enable*1 0: Master arbitration-lost detection disables. Disables the arbitration-lost detection function and does not clear the CRMS and TRMD bits in PRSST automatically when arbitration is lost. 1: Master arbitration-lost detection enables. Enables the arbitration-lost detection function and clears the CRMS and TRMD bits in PRSST automatically when arbitration is lost.

Note 1. This bit supports for I^2C mode.

MALE bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCSYNE bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCSYNE bit set to 0 (no SCL synchronous circuit used), I3C does not synchronize the SCL clock with the SCL input clock. In this setting, I3C outputs the SCL clock with the transfer rate set in STDBR and EXTBR regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit uses, it also affects the issuance of a START condition, Repeated START condition, and STOP condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE bit (Fast-mode Plus Enable*[1])

This bit is used to specify whether to use a slope control circuit for Fast mode Plus [Fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control specification (tof) of the I3C-bus is selected. When this bit is set to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast- mode [fm] slope control specification (tof) of the I3C-bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the I3C-bus specification. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [Fm]).

Note: When communicating in Hs-mode, set as follows.
- Set FMPE to 0 when sending Hs-mode master code (0000_1XXXb) with Fast-mode.
- Set FMPE to 1 when sending Hs-mode master code (0000_1XXXb) with Fast-mode Plus.

HSME bit (High Speed Mode Enable)

This bit is used for communicating in Hs-mode.

When this bit is set to 1, the Hs-mode master code is recognized, and Hs-mode communication is possible.

After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from Repeated START after receiving the NACK response.

It communicates at the bit rate set in STDBR until the NACK response, and automatically switches from Repeated START condition issuance after receiving the NACK response to the bit rate set in EXTBR.

Hs-mode continues until a STOP condition is detected.

When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in STDBR.

Note: When this bit is set to 1, the BST.NACKDF bit will not be set even if a NACK response is received after sending the Hs-mode master code.

7.8.2.14 Slave Control Register (SVCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SVAE[2:0]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HOAE	—	—	—	—	—	—	—	—	DVIDE	HSMCE	—	—	—	—	GCAE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
18 to 16	SVAE[2:0]	000b	R/W	Slave Address Enable [2:0]*2 0: Slave [2:0] disables 1: Slave [2:0] enables
15	HOAE	0b	R/W	Host Address Enable*1 0: Host address detection disables. 1: Host address detection enables.
14 to 7	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
6	DVIDE	0b	R/W	Device-ID Address Enable*1 0: Device-ID address detection disables. 1: Device-ID address detection enables.
5	HSMCE	0b	R/W	Hs-mode Master Code Enable*1 0: Hs-mode Master Code Detection disables. 1: Hs-mode Master Code Detection enables.
4 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	GCAE	0b	R/W	General Call Address Enable*1 0: General call address detection disables. 1: General call address detection enables.

Note 1. This bit supports for I^2C mode.

Note 2. These bits support for I^2C, I3C secondary master, and I3C slave mode.

GCAE bit (General Call Address Enable) (y = 0 to 2)

This bit is used to specify whether to ignore the general call address (000_0000 + 0 (write): All 0) when it is received.

- When this bit is set to 1, if the received slave address matches the general call address, I3C recognizes the received slave address as the general call address independently of the slave addresses set in the SVDVADy.SVAD[9:0] bits (n = 0) and performs data receive operation.
- When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

HSMCE bit (Hs-mode Master Code Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (00001xxxb) is received in the first byte after a START condition is detected.

- When this bit is set to 1, if the received first byte matches the Hs-mode master code, IIC recognizes that the Hs-mode master code has been received.
  The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADy.SVAD[9:0].
  If the addresses match, the transmission/reception operation continues according to the R/W# bit value.
  Hs-mode continues until a STOP condition is detected.
- When this bit is set to 0, I3C will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

Note: When this bit is set to 1, SCSTRCTL.ACKTWE bit must be set to 0 and SCSTRCTL.RWE bit must be set to 1.

DVIDE bit (Device-ID Address Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100) is received in the first byte after a START condition or Repeated START condition is detected.

- When this bit is set to 1, if the received first byte matches the Device-ID, I3C recognizes that the Device-ID address has been received. When the following R/W# bit is 0 (write), I3C recognizes the second and the following bytes as slave addresses and continues the receive operation.
- When this bit is set to 0, I3C ignores the received first byte even if it matches the Device ID address and recognizes the first byte as a normal slave address.

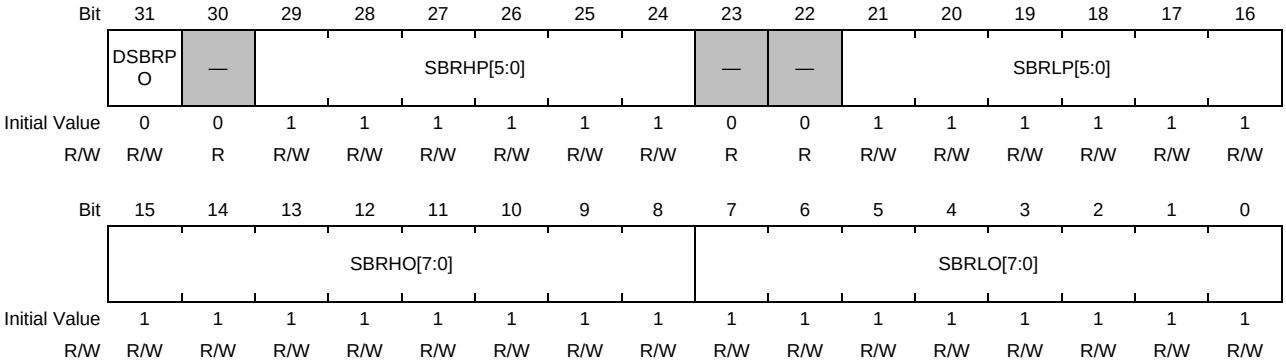
For details on the Device-ID address detection, refer to **7.8.3.2.3(4) (c) Device-ID Address Detection [I2C mode]**.

SVAE[2:0] bits (Slave Address Enable [2:0]) (y = 0 to 2)

This bit is used to enable or disable the slave address set in the SVDVADy.SVAD[9:0] bits.

- When this bit is set to 1, the slave address set in the SVAD[9:0] bits is enabled and is compared with the received slave address.
- When this bit is set to 0, the slave address set in the SVAD[9:0] bits is disabled and is ignored even if it matches the received slave address.

7.8.2.15 Reference Clock Control Register (REFCKCTL)



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	IREFCKS[2:0]*1		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2 to 0	IREFCKS[2:0] *1	000b	R/W	Internal Reference Clock Selection Selects the internal reference clock source (I3Cϕ) for I3C. 0 0 0: PCLKD/1 clock 0 0 1: PCLKD/2 clock 0 1 0: PCLKD/4 clock 0 1 1: PCLKD/8 clock 1 0 0: PCLKD/16 clock 1 0 1: PCLKD/32 clock 1 1 0: PCLKD/64 clock 1 1 1: PCLKD/128 clock

Note 1. Set the IREFCKS[2:0] bit to 000 in I3C mode.

7.8.2.16 Standard Bit Rate Register (STDBR)

Bit	Bit Name	Initial Value	R/W	Description
31	DSBRPO	0b	R/W	Double the Standard Bit Rate Period for Open-Drain*4 0: The time period set for SBRHO[7:0] and SBRLO[7:0] is not doubled. 1: The time period set for SBRHO[7:0] and SBRLO[7:0] is doubled.
30	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
29 to 24	SBRHP[5:0]	All 1	R/W	Standard Bit Rate High-Level Period Push-Pull*3 Count value of the high-level period of SCL clock
23, 22	—	00b	R	Reserved These bits are read as 0. The write value should be 0.
21 to 16	SBRLP[5:0]	All 1	R/W	Standard Bit Rate Low-level Period Push-Pull*2 Count value of the low-level period of SCL clock
15 to 8	SBRHO[7:0]	All 1	R/W	Count value of the High-level period of SCL clock*1
7 to 0	SBRLO[7:0]	All 1	R/W	Count value of the Low-level period of SCL clock*1

Note 1. These bits support for I^2C, I3C master, and I3C secondary master mode.

Note 2. These bits support for I3C master mode and I3C secondary master mode.

Note 3. These bits support for all I3C mode.

Note 4. This bit supports for I^2C, I3C master, and I3C secondary master mode.

The STDBR register sets the bit rate according to the operating speed.

- I^2C mode: Bit rate setting when communicating with Standard-mode / Fast-mode / Fast-mode plus
- I3C master mode: Bit rate setting selected by mode bit of command descriptor
- I3C slave mode: I3C bit rate setting

The I^2C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / {[(High-Level Period + α*1) + (Low-Level Period + α)] / I3Cϕ*2 + SCLn line rising time [tr]*3 + SCLn line falling time [tf]*3}

Duty cycle = {SCLn line rising time [tr] + (High-Level Period + α) / I3Cϕ} / {SCLn line falling time [tf] + (Low-Level Period + α) / I3Cϕ}

Note 1. α depend on the number of stages in the noise filter.

Note 2. I3Cϕ = PCLKD × Division ratio

Note 3. The SCLn line rising time [tr] and SCLn line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I^2C-bus specification from NXP Semiconductors.

The I3C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / [(High-Level Period + Low-Level Period) / I3Cϕ + SCLn line rising time [tr] + SCLn line falling time [tf]]

Duty cycle = [SCLn line rising time [tr] + High-Level Period / I3Cϕ] / [SCLn line falling time [tf] + Low-Level Period / I3Cϕ]

SBRLO[7:0] bits (Count value of the Low-level period of SCL clock)

The SBRLO[7:0] bits are used to set the low-level period of SCL clock in Open-Drain mode.

I3C counts the low-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits. It also works to generate the data setup time for automatic SCL low-hold operation (refer to **7.8.3.2.3 (6) Clock Stretching [I2C mode]**); when I3C is used in I^2C slave mode, these bits need to be set to a value longer than the data setup time*[1].

If the digital noise filter is enabled (INCTL.DNFE = 1), set the SBRLO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: Standard-mode [Sm])
100 ns (up to 400 kbps: Fast-mode [Fm])
50 ns (up to 1 Mbps: Fast-mode plus [Fm+])
10 ns (up to 3.4 Mbps: Hs-mode [HS])

SBRHO[7:0] bits (Count value of the High-level period of SCL clock)

The SBRHO[7:0] bits use to set the high-level period of SCL clock in Open-Drain mode. SBRHO[7:0] bits are valid in master mode. If I3C is used only in I^2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRLP[5:0] bits (Standard Bit Rate Low-level Period Push-Pull)

SBRLP[5:0] bits are used to set the low-level period of SCL clock in Push-Pull.

I3C counts the low-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRLP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRHP[5:0] bits (Standard Bit Rate High-Level Period Push-Pull)

SBRHP[5:0] bits is used to set the high-level period of SCL clock in Push-Pull mode.

SBRHP[5:0] bits are valid in master mode. If I3C is used only in I^2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

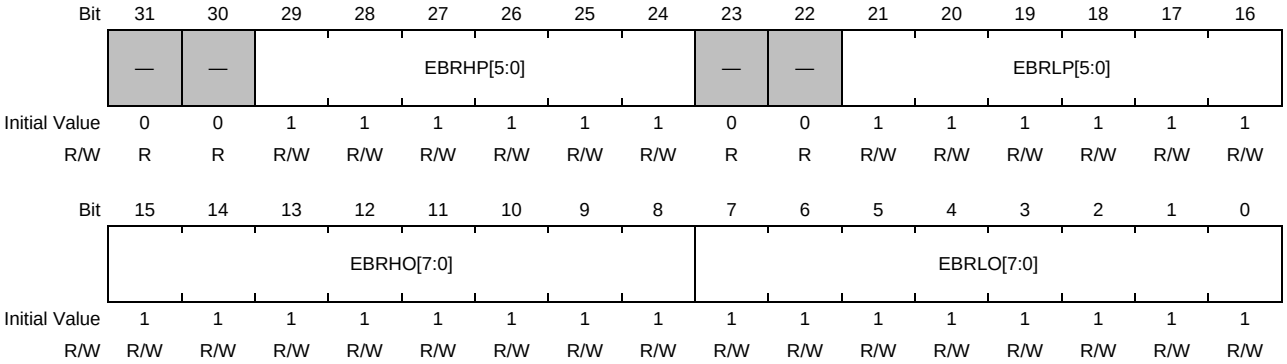
DSBRPO bit (Double the Standard Bit Rate Period for Open-Drain)

When DSBRPO = 1, double the high-level period that is set in SBRHO[7:0] and double the low-level period that is set in SBRLO[7:0].

Table 7.8-5 Requirement and Usage of Setting in Each Mode

	Device Mode				
Bit Name	I^2C Master	I^2C Slave	I3C Master	I3C Secondary Master	I3C Slave
SBRHP[5:0]	do not use	do not use	Setting required*3	Setting required*4	do not use
SBRLP[5:0]	do not use	do not use	Setting required*3	Setting required*5	do not use
SBRHO[7:0]	Setting required*1	do not use	Setting required*3	Setting required*5	do not use
SBRLO[7:0]	Setting required*1	Setting required*2	Setting required*3	Setting required*5	do not use

Note 1. The setting value is used for the data rate of ST, FM, and FM+ mode.



Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation.

Note 3. The setting value is used for the data rate of each communication.

Note 4. When operating with I3C Master, the setting value is used for the data rate of each communication.

Note 5. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, do not use.

7.8.2.17 Extended Bit Rate Register (EXTBR)

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	00b	R	Reserved These bits are read as 0. The write value should be 0.
29 to 24	EBRHP[5:0]	All 1	R/W	Extended Bit Rate Low-Level Period Push-Pull*2 Count value of the high-level period of SCL clock
23, 22	—	00b	R	Reserved These bits are read as 0. The write value should be 0.
21 to 16	EBRLP[5:0]	All 1	R/W	Extended Bit Rate Low-Level Period Push-Pull*2 Count value of the low-level period of SCL clock
15 to 8	EBRHO[7:0]	All 1	R/W	Extended Bit Rate High-Level Period Open-Drain*1 Count value of the high-level period of SCL clock
7 to 0	EBRLO[7:0]	All 1	R/W	Extended Bit Rate Low-Level Period Open-Drain*1 Count value of the low-level period of SCL clock

Note 1. These bits support for I^2C, I3C master, and I3C secondary master mode.

Note 2. These bits support for I3C master mode and I3C secondary master mode.

The EXTBR register sets the bit rate according to the operating speed.

- I^2C mode: Bit rate setting for communicating in high-speed mode
- I3C master mode: Bit rate setting selected by mode bit of command descriptor
- I3C slave mode: unused

EBRLO[7:0] bits (Extended Bit Rate Low-Level Period Open-Drain)

Refer to SBRLO[7:0] bits of **7.8.2.16 Standard Bit Rate Register (STDBR)** for details. Watch SBRHO, SBRLO as EBRHO[7:0], EBRLO[7:0].

EBRHO[7:0] bits (Extended Bit Rate High-Level Period Open-Drain)

Refer to SBRHO[7:0] bits of **7.8.2.16 Standard Bit Rate Register (STDBR)** for details. Watch SBRHO, SBRLO as EBRHO[7:0], EBRLO[7:0].

EBRLP[5:0] bits (Extended Bit Rate Low-Level Period Push-Pull)

Refer to SBRLP[5:0] bits of **7.8.2.16 Standard Bit Rate Register (STDBR)** for details. Watch SBRHP, SBRLP as EBRHP[5:0], EBRLP[5:0].

EBRHP[5:0] bits (Extended Bit Rate Low-Level Period Push-Pull)

Refer to SBRHP[5:0] bits of **7.8.2.16 Standard Bit Rate Register (STDBR)** for details. Watch SBRHP, SBRLP as EBRHP[5:0], EBRLP[5:0].

Table 7.8-6 Requirement and Usage of Setting in Each Mode

Bit Name	Device Mode				
	I^2C Master	I^2C Slave	I3C Master	I3C Secondary Master	I3C Slave
EBRHP[5:0]	do not use	do not use	Setting required*2	Setting required*3	do not use
EBRLP[5:0]	do not use	do not use	Setting required*2	Setting required*3	do not use
EBRHO[7:0]	Setting required*1	do not use	Setting required*2	Setting required*3	do not use
EBRLO[7:0]	Setting required*1	do not use	Setting required*2	Setting required*3	do not use

Note 1. The setting value is used for the data rate of High-Speed mode.

Note 2. The setting value is used for the data rate of each communication.

Note 3. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, do not use.

7.8.2.18 Bus Free Condition Detection Time Register (BFRECDT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
8 to 0	FRECYC[8:0]	All 0	R/W	Bus Free Condition Detection Cycle The count value is a period for detecting the Bus free condition.

FRECYC[8:0] bits (Bus Free Condition Detection Cycle)

I3C counts the period for detecting the Bus free condition with the I3Cϕ.

These bits set the Bus Free period. This Bus Free period is counted by the internal reference clock (I3Cϕ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BFREF flag for Bus Free detection behavior.

7.8.2.19 Bus Available Condition Detection Time Register (BAVLCDT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
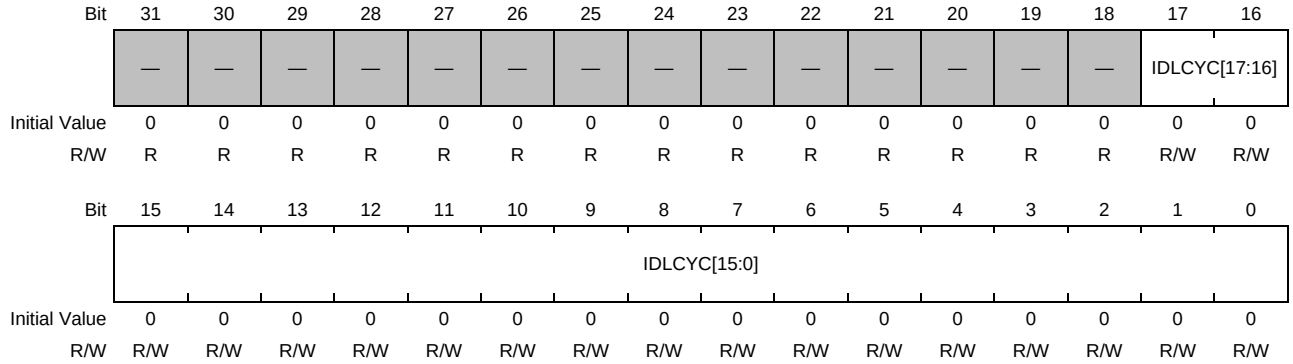
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
8 to 0	AVLCYC[8:0]	All 0	R/W	Bus Available Condition Detection Cycle The count value is a period for detecting the Bus available condition.



Note: This register supports for all I3C mode.

AVLCYC[8:0] bits (Bus Available Condition Detection Cycle)

I3C counts the period for detecting the Bus available condition with the I3Cϕ.

These bits set the Bus Available period. This Bus Available period is counted by the internal reference clock (I3Cϕ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BAVLF flag for Bus Available detection behavior.

7.8.2.20 Bus Idle Condition Detection Time Register (BIDLCDT)

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
17 to 0	IDLCYC[17:0]	All 0	R/W	Bus Idle Condition Detection Cycle The count value is a period for detecting the Bus idle condition.

Note: This register supports for all I3C mode.

IDLCYC[17:0] bits (Bus Idle Condition Detection Cycle)

I3C counts the period for detecting the Bus idle condition with the I3Cϕ.

These bits set the Bus Idle period. This Bus Idle period is counted by the internal reference clock (I3Cϕ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BIDLF flag for Bus Available detection behavior.

7.8.2.21 Output Control Register (OUTCTL)

7 to 5	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
4	EXCYC	0b	R/W	Extra SCL Clock Cycle Output*3 The EXCYC bit is cleared automatically after one clock cycle is output. 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle.
3	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
2	SOCWP	0b	W	SCL/SDA Output Control Write Protect*1 0: Bits SCOC and SDOC are protected. 1: Bits SCOC and SDOC can be written (When writing simultaneously with the value of the target bit). This bit is read as 0.

Bit	Bit Name	Initial Value	R/W	Description
1	SCOC	1b	R/W	SCL Output Control*1 High level output is achieved through an external pull-up resistor. 0: I3C drives the SCLn pin low. 1: I3C releases the SCLn pin.
0	SDOC	1b	R/W	SDA Output Control*1 0: I3C drives the SDAn pin low. 1: I3C releases the SDAn pin.

Note 1. This bit supports for I^2C, I3C master, and I3C secondary master mode.

Note 2. These bits support for I^2C mode.

Note 3. This bit supports for I^2C mode.

Note 4. The setting SDODCS = 1 (I3Cϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting SDODCS = 1 becomes invalid and the clock source becomes the internal reference clock (I3Cϕ).

SDOC bit (SDA Output Control) and SCOC bit (SCL Output Control)

These bits are used to directly control the SDAn and SCLn signals output from this module.

When writing to these bits, also write 1 to the SOCWP bit at the same time.

The result of setting these bits is input to I3C via the input buffer. When slave mode is selected, a START condition may be detected, and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, Repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

EXCYC bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, refer to **7.8.3.2.3(11) (a) Extra SCL Clock Cycle Output Function**.

7.8.2.22 Input Control Register (INCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
7, 6	—	11b	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
5	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
4	DNFE	1b	R/W	Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.
3 to 0	DNFS[3:0]	All 0	R/W	Digital Noise Filter Stage Selection H'0: Noise of up to one I3Cϕ cycle is filtered out (singlestage filter). H'1: Noise of up to two I3Cϕ cycles is filtered out (2-stage filter). H'2: Noise of up to three I3Cϕ cycles is filtered out (3-stage filter). H'3: Noise of up to four I3Cϕ cycles is filtered out (4-stage filter). H'4: Noise of up to five I3Cϕ cycles is filtered out (5-stage filter). ⋮ H'F: Noise of up to sixteen I3Cϕ cycles is filtered out (16-stage filter).

Note: This register supports for I²C mode.

DNFS[3:0] bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, refer to **7.8.3.2.6 (3) Digital Noise-Filter Circuits [I2C mode]**.

In I²C High Speed mode, the module changes the number of noise filter stage to a quarter of the number of noise filter stage automatically.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCLn line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or low-level period, whichever is shorter) - [1.5 internal reference clock (I3Cϕ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of I3C, which may prevent I3C from operating normally.

Note: In I²C High Speed mode, the lower 2 bits of the DNFS[3:0] bits are ignored, and the number of filter stages for 1 to 4 stages is selected by the upper 2 bits.

7.8.2.23 Timeout Control Register (TMOCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
7, 6	TOMDS[1:0]	00b	R/W	Timeout Operation Mode Selection 00: Timeout is detected during the following conditions: • The bus is busy (BCST.BFREF = 0) in master mode. • I3C's own slave address is detected, and the bus is busy in slave mode. • The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1). 01: Timeout is detected while the bus is busy. 10: Timeout is detected while the bus is free. 11: Setting prohibited
5	TOHCTL	1b	R/W	Timeout H Count Control 0: Count is disabled while the SCLn line is at a high level. 1: Count is enabled while the SCLn line is at a high level.
4	TOLCTL	1b	R/W	Timeout L Count Control 0: Count is disabled while the SCLn line is at a low level. 1: Count is enabled while the SCLn line is at a low level.
3, 2	—	00b	R	Reserved These bits are read as 0. The write value should be 0.
1, 0	TODTS[1:0]	00b	R/W	Timeout Detection Time Selection 0 0: 16bit-timeout 0 1: 14bit-timeout 1 0: 8bit-timeout 1 1: 6bit-timeout

TODTS[1:0] bits (Timeout Detection Time Selection)

These bits are used to select for the timeout detection time when the timeout function is enabled (BSTE.TODE bit = 1).

- When these bits are set to 00b, the timeout detection internal counter functions as a 16-bit counter.
- When these bits are set to 01b, the counter functions as a 14-bit counter.
- When these bits are set to 10b, the counter functions as a 8-bit counter.
- When these bits are set to 11b, the counter functions as a 6-bit counter.

While the SCLn line is in the state that enables this counter as specified by bits TOHCTL and TOLCTL, the counter counts up in synchronization with the internal reference clock (I3Cϕ) as a count source.

For details on the timeout function, refer to **7.8.3.2.4 (3) Timeout Error Detection**.

TOLCTL bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held low when the timeout function is enabled (BSTE.TODE = 1).

TOHCTL bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held high when the timeout function is enabled (BSTE.TODE = 1).

TOMDS[1:0] bits (Timeout Operation Mode Selection)

These bits are used to select the detection condition for timeout when the timeout function is enabled.

NOTE

When working with I^2C Slave, during 10-bit address communication, the timeout count starts when the upper address match is detected.

7.8.2.24 Wake Up Unit Control Register (WUCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial Value	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
7	WUFE	0b	R/W	Wake Up function enable 0: Wake-up function disables 1: Wake-up function enables. Do not set WUFE = 0 during WakeUp operation.
6	WUFSYNE	1b	R/W	Wake-Up function Synchronous Enable 0: This IP asynchronous circuit enable 1: This IP synchronous circuit enable
5	—	0b	R	Reserved These bits are read as 0. The write value should be 0.
4	WUANFS	0b	R/W	Wake-Up Analog Noise Filter Selection*1 0: Do not add the Wake-Up analog filter. 1: Add the Wake-Up analog filter.
3 to 1	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
0	WUACKS	1b	R/W	Wake-Up Acknowledge Selection Choice of four response mode with a combination of RSTCTL.INTLRST bit and WUACKS bit. Shown in the **Table 7.8-7**.

Note 1. This bit supports I^2C mode.

Table 7.8-7 Wake-Up Mode

INTLRST	WUACKS	Operation Mode	Description
0	0	Normal Wake-Up mode 1	ACK response at 9th SCL and SCL low hold after at 9th SCL.
0	1	Normal Wake-Up mode 2	No ACK response immediately and SCL low hold between 8th and 9th SCL. Release SCL low hold and ACK response at 9th SCL.
1	0	Command recovery mode	ACK response at 9th SCL and not SCL low hold.
1	1	EEP response mode	NACK response at 9th SCL and not SCL low hold.

WUFSYNE bit (Wake-Up function PCLK synchronous enable bit)

This bit is used to switch between the PCLK synchronous operation and the PCLK asynchronous operation.

The bit is used in combination with the WUASYNF flag at Wake-Up effective function (WUCTL.WUFE bit = 1).

[When switching from the PCLK synchronous operation to the PCLK asynchronous operation]

This IP operation changes into the PCLK asynchronous operation during BCST.BFREF flag = “1”, when the WUASYNF flag set to “1” during WUFSYNE bit = “0”.

The reception can operate without depending on the state of operation of PCLK (With PCLK stopped) after it switches to the PCLK asynchronous operation (Wake-Up event detection operation).

[When switching from the PCLK asynchronous operation to the PCLK synchronous operation]

- This IP operation changes into the PCLK synchronous operation at the following conditions.
  (At the same timing when WUASYNF flag becomes “0”)
  - In the case Wake-Up event detects: right after WUFSYNE bit is set to “1”.
  - In the case Wake-Up event does not detect: when STOP condition is detected after WUFSYNE bit is set to “1”.

[Setting condition]

- When 1 is written to the WUFSYNE bit.
- WUCTL.WUFE = 0

[Clearing conditions]

- When 0 is written to the WUFSYNE bit.

7.8.2.25 Acknowledge Control Register (ACKCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ACKTWP	ACKT	ACKR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2	ACKTWP	0b	W	ACKT Write Protect 0: The ACKT bit are protected. 1: The ACKT bit can be written (when writing simultaneously with the value of the target bit). This bit is read as 0.
1	ACKT	0b	R/W	Acknowledge Transmission 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).
0	ACKR	0b	R	Acknowledge Reception 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).

Note: This register supports for I^2C mode.

ACKR bit (Acknowledge Reception)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the PRSST.TRMD bit set to 1.

[Clearing condition]

- When 0 is received as the acknowledge bit with the PRSST.TRMD bit set to 1.

ACKT bit (Acknowledge Transmission)

[Setting condition]

- When 1 is written to the ACKT bit and 1 is written to the ACKTWP bit at the same time.

[Clearing conditions]

- When 0 is written to the ACKT bit and 1 is written to the ACKTWP bit at the same time.
- When a STOP condition is detected. (When a STOP condition is detected with the CNDCTL.SPCND bit set to 1.)

Note: Set the ACKT bit to 0 in I^2C Slave mode.

ACKTWP bit (ACKT Write Protect)

This bit is used to control the modification of the ACKT bit.

When changing the ACKT bit, setting this bit to 1 at the same time can change the ACKT bit.

When this bit is read, 0 is always read.

7.8.2.26 SCL Stretch Control Register (SCSTRCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RWE	ACKTWE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
1	RWE	0b	R/W	Receive Wait Enable 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low hold is released by reading NTDTBP0NTDTBP.
0	ACKTWE	0b	R/W	Acknowledge Transmission Wait Enable 0: NTST.RDBFF0 is set at the rising edge of the ninth SCL clock cycle. (The SCLn line is not held low at the falling edge of the eighth clock cycle.) 1: NTST.RDBFF0 is set at the rising edge of the eighth SCL clock cycle. (The SCLn line is held low at the falling edge of the eighth clock cycle.) Low hold is released by writing a value to the ACKCTL.ACKT bit.

Note: This register supports for I^2C mode.

ACKTWE bit (Acknowledge Transmission Wait Enable)

This bit is used to select the NTST.RDBFF0 flag set timing in receive mode and also to select whether to hold the SCLn line low at the falling edge of the eighth SCL clock cycle.

- When ACKTWE = 0, the SCLn line is not held low at the falling edge of the eighth SCL clock cycle, and the NTST.RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.
- When ACKTWE = 1, the NTST.RDBFF0 flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCLn line is held low at the falling edge of the eighth SCL clock cycle. The low hold of the SCLn line is released by writing a value to the ACKCTL.ACKT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKCTL.ACKT = 0) or NACK (ACKCTL.ACKT = 1) according to receive data.

RWE bit (Receive Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (NTDTBP0) is completely read each time single-byte data is received in receive mode.

- When RWE = 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the ACKTWE and RWE bits = 0, continuous receive operation is enabled with the double buffer.
- When RWE = 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the NTDTBP0 value is read each time single-byte data is received.

This enables receive operation in byte units.

Note: When the value of the RWE bit is to be read, be sure to read the NTDTBP0 beforehand.

7.8.2.27 SCL Stalling Control Register (SCSTLCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ACKPE	PARPE	—	AAPE	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	ACKPE	0b	R/W	ACK phase Enable Stall enable bit during ACK/NACK phase 0: Does not stall the SCL clock during the ACK/NACK phase. 1: Stall the SCL clock during the ACK/NACK phase.
30	PARPE	0b	R/W	Parity Phase Enable Stall enable bit in parity bit period 0: Does not stall the SCL clock during the parity bit period. 1: Stall the SCL clock during the parity bit period.
29	—	0b	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
28	AAPE	0b	R/W	Assigned Address Phase Enable Enable bit that allows stall by the first bit at address assignment 0: Does not stall the SCL clock during the address assignment phase. 1: Stall the SCL clock during address assignment phase.
27 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15 to 0	STLCYC [15:0]	All 0	R/W	Stalling Cycle Counter setting of stall period (I3Cϕ cycle). Common use for each phase.

Note: This register supports for I3C master mode and I3C secondary master mode.

When setting this register, follow *Chapter 5.1.2.5 Master Clock Stalling of MIPI I3C Spec V1.0*, and use it only when necessary, because of its negative impacts on bus performance.

STLCYC[15:0] bits (Stalling Cycle)

These bits set the SCL stall period. The SCL stall period is counted by the internal reference clock (I3Cϕ). This is a counter common to the enable bits of each phase.

AAPE bit (Assigned Address Phase Enable)

The master can stall SCL during the low period of the first bit of the assigned address phase of the Enter Dynamic Address Assignment CCC command. It can gain time in assigning dynamic address to the device based on the BCR and DCR of the slave. However, because the Dynamic Address Assignment procedure sends the dynamic address set in the DATBASm register in sequence, it is not necessary to set this bit and it is prohibited.

PARPE bit (Parity Phase Enable)

The parity bit of the transmission data of I3C write transfer can be used for SCL stalling to avoid underrun of the transmission data FIFO. However, when the transmission data FIFO of the I3C master becomes empty, SCL stalling is performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited. It is necessary to set this bit when the I3C slave requires preparation time to receive data.

ACKPE bit (ACK phase Enable)

Determine the need to perform SCL stalling in the ACK/NACK phase based on the following criteria:

- It is necessary to set this bit when the I3C and I^2C slaves connected to the bus require preparation time to receive or transmit data.
- In legacy I^2C communication, if there is a possibility that the data FIFO of the I3C master might underrun or overflow, it is not necessary to set this bit because SCL Stalling is performed by FIFO Empty or Full regardless of the setting of this bit.
- Other than legacy I^2C communication, the data FIFO of I3C master might underrun or overflow, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overflow due to the interrupt generated according to the FIFO threshold setting (NQTHCTL, NTBTHCTL, NRQTHCTL).
- When I3C master responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by BCTL.HJACK, DATBASm.DVMRRJ and DATBASm.DVS IRRJ.
- It is necessary to set this bit when the I3C slave connected to the bus requires preparation time to transmit data for Direct GET CCC.

7.8.2.28 Slave Transfer Data Length Register 0 (SVTDLG0)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	ATCE	0b	R/W	Asynchronous Timing Counter Enable for MREF, MC2, SC1, SC2. 0: Disable 1: Enable

7.8.2.33 Condition Control Register (CNDCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SPCND	SRCND	STCND
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2	SPCND	0b	R/W	STOP (P) Condition Issuance 0: Does not request to issue a STOP condition. 1: Requests to issue a STOP condition.
1	SRCND	0b	R/W	Repeated START (Sr) Condition Issuance 0: Does not request to issue a Repeated START condition. 1: Requests to issue a Repeated START condition.
0	STCND	0b	R/W	START (S) Condition Issuance 0: Does not request to issue a START condition. 1: Requests to issue a START condition.

Note: This register supports for I^2C mode.

STCND bit (START (S) Condition Issuance)

This bit is used to request transition to master mode and issuance of a START condition.

For details on the START condition issuance, refer to **7.8.3.2.3 (3) START Condition / Repeated START Condition / STOP Condition Issuing Function**.

[Setting condition]

- When 1 is written to the STCND bit

[Clearing conditions]

- When 0 is written to the STCND bit
- When a START condition has been issued (A START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state). Note that arbitration may be lost due to a START condition issuance error if the STCND bit is set to 1 (START condition issuance request) when the BFREF flag is set to 0 (bus busy state).

SRCND bit (Repeated START (Sr) Condition Issuance)

This bit is used to request that a Repeated START condition be issued in master mode.

When this bit is set to 1 to request to issue a Repeated START condition, a Repeated START condition is issued when the BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the Repeated START condition issuance, refer to **7.8.3.2.3 (3) START Condition / Repeated START Condition / STOP Condition Issuing Function**.

[Setting condition]

- When 1 is written to the SRCND bit with the BCST.BFREF flag set to 0

[Clearing conditions]

- When 0 is written to the SRCND bit
- When a Repeated START condition has been issued (A Repeated START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Do not set the SRCND bit to 1 while issuing a STOP condition.
If 1 (requests to issue a Repeated START condition) is written to the SRCND bit in slave mode, the Repeated START condition is not issued but the SRCND bit remains set to 1.
If the operating mode changes to master mode with the bit not being cleared, note that the Repeated START condition may be issued.

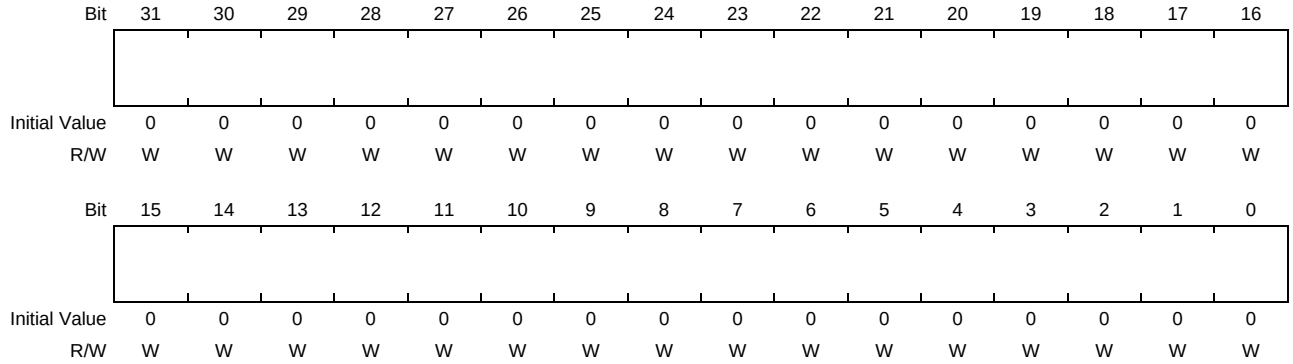
SPCND bit (STOP (P) Condition Issuance)

This bit is used to request that a STOP condition be issued in master mode.

When this bit is set to 1 to request to issue a STOP condition, a STOP condition is issued when the BCST.BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the STOP condition issuance, refer to **7.8.3.2.3 (3) START Condition / Repeated START Condition / STOP Condition Issuing Function**.

[Setting condition]



- When 1 is written to the SPCND bit with the BCST.BFREF flag set to 0 and the PRSST.CRMS bit set to 1

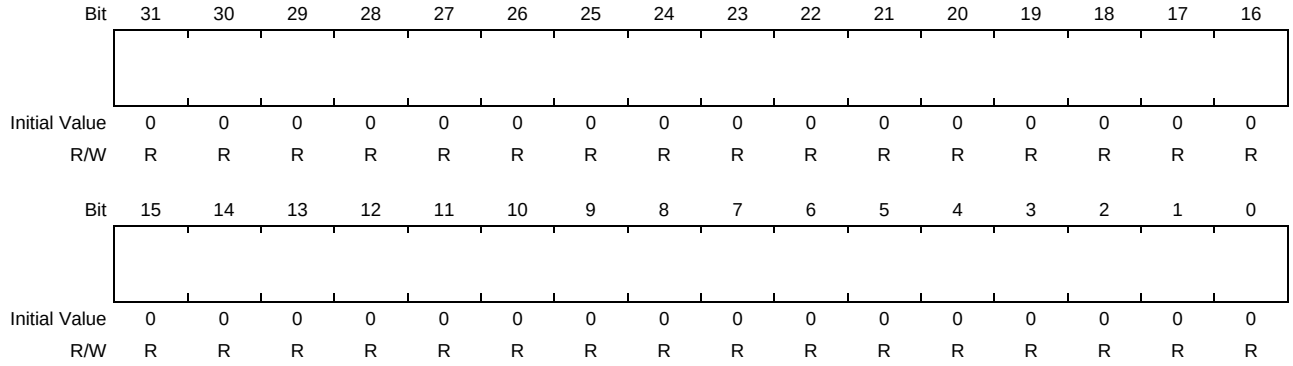
[Clearing conditions]

- When 0 is written to the SPCND bit
- When a STOP condition has been issued (A STOP condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1
- When a START condition and a Repeated START condition are detected

Note: Writing to the SPCND bit is not possible while the setting of the BCST.BFREF flag = 1 (bus free state).
Do not set the SPCND bit to 1 while a Repeated START condition is being issued.

7.8.2.34 Normal Command Queue Port Register (NCMDQP)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	W	Normal Command Queue Port



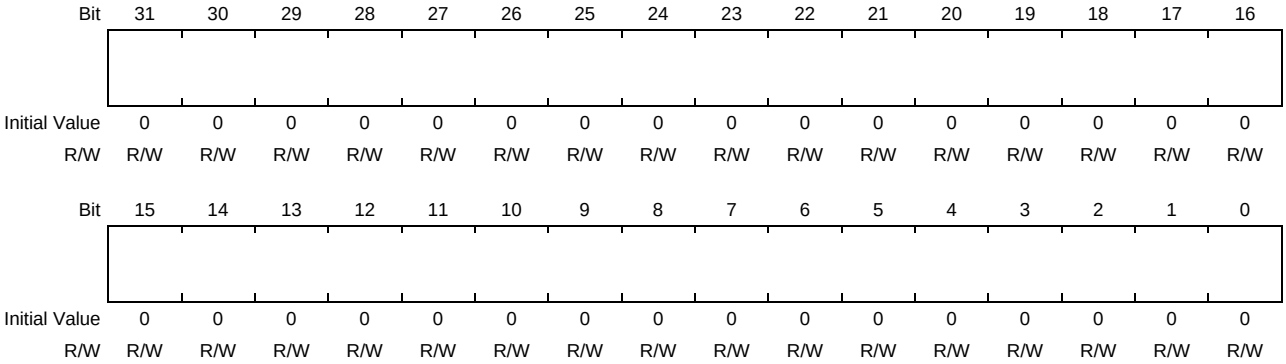
Note: This register supports for all I3C mode.

32-bit mailbox register NCMDQP contains a command descriptor structure that depends on the requested transfer type:

1. Address Assignment Command (refer to **7.8.3.1.1 (1) Address Assign Command**)
2. Immediate Data Transfer (refer to **7.8.3.1.1 (2) Immediate Transfer Command**)
3. Regular Data Transfer (refer to **7.8.3.1.1 (3) Regular Transfer Command**)
4. Write + Write/Read Combo Transfer (refer to **7.8.3.1.1 (4) Combo Transfer Command**)
5. Internal Control Command (refer to **7.8.3.1.1 (5) Internal Control Command**)

Within the command descriptor, DWORDs appear starting with the Least Significant DWORD, in order until the Most Significant DWORD.

7.8.2.35 Normal Response Queue Port Register (NRSPQP)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R	Normal Response Queue Port

Note: This register supports for all I3C mode.

32-bit mailbox register NRSPQP contains a response structure (refer to **7.8.3.1.2 Response Descriptor**).

7.8.2.36 Normal Transfer Data Buffer Port Register 0 (NTDTBP0/NTDTBP0_BY)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R/W	Normal Transfer Data Buffer Port NTDTBP0 is a 32-bit read/write register. NTDTBP0_BY (NTDTBP0[7:0]) is a 8-bit read/write register.

Note: NTDTBP0 is 32-bit access in I3C mode.
NTDTBP0_BY is 8-bit access in I^2C mode.

32-bit mailbox register NTDTBP0 is a 32-bit bi-directional data transfer register which is used both to read from the Normal Receive Data Buffer, and to write to the Normal Transmit Data Buffer.

In other words, the Normal Receive Data Buffer and the Normal Transmit Data Buffer have the same offset, forming a single bidirectional port for transmitting or receiving I3C data.

Read Operations:

[I3C protocol mode]

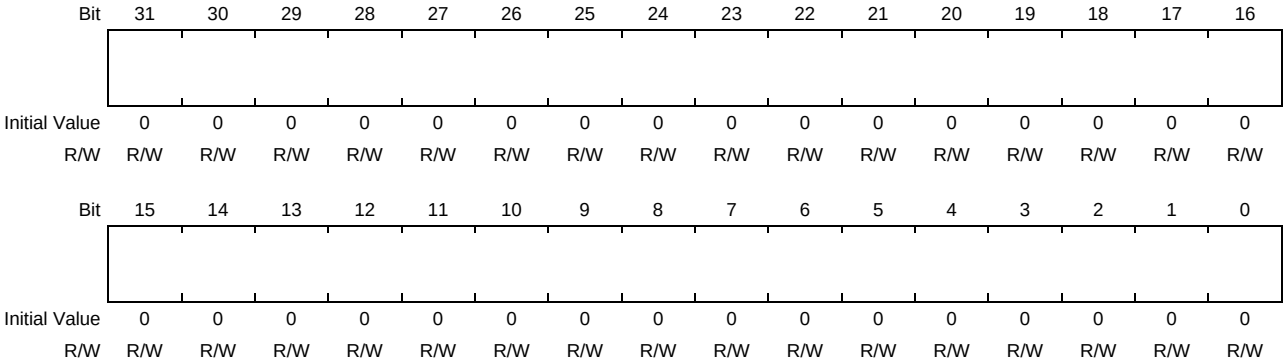
Data Read from the Normal Receive Data Buffer. Its should be read based on Normal Queue Status Level indications. The Receive data is always aligned to a 4-byte boundary and stored in the Normal Receive Data Buffer. If the length of the data transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. The valid data must be identified using the DATA_LENGTH field in the Response Descriptor.

[I^2C protocol mode]

When 1 byte of data has been received, the received data is transferred from the internal shift register to NTDTBP0 to enable the next data to be received. The double-buffer structure of the internal shift register and NTDTBP0 allows continuous receive operation if the received data has been read from NTDTBP0 while the internal shift register is receiving data. Read data from NTDTBP0 once when a receive data full interrupt (I3Cn_RX) request is generated. If NTDTBP0 receives the next receive data before the current data is read from NTDTBP0 (while the RDBFF0 flag in NTST is 1), this module automatically holds the SCL clock low one cycle before the RDBFF0 flag is set to 1 next. The lower 8 bits of the read 32-bit data are valid as received data.

Write Operations:

[I3C protocol mode]



Data Written to the Normal Tx Data Buffer. Data DWORDs written to the Normal Transmit Data Buffer are placed onto the I3C bus one byte at a time, with the DWORD LSB first. Within each byte, bits are placed onto the I3C bus in big-endian order, with bit 7 going out first on the bus. The transmit data should always start aligned to a 4-byte boundary and written to the NTDTBP0 register. If the length of the transfer is not aligned to a 4-byte boundary, then

there will be extra (unused) bytes at the end of the transferred data. I3C shall only send the valid number of bytes indicated in the DATA_LENGTH field of the Command Descriptor.

[I^2C protocol mode]

When NTDTBP0 detects a space in the internal shift register, it transfers the transmit data that has been written to NTDTBP0 to the internal shift register and starts transmitting data in transmit mode. The double-buffer structure of NTDTBP0 and the internal shift register allows continuous transmit operation if the next transmit data has been written to NTDTBP0 while the the internal shift register data is being transmitted. Write transmit data to NTDTBP0 once when a transmit data empty interrupt (I3Cn_TX) request is generated. The lower 8 bits of the written 32-bit data are valid as transmission data.

7.8.2.37 Normal IBI Queue Port Register (NIBIQP)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R/W	Normal IBI Queue Port

Note: This register supports for all I3C mode.

When receiving an IBI, 32-bit mailbox register NIBIQP is used for both:

- Read the IBI status descriptor (refer to **7.8.3.1.3 IBI Status Descriptor**)
- Read the IBI data (which is raw/opaque data).

The IBI status descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C bus.

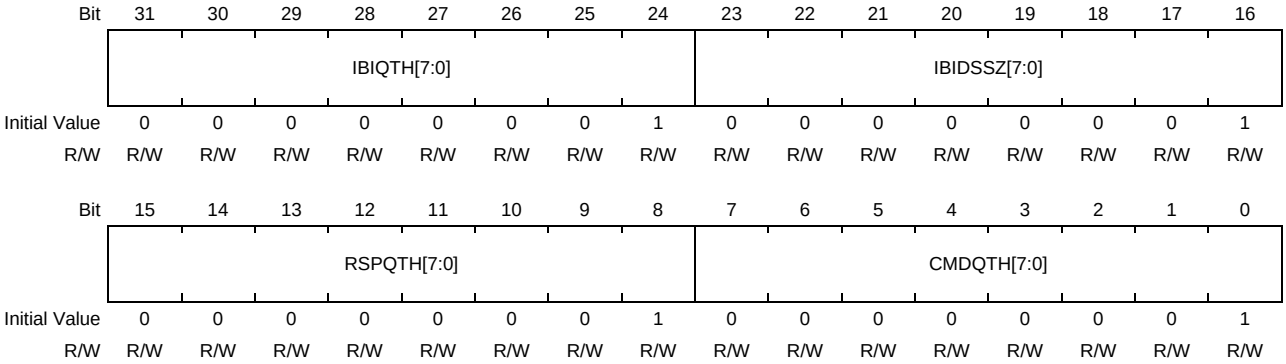
NOTE

If the I3C HCI auto-read feature is used, then the IBI data includes the data received from the auto-generated private read operation.

Even if LAST_STATUS is set to 0, the driver software still evaluates the data payload length by examining the CHUNKS field.

7.8.2.38 Normal Receive Status Queue Port Register (NRSQP)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R	Normal Receive Status Queue Port

Note: This register supports for I3C secondary master mode and I3C slave mode.

32-bit mailbox register NRSQP contains a receive status structure (refer to **7.8.3.1.4 Receive Status Descriptor**).

7.8.2.39 Normal Queue Threshold Control Register (NQTHCTL)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	IBIQTH[7:0]	H'01	R/W	Normal IBI Queue Threshold*1 H'00: I3C Protocol mode (Master): Interrupt is generated when the Outstanding IBI Status count is 1 or more. I3C Protocol mode (Slave): Interrupt is issued when IBI Data Buffer is completely empty. Others: I3C Protocol mode (Master): Interrupt is generated when the Outstanding IBI Status count is N + 1 or more. (N = CMDQTH[7:0]) I3C Protocol mode (Slave): Interrupt is issued when IBI Data Buffer contains N empties.
23 to 16	IBIDSSZ[7:0]	H'01	R/W	Normal IBI Data Segment Size*2 Supported Values: Minimum: 1 (4 bytes) Maximum: 63 (252 bytes), provided that the configured IBI Queue depth is 64 or more. When ATCCNTE.ATCE = 1, restrict to the number of slices ≥ 2.
15 to 8	RSPQTH[7:0]	H'01	R/W	Normal Response Queue Threshold*1 H'00: Interrupt is issued when Response Queue contains 1 entry (DWORD). Others: Interrupt is triggered when Response Queue contains N + 1 entries (DWORD). (N = CMDQTH[7:0])
7 to 0	CMDQTH[7:0]	H'01	R/W	Normal Command Ready Queue Threshold*1 H'00: Interrupt is issued when Command Queue is completely empty. Others: Interrupt is issued when Command Queue contains N empties. (N = CMDQTH[7:0])

Note 1. These bits support for all I3C mode.

Note 2. These bits support for I3C master mode and I3C secondary master mode.

The Queue Threshold Control register controls the interrupt trigger thresholds for the Command Queue, the Response Queue, and the IBI Queue.

The specific reset values are indicative and could be hardware implementation specific.

CMDQTH[7:0] bits (Normal Command Ready Queue Threshold)

Controls the minimum number of Command Queue empties needed to trigger the INTCMD interrupt.

If this field is greater than (Command Queue size – 1), then only the number of bits required to address the full buffer depth will be considered.

Note: It is assumed that I3C has exactly one Command Queue, exactly one Response Queue, and exactly one IBI Queue.

RSPQTH[7:0] bits (Normal Response Queue Threshold)

Controls the minimum number of Response Queue entries needed to trigger the INTRESP interrupt.

If this field is greater than (Response Status Queue size – 1), then only the number of bits required to address the full buffer depth will be considered.

IBIDSSZ[7:0] bits (Normal IBI Data Segment Size)

This is the IBI data segment size, in DWORDs (4 bytes).

In PIO mode, this field allows the incoming IBI data to be sliced into multiple segments generating status individually, to support cutthrough readout of a long IBI payload data.

IBIQTH[7:0] bits (Normal IBI Queue Threshold)

For I3C protocol mode (Master): PRTS.PRTMD = 0 and PRSST.CRMS = 1.

Controls generation of the INTIBI interrupt, based on the value of the IBI Queue's Outstanding IBI status count.

Each IBI status entry can represent either the complete IBI payload (if the IBI payload byte size is 4×IBIDSSZ or less), or a segment of the IBI payload (if the IBI payload byte size is more than 4×IBIDSSZ).

For I3C protocol mode (Slave): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

Controls the minimum number of IBI Data Buffer empties needed to trigger the INTIBI interrupt.

If this field is greater than (IBI Data Buffer size? 1), then only the number of bits required to address the full buffer depth will be considered.

7.8.2.40 Normal Transfer Data Buffer Threshold Control Register 0 (NTBTHCTL0)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
26 to 24	RXSTTH [2:0]*3	001b	R/W	Normal Rx Start Threshold*2 000: Wait for 2 empty DWORDs 001: Reserved Others: Setting prohibited
23 to 19	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
18 to 16	TXSTTH [2:0]*3	001b	R/W	Normal Tx Start Threshold*2 000: Wait for 2 DWORDs 001: Reserved Others: Setting prohibited
15 to 11	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
10 to 8	RXDBTH[2:0]	001b	R/W	Normal Receive Data Buffer Threshold*1 000: Interrupt triggers at 2 Rx Buffer entries, DWORDs 001: Reserved Others: Setting prohibited
7 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2 to 0	TXDBTH[2:0]	001b	R/W	Normal Transmit Data Buffer Threshold*1 000: Interrupt triggers at 2 Tx Buffer empties, DWORDs 001: Reserved Others: Setting prohibited

Note 1. These bits support for all I3C mode.

Note 2. These bits support for I3C master mode and I3C secondary master mode.

Note 3. The RXSTTH[2:0] and TXSTTH[2:0] bits are only present in NTBTHCTL0.

The Data Buffer Control register controls the interrupt trigger thresholds for the Receive Data Buffer Queue and the Transmit Data Buffer Queue.

TXDBTH[2:0] bits (Normal Transmit Data Buffer Threshold)

Minimum number of Transmit FIFO empties, in DWORDs, that will trigger the INTTXn interrupt.

The software must program a value less than Transmit Data Buffer size in this register.

RXDBTH[2:0] bits (Normal Receive Data Buffer Threshold)

Minimum number of Receive FIFO entries in DWORDs that will trigger the INTRXn interrupt.

The software must program a value less than Receive Data Buffer size in this register.

TXSTTH[2:0] bits (Normal Tx Start Threshold)

When preparing to initiate a Write Transfer on the I3C Bus, I3C shall wait until the Transmit Buffer has at least the indicated number of locations available.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the TXSTTH[2:0] field is set to the Transmit Buffer size, then I3C shall delay initiation of the Write Command as follows:
   - If the data length to be transferred is more than the Transmit Buffer size, then this module shall wait until the Transmit FIFO is completely full.
   - If the data length to be transferred is less than the Transmit Buffer size, then I3C shall wait until enough Transmit FIFO locations are available to store the data to be transferred.
2. Threshold Mode
   If the TXSTTH[2:0] field value is less than the Transmit Buffer size, then I3C shall initiate the Write Command as soon as the indicated number of Transmit FIFO locations are entries.

RXSTTH[2:0] bits (Normal Rx Start Threshold)

When preparing to initiate a Read Transfer on the I3C bus, I3C shall wait until the Receive Buffer has at least the indicated number of empty locations in DWORDs.

Two optional configurable Modes are available:

1. Store and Forward Mode If the RXSTTH[2:0] field is set to the Receive Buffer size, then I3C shall delay initiation of the Read Command as follows:
   - If the data length to be transferred is more than the Receive Buffer size, then this module shall wait until the Receive FIFO is completely empty.
   - If the data length to be transferred is less than the Receive Buffer size, then I3C shall wait until enough Receive FIFO locations are available to store the data to be transferred.
2. Threshold Mode
   If the RXSTTH[2:0] field value is less than the Receive Buffer size, then I3C shall initiate the Read Command as soon as the indicated number of Receive FIFO locations are empty.

7.8.2.41 Normal Receive Status Queue Threshold Control Register (NRQTHCTL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
7 to 0	RSQTH[7:0]	H'01	R/W	Normal Receive Status Queue Threshold H'00: Interrupt is issued when Receive Status Queue contains 1 entry (DWORD). Others: Interrupt is triggered when Receive Status Queue contains N+1 entries (DWORD). (N = RSQTH[7:0])

RSQTH[7:0] bits (Normal Receive Status Queue Threshold)

Controls the minimum number of receive status queue entries needed to trigger the INTRCV interrupt.

If this field is greater than (Receive Status Queue size – 1), then only the number of bits required to address the full buffer depth will be considered.

7.8.2.42 Bus Status Register (BST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	WUCNDDF	—	—	—	TODF	—	—	—	ALF

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
24	WUCNDDF	0b	R/W*2	Wake-Up Condition Detection Flag 0: Wake-Up Condition is not detected. 1: Wake-Up Condition is detected.
23 to 21	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
20	TODF	0b	R/W*2	Timeout Detection Flag 0: Timeout is not detected. 1: Timeout is detected.
19 to 17	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
16	ALF	0b	R/W*2	Arbitration Lost Flag*1 0: Arbitration is not lost 1: Arbitration is lost.
15 to 9	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
8	TENDF	0b	R/W*2	Transmit End Flag*1 0: Data is being transmitted. 1: Data has been transmitted.
7 to 5	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
4	NACKDF	0b	R/W*2	NACK Detection Flag*1 0: NACK is not detected. 1: NACK is detected.
3	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
2	—	0b	R/W	Reserved This bit is read as 0. The write value should be 0.
1	SPCNDDF	0b	R/W*2	STOP Condition Detection Flag 0: STOP condition is not detected. 1: STOP condition is detected.
0	STCNDDF	0b	R/W*2	START Condition Detection Flag 0: START condition is not detected. 1: START condition is detected.

Note 1. This bit supports for I^2C mode.

Note 2. Clearing (to 0) condition: Writing 0 after 1 is read.

STCNDDF bit (START Condition Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The BSTE.STCNDDE bit = 1.
  2. When a START condition (or a Repeated START condition) is detected.

[Clearing conditions]

- When 0 is written to the STCNDDF flag after reading STCNDDF flag = 1.
- When a STOP condition is detected.

SPCNDDF bit (STOP Condition Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The BSTE.SPCNDDE bit = 1.
  2. When a STOP condition is detected.

[Clearing condition]

- When 0 is written to the SPCNDDF flag after reading SPCNDDF flag = 1.

NACKDF bit (NACK Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The PRTS.PRTMD bit = 1 (I^2C protocol mode).
  2. The BSTE.NACKDE bit = 1 (Enables NACK detection interrupt status logging).
  3. When acknowledge is not received (NACK is received) from the receive device in transmit mode.

[Clearing condition]

- When 0 is written to the NACKDF flag after reading NACKDF flag = 1.

TENDF bit (Transmit End Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The PRTS.PRTMD bit = 1 (I^2C protocol mode).
  2. The BSTE.TENDE bit = 1 (Enables Transmit End Interrupt Status logging).
  3. At the rising edge of the ninth SCL clock cycle while the NTST.TDBEF0 flag = 1. Excluding when sending an address.

[Clearing conditions]

- When 0 is written to the TENDF flag after reading TENDF flag = 1.
- When data is written to the NTDTBP0 register.
- When a STOP condition is detected.

ALF bit (Arbitration Lost Flag)

[Setting conditions]

When master arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.MALE = 1.

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high impedance state)).
- All of the followings are satisfied.
  1. When the START condition is detected while the CNDCTL.STCND bit = 1.
  2. When the internal SDA output state does not match the SDA line level.
- When the CNDCTL.STCND bit is set to 1 (START condition issuance request) while the BCST.BFREF flag = 0.

When NACK arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.NALE = 1.

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.SALE = 1.

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode.

[Clearing condition]

- When 0 is written to the ALF flag after reading ALF flag = 1.

TODF bit (Timeout Detection Flag)

[Setting conditions]

- All of the followings are satisfied.
  1. The BSTE.TODE bit = 1 (Enables Timeout Detection Interrupt Status logging).
  2. When the master mode or the received slave address matches the slave address n in Slave mode.
  3. When the SCL line state remains unchanged for the period specified by TMOCTL register.

[Clearing condition]

- When 0 is written to the TODF flag after reading TODF flag = 1.

7.8.2.43 Bus Status Enable Register (BSTE)

7 to 5	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
4	NACKDE	0b	R/W	NACK Detection Enable*1 0: Disables NACK Detection Interrupt Status logging. 1: Enables NACK Detection Interrupt Status logging.
3	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
2	—	0b	R/W	Reserved This bit is read as 0. The write value should be 0.
1	SPCNDDE	0b	R/W	STOP Condition Detection Enable 0: Disables STOP condition Detection Interrupt Status logging. 1: Enables STOP condition Detection Interrupt Status logging.
0	STCNDDE	0b	R/W	START Condition Detection Enable 0: Disables START condition Detection Interrupt Status logging. 1: Enables START condition Detection Interrupt Status logging.

Note 1. This bit supports for I^2C mode.

STCNDDE bit (START Condition Detection Enable)

When this bit is 1, operation of BST.STCNDDF is enabled. For the setting conditions and clearing conditions of the BST.STCNDDF flag, see the details of BST.STCNDDF.

SPCNDDE bit (STOP Condition Detection Enable)

When this bit is 1, operation of BST.SPCNDDF is enabled. For the setting conditions and clearing conditions of the BST.SPCNDDF flag, see the details of BST.SPCNDDF.

NACKDE bit (NACK Detection Enable)

When this bit is 1, the operation of BST.NACKDF is enabled. This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1. For the setting conditions and clearing conditions of the BST.NACKDF flag, see the details of BST.NACKDF.

TENDE bit (Transmit End Enable)

When this bit is 1, the operation of BST.TENDF is enabled. For the setting conditions and clearing conditions of the BST.TENDF flag, see the details of BST.TENDF.

ALE bit (Arbitration Lost Enable)

When this bit is 1, the operation of BST.ALF is enabled. For the setting conditions and clearing conditions of the BST.ALF flag, see the details of BST.ALF.

TODE bit (Timeout Detection Enable)

When this bit is 1, the operation of BST.TODF is enabled. For the setting conditions and clearing conditions of the BST.TODF flag, see the details of BST.TODF.

7.8.2.44 Bus Interrupt Enable Register (BIE)

7 to 5	—	000b	R	Reserved This bit is read as 0. The write value should be 0.
4	NACKDIE	0b	R/W	NACK Detection Interrupt Enable*1 0: Disables NACK Detection Interrupt Signal. 1: Enables NACK Detection Interrupt Signal.
3	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
2	—	0b	R/W	Reserved This bit is read as 0. The write value should be 0.
1	SPCNDDIE	0b	R/W	STOP Condition Detection Interrupt Enable 0: Disables STOP condition Detection Interrupt Signal. 1: Enables STOP condition Detection Interrupt Signal.
0	STCNDDIE	0b	R/W	START Condition Detection Interrupt Enable 0: Disables START condition Detection Interrupt Signal. 1: Enables START condition Detection Interrupt Signal.

Note 1. This bit supports for I^2C mode.

The BIE register enables signaling of outstanding bus interrupts received by I3C.

STCNDDIE bit (START Condition Detection Interrupt Enable)

This bit enables or disables the START Condition Detection interrupt requests when the BST.STCNDDF flag is set to 1.

SPCNDDIE bit (STOP Condition Detection Interrupt Enable)

This bit enables or disables the STOP Condition Detection interrupt requests when the BST.SPCNDDF flag is set to 1.

NACKDIE bit (NACK Detection Interrupt Enable)

This bit enables or disables the NACK Detection interrupt requests when the BST.NACKDF flag is set to 1.

TENDIE bit (Transmit End Interrupt Enable)

This bit enables or disables the Transmit End interrupt (I3C_TEND) requests when the BST.TENDF flag is set to 1.

ALIE bit (Arbitration Lost Interrupt Enable)

This bit enables or disables the Arbitration Llost interrupt requests when the BST.ALF flag is set to 1.

TODIE bit (Timeout Detection Interrupt Enable)

This bit enables or disables the Timeout Detection interrupt requests when the BST.TODF flag is set to 1.

WUCNDDIE Bit

This bit is used to enable or disable the Wake-up condition detection interrupt (INTWU) requests when the BST.WUCNDDF flag is set to 1.

7.8.2.45 Bus Status Force Register (BSTFC)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

5	TABTF	0b	R/W*3	Normal Transfer Abort Flag*1 0: Transfer Abort does not occur. 1: Transfer Abort occur. To clear, write 0 to this bit after 1 state is read.
4	RSPQFF	0b	R/W*3	Normal Response Queue Full Flag*1 0: The number of Response Queue entries is the NQTHCTL.RSPQTH threshold or less. 1: The number of Response Queue entries is more than the NQTHCTL.RSPQTH threshold.
3	CMDQEF	0b	R/W*3	Normal Command Queue Empty Flag*1 0: If the NQTHCTL.CMDQTH = 0: The number of Command Queue empties is less than the Command Queue size. If the NQTHCTL.CMDQTH is other than 0: The number of Command Queue empties is less than the NQTHCTL.CMDQTH threshold. 1: If the NQTHCTL.CMDQTH = 0: The number of Command Queue empties is the Command Queue size. If the NQTHCTL.CMDQTH is other than 0: 1: The number of Command Queue empties is the NQTHCTL.CMDQTH threshold or more.

Bit	Bit Name	Initial Value	R/W	Description
2	IBIQEFF	0b	R/W*3	Normal IBI Queue Empty/Full Flag*1 0: For I3C protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1. The number of IBI Status Queue entries is the NQTHCTL.IBIQTH threshold or less. For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0. If the NQTHCTL.IBIQTH = 0: The number of IBI Data Buffer empties is less than the IBI Data Buffer size. If the NQTHCTL.IBIQTH is other than 0: The number of IBI Data Buffer empties is less than the NQTHCTL.IBIQTH threshold. 1: For I3C protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1. The number of IBI Status Queue entries is more than the NQTHCTL.IBIQTH threshold. For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0. If the NQTHCTL.IBIQTH = 0: The number of IBI Data Buffer empties is the IBI Data Buffer size. If the NQTHCTL.IBIQTH is other than 0: The number of IBI Data Buffer empties is the NQTHCTL.IBIQTH threshold or more.
1	RDBFF0	0b	R/W*3	Normal Receive Data Buffer Full Flag 0*1 0: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Receive Data Buffer0 contains no receive data. For I3C Protocol mode: PRTS.PRTMD bit = 0. The number of entries in the Normal Receive Data Buffer 0 is less than the NTBTHCTL0.RXDBTH[2:0] threshold. 1: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Receive Data Buffer0 contains receive data. For I3C Protocol mode: PRTS.PRTMD bit = 0. The number of entries in the Normal Receive Data Buffer 0 is the NTBTHCTL0.RXDBTH[2:0] threshold or more.
0	TDBEF0	0b	R/W*3	Normal Transmit Data Buffer Empty Flag 0*1 0: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Transmit Data Buffer 0 contains transmit data. For I3C protocol mode: PRTS.PRTMD bit = 0. The number of empties in the Normal Transmit Data Buffer 0 is less than the NTBTHCTL0.TXDBTH[2:0] threshold. 1: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Transmit Data Buffer 0 contains no transmit data. For I3C protocol mode: PRTS.PRTMD bit = 0. The number of empties in the Normal Transmit Data Buffer 0 is the NTBTHCTL0.TXDBTH[2:0] threshold or more.

Note 1. This bit supports for all I3C mode.

Note 2. This bit supports for I3C secondary master mode and I3C slave mode.

Note 3. Clearing (to 0) condition: Writing 0 after the 1 state is read.

TDBEF0 bit (Normal Transmit Data Buffer Empty Flag 0)

[Setting conditions]

For I2C Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following conditions 2 to 4 are satisfied:

1. The NTSTE.TDBEE0 bit = 1 (enables Tx0 Data Buffer Empty Interrupt Status logging).
2. When data has been transferred from the Normal Transmit Data Buffer 0 to the Shift Register and the Normal Transmit Data Buffer 0 becomes empty*1.
3. When the PRSST.TRMD bit is set to 1.
4. When the received slave address matches while the TRMD bit = 1.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

The following conditions 1 and 2 are satisfied:

1. The NTSTE.TDBEE0 bit = 1 (enables Tx0 Data Buffer Empty Interrupt Status logging).
2. When the number of empties in the Normal Transmit Data Buffer 0 is the NTBTHCTL0.TXDBTH[2:0] threshold or more (refer to NTBTHCTL0 register).

[Clearing conditions]

For I^2C Protocol mode: PRTS.PRTMD bit = 1.

- When data is written to NTDTBP0.
- When the TRMD bit in PRSST is set to 0.

For I3C protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Transmit Data by DTC.
- When the number of empties in the Normal Transmit Data Buffer 0 is less than the NTBTHCTL0.TXDBTH[2:0] threshold (refer to NTBTHCTL0 register).

Note 1. When the BST.NACKDF flag is set to 1 while the BSTE.NACKDE bit = 1, I3C aborts data transmission/reception. If the TDBEF0 flag = 0 (next transmit data has been written), data is transferred to the Shift Register and the Normal Transmit Data Buffer 0 register becomes empty at the rising edge of the 9th clock cycle, but the TDBEF0 flag is not set to 1.

RDBFF0 bit (Normal Receive Data Buffer Full Flag 0)

[Setting conditions]

For I^2C Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following condition 2 or 3 is satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Rx0 Data Buffer Full Interrupt Status logging).
2. When receive data is transferred from Shift Register to Normal Receive Data Buffer 0.
   The RDBFF0 flag is set to 1 on the rising edge of the 8th or 9th SCL clock cycle (selected in the ACKTWE bit in SCSTRCTL).
3. When the received slave address matches after a START (or Repeated START) condition is detected with the TRMD bit in PRSST set to 0.

For I3C Protocol mode: PRTS.PRTMD bit = 0. The following conditions 1 and 2 are satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Rx0 Data Buffer Full Interrupt Status logging).
2. When the number of Normal Receive Data Buffer 0 entries is the NTBTHCTL0.RXDBTH[2:0] threshold or more (refer to NTBTHCTL0 register).

[Clearing conditions]

For I^2C Protocol mode: PRTS.PRTMD bit = 1.

- When data is read from NTDTBP0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Data by DTC.

- When the number of Normal Receive Data Buffer 0 entries is less than the NTBTHCTL0.RXDBTH[2:0] threshold (refer to NTBTHCTL0 register).

IBIQEFF bit (Normal IBI Queue Empty/Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.IBIQEFE bit = 1 (enables IBI Status Buffer Empty/Full Interrupt Status logging)
2. For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.
   - When the number of IBI Status Queue entries is more than the NQTHCTL.IBIQTH threshold (refer to NQTHCTL register).

   For I3C protocol mode (slave): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.
   If the NQTHCTL.IBIQTH = 0:
   - When IBI Data Buffer is completely empty.

   If the NQTHCTL.IBIQTH is other than 0:
   - When the number of IBI Data Buffer empties is the NQTHCTL.IBIQTH threshold or more (refer to NQTHCTL register).

[Clearing conditions]

For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to IBI Status by DTC.
- When the number of IBI Status Queue entries is the NQTHCTL.IBIQTH threshold or less (refer to NQTHCTL register).

For I3C protocol mode (slave): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to IBI Status by DTC.

If the NQTHCTL.IBIQTH = 0:

- When IBI Data Buffer is not completely empty.

If the NQTHCTL.IBIQTH is other than 0:

- When the number of IBI Data Buffer empties is less than the NQTHCTL.IBIQTH threshold (refer to NQTHCTL register).

CMDQEF bit (Normal Command Queue Empty Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.CMDQEE bit = 1 (enables Command Buffer Empty Interrupt Status logging).
2. If the NQTHCTL.CMDQTH = 0:
   - When Command Queue is completely empty.

   If the NQTHCTL.CMDQTH is other than 0:

- When the number of Command Queue empties is the NQTHCTL.CMDQTH threshold or more (refer to NQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Command by DTC.

If the NQTHCTL.CMDQTH = 0:

- When Command Queue is not completely empty.

If the NQTHCTL.CMDQTH is other than 0:

- When the number of Command Queue empties is less than the NQTHCTL.CMDQTH threshold (refer to NQTHCTL register).

RSPQFF bit (Normal Response Queue Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.RSPQFE bit = 1 (enables Response Buffer Full Interrupt Status logging).
2. When the number of Response Queue entries is more than the NQTHCTL.RSPQTH threshold (refer to NQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Status by DTC.
- When the number of Response Queue entries is the NQTHCTL.RSPQTH threshold or less (refer to NQTHCTL register).

TABTF bit (Normal Transfer Abort Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.TABTE bit = 1 (enables Ttransfer Abort Interrupt Status logging).
2. When any transfer is aborted.

[Clearing condition]

- Write 0 to this bit after 1 is read.

TEF bit (Normal Transfer Error Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.TEE bit = 1 (enables Ttransfer Error Interrupt Status logging).
2. When any transfer error occurs on the I3C bus. The Error type for this error is available in the Response or Receive Status structure corresponding to the Transfer command.

[Clearing condition]

- Write 0 to this bit after 1 is read.

RSQFF bit (Normal Receive Status Queue Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.RSQFE bit = 1 (Normal Receive Status Queue Full Enable).
2. When the number of Receive Status Queue entries is more than the NRQTHCTL.RSQTH threshold (refer to NRQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read accsess to Normal Receive Status by DTC.
- When the number of Receive Status Queue entries is the NRQTHCTL.RSQTH threshold or less (refer to NRQTHCTL register).

7.8.2.47 Normal Transfer Status Enable Register (NTSTE)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
20	RSQFE	0b	R/W	Normal Receive Status Queue Full Enable*2 0: Disables Receive Status Buffer Full Interrupt Status logging. 1: Enables Receive Status Buffer Full Interrupt Status logging.
19 to 10	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
9	TEE	0b	R/W	Normal Transfer Error Enable*1 0: Disables Transfer Error Interrupt Status logging. 1: Enables Transfer Error Interrupt Status logging.
8 to 6	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
5	TABTE	0b	R/W	Normal Transfer Abort Enable*1 0: Disables Transfer Abort Interrupt Status logging. 1: Enables Transfer Abort Interrupt Status logging.
4	RSPQFE	0b	R/W	Normal Response Queue Full Enable*1 0: Disables Response Buffer Full Interrupt Status logging. 1: Enables Response Buffer Full Interrupt Status logging.
3	CMDQEE	0b	R/W	Normal Command Queue Empty Enable*1 0: Disables Command Buffer Empty Interrupt Status logging. 1: Enables Command Buffer Empty Interrupt Status logging.
2	IBIQEFE	0b	R/W	Normal IBI Queue Empty/Full Enable*1 0: Disables IBI Status Buffer Empty/Full Interrupt Status logging. 1: Enables IBI Status Buffer Empty/Full Interrupt Status logging.
1	RDBFE0	0b	R/W	Normal Receive Data Buffer Full Enable 0 0: Disables Rx0 Data Buffer Full Interrupt Status logging. 1: Enables Rx0 Data Buffer Full Interrupt Status logging.
0	TDBEE0	0b	R/W	Normal Transmit Data Buffer Empty Enable 0 0: Disables Tx0 Data Buffer Empty Interrupt Status logging. 1: Enables Tx0 Data Buffer Empty Interrupt Status logging.

Note 1. This bit supports for all I3C mode.

Note 2. This bit supports for I3C secondary master mode and I3C slave mode.

TDBEE0 bit (Normal Transmit Data Buffer Empty Enable 0)

When this bit is 1, the operation of NTST.TDBEF0 is enabled.

For the setting conditions and clearing conditions of the NTST.TDBEF0 flag, see the details of NTST.TDBEF0.

RDBFE0 bit (Normal Receive Data Buffer Full Enable 0)

When this bit is 1, the operation of NTST.RDBFF0 is enabled.

For the setting conditions and clearing conditions of the NTST.RDBFF0 flag, see the details of NTST.RDBFF0.

IBIQEFE bit (Normal IBI Queue Empty/Full Enable)

When this bit is 1, the operation of NTST.IBIQEFF is enabled.

For the setting conditions and clearing conditions of the NTST.IBIQEFF flag, see the details of NTST.IBIQEFF.

CMDQEE bit (Normal Command Queue Empty Enable)

When this bit is 1, the operation of NTST.CMDQEF is enabled.

For the setting conditions and clearing conditions of the NTST.CMDQEF flag, see the details of NTST.CMDQEF.

RSPQFE bit (Normal Response Queue Full Enable)

When this bit is 1, the operation of NTST.RSPQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSPQFF flag, see the details of NTST.RSPQFF.

TABTE bit (Normal Transfer Abort Enable)

When this bit is 1, the operation of NTST.TABTF is enabled.

For the setting conditions and clearing conditions of the NTST.TABTF flag, see the details of NTST.TABTF.

TEE bit (Normal Transfer Error Enable)

When this bit is 1, the operation of NTST.TEF is enabled.

For the setting conditions and clearing conditions of the NTST.TEF flag, see the details of NTST.TEF.

RSQFE bit (Normal Receive Status Queue Full Enable)

When this bit is 1, the operation of NTST.RSQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSQFF flag, see the details of NTST.RSQFF.

7.8.2.48 Normal Transfer Interrupt Enable Register (NTIE)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	RSQFIE	—	—	—	—

R/W	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
20	RSQFIE	0b	R/W	Normal Receive Status Queue Full Interrupt Enable*2 0: Disables Receive Status Buffer Full Interrupt Signal. 1: Enables Receive Status Buffer Full Interrupt Signal.
19 to 10	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
9	TEIE	0b	R/W	Normal Transfer Error Interrupt Enable*1 0: Disables Transfer Error Interrupt Signal. 1: Enables Transfer Error Interrupt Signal.
8 to 6	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
5	TABTIE	0b	R/W	Normal Transfer Abort Interrupt Enable*1 0: Disables Transfer Abort Interrupt Signal. 1: Enables Transfer Abort Interrupt Signal.
4	RSPQFIE	0b	R/W	Normal Response Queue Full Interrupt Enable*1 0: Disables Response Buffer Full Interrupt Signal. 1: Enables Response Buffer Full Interrupt Signal.
3	CMDQEIE	0b	R/W	Normal Command Queue Empty Interrupt Enable*1 0: Disables Command Buffer Empty Interrupt Signal. 1: Enables Command Buffer Empty Interrupt Signal.
2	IBIQEFIE	0b	R/W	Normal IBI Queue Empty/Full Interrupt Enable*1 0: Disables IBI Status Buffer Empty/Full Interrupt Signal. 1: Enables IBI Status Buffer Empty/Full Interrupt Signal.
1	RDBFIE0	0b	R/W	Normal Receive Data Buffer Full Interrupt Enable 0 0: Disables Rx0 Data Buffer Full Interrupt Signal. 1: Enables Rx0 Data Buffer Full Interrupt Signal.
0	TDBEIE0	0b	R/W	Normal Transmit Data Buffer Empty Interrupt Enable 0 0: Disables Tx0 Data Buffer Empty Interrupt Signal. 1: Enables Tx0 Data Buffer Empty Interrupt Signal.

Note 1. This bit supports for all I3C mode.

Note 2. This bit supports for I3C secondary master mode and I3C slave mode.

The PIO Interrupt Signal Enable register enables signaling of outstanding interrupts received by I3C.

TDBEIE0 bit (Normal Transmit Data Buffer Empty Interrupt Enable 0)

This bit is used to enable or disable the Normal Tx Data buffer 0 empty interrupt (I3Cn_TX) requests when the NTST.TDBEF0 flag is set to 1.

RDBFIE0 bit (Normal Receive Data Buffer Full Interrupt Enable 0)

This bit is used to enable or disable the Normal Rx Data buffer 0 full interrupt (I3Cn_RX) requests when the NTST.RDBFF0 flag is set to 1.

IBIQEFIE bit (Normal IBI Queue Empty/Full Interrupt Enable)

This bit is used to enable or disable the Normal IBI Status buffer full interrupt (INTIBI) requests when the NTST.IBIQEFF flag is set to 1.

CMDQEIE bit (Normal Command Queue Empty Interrupt Enable)

This bit is used to enable or disable the Normal Command buffer empty interrupt (INTCMD) requests when the NTST.CMDQEF flag is set to 1.

RSPQFIE bit (Normal Response Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Response Status buffer full interrupt (INTRESP) requests when the NTST.RSPQFF flag is set to 1.

TABTIE bit (Normal Transfer Abort Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Abort interrupt (INTABORT) requests when the NTST.TABTF flag is set to 1.

TEIE bit (Normal Transfer Error Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Error interrupt (INTTERR) requests when the NTST.TEF flag is set to 1.

RSQFIE bit (Normal Receive Status Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Receive Status buffer full interrupt (INTRCV) requests when the NTST.RSQFF flag is set to 1.

7.8.2.49 Normal Transfer Status Force Register (NTSTFC)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	RSQFFC	—	—	—	—

R/W	R	R	R	R	R	R	W	R	R	R	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved The write value should be 0.
20	RSQFFC	0b	W	Normal Receive Status Queue Full Force*2 0: Not Force Receive Status Buffer Full Interrupt for software testing. 1: Force Receive Status Buffer Full Interrupt for software testing.
19 to 10	—	All 0	R	Reserved The write value should be 0.
9	TEFC	0b	W	Normal Transfer Error Force*1 0: Not Force Transfer Error Interrupt for software testing. 1: Force Transfer Error Interrupt for software testing.
8 to 6	—	000b	R	Reserved The write value should be 0.
5	TABTFC	0b	W	Normal Transfer Abort Force*1 0: Not Force Transfer Abort Interrupt for software testing. 1: Force Transfer Abort Interrupt for software testing.
4	RSPQFFC	0b	W	Normal Response Queue Full Force*1 0: Not Force Response Buffer Full Interrupt for software testing. 1: Force Response Buffer Full Interrupt for software testing.
3	CMDQEFC	0b	W	Normal Command Queue Empty Force*1 0: Not Force Command Buffer Empty Interrupt for software testing. 1: Force Command Buffer Empty Interrupt for software testing.
2	IBIQEFFC	0b	W	Normal IBI Queue Empty/Full Force*1 0: Not Force IBI Status Buffer Full Interrupt for software testing. 1: Force IBI Status Buffer Full Interrupt for software testing.
1	RDBFFC0	0b	W	Normal Receive Data Buffer Full Force 0 0: Not Force Rx0 Data Buffer Full Interrupt for software testing. 1: Force Rx0 Data Buffer Full Interrupt for software testing.
0	TDBEFC0	0b	W	Normal Transmit Data Buffer Empty Force 0 0: Not Force Tx0 Data Buffer Empty Interrupt for software testing. 1: Force Tx0 Data Buffer Empty Interrupt for software testing.

Note 1. This bit supports for all I3C mode.

Note 2. This bit supports for I3C secondary master mode and I3C slave mode.

The PIO Interrupt Force register is used to force specific interrupt. It can be used for debug purposes.

TDBEFC0 bit (Normal Transmit Data Buffer Empty Force 0)

For software testing, when set to 1, forces the corresponding interrupt, subject to TDBEE0 and TDBEIE0 configuration.

RDBFFC0 bit (Normal Receive Data Buffer Full Force 0)

For software testing, when set to 1, forces the corresponding interrupt, subject to RDBFE0 and RDBFIE0 configuration.

IBIQEFFC bit (Normal IBI Queue Empty/Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to IBIQEFE and IBIQEFIE configuration.

CMDQEFC bit (Normal Command Queue Empty Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to CMDQEE and CMDQEIE configuration.

RSPQFFC bit (Normal Response Queue Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to RSPQFEand RSPQFIE configuration.

TABTFC bit (Normal Transfer Abort Force)

For software testing, forces the corresponding interrupt, subject to TABTE and TABTIE configuration.

TEFC bit (Normal Transfer Error Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to TEE and TEIE configuration.

RSQFFC bit (Normal Receive Status Queue Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to RSQFE and RSQFIE configuration.

7.8.2.50 Bus Condition Status Register (BCST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BIDLF	BAVLF	BFREF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are read as 0.
2	BIDLF	0b	R	Bus Idle Detection Flag*1 0: Have not Detected Bus Idle 1: Have Detected Bus Idle
1	BAVLF	0b	R	Bus Available Detection Flag*1 0: Have not Detected Bus Available 1: Have Detected Bus Available
0	BFREF	0b	R	Bus Free Detection Flag 0: Have not Detected Bus Free 1: Have Detected Bus Free

Note 1. This bit supports for all I3C mode.

BFREF bit (Bus Free Detection Flag)

The Bus Free Condition is a period occurring after a STOP and before a START, and with the following duration:

- For Pure Bus: A duration of at least tCAS
- For Mixed Bus (at least one Legacy I^2C is present on the I3C Bus): A duration of at least tBUF

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cϕ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cϕ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

BAVLF bit (Bus Available Detection Flag)

The Bus Available Condition is a period during which the Bus Free Condition is sustained continuously for a duration of at least tAVAL. A Slave can only issue a START Request (for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cϕ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cϕ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

BIDLF bit (Bus Idle Detection Flag)

The I3C Bus Idle Condition is in order to help ensure Bus stability during Hot-Join events. The Bus Idle Condition is a period during which the Bus Available Condition is sustained continuously for a duration of at least tIDLE.

If a Hot-Join Device is powered up onto the I3C Bus at the same time as the Main Master, then the Hot-Join Device may pull SDA Low after 1 ms if (1) the Main Master has SCL and SDA pulled up, and (2) the Master does not act on the I3C Bus within the same Idle period.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cϕ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cϕ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

7.8.2.51 Slave Status Register (SVST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SVAF[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HOAF	—	—	—	—	—	—	—	—	DVIDF	HSMCF	—	—	—	—	GCAF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
18 to 16	SVAF[2:0]	000b	R/W*1	Slave Address Detection Flag [2:0] 0: Slave [2:0] does not detect 1: Slave [2:0] detect
15	HOAF	0b	R/W*1	Host Address Detection Flag 0: Host address does not detect. 1: Host address detects. • This bit set to 1 when the received slave address matches the host address (000_1000).
14 to 7	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
6	DVIDF	0b	R/W*1	Device-ID Address Detection Flag 0: Device-ID command does not detect. 1: Device-ID command detects. • This bit set to 1 when the first frame received immediately after a START condition is detected matches a value of (device ID (111_1100) + 0[W]).
5	HSMCF	0b	R/W*1	Hs-mode Master Code Detection Flag 0: Hs-mode Master Code does not detect. 1: Hs-mode Master Code detects.
4 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	GCAF	0b	R/W*1	General Call Address Detection Flag 0: General call address does not detect. 1: General call address detects.

Note: This register supports for I^2C mode.

Note 1. Clearing (to 0) condition: Writing 0 after the 1 state is read.

GCAF flag (General Call Address Detection Flag)

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

  1. The SVCTL.GCAE bit = 1 (General call address detection is enabled).

  2. When the received slave address matches the general call address (000_0000 + 0 (write)).

[Clearing conditions]

- When 0 is written to the GCAF flag after reading GCAF flag to be 1.
- When a STOP condition is detected.
- When a Repeated START condition is detected.

HSMCF flag (Hs-mode Master Code Detection Flag)

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

  1. The SVCTL.HSMCE bit = 1 (Hs-mode master code detection is enabled).

  2. When the first byte received immediately after a START condition is detected matches a value of Hs-mode master code (0000_1XXX) + 1 (NACK).

[Clearing conditions]

- When 0 is written to the HSMCF flag after reading HSMCF flag to be 1.
- When a STOP condition is detected.

DVIDF flag (Device-ID Address Detection Flag)

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

  1. The SVCTL.DVIDE bit = 1 (Device-ID address detection is enabled).

  2. When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of Device ID (111_1100) + 0 (write).

[Clearing conditions]

- When 0 is written to the DVIDF flag after reading DVIDF flag to be 1.
- When a STOP condition is detected.
- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte when the following 1 and 2 or 1 and 3 are satisfied.

  1. The SVCTL.DVIDE bit = 1 (Device-ID address detection is enabled).

  2. When the first byte received immediately after a START condition or Repeated START condition is detected does not match a value of Device ID (111_1100).

  3. When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of (device ID (111_1100) + 0 [W]) and the second byte does not match any of slave addresses 0 to 2.

HOAF flag (Host Address Detection Flag)

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

  1. The SVCTL.HOAE bit = 1 (Host address detection is enabled).

  2. When the received slave address matches the host address (000_1000).

[Clearing conditions]

- When 0 is written to the HOAF flag after reading HOAF flag to be 1.
- When a STOP condition is detected.
- When a Repeated START condition is detected.

SVAFy flags (Slave Address Detection Flag y) (y = 0 to 2)

[Setting conditions]

For 7-bit address format: SVDVADy.SADLG bit = 0.

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.SVAEy bit = 1 (Slave n enabled).
  2. When the received slave address matches the SVDVADy.SVAD[6:0] bits value.

For 10-bit address format: SVDVADy.SADLG bit = 1.

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the second byte when all of the followings are satisfied.
  1. The SVCTL.SVAEy bit = 1 (Slave n enabled).
  2. When the received slave address matches a value of 1_1110 + SVDVADy.SVAD[9:8] bits and the following address matches the SVDVADy.SVAD[7:0] value.

[Clearing conditions]

- When 0 is written to the SVAFy flag after reading SVAFy flag to be 1.
- When a STOP condition is detected.

For 7-bit address format: SVDVADy.SADLG bit = 0.

- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.SVAEy bit = 1 (Slave n enabled).
  2. When the received slave address does not match SVDVADy.SVAD[6:0] bits value.

For 10-bit address format: SVDVADy.SADLG bit = 1.

- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.SVAEy bit = 1 (Slave n enabled).
  2. When the received slave address does not match a value of 1_1110 + SVDVADy.SVAD[9:8] bits.
- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the second byte when all of the followings are satisfied.
  1. The SVCTL.SVAEn bit = 1 (Slave n enabled).
  2. When the received slave address matches a value of 1_1110 + SVDVADy.SVAD[9:8] bits and the following address does not match the SVDVADy.SVAD[7:0] value.

7.8.2.52 Wake Up Unit Operating Status Register (WUST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUASYNF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	WUASYNF	0b	R	Wake-Up function Asynchronous operation status Flag 0: This IP synchronous circuit enable condition 1: This IP asynchronous circuit enable condition

WUASYNF Flag (Wake-Up function asynchronous operation status flag)

This bit shows whether this IP is in the TCLK asynchronous operation (WUCTL.WUFE bit = 1).

[Setting condition]

The following 1 and 2 are satisfied.

1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
2. When the BCST.BFREF flag = 1 after 0 is written to the WUCTL.WUFSYNE bit

[Clearing condition: I^2C slave]

The WUCTL.WUFE bit = 0 (Wake-up function is disabled)

All of the following 1 to 3 are satisfied.

1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
2. Wake-Up event is detected
3. When 1 is written to the WUCTL.WUFSYNE bit during WUASYNF flag = 1

[Clearing condition: I3C slave]

The WUCTL.WUFE bit = 0 (Wake-up function is disabled)

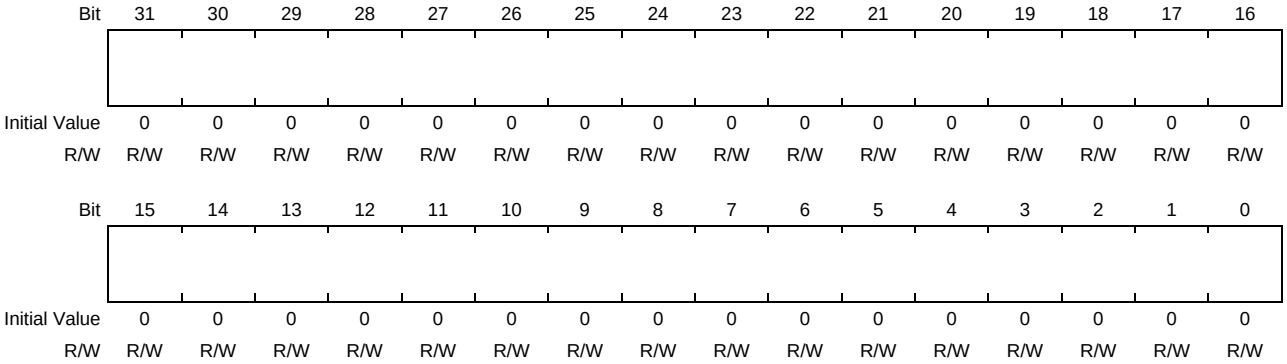
All of the following 1 to 4 are satisfied.

1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
2. Wake-Up event is detected
3. When 1 is written to the WUCTL.WUFSYNE bit during WUASYNF flag = 1
4. When a STOP condition is detected.

[Clearing condition: I^2C/I3C slave]

All of the following 1 to 5 are satisfied.

1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
2. Wake-Up event is not detected
3. The WUASYNF flag = 1
4. The WUCTL.WUFSYNE bit = 1
5. When a STOP condition is detected.



[Clearing condition: I3C master]

The WUCTL.WUFE bit = 0 (Wake-up function is disabled)

All of the following 1 to 4 are satisfied.

1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
2. Wake-Up event is detected
3. The WUASYNF flag = 1
4. The WUCTL.WUFSYNE bit = 1

7.8.2.53 MsyncCNT Counter Capture Register (MRCCPT)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R/W	MSyncCNT Counter Capture Used in Async Mode 1, not used in Async Mode0.

Note: This register supports for I3C secondary master mode and I3C slave mode.

MRCCPT[31:0] Bits

Async Mode 1 (Asynchronous Advanced Mode)

When ATCCNTE.ATCE is enabled, it starts counting. It captures as MSyncCNT for each aME (SDA falling edge of START condition) and store it in the capture register.

7.8.2.54 Device Address Table Basic Register m (DATBASm) (m = 0 to 7)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DVTYP	DVNACK[1:0]		—	—	—	—	—	DVDYAD[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DVIBITS	DVMRRJ	DVSIRRJ	DVIBIPL	—	—	—	—	—	DVSTAD[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	DVTYP	0b	R/W	Device Type 0: I3C Device 1: I^2C Device
30, 29	DVNACK[1:0]	00b	R/W	Device NACK Retry Count Device-specific retry count
28 to 24	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
23 to 16	DVDYAD[7:0]	All 0	R/W	Device I3C Dynamic Address Bit 23 is the parity bit, per the I3C specification, computed and updated by the software driver.
15	DVIBITS	0b	R/W	Device IBI Time-stamp 0: The Master shall not time-stamp IBIs from this Device with Master Time-stamps. 1: The Master shall time-stamp IBIs for this Device with Master Time-stamps.
14	DVMRRJ	0b	R/W	Device In-Band Master Request Reject 0: This Device shall ACK Master Requests. 1: This Device shall NACK Master Requests and send the auto-disable command.
13	DVSIRRJ	0b	R/W	Device In-Band Slave Interrupt Request Reject 0: This Device shall ACK the SIR. 1: This Device shall NACK the SIR and send the auto-disable CCC.
12	DVIBIPL	0b	R/W	Device IBI Payload 0: IBIs from this Device do not carry a Data Payload. 1: IBIs from this Device do carry a Data Payload.
11 to 7	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
6 to 0	DVSTAD[6:0]	All 0	R/W	Device Static Address I3C Static Address

Note: This register supports for I3C master mode and I3C secondary master mode.

DVIBIPL bit (Device IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This field reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).

During IBI handling for this Device, the Master shall use this field to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

DVSIRRJ bit (Device In-Band Slave Interrupt Request Reject)

Controls whether this Device, when operating in the Master role, will accept vs. reject Slave Interrupt Requests from other Devices.

DVMRRJ bit (Device In-Band Master Request Reject)

Controls whether this Device, when operating in the Master role, will accept vs. reject Master requests from other Devices. This bit is only valid if I3C declares Non-Current Master Capability.

DVIBITS bit (Device IBI Time-stamp)

Enables or disables IBI time-stamping for a specific Device.

Note: The IBI Status Descriptor for each IBI event indicates whether or not the individual IBI event was actually time- stamped. Set to 0 except for Async mode 0 and Async mode 1 of timing control.

DVNACK[1:0] bits (Device NACK Retry Count)

These bits set the number of retries when a NACK response is received from the slave for the transaction set in the Command Descriptor.

Note 1. When ENTDAA is executed by Address Assign Command, the setting of this bit is ignored and the transaction ends when NACK is received once.

Note 2. I3C will retry according to the setting of DVNACK[1:0], even if it receives a NACK for the broadcast address.

Note 3. If DVNACK[1:0] is 00b, I3C will not retry even for Direct CCCs.

7.8.2.55 Slave Device Address Table Basic Register n (SDATBASn) (n = 0 to 2)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	SDDYAD[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	SDIBIPL	—	SDADLS	SDSTAD[9:0]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
22 to 16	SDDYAD[6:0] *1	All 0	R/W	Slave Device I3C Dynamic Address*5
15 to 13	—	000b	R	Reserved These bits are read as 0. The write value should be 0.
12	SDIBIPL*1	0b	R	Slave Device IBI Payload*4 This bit is the mirror bit of the SVDCT.TBCR[2]. 0: IBIs from this device do not carry a data payload. 1: IBIs from this device carry a data payload.
11	—	0b	R	Reserved These bits are read as 0. The write value should be 0.
10	SDADLS	0b	R/W	Slave Device Address Length Selection*3 0: Slave device address length 7 bits selected. 1: Slave device address length 10 bits selected. (I^2C device only)
9 to 0	SDSTAD[9:0]	All 0	R/W	Slave Device Static Address*2 I3C / I^2C Static Address

Note: SW write to the SDATBAS register of the main master is prohibited.

Note 1. This bit is valid only in SDATBAS0 register.

Note 2. These bits support for I^2C, I3C secondary master, and I3C slave mode.

Note 3. This bit supports for I^2C mode.

Note 4. This bit supports for I3C secondary master mode and I3C slave mode.

Note 5. These bits support for I3C secondary master mode and I3C slave mode.

SDSTAD[9:0] bits (Slave Device Static Address)

When the 7-bit address format is selected (SDADLS bit is 0), the lower 7 bits of SDSTAD[9:0] function as the 7-bit address.

When the 10-bit address format is selected (SDADLS bit is 1), the SDSTAD[9:0] function as the 10-bit address. While the SVCTL.SVAEn bit is 0, the setting of this bit is ignored.

SDIBIPL bit (Slave Device IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This field reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).

During IBI handling for this Device, the Master shall use this field to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

SDDYAD[6:0] bits (Slave Device I3C Dynamic Address)

[Update conditions]

- When writing Dynamic Address value.
- When Slave Address value is its own Static Address in receiving SETDASA CCC (Direct), these bits are updated to Dynamic Address value.*1
- When Dynamic Address Assignment procedure that starts by receiving ENTDAA CCC (Broadcast) is established.*1
- When receiving RSTDAA CCC (Broadcast), all bits are cleared to 0.*1
- When Slave Address value is its own Dynamic Address in receiving RSTDAA CCC (Direct), all bits are cleared to 0.*1
- When Slave Address value is its own Dynamic Address in receiving SETNEWDA CCC (Direct), these bits are updated to the Dynamic Address value.*1
- When receiving SETAASA CCC (Broadcast), these bits are updated to the value of SDSTAD[6:0] bits*2.

Note 1. See *the MIPI I3C Specification v1.0*.

Note 2. See *the MIPI I3C Basic Specification v1.0*.

7.8.2.56 Master Device Characteristic Table Register m (MSDCTm) (m = 0 to 7)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	RBCR76[1:0]		–	RBCR4	RBCR3	RBCR2	RBCR1	RBCR0	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15, 14	RBCR76[1:0]	00b	R/W	Device Role 0 0: I3C Slave 0 1: I3C Master*3 Others: Setting prohibited
13	—	0b	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
12	RBCR4	0b	R/W	Bridge Identifier 0: Not a Bridge Device 1: Is a Bridge Device
11	RBCR3	0b	R/W	Offline Capable*2 0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.
10	RBCR2	0b	R/W	IBI Payload 0: No data byte follows the accepted IBI. 1: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.
9	RBCR1	0b	R/W	IBI Request Capable 0: Not Capable 1: Capable
8	RBCR0	0b	R/W	Max Data Speed Limitation*1 0: No Limitation 1: Limitation
7 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

Note: This register supports for I3C master mode and I3C secondary master mode.

Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.

Note 2. Offline Capable Devices retain the Dynamic Address.

Note 3. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01.

The DCT table captures the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each Device on the I3C Bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.

RBCRn bits (Received Bus Characteristic Register)

Each I3C Device that is connected to the I3C Bus shall have an associated read-only Bus Characteristics Register (BCR). This read-only register describes the I3C compliant Device's role and capabilities for use in Dynamic Address assignment and Common Command Codes.

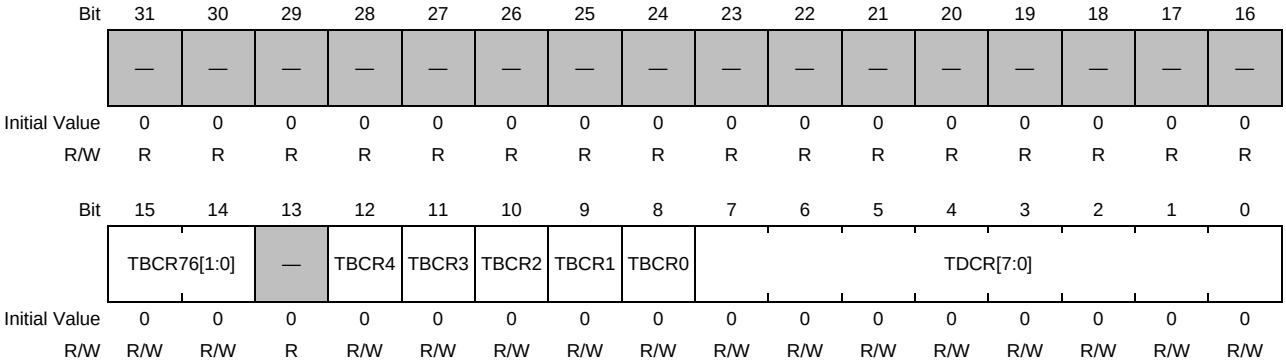
Note: When RBCR[2] is 0 and when ACK response to Slave Interrupt Request from I3C Slave by DATBASm.DVSIRR J = 0, STOP Condition is issued after ACK response. When RBCR[2] is 1 and when ACK response to Slave Interrupt Request from I3C Slave by DATBASm.DVSIRRJ = 0, IBI Payload is received after ACK response. STOP Condition is issued after end of IBI Payload.

[Update condition]

- When receiving of Bus Characteristics Register (BCR) from Device in the Dynamic Address Assignment procedure starting by receiving ENTDAA CCC (Broadcast).*[1]

Note 1. See *the MIPI I3C Specification v1.0*.

7.8.2.57 Extended Device Address Table Basic Register (EXDATBAS)



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31	EDTYP	0b	R/W	Extended Device Type 0: I3C Device 1: I^2C Device
30, 29	EDNACK[1:0]	00b	R/W	Extended Device NACK Retry Count Device-specific retry count
28 to 24	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
23 to 16	EDDYAD[7:0]	All 0	R/W	Extended Device I3C Dynamic Address Bit 23 is the parity bit, per the I3C specification, computed and updated by the software driver.
15 to 7	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
6 to 0	EDSTAD[6:0]	All 0	R/W	Extended Device Static Address I3C / I^2C static address

Note: This register supports for I3C master mode and I3C secondary master mode.

7.8.2.58 Slave Device Characteristic Table Register (SVDCT)

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15 to 14	TBCR76[1:0]	00b	R/W	Device Role 0 0: I3C Slave 0 1: I3C Master*3 1 0: Reserved for future definition by MIPI Sensor WG 1 1: Reserved for future definition by MIPI Sensor WG
13	—	0b	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
12	TBCR4	0b	R/W	Bridge Identifier 0: Not a Bridge Device 1: Is a Bridge Device
11	TBCR3	0b	R/W	Offline Capable*2 0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.
10	TBCR2	0b	R/W	IBI Payload 0: No data byte follows the accepted IBI. 1: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.
9	TBCR1	0b	R/W	IBI Request Capable 0: Not Capable 1: Capable
8	TBCR0	0b	R/W	Max Data Speed Limitation*1 0: No Limitation 1: Limitation
7 to 0	TDCR[7:0]	All 0	R/W	Transfar Device Characteristic Register 255 available codes for describing the type of sensor, or device. Examples: Accelerometer, gyroscope, composite devices Default value is 0: Generic Device

Note: This register supports for I3C secondary master mode and I3C slave mode.

Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.

Note 2. Offline Capable Devices retain the Dynamic Address.

Note 3. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01.

The DCT table captures the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.

TDCR[7:0] bits (Transfar Device Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Device Characteristics Register (DCR). This register describes the I3C compliant device type such as accelerometer and gyroscope, for use in Dynamic Address assignment and Common Command Codes.

TBCRn bits (Transfar Bus Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Bus Characteristics Register (BCR). This register describes the role and capabilities of the I3C compliant device for use in Dynamic Address assignment and Common Command Codes.

When I3C Slave issues IBI by Command Descriptor, the condition of TBCR[7:0] is described as follows:

[Slave Interrupt Request: No IBI Payload follow the accepted IBI]

- TBCR1 = 1
- TBCR2 = 0

Note: Set DATA_LENGTH[15:0] of Command Descriptor to 0.

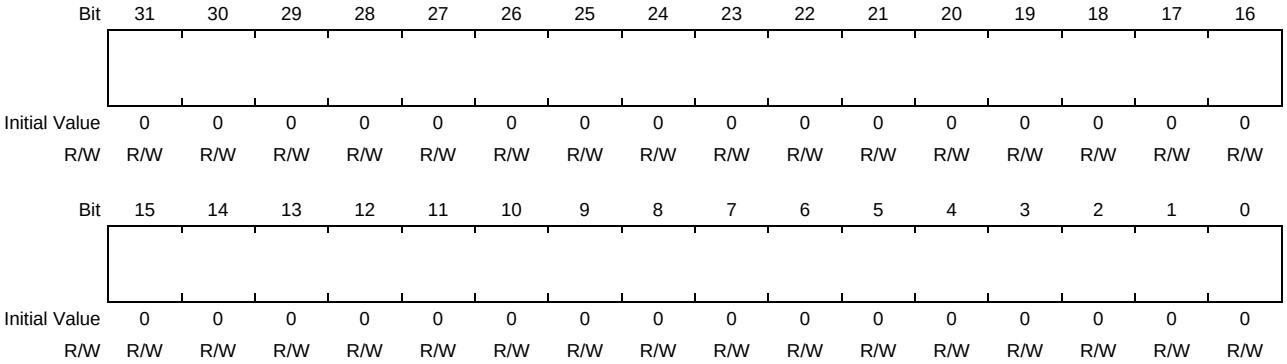
[Slave Interrupt Request: IBI Payload follow the accepted IBI]

- TBCR1 = 1
- TBCR2 = 1

Note: Set DATA_LENGTH[15:0] of Command Descriptor to any value.

[Mastership Request]

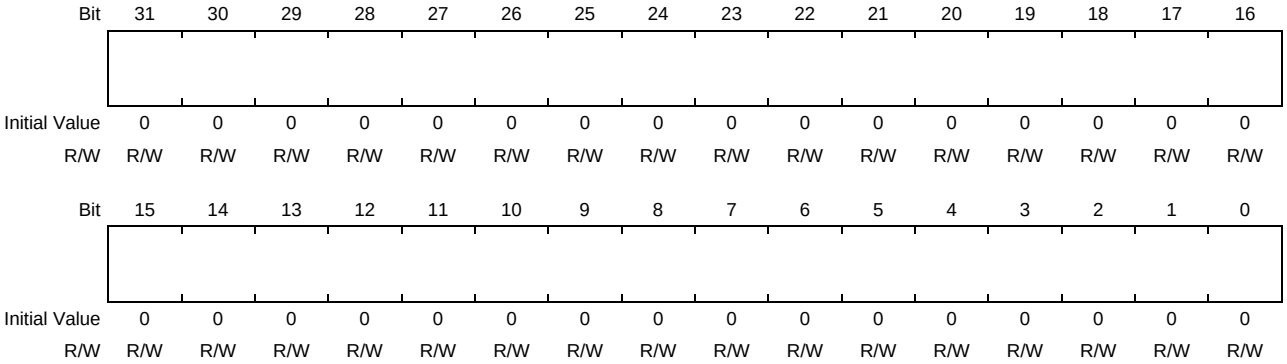
- TBCR1 = 1
- TBCR76[1:0] = 01b



[Hot-join Event]

- TBCR1 = 1

When I3C Slave receives CCC from I3C Master, it performs the following operations according to the setting of TBCR[7:0]:



- When TBCR2 = 1, CMRLG.IBIPSZ[7:0] is sent as the 3rd byte data to GETMRL CCC from I3C Master
- When TBCR0 = 0, NACK responses to GETMXDS CCC from I3C Master
- When TBCR0 = 1, ACK responses to GETMXDS CCC from I3C Master and sends data from CMDSPW, CMDSPR, and CMDSPT registers

7.8.2.59 Slave Device Characteristic Table Provisional ID Low Register (SDCTPIDL)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R/W	Transfar Device Provisional ID Low Bits 31 to 16 are read as 0. Bits 15 to 0 are bits [15:0] of device's I3C PID.

7.8.2.60 Slave Device Characteristic Table Provisional ID High Register (SDCTPIDH)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	n/a	All 0	R/W	Transfar Device Provisional ID High Bits [47:16] of device's I3C PID.

Note: This register supports for I3C secondary master mode and I3C slave mode.

7.8.2.61 Slave Device Address Register n (SVDVADn) (n = 0 to 2)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SDYADV*4	SSTADV	—	—	SADLG	—	SVAD[9:0]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	SDYADV*4	0b	R	Slave Dynamic Address Valid*3 0: Dynamic Address is disabled. 1: Dynamic Address is enabled.
30	SSTADV	0b	R	Slave Static Address Valid*1 0: Slave address is disabled. 1: Slave address is enabled.
29, 28	—	00b	R	Reserved These bits are read as 0.
27	SADLG	0b	R	Slave Address Length*2 0: The 7-bit address format is selected. 1: The 10-bit address format is selected.
26	—	0b	R	Reserved This bit is read as 0.
25 to 16	SVAD[9:0]	All 0	R	Slave Address*1 A slave address is set. When rewriting SVAD, change to SVAE = 0 and rewrite.
15 to 0	—	All 0	R	Reserved These bits are read as 0.

Note 1. These bits support for I^2C, I3C secondary master, and I3C slave mode.

Note 2. This bit supports for I^2C mode.

Note 3. This bit supports for I3C secondary master mode and I3C slave mode.

Note 4. This bit is valid only in SVDVAD0 register.

SVAD[9:0] bits (Slave Address)

The SVAD[9:0] bits indicate a valid slave address.

[The SVDVAD0.SDYADV bit = 1]

Note: This condition is only for SVDVAD0.SVAD[9:0].

- The SVAD[9:7] bits = 0
- The SVAD[6:0] bits = the SDATBAS0.SDDYAD[6:0] bits

[The SVDVADy.SSTADV bit = 1 and the SVDVADy.SADLG bit = 0]

- The SVAD[9:7] bits = 0
- The SVAD[6:0] bits = the SDATBASy.SDSTAD[6:0] bits

[The SVDVADy.SSTADV bit = 1 and the SVDVADy.SADLG bit = 1]

- The SVAD[9:0] bits = the SDATBASy.SDSTAD[9:0] bits

SADLG bit (Slave Address Length)

[Setting conditions]

- All of the followings are satisfied:

1. The PRTS.PRTMD bit = 1 (I^2C Protocol mode)
2. The SVCTL.SVAEy bit = 1 (Slave y is enabled)
3. The SDATBASy.SDADLS bit = 1 (The address length is 10 bits)

[Clearing condition]

- [Setting condition] is not satisfied.

SSTADV bit (Slave Static Address Valid)

[Setting conditions]

- All of the followings are satisfied:

1. The SVCTL.SVAEy bit = 1 (Slave y is enabled)
2. The SVDVAD0.SDYADV bit = 0 (Dynamic Address is disabled)

   Note: This condition is only for SVDVAD0.SSTADV.
3. If the SVDVADy.SADLG bit = 0, the SDATBASy.SDSTAD[6:0] bits are not all 0
   If the SVDVADy.SADLG bit = 1, the SDATBASy.SDSTAD[9:0] bits are not all 0

[Clearing condition]

- [Setting condition] is not satisfied.

SDYADV*4 bit (Slave Dynamic Address Valid)

[Setting conditions]

- All of the followings are satisfied:

1. The PRTS.PRTMD bit = 0 (I3C Protocol mode)
2. The SVCTL.SVAEy bit = 1 (Slave y is enabled)
3. The SDATBAS0.SDDYAD[6:0] bits are not all 0

   Note: This condition is only for SVDVAD0.SDYADV.

[Clearing condition]

- [Setting condition] is not satisfied.

7.8.2.62 CCC Slave Events Command Register (CSECMD)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	HJEVE	—	MSRQE	SVIRQE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
3	HJEVE	0b	R/W	Hot-Join Event Enable 0: DISABLED: Slave-initiated Hot-Join is Disabled by the Master to control. 1: ENABLED: Slave-initiated Hot-Join is Enabled by the Master to control.
2	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
1	MSRQE	0b	R/W	Mastership Requests Enable 0: DISABLED: Mastership requests from Secondary master's is Disabled by the Current Master to control. 1: ENABLED: Mastership requests from Secondary master's is Enabled by the Current Master to control.
0	SVIRQE	0b	R/W	Slave Interrupt Requests Enable 0: DISABLED: Slave-initiated Interrupts is Disabled by the Master to control. 1: ENABLED: Slave-initiated Interrupts is Enabled by the Master to control.

Note: This register supports for I3C secondary master mode and I3C slave mode.

SVIRQE bit (Slave Interrupt Requests Enable)

This bit allows the Master to control when Slave-initiated Interrupts are allowed on the I3C Bus.

These four Direct (ENEC/DISEC Format 1) or Broadcast (ENEC/DISEC Format 2) CCCs allows the Master to control when Slave- initiated traffic is (Enable) vs. is not (Disable) allowed on the I3C Bus. This control governs a Slave's attempts to request an Interrupt (ENI), to request Mastership (ENMR), or to signify a Hot-Join event (ENHJ).

[Setting conditions]

- When writing 1
- When receiving ENEC CCC (Broadcast) with ENINT bit = 1.*1
- When ENINT bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISINT bit = 1.*1
- When DISINT bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

MSRQE bit (Mastership Requests Enable)

This bit allows the Current Master to control when Mastership requests from Secondary masters are allowed on the I3C Bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with ENMR bit = 1.*1
- When ENMR bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISMR bit = 1.*1
- When DISMR bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

HJEVE bit (Hot-Join Event Enable)

This bit allows the Master to control when Slave-initiated Hot-Join is allowed on the I3C Bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with ENHJ bit = 1.*1
- When ENHJ bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISHJ bit = 1.*1
- When DISHJ bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

Note 1. See *the MIPI I3C Specification v1.0*.

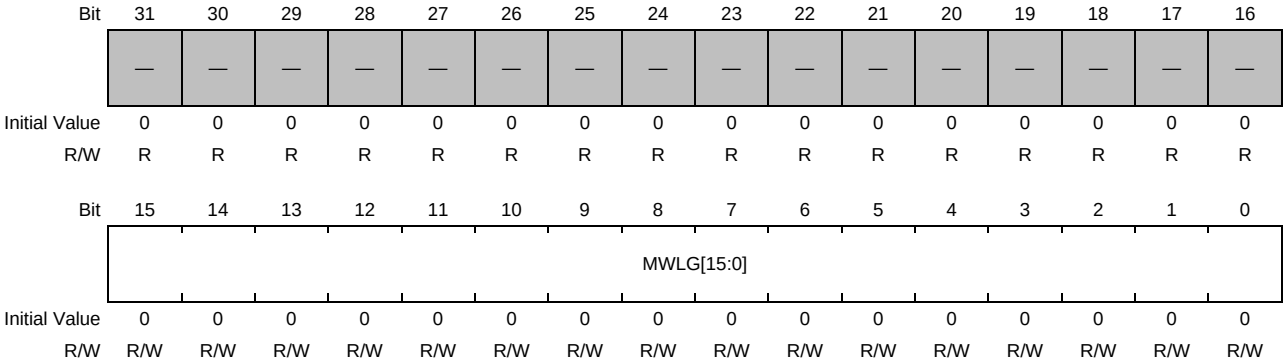
7.8.2.63 CCC Enter Activity State Register (CEACTST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	ACTST[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
3 to 0	ACTST[3:0]	All 0	R/W	Activity State H'1: ENTAS0 (1 µs: Latency-free operation) H'2: ENTAS1 (100 µs) H'4: ENTAS2 (2 ms) H'8: ENTAS3 (50 ms: Lowest-activity operation) Others: Setting prohibited

Note: This register supports for I3C secondary master mode and I3C slave mode.



ACTST[3:0] bits (Activity State)

[Update conditions]

- When writing Activity State value.
- When receiving ENTAS0 CCC (Broadcast), these bits are updated to H'1.*1
- When receiving ENTAS1 CCC (Broadcast), these bits are updated to H'2.*1
- When receiving ENTAS2 CCC (Broadcast), these bits are updated to H'4.*1
- When receiving ENTAS3 CCC (Broadcast), these bits are updated to H'8.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS0 CCC (Direct), these bits are updated to H'1.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS1 CCC (Direct), these bits are updated to H'2.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS2 CCC (Direct), these bits are updated to H'4.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS3 CCC (Direct), these bits are updated to H'8.*1

Note 1. See *the MIPI I3C Specification v1.0*.

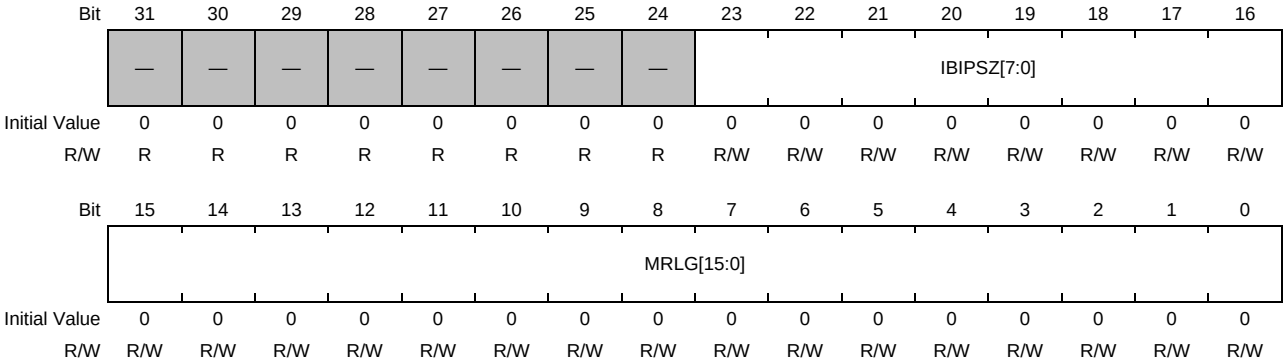
7.8.2.64 CCC Max Write Length Register (CMWLG)

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15 to 0	MWLG[15:0]	All 0	R/W	Max Write Length

Note: This register supports for I3C secondary master mode and I3C slave mode.

MWLG[15:0] bits (Max Write Length)

These bits use for the I3C Master to set or get a maximum data write length in bytes for one Slave Device.



This Max Write Length does not affect data write lengths for Broadcast CCCs. The Set/Get Max Write Length value is transmitted over two bytes, with the most significant byte (MSB) transmitted first. The minimum value that Maxes Write Length can be set to is 8.

[Update conditions]

- When writing Max Write Length value.
- When receiving SETMWL CCC (Broadcast), these bits are updated to MWL value.*[1]
- When Slave Address value is its own Slave Address in receiving SETMWL CCC (Direct), these bits are updated to MWL value.*[1]

Note 1. See *the MIPI I3C Specification v1.0*.

7.8.2.65 CCC Max Read Length Register (CMRLG)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
23 to 16	IBIPSZ[7:0]	All 0	R/W	IBI Payload Size
15 to 0	MRLG[15:0]	All 0	R/W	Max Read Length

Note: This register supports for I3C secondary master mode and I3C slave mode.

MRLG[15:0] bits (Max Read Length)

These bits use for the I3C Master to set or get a maximum data read length for one Slave Device.

The Set/Get Max Read Length value is transmitted over the first two bytes, with most significant byte (MSB) transmitted first. The minimum value to which Max Read Length can be set is 16.

[Update conditions]

- When writing Max Read Length value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to MRL value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to MRL value.*1

IBIPSZ[7:0] bits (IBI Payload Size)

These bits use for the I3C Master to set or get optionally a maximum IBI payload size.

For devices with BCR bit 2 set to 1, the Max IBI payload size value is added as a third byte, where a value of 0 indicates an unlimited payload size.

This CCC is optional for the Slave, with two exceptions:

1. This CCC is required if both (a) any private Read Request Message (s) and/or any extended Read Request CCC (s) implemented by the Slave support a variable limit on the maximum number of data bytes that the Slave may return per Message, and (b) this limit is greater than 16 bytes.
2. This CCC is required if the Slave both (a) supports an IBI Payload (as indicated with BCR bit 1), and (b) will transmit more than one byte of private payload.

[Update conditions]

- When writing Max IBI payload size value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to IBI payload size value.*1

- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to IBI payload size value.*[1]

Note 1. See *the MIPI I3C Specification v1.0*.

7.8.2.66 CCC Enter Test Mode Register (CETSTMD)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TSTMD[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0.
7 to 0	TSTMD[7:0]	All 0	R	Test Mode H'00: Exit Test Mode This value removes all I3C devices from Test Mode. H'01: Vendor Test Mode This value indicates that I3C devices shall return a random 32bit value in the provisional ID during the Dynamic Address Assignment procedure. Others: MIPI reserved Reserved for future use by the MIPI Alliance

Note: This register supports for I3C secondary master mode and I3C slave mode.

TSTMD[7:0] bits (Test Mode)

When these bits set to H'00, all I3C Devices remove from Test Mode.

When these bits set to H'01, I3C Devices shall return a random 32bit value in the Provisional ID during the Dynamic Address Assignment procedure.

The Broadcast CCC informs all I3C Devices that the Master is entering a specified Test Mode during manufacturing or Device test. The Enter Test Mode command Frame format includes a byte that specifies which Test Mode to enter.

Supporting I3C Devices shall enter the indicated Test Mode upon receipt of the Enter Test Mode CCC.

[Update condition]

- When receiving ENTTM CCC (Broadcast), these bits are updated to Test Mode Byte value.*[1]

Note 1. See *the MIPI I3C Specification v1.0*.

7.8.2.67 CCC Get Device Status Register (CGDVST)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VDRSV[7:0]								ACTMD[1:0]		PRTE	—	PNDINT[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15 to 8	VDRSV[7:0]	All 0	R/W	Vendor Reserved Reserved for vendor-specific meaning
7, 6	ACTMD[1:0]	00b	R/W	Slave Device's current Activity Mode 0 0: Activity Mode 0 0 1: Activity Mode 1 1 0: Activity Mode 2 1 1: Activity Mode 3
5	PRTE	0b	R	Protocol Error 0: The Slave has not detected a protocol error since the last Status read. 1: The Slave has detected a protocol error since the last Status read.
4	—	0b	R	Reserved This bit is read as 0. The write value should be 0.
3 to 0	PNDINT[3:0]	All 0	R/W	Pending Interrupt Contains the interrupt number of any pending interrupt, or 0 if no interrupts are pending. This encoding allows for up to 15 numbered interrupts. If more than one interrupt is set, then the highest priority interrupt shall be returned.

Note: This register supports for I3C secondary master mode and I3C slave mode.

PRTE bit (Protocol Error)

If this bit set to 1, then the Slave detects a protocol error since the last Status read.

The Slave checks for such errors. Note that this value self-clears by the hardware upon every successful completion of a Master read of the Slave's Status.

The Direct CCC is a Get request for one I3C Slave Device to return its current Status, in the two-byte format detailed. Note that byte 0 is the LSb, and byte 1 is the MSB.

[Setting condition]

- When the Slave detected a protocol error.*1

[Clearing condition]

- When transmission by own Slave Address is completed without error after receiving GETSTATUS CCC (Direct).*1

ACTMD[1:0] bits (Slave Device’s current Activity Mode)

Contains the two-bit ID of the Slave Device’s current Activity Mode (readiness to support data read of sensor or related information).

Note 1. See *the MIPI I3C Specification v1.0*.

7.8.2.68 CCC Max Data Speed W (Write) Register (CMDSPW)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2	SPTASYN1	0b	R/W	Support Async Mode 1 0: Async Mode 1 is not supported. 1: Async Mode 1 is supported.

Bit	Bit Name	Initial Value	R/W	Description
1	SPTASYN0	0b	R/W	Support Async Mode 0 0: Async Mode 0 is not supported. 1: Async Mode 0 is supported.
0	SPTSYN	0b	R/W	Supports Sync Mode 0: Sync Mode is not supported. 1: Sync Mode is supported.

Note: This register supports for I3C secondary master mode and I3C slave mode.

The Directed CCC provides the framework for the Master to query the Exchange Timing capabilities supported by the I3C Slaves. The Get Exchange Timing Support Information CCC causes the addressed Slave to return four data bytes containing key information on supported current state, and internal oscillator/clock frequency and inaccuracy.

7.8.2.72 CCC Exchange Timing Support Information S (State) Register (CETSS)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
7	ICOVF	0b	R/W	Internal Counter Overflow 0: Slave has not experienced a counter overflow since the most recent previous check. 1: Slave experienced a counter overflow since the most recent previous check.
6 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2, 1	ASYNE[1:0]	00b	R/W	Async Mode Enabled 00: All Mode Disable 01: Async Mode 0 Enabled. 10: Async Mode 1 Enabled. Other Setting prohibited
0	SYNE	0b	R/W	Sync Mode Enabled 0: Sync Mode Disabled. 1: Sync Mode Enabled.

Note: This register supports for I3C secondary master mode and I3C slave mode.

ASYNE[0] Bit

Slave Timing Control Async Mode 0 is enabled.

[Setting condition]

- When writing “1”.
- When CETSM.SPTASYN[0] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value H’DF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value H’DF.

[Clearing condition]

- When writing “0”.
- When CETSM.SPTASYN[0] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value H’EF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value H’EF.

ASYNE[1] Bit

Slave Timing Control Async Mode 1 is enabled.

[Setting condition]

- When writing “1”.
- When CETSM.SPTASYN[1] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value H’EF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value H’EF.

[Clearing condition]

- When writing “0”.
- When CETSM.SPTASYN[1] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value H’DF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value H’DF.

ICOVF bit

Bit mask indicating which Timing Control Mode (if any) is currently enabled for the target Slave, and whether any counter overflows have occurred since the most recent previous check. If a Timing Control Mode bit is set (has value 1b), then that Slave has currently enabled the corresponding Timing Control Mode. If the Overflow bit is set (has value 1b), then that Slave experienced a counter overflow since the most recent previous check.

7.8.2.73 Bit Count Register (BITCNT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are read as 0.
4 to 0	BCNT[4:0]	All 0	R	Bit Counter Indicates the number of bits remaining to be transferred. For details on the values, refer to **Table 7.8-8** and **Table 7.8-9**.

BCNT[4:0] bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a sampling edge on the SCLn line.

Table 7.8-8 I^2C / Legacy I^2C transfer

	Master		Slave	
BCNT[4:0]	Address phase	Data phase	Address phase	Data phase

Note 1. The address phase is the same as in **Table 7.8-8**.

7.8.2.74 Normal Queue Status Level Register (NQSTLV)

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	000b	R	Reserved These bits are read as 0.
28 to 24	IBISCNT[4:0]	All 0	R	Normal IBI Status Count*2 Number of IBI Status entries currently in the IBI Queue.
23 to 16	IBIQLV[7:0]	All 0	R	Normal IBI Queue Level*1 Number of buffer entries currently in the IBI Queue.
15 to 8	RSPQLV[7:0]	All 0	R	Normal Response Queue Level*1 Number of buffer entries currently in the Response Queue.
7 to 0	CMDQFLV [7:0]	H'04	R	Normal Command Queue Free Level*1 Number of free buffer entries currently in the Command Queue. Reset value is the depth of the Command Queue.

Note 1. These bits support for all I3C mode.

Note 2. These bits support for I3C master mode and I3C secondary master mode.

7.8.2.75 Normal Data Buffer Status Level Register 0 (NDBSTLV0)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDBLV[7:0]								TDBFLV[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0.
15 to 8	RDBLV[7:0]	All 0	R	Normal Receive Data Buffer Level Indicates the number of Receive Data Buffer entries in the Receive Data Queue.
7 to 0	TDBFLV[7:0]	H'01	R	Normal Transmit Data Buffer Free Level Indicates the number of free Transmit Data Buffer entries in the Transmit Data Queue. Reset value is the depth of the Transmit Data Queue.

Note: This register supports for all I3C mode.

7.8.2.76 Normal Receive Status Queue Status Level Register (NRSQSTLV)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RSQLV[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are read as 0.
7 to 0	RSQLV[7:0]	All 0	R	Normal Receive Status Queue Level

Note: This register supports for I3C secondary master mode and I3C slave mode.

7.8.2.77 Present State Debug Register (PRSTDBG)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SDOLV	SCOLV	SDILV	SCILV
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
3	SDOLV	1b	R	SDA Output Level 0: I3C has driven the SDA pin low. 1: I3C has released the SDA pin.
2	SCOLV	1b	R	SCL Output Level 0: I3C has driven the SCL pin low. 1: I3C has released the SCL pin.
1	SDILV	1b	R	SDA Line Signal Level This bit is used to check the SDA Line level, in order to recover from errors and for debugging.
0	SCILV	1b	R	SCL Line Signal Level This bit is used to check the SCL Line level, in order to recover from errors and for debugging.

SDOLV bit (SDA Output Level) and SCOLV bit (SCL Output Level)

When reading these bits, the state of signals output from I3C can be read.

SCILV bit (SCL Line Signal Level)

This bit is used to check the SCL Line level, in order to recover from errors and for debugging.

SDILV bit (SDA Line Signal Level)

This bit is used to check the SDA Line level, in order to recover from errors and for debugging.

SCOLV bit (SCL Output Level)

This bit is used to select the output level of SCL pin.

SDOLV bit (SDA Output Level)

This bit is used to select the output level of SDA pin.

7.8.2.78 Master Error Counters Register (MSERRCNT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	M2ECNT[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0b	R	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
30 to 8	—	All 0	R	Reserved These bits are read as 0.
7 to 0	M2ECNT[7:0]	All 0	R	M2 Error Counter Counts I3C Type M2 errors on the I3C Bus. Cleared upon read out.

Note: This register supports for I3C master mode and I3C secondary master mode.

7.8.2.79 SC1 Capture monitor Register (SC1CPT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SC1C[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0.
15 to 0	SC1C[15:0]	All 0	R	SC1 Capture

Note: This register supports for all I3C mode.

SC1C[15:0] Bits

- Async Mode 0 (Asynchronous Basic Mode)

  After enabling ATCCNTE.ATCE, SC1 Counter counts up from SC1 count trigger to SCL rise edge next to ACK for the IBI and capture it as SC1.

- Async Mode 1 (Asynchronous Advanced Mode)

  After enabling ATCCNTE.ATCE, SC1 Counter counts up from SC1 count trigger to the first aME and capture it as SC1.

CAUTION

As the timing control specification, the SC1 counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

7.8.2.80 SC2 Capture monitor Register (SC2CPT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SC2C[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0.
15 to 0	SC2C[15:0]	All 0	R	SC2 Capture

Note: This register supports for all I3C mode.

SC2C[15:0] Bits

- Async Mode 0 (Asynchronous Basic Mode)

  After enabling ATCCNTE.ATCE, SC2 Counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.

- Async Mode 1 (Asynchronous Advanced Mode)

  After enabling ATCCNTE.ATCE, SC2 Counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.

CAUTION

As the timing control specification, the SC2 counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

7.8.3 Operation

7.8.3.1 Data Structures

7.8.3.1.1 Command Descriptor

The write-only Command Descriptor structure is 64 bits in length. The Command Descriptor is put to the Command Queue with writes to the Command Queue Port.

Write to the Command Queue Port in the following order:

1. First write: The least significant DWORD (Command Descriptor Structure Low).
2. Second write: The most significant DWORD (Command Descriptor Structure High).

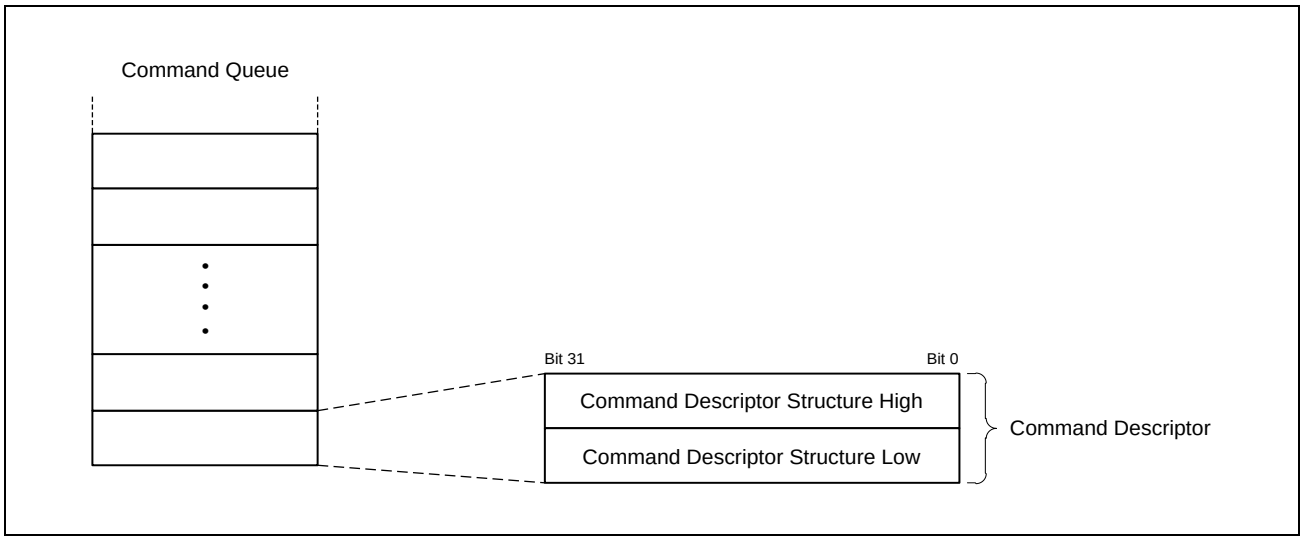

Figure 7.8-2 Command Descriptor Data Structure

I3C provides a Command Descriptor structure for each command type as follows:

- Address Assign Command
- Immediate Transfer Command
- Regular Transfer Command
- Combo Transfer Command
- Internal Control Command

Details are explained in the following sections.

(1) Address Assign Command

This command is used for address assignment (ENTDAA, SETDASA).

Remark When issuing SETAASA CCC, use the Immediate Transfer command.

The I3C provides an address assign command for the following mode:

- I3C Master Mode

Details of the Address Assign command structure are as follows.

Bit position	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	TOC	ROC	DEV_COUNT[3:0]				—	—	—	—	EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	—	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	R/W	Description
63 to 32	—	W	The write value should be 0.
31	TOC	W	Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of transfer 1: STOP: Issue STOP (P) at end of transfer
30	ROC	W	Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.
29 to 26	DEV_COUNT[3:0]	W	Device Count
25 to 22	—	W	The write value should be 0.
21	EXT_DEVICE	W	Extended Device Index 0: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.
20 to 16	DEV_INDEX[4:0]	W	Device Index
15	—	W	The write value should be 0.
14 to 7	CMD[7:0]	W	Transfer Command CCC Value
6 to 3	TID[3:0]	W	Transaction ID

Bit	Bit Name	R/W	Description
2 to 0	CMD_ATTR[2:0]	W	Command Attributes 000: XFER: Regular Transfer 001: IMMED_DATA_XFER: Immediate Data Transfer 010: ADDR_ASSGN_CMD: Address Assignment Command 011: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 111: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited

CMD_ATTR[2:0] bits (Command Attributes)

Command Type, defining the format of the other fields.

TID[3:0] bits (Transaction ID)

is reflected in the Response Descriptor.

CMD[7:0] bits (Transfer Command CCC Value)

Specifies CCC code indicating whether Address Assignment uses ENTDAA or SETDASA commands. The field comprises the entire command code (ENTDAA or SETDASA).

DEV_INDEX[4:0] bits (Device Index)

Indicates the DATBASm table index for the Slave device being addressed with the transfer. Static and device addressing related information are stored to this index in the DATBASm.

DEV_COUNT[3:0] bits (Device Count)

Indicates the number of devices that a dynamic address is assigned to.

ROC bit (Response on Completion)

Controls whether Response Status is sent after successful completion of the Transfer command. The successful completion is read from register NRSPQP. Upon unsuccessful transfer the Response Status is sent.

TOC bit (Terminate on Completion)

Controls what bus condition to issue after the Transfer command completes.

For ENTDAA, a STOP condition is issued regardless of the setting value of TOC. It is meaningful for SETDASA transfers.

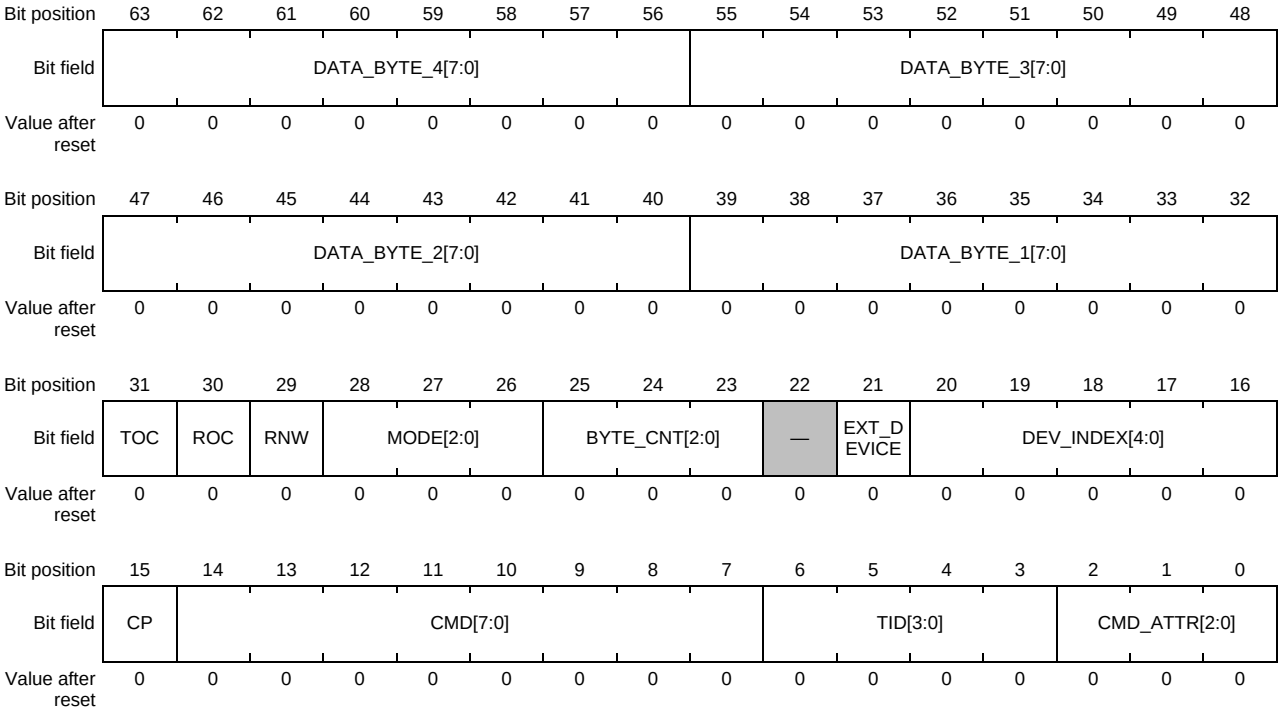
When sending SETDASA CCC by TOC = 0 (RESTART), the next command must be set to SETDASA CCC with the Address Assign Command.

When the next command is not the same SETDASA CCC flame, it must be set to TOC = 1 (STOP).

(2) Immediate Transfer Command

This structure directly contains data (max 4 bytes) to be transferred, and as a result is only useful for Transfers/CCCs that write data. This structure shall not be used for Read operations (for example, to receive data).

When transmitting data of 4 bytes or less, use this Immediate Transfer Command to communicate.



When transmitting data of 5 bytes or more, use the Regular Transfer Command to communicate.

For the Regular Transfer Command, refer to **7.8.3.1.1 (3) Regular Transfer Command**.

I3C provides an Immediate Transfer Command for the following mode:

- I3C Master Mode

Details of the Immediate Transfer Command Structure of each mode are shown in this section.

Bit	Bit Name	R/W	Description
63 to 56	DATA_BYTE_4[7:0]	W	Immediate Data Transfer Data Byte 4 Direct argument
55 to 48	DATA_BYTE_3[7:0]	W	Immediate Data Transfer Data Byte 3 Direct argument
47 to 40	DATA_BYTE_2[7:0]	W	Immediate Data Transfer Data Byte 2 Direct argument
39 to 32	DATA_BYTE_1[7:0]	W	Immediate Data Transfer Data Byte 1 Direct argument
31	TOC	W	Immediate Data Transfer Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of data transfer 1: STOP: Issue STOP (P) at end of data transfer
30	ROC	W	Immediate Data Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.
29	RNW	W	Immediate Data Transfer R/W 0: WRITE: Write transfer 1: READ: Read transfer

Bit	Bit Name	R/W	Description
28 to 26	MODE[2:0]	W	Immediate Data Transfer Mode and Speed Values for I3C Mode: 000: I3C SDR0 Data rate: STDBR (e.g., 12.5 MHz) 001: I3C SDR1 Data rate: EXTBR (e.g., 8 MHz) 010: I3C SDR2 Data rate: STDBR × 2 (e.g., 6.25 MHz) 011: I3C SDR3 Data rate: EXTBR × 2 (e.g., 4 MHz) 100: I3C SDR4 Data rate: EXTBR × 4 (e.g., 2 MHz) Others: Setting prohibited Values for I^2C Mode: 000: Legacy I2C Message 0 Data rate: STDBR (e.g., 400 kHz) 001: Legacy I^2C Message 0 Data rate: EXTBR (e.g., 1 MHz) Others: Setting prohibited
25 to 23	BYTE_CNT[2:0]	W	Immediate Data Transfer Byte Count 000: No payload 001 to 100: N bytes are valid. Others: Setting prohibited
22	—	W	The write value should be 0.
21	EXT_DEVICE	W	Immediate Data Transfer Extended Device Index 0: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.
20 to 16	DEV_INDEX[4:0]	W	Immediate Data Transfer Device Index
15	CP	W	Immediate Data Transfer Command Present 0: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC: This structure describes a CCC transfer, so the CMD field is valid.
14 to 7	CMD[7:0]	W	Immediate Data Transfer CCC Value For CCC: 8 bits
6 to 3	TID[3:0]	W	Immediate Data Transfer Transaction ID
2 to 0	CMD_ATTR[2:0]	W	Immediate Data Transfer Command Attribute 000: XFER: Regular Transfer 001: IMMED_DATA_XFER: Immediate Data Transfer 010: ADDR_ASSGN_CMD: Address Assignment Command 011: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 111: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited

CMD_ATTR[2:0] bits (Immediate Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Immediate Data Transfer Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Immediate Data Transfer Command Present)

Indicates whether CMD field is valid for CCC Transfer.

DEV_INDEX[4:0] bits (Immediate Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

BYTE_CNT[2:0] bits (Immediate Data Transfer Byte Count)

Number of valid data bytes to use in this Immediate Data Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

MODE[2:0] bits (Immediate Data Transfer Mode and Speed Values)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Immediate Data Transfer R/W)

Identifies direction of the transfer.

This field shall always be set to 0, because Immediate transfers are valid for Write transactions only.

ROC bit (Immediate Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Immediate Data Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1 (STOP).

(3) Regular Transfer Command

This structure does not contain data to be transferred.

For Master Mode, the data buffer is available through Transfer Data Queue Port (Receive Data Queue Port and Transmit Data Queue Port).

When transmitting data of 5 bytes or more, use this Regular Transfer Command to communicate.

When transmitting data of 4 bytes or less, use the Immediate Transfer Command to communicate.

For the Regular Transfer Command, refer to **7.8.3.1.1 (2) Immediate Transfer Command**.

For I3C Slave Mode, the IBI Payload buffer is available through IBI Status Queue Port.

I3C provides a Regular Transfer Command for each mode below.

- I3C Master Mode
- I3C Slave Mode

Details of the regular transfer command structure of each mode are shown below.

(a) I3C Master Mode

Bit position	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field	DATA_LENGTH[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	TOC	ROC	RNW	MODE[2:0]			—	—	—	—	EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	CP	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	R/W	Description
63 to 48	DATA_LENGTH[15:0]	W	Data Transfer Data Length Indicates the number of bytes to be transferred. This field must be set to non-zero value, except for CCCs that does not have payload defined.
47 to 32	—	W	The write value should be 0.
31	TOC	W	Data Transfer Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of transfer 1: STOP: Issue STOP (P) at end of transfer

Bit	Bit Name	R/W	Description
30	ROC	W	Data Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.
29	RNW	W	Data Transfer R/W 0: WRITE: Write transfer 1: READ: Read transfer
28 to 26	MODE[2:0]	W	Data Transfer Speed and Mode Values for I3C Mode: 000: I3C SDR0 Data rate: STDBR (e.g., 12.5 MHz) 001: I3C SDR1 Data rate: EXTBR (e.g., 8 MHz) 010: I3C SDR2 Data rate: STDBR × 2 (e.g., 6.25 MHz) 011: I3C SDR3 Data rate: EXTBR × 2 (e.g., 4 MHz) 100: I3C SDR4 Data rate: EXTBR × 4 (e.g., 2 MHz) Others: Setting prohibited Values for I^2C Mode: 000: Legacy I^2C Message 0 Data rate: STDBR (e.g., 400 kHz) 001: Legacy I^2C Message 0 Data rate: EXTBR (e.g., 1 MHz) Others: Setting prohibited
25 to 22	—	W	The write value should be 0.
21	EXT_DEVICE	W	Data Transfer Extended Device Index 0: Use the DATBASm Table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.
20 to 16	DEV_INDEX[4:0]	W	Data Transfer Device Index
15	CP	W	Data Transfer Command Present 0: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC: This structure describes a CCC transfer, so the CMD field is valid.
14 to 7	CMD[7:0]	W	Data Transfer CCC Code Value Specifies the I3C Command code. For CCC: 8 bits
6 to 3	TID[3:0]	W	Data Transfer Transaction ID Identification tag for this command
2 to 0	CMD_ATTR[2:0]	W	Data Transfer Command Attribute Command Type, defining the format of the other fields. Values: 000: XFER: Regular Transfer 001: IMMED_DATA_XFER: Immediate Data Transfer 010: ADDR_ASSGN_CMD: Address Assignment Command 011: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 111: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited

CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Data Transfer Transaction ID Identification tag for this command)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Data Transfer Command Present)

Indicates whether he contents of the CMD field is valid for a CCC Transfer.

DEV_INDEX[4:0] bits (Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

MODE[2:0] bits (Data Transfer Speed and Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

ROC bit (Data Transfer Response on Completion)

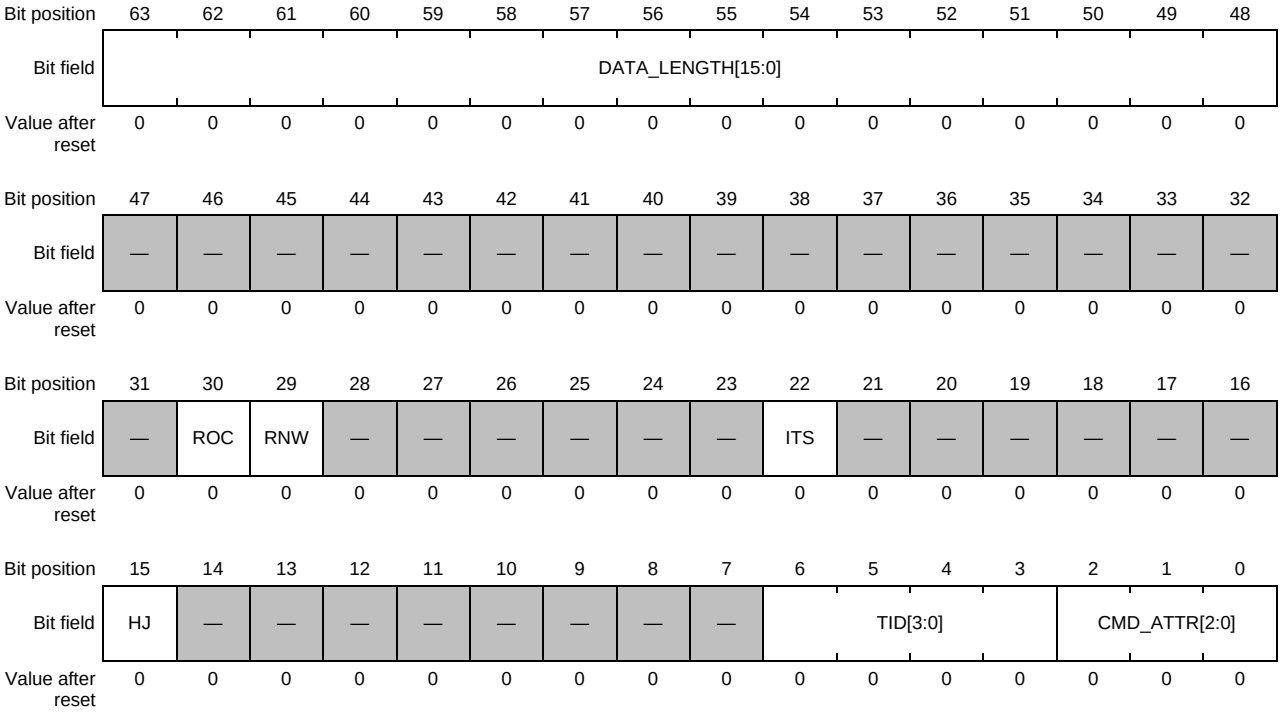
Controls whether Response Status is required after successful completion of the transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Data Transfer Terminate on Completion)

Controls what Bus condition will be issued after completion of the transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC b , must be set to TOC = 1 (STOP).



DATA_LENGTH[15:0] bits (Data Transfer Data Length)

Number of valid data bytes to use in this Regular Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

Length setting of GETMXDS command should be fixed to 5.

(b) I3C Slave Mode

Bit	Bit Name	R/W	Description
63 to 48	DATA_LENGTH[15:0]	W	Data Transfer Data Length Indicates the number of bytes to be transferred. This field must be set to non-zero value, except for CCCs that does not have payload defined.
47 to 31	—	W	The write value should be 0.
30	ROC	W	Data Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.
29	RNW	W	Data Transfer R/W 0: WRITE: Write transfer (Mastership Request) 1: READ: Read transfer (Slave Interrupt Request)
28 to 23	—	W	The write value should be 0.
22	ITS	W	Include timestamp for Async Mode 0: Do not include timestamp. 1: Include timestamp.
21 to 16	—	W	The write value should be 0.
15	HJ	W	Data Transfer Hot-Join Event 0: Slave Interrupt Request or Mastership Request, so the RNW field is valid. 1: Hot-Join Event, so the RNW field is not valid.
14 to 7	—	W	The write value should be 0.
6 to 3	TID[3:0]	W	Data Transfer Transaction ID Identification tag for this command
2 to 0	CMD_ATTR[2:0]	W	Data Transfer Command Attribute Command Type, defining the format of the other fields. Values: 000: XFER: Regular Transfer 001: IMMED_DATA_XFER: Immediate Data Transfer 010: ADDR_ASSGN_CMD: Address Assignment Command 011: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 100 to 110: Reserved, do not use 111: INTERNAL_CONTROL: Internal Control command

CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Data Transfer Transaction ID Identification tag for this command)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

HJ bit (Data Transfer Hot-Join Event)

Indicates whether Hot-Join Event is valid in this IBI Data transfer.

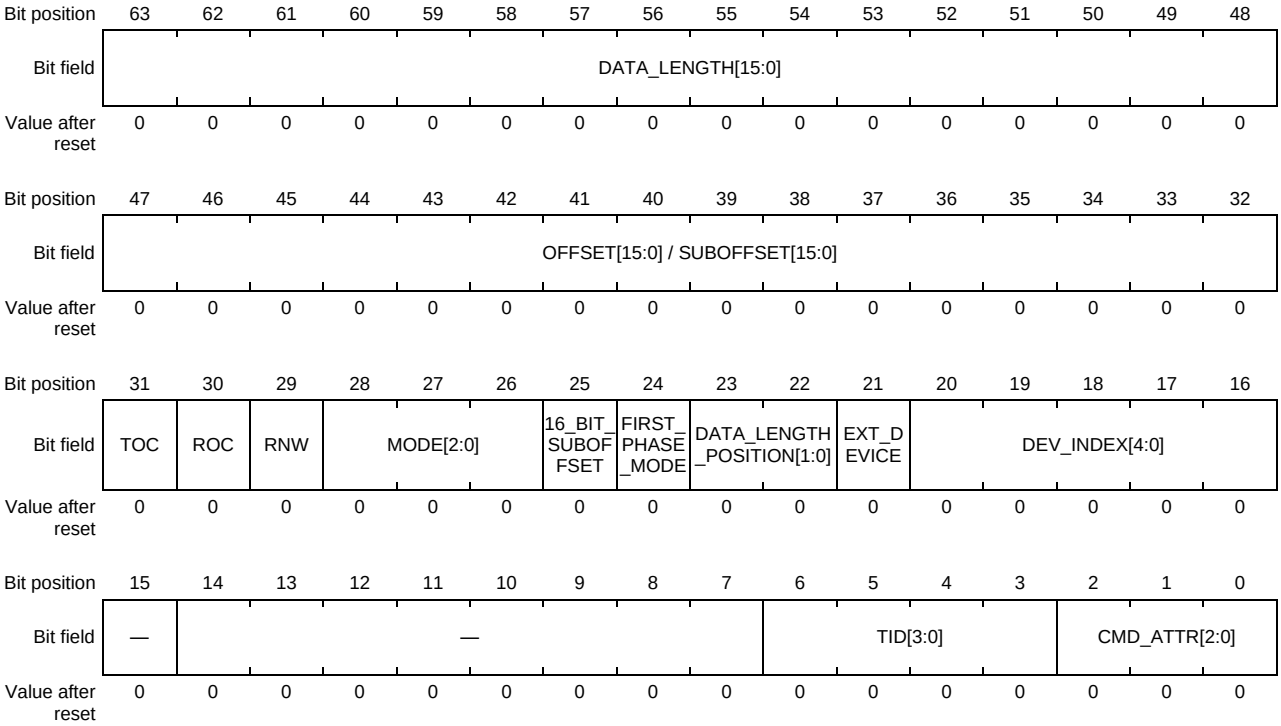
RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

(4) Combo Transfer Command



This structure contains a combined Write + Read/Write operation.

The data buffer is available through Transfer Data Queue Port (Receive Data Queue Port and Transmit Data Queue Port).

I3C provides a Combo Transfer Command for the following mode:

- I3C Master Mode

Details of the Combo Transfer Command Structure of each mode are as follows.

Bit	Bit Name	R/W	Description
63 to 48	DATA_LENGTH[15:0]	W	Combo Transfer Data Length Number of bytes to be transferred. This field must be set to non-zero value.
47 to 32	OFFSET[15:0]/ SUBOFFSET[15:0]	W	Combo Transfer Offset/Sub-Offset Offset of the target operation
31	TOC	W	Combo Transfer Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of transfer 1: STOP: Issue STOP (P) at end of transfer
30	ROC	W	Combo Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.
29	RNW	W	Combo Transfer R/W Identifies direction of the transfer. 0: WRITE: Write transfer 1: READ: Read transfer

Bit	Bit Name	R/W	Description
28 to 26	MODE[2:0]	W	Combo Transfer Speed and Mode Values for I3C Mode: 000: I3C SDR0 Data rate: STDBR (e.g., 12.5 MHz) 001: I3C SDR1 Data rate: EXTBR (e.g., 8 MHz) 010: I3C SDR2 Data rate: STDBR × 2 (e.g., 6.25 MHz) 011: I3C SDR3 Data rate: EXTBR × 2 (e.g., 4 MHz) 100: I3C SDR4 Data rate: EXTBR × 4 (e.g., 2 MHz) Others: Setting prohibited
25	16_BIT_SUBOFFSET	W	Combo Transfer Sub Offset Size 0: 8_BIT_SUBOFFSET: Sub-offset is 8-bits long. Value is encoded in Lower Byte of OFFSET/SUBOFFSET field. 1: 16_BIT_SUBOFFSET: Sub-offset is 16-bits long.
24	FIRST_PHASE_MODE	W	Combo Transfer First Phase Mode 0: SDR: First phase is executed in SDR mode. 1: MODE: First phase is executed in the mode indicated by the MODE field.
23, 22	DATA_LENGTH_POSITION[1:0]	W	Data Length Field Position 0 0: NO: Do not put length field. 0 1: FIRST: Put length as first field. 1 0: SECOND: Put length as second field. Others: Setting prohibited
21	EXT_DEVICE	W	Combo Transfer Extended Device Index 0: Use the DAT table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.
20 to 16	DEV_INDEX[4:0]	W	Combo Transfer Device Index Indicates the DAT table index for the Slave device being addressed with the transfer. Static and device addressing related information are stored to this index in the DAT.
15 to 7	—	W	The write value should be 0.
6 to 3	TID[3:0]	W	Combo Transfer Transaction ID Identification tag for the command
2 to 0	CMD_ATTR[2:0]	W	Combo Transfer Command Attribute Command Type, defining the format of the other fields. 000: XFER: Regular Transfer 001: IMMED_DATA_XFER: Immediate Data Transfer 010: ADDR_ASSGN_CMD: Address Assignment Command 011: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 111: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited

CMD_ATTR[2:0] bits (Combo Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Combo Transfer Transaction ID Identification tag for the command)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

DEV_INDEX[4:0] bits (Combo Transfer Device Index)

Indicates the DAT table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DAT.

DATA_LENGTH_POSITION[1:0] bits (Data Length Field Position)

Indicates whether and where to put Data Length (DATA_LENGTH) in the first phase of the transfer.

Whether 8-bit or 16-bit of Data Length field is used is indicated with 16_BIT_SUBOFFSET field. In case of 8-bit value, it is encoded in Lower Byte of DATA_LENGTH field.

FIRST_PHASE_MODE bits (Combo Transfer First Phase Mode)

Indicates whether the first phase of the Combo Transfer is executed in SDR Mode, vs. the Mode indicated by the MODE field.

MODE[2:0] bits (Combo Transfer Speed and Mode Values for I3C Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DAT Table entry indexed by field DEV_INDEX).

RNW bit (Combo Transfer R/W Identifies direction of the transfer)

Identifies direction of the transfer.

ROC bit (Combo Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Combo Transfer Terminate on Completion)

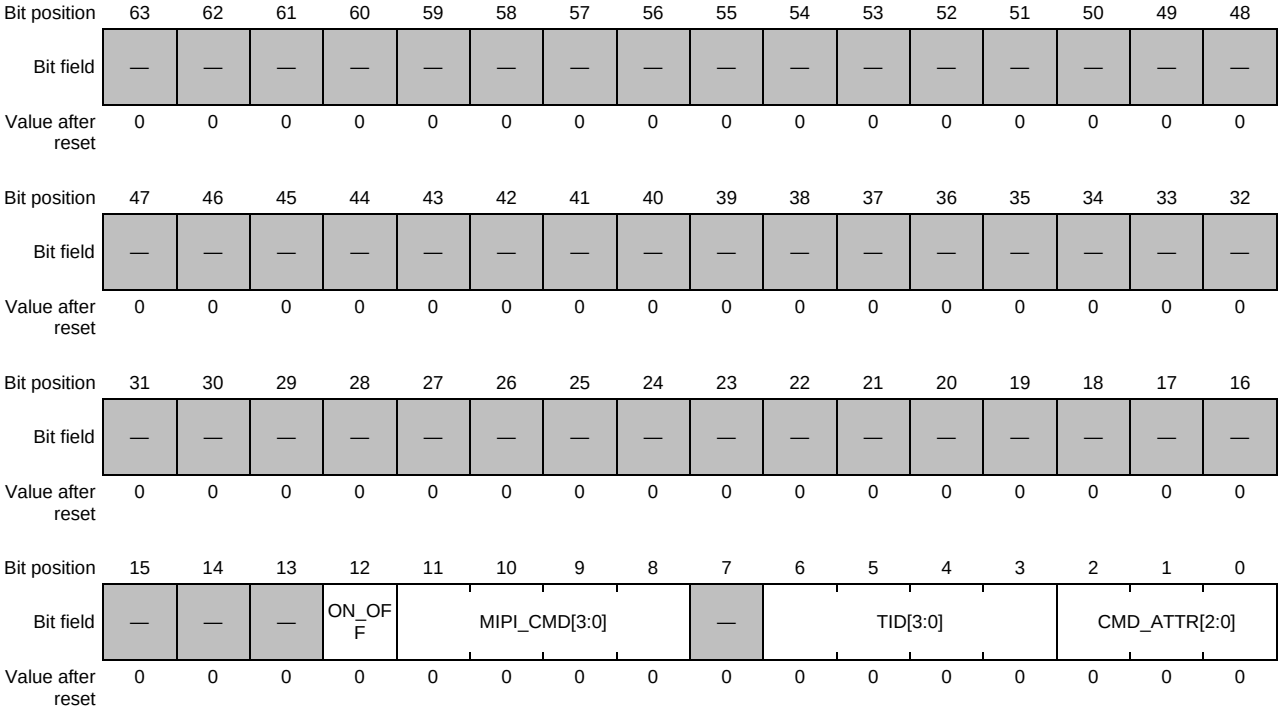
Controls what Bus condition is issued after completion of the data transfer.

When the next command is SDR mode, must be set to TOC = 1 (STOP).

DATA_LENGTH[15:0] bit (Combo Transfer Data Length Number of bytes to be transferred. This field must be set to non-zero value.)

Number of valid data bytes to use in this Combo Transfer Descriptor.

This field must be set to non-zero value.



(5) Internal Control Command

This structure is used for controlling I3C itself (not for transfer commands).

I3C provides an Internal Control Command for the following mode:

- I3C Master Mode

Details of the Internal Control Command Structure are as follows:

Bit	Bit Name	R/W	Description
63 to 13	—	W	The write value should be 0.
12	ON_OFF	W	Bus Instance 7E On/Off*1 Enables or disables automatic transmission of the I3C Broadcast Header after every START condition on this I3C Bus instance. 0: IBA_INCLUDE off 1: IBA_INCLUDE on
11 to 8	MIPI_CMD[3:0]	W	MIPI Alliance Command H'0: NoOp, so the ON_OFF field is not valid. H'2: Include 7E (IBA), so the ON_OFF field is valid. Others: Setting prohibited
7	—	W	The write value should be 0.
6 to 3	TID[3:0]	W	Transaction ID Identification tag for the command
2 to 0	CMD_ATTR[2:0]	W	Command Attribute*2 Command Type, defining the format of the other fields. 000: XFER: Regular Transfer 001: IMMED_DATA_XFER: Immediate Data Transfer 010: ADDR_ASSGN_CMD: Address Assignment Command 011: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 111: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited

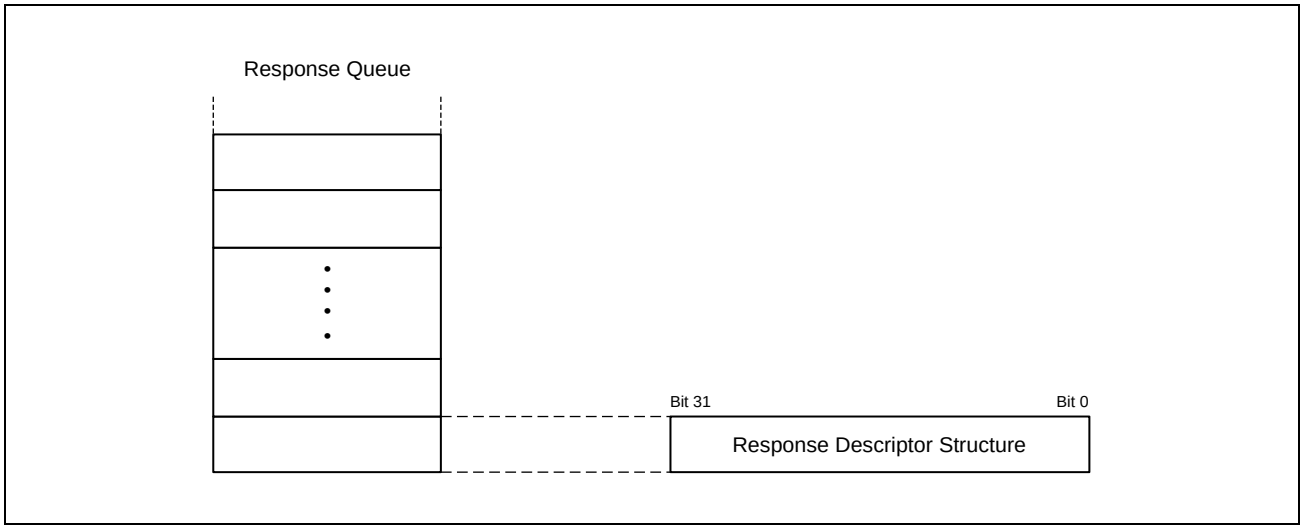
Note 1. The IBA_INCLUDE on state set by MIPI_CMD[3:0] = 0010b and ON_OFF = 1 is cleared by setting RSTCTL.INTLRST to 1.

Note 2. The Response descriptor is not stored when the Internal Control Command is executed.

7.8.3.1.2 Response Descriptor

The Response Descriptor is a read-only structure describing the success or failure of a command, and the amount of data transferred.

The Response Descriptor is read from Response Queue with reads from Response Queue Port.



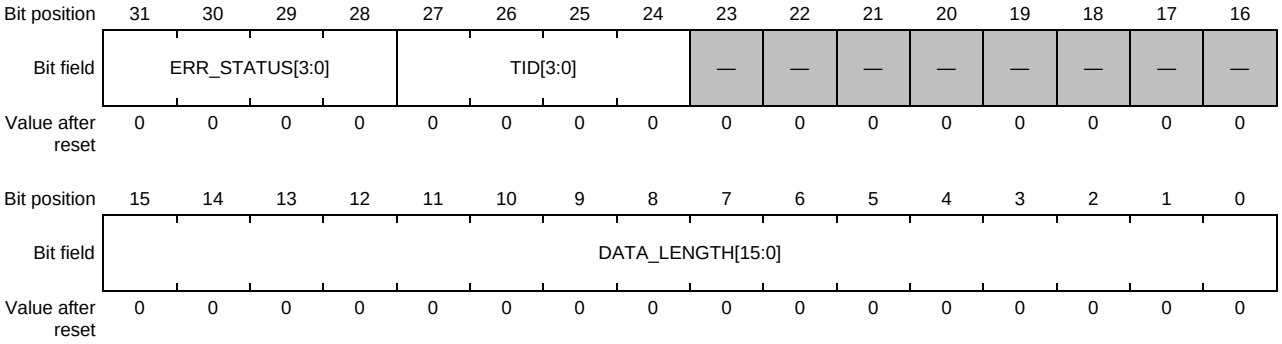


Figure 7.8-3 Response Descriptor Data Structure

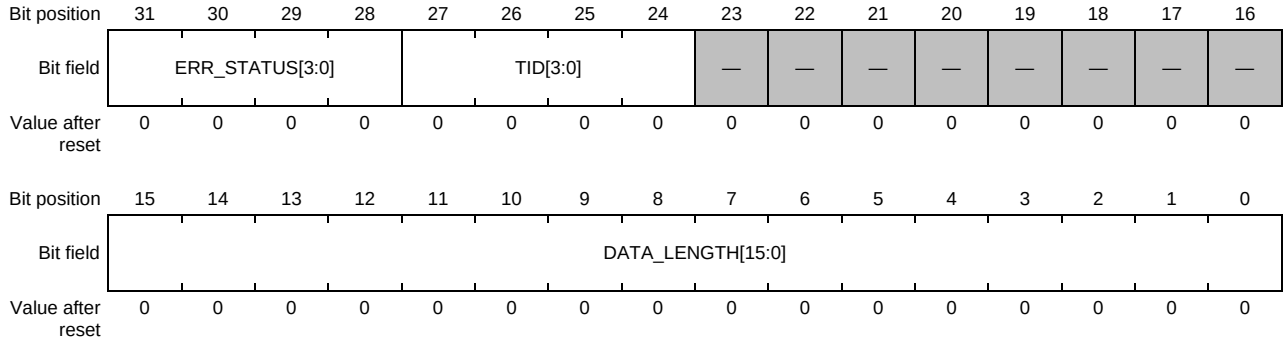
I3C provides a Response Descriptor for the following modes:

- I3C Master Mode
- I3C Slave Mode

Details of the Response Descriptor structure of each mode are shown in the following sections.



(a) I3C Master Mode

Bit	Bit Name	R/W	Description
31 to 28	ERR_STATUS[3:0]	R	MIPI Alliance Command H'0: SUCCESS: Transfer successful, no error H'1: CRC: CRC Error H'2: PARITY: Parity Error H'3: FRAME: Frame Error H'4: ADDR_HEADER: Address Header Error H'5: NACK: Address NACKed or Dynamic Address Assignment NACKed H'6: OVL: Receive Overflow or Transfer Underflow Error H'8: ABORTED: Aborted H'9: I^2C_WR_DATA_NACK: NACK received for the I^2C Write Data transfer H'A: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported) Others: Setting prohibited
27 to 24	TID[3:0]	R	Command/Response Transaction ID Identification tag for the command. This value shall match one of commands sent on the Bus. H'0 to H'7: Valid Transaction IDs Others: Setting prohibited
23 to 16	—	R	These bits are read as 0.
15 to 0	DATA_LENGTH[15:0]	R	Data Length/Device Count The meaning of this field depends on the context: For Write Transfer: Remaining data length (in bytes) For Read Transfer: Received data length (in bytes) For Address Assignment: Remaining Device count

Note: In I3C Master mode, when an abnormal command with a specific parameter that is not supported is stored in Command Descriptor, it is indicated as NOT_SUPPORTED (H'A) in ERR_STATUS[3:0].

(b) I3C Slave Mode

Bit	Bit Name	R/W	Description
31 to 28	ERR_STATUS[3:0]	R	Response Error Status H'0: SUCCESS: Transfer successful, no error. H'3: FRAME: Frame Error H'4: ADDR_HEADER: Address Header Error H'5: NACK: Address NACK'ed or Dynamic Address Assignment NACK'ed H'6: OVL: Receive Overflow or Transfer Underflow Error H'8: ABORTED: Aborted H'A: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported) Others: Setting prohibited
27 to 24	TID[3:0]	R	Command/Response Transaction ID Identification tag for the command. This value matches one of commands sent on the bus. H'0 to H'7: Valid Transaction IDs Others: Setting prohibited
23 to 16	—	R	These bits are read as 0.
15 to 0	DATA_LENGTH[15:0]	R	Data Length Remaining data length (in bytes) for Slave Interrupt Request

Note: In I3C Slave mode, it is indicated as NOT_SUPPORTED (H'A) in ERR_STATUS[3:0] in the following cases:
- When an abnormal command with a specific parameter that is not supported is stored in the Command Descriptor.
- When the IBI to be transmitted is disabled in the CSECMD register.
- After the normal command for IBI transmission is prepared in the Command Queue, when that IBI is disabled in the CSECMD register by the DISEC CCC frame from the I3C Master.

7.8.3.1.3 IBI Status Descriptor

The IBI Status Descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C Bus.

The IBI Status Descriptor is read from IBI Status Queue with reads from IBI Status Queue Port.

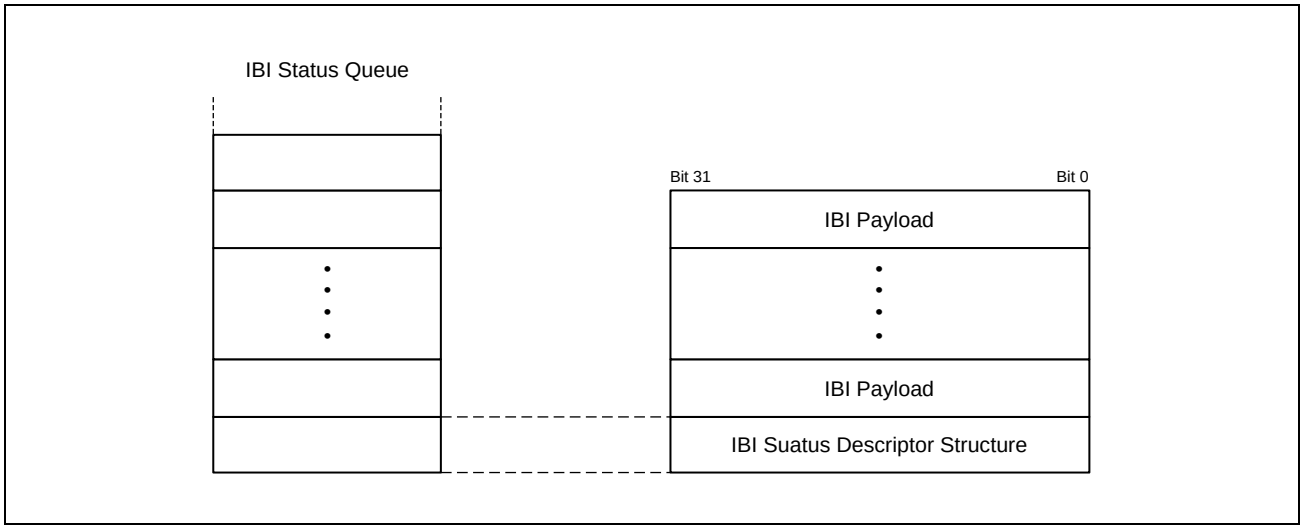


Figure 7.8-4 IBI Status Descriptor Data Structure

I3C provides a IBI Status Descriptor for the following mode:

- I3C Master Mode

Details of the IBI Status Descriptor Structure are as follows.

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	IBI_ST	—	—	ERR_STATUS[2:0]			TS	LAST_STATUS	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	IBI_ID[7:0]								DATA_LENGTH[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	R/W	Description
31	IBI_ST	R	IBI Received Status Indicates how the received IBI was handled. 0: The IBI was handled with ACK. 1: NACK: The IBI was handled with NACK, and then Auto-Disabled.
30, 29	—	R	These bits are read as 0. The write value should be 0.
28:26	ERR_STATUS[2:0]	R	IBI Error Status 000: SUCCESS 011: ERROR: FRAME (Frame Error) 100: ERROR: ADDR_HEADER (Address Header Error) 101: NACK: Address NACKed 111: ERROR: ABORT (Aborted to Master) Others: Setting prohibited

Bit	Bit Name	R/W	Description
25	TS	R	IBI Time-stamp Present Indicates whether a timestamp is available for the IBI. 0: OFF: IBI is not time-stamped. 1: ON: IBI is time-stamped.
24	LAST_STATUS	R	Last IBI Status Last IBI status for the IBI transaction.
23:16	—	R	These bits are read as 0. The write value should be 0.
15:8	IBI_ID[7:0]	R	IBI Received ID The meaning of this field depends on the context: For Slave Interrupt or Master Request: Bits 15:9 contain the Slave's Device Address, and bit 8 contains the R/W bit. For Hot-Join IBI: Bits 15:8 contain the Hot-Join ID for the IBI.
7:0	DATA_LENGTH[7:0]	R	IBI Data Length Number of data bytes in IBI Data.

LAST_STATUS bits (Last IBI Status)

Even if LAST_STATUS is set to 0, the software driver still evaluates the data payload length by examining the CHUNKS field.

7.8.3.1.4 Receive Status Descriptor

The Receive Status Descriptor is a read-only structure describing the success or failure of read/write operation from the master, and the amount of data transferred.

The Receive Status Descriptor is read from Receive Status Queue with reads from Receive Status Queue Port.

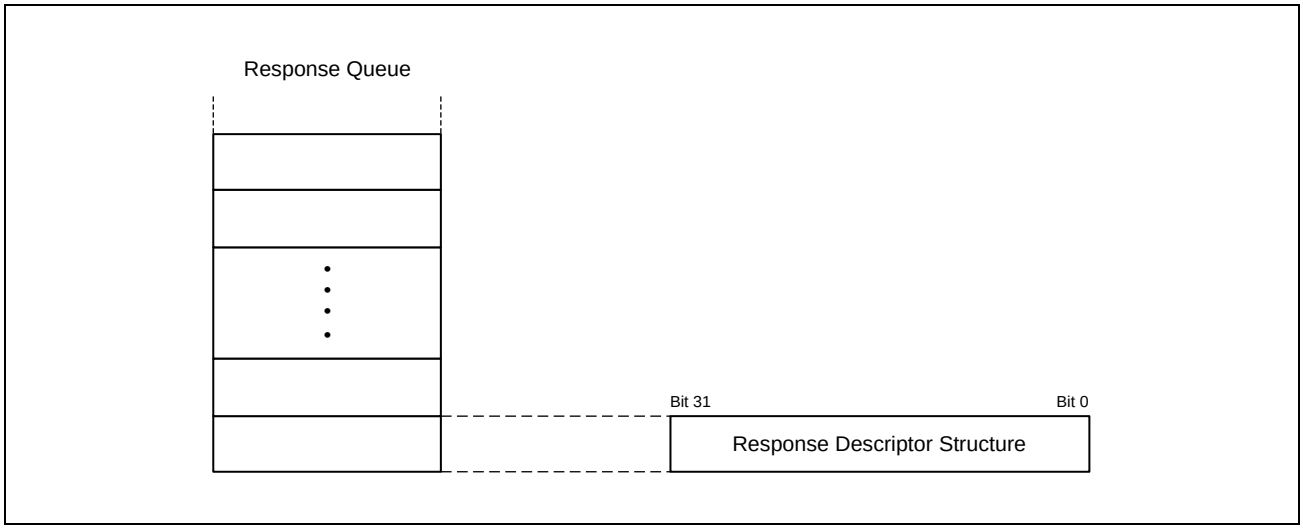

Figure 7.8-5 Receive Status Descriptor Data Structure

I3C provides a Receive Status Descriptor for the following mode:

- I3C Slave Mode

Details of the Receive Status Descriptor structure of each mode are as follows.

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	DEV_INDEX[2:0]			TRANSFER_TYPE[1:0]		ERR_STATUS[2:0]			CMD[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	DATA_LENGTH[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	R/W	Description
31 to 29	DEV_INDEX[2:0]	R	Device Index Indicates the SVDVADn index for the response with the transfer.
28, 27	TRANSFER_TYPE [1:0]	R	Transfer Type 00: I3C SDR/I^{2}C Message 01: I3C CCC 10: Setting prohibited 11: Setting prohibited

Bit	Bit Name	R/W	Description
26 to 24	ERR_STATUS[2:0]	R	Error Status 000: SUCCESS 001: ERROR: CRC (CRC Error) 010: ERROR: PARITY (Parity Error) 011: ERROR: FRAME (Frame Error) 100: ERROR: ADDR_HEADER (Address Header Error) 101: ERROR: NACK (Slave NACKed) 110: ERROR: OVL (FIFO Overflow/Underflow) 111: ERROR: ABORT (Aborted to Master)
23 to 16	CMD[7:0]	R	The contents are different depending on the operation mode. Details are are follows: [SDR Private Message Mode] Bit 23: R/W Type Bits 22 to 20: Setting prohibited Bit 19: I3C_I^2C Type Bits 18 to 16: Setting prohibited [SDR CCC Mode] CCC code[7:0]
15 to 0	DATA_LENGTH[15:0]	R	Data Length The meaning of this field depends on the context. For Write Transfer: Received data length (in bytes) For Read Transfer: Transmitted data length (in bytes)

7.8.3.2 Details of Function

7.8.3.2.1 Operation Mode

The support relationship between the mode selects (I3C mode/I²C mode) and operation mode (Master/Slave) on the I3C bus or the I²C bus is shown in **Table 7.8-10**.

Table 7.8-10 Support of Operating Mode

	I3C Mode		I²C Mode	
I3C/I²C Bus	Master	Slave	Master	Slave
I3C Bus	✓	✓	—	✓
I²C Bus	—	—	✓	✓

Note: ✓: Supported
— : Un-Supported

(1) Master Mode Operation

(a) I²C Master Operation

1) Data Write Transfer (Single Buffer transfer)

In master transmit operation, I3C outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. **Figure 7.8-6** shows an example of usage of master transmission and **Figure 7.8-6** to **Figure 7.8-8** show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

1. Initial settings. For details, refer to **7.8.3.3.1 Initial Setting Flow**.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag bit is automatically set to 0, the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Transmit Data Buffer 0 to the Shift Register, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Because the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1_1110, the 2 higher-order bits of the slave address, and W to the NTDTBP0 register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the NTDTBP0 register.
4. After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the SCLn line low until the data for transmission are ready or a STOP condition is issued.

5. After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then set the CNDCTL.SPCND bit to 1 (STOP condition issuance request). Upon receiving a STOP condition issuance request, I3C issues the STOP condition.
6. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, it automatically sets the TDBEF0 and TENDF flags to 0, and sets the BST.SPCNDDF flag to 1.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

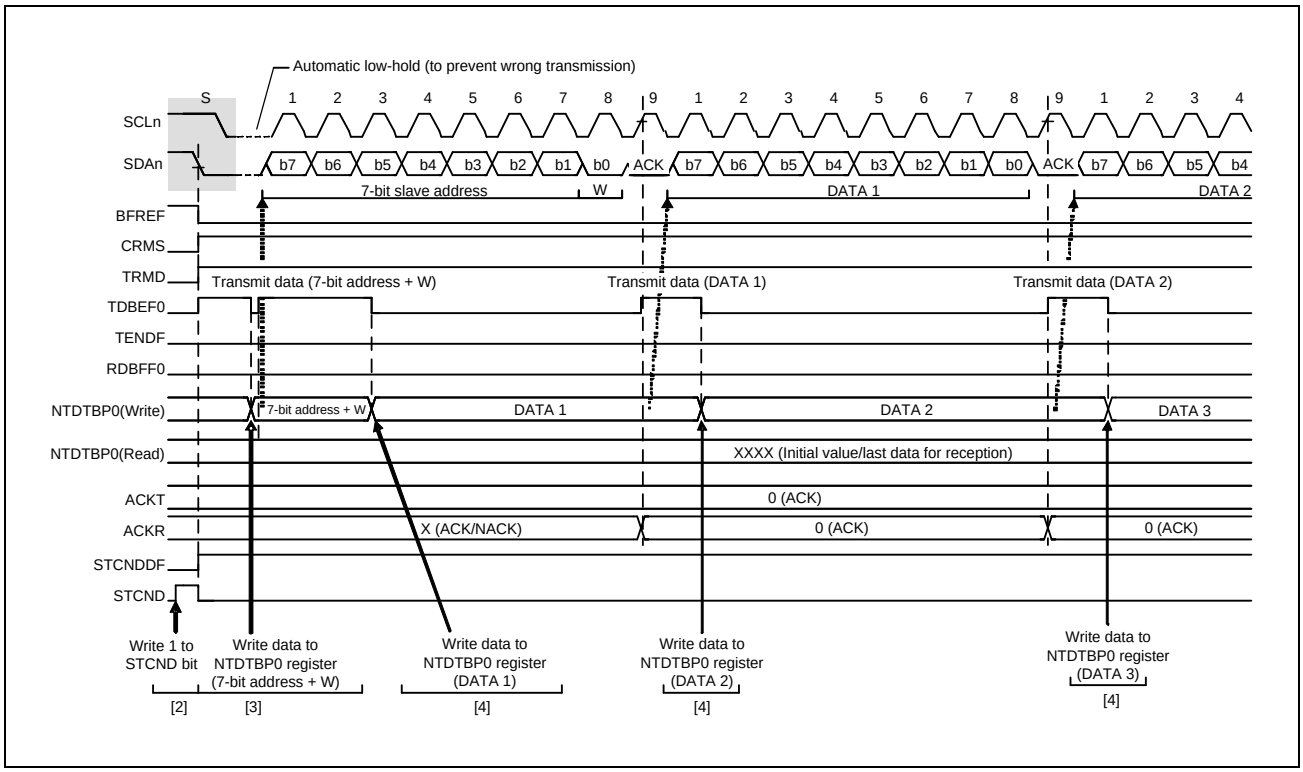

Figure 7.8-6 Master Transmit Operation Timing (1) (7-bit Address Format)

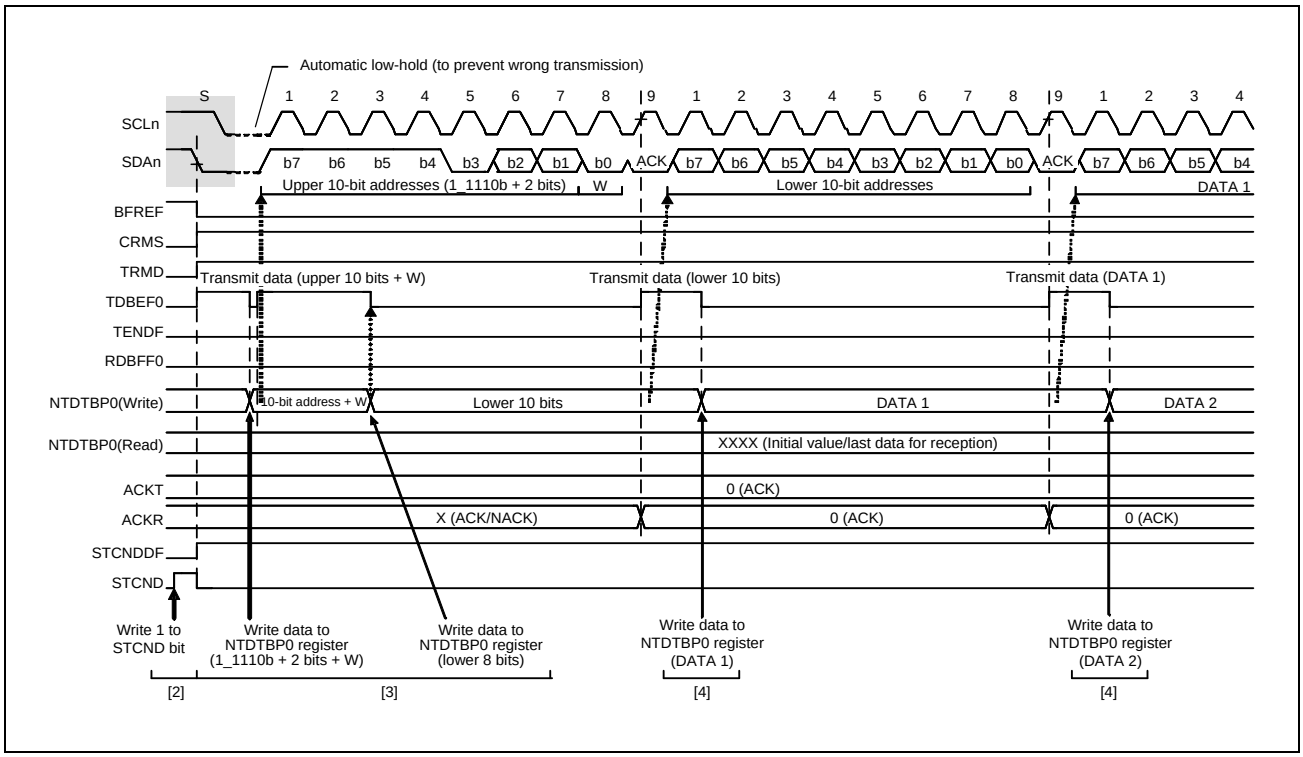

Figure 7.8-7 Master Transmit Operation Timing (2) (10-bit Address Format)

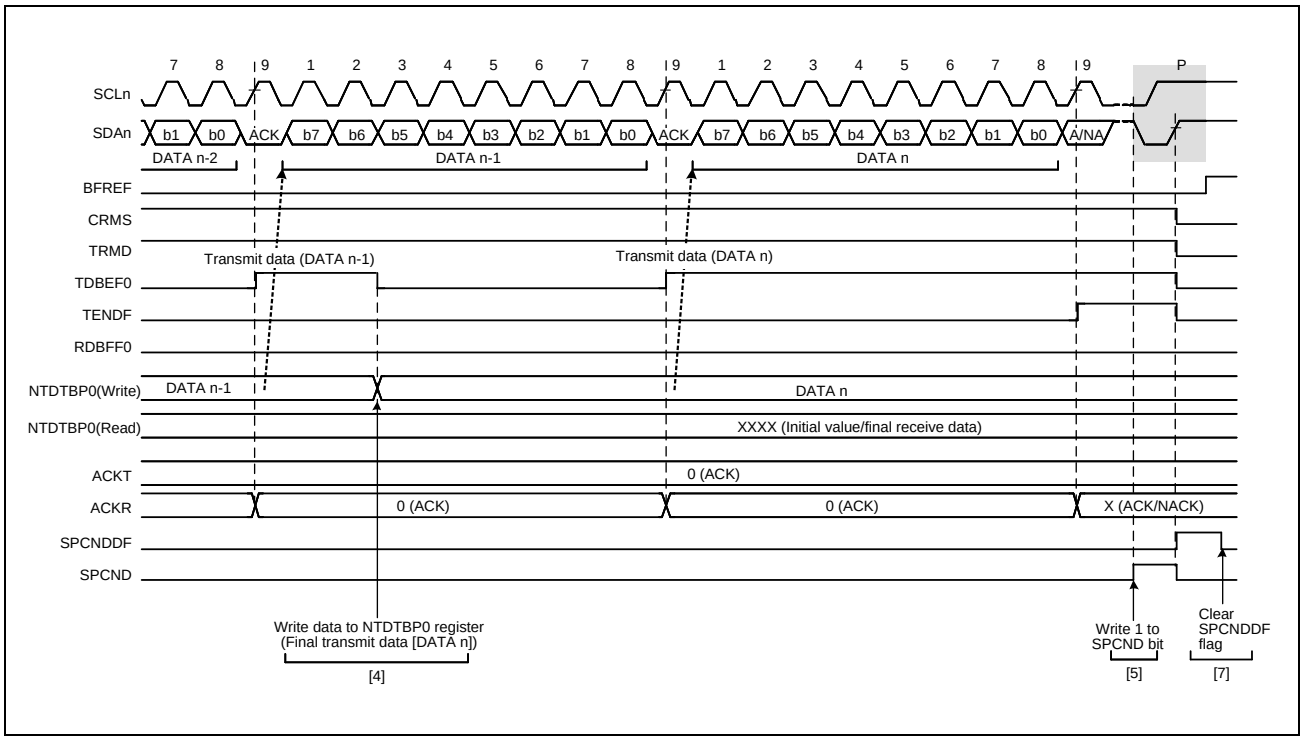

Figure 7.8-8 Master Transmit Operation Timing (3)

2) Data Read Transfer (Single Buffer transfer)

In master receive operation, I3C as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because I3C must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 7.8-121 and **Figure 7.8-122** show examples of usage of master reception (7-bit address format) and **Figure 7.8-9** to **Figure 7.8-11** show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

1. Initial settings. For details, refer to **7.8.3.3.1 Initial Setting Flow**.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. When I3C detects the START condition, the BFREF flag is automatically set to 0 and the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the SDAn line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Transmit Data Buffer 0 to the Shift Register, and the TDBEF0 flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the PRSST.TRMD bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRMD bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing I3C in master receive mode. At this time, the TDBEF0 flag is set to 0. The NTST.RDBFF0 flag is automatically set to 1 when ACK response is received from the slave device. If the slave device is not recognized or a communication failure occurs, the BST.NACKDF flag will be set to 1. At this time, set 1 to the CNDCTL.SPCND bit to issue a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a Repeated START condition. After that, transmitting 1_1110, the two higher-order bits of the slave address, and the R bit places I3C in master receive mode.
4. Dummy read the NTDTBP0 register after confirming that the NTST.RDBFF0 flag = 1; this makes I3C start output of the SCL clock and start data reception.
5. After 1 byte of data has been received, the NTST.RDBFF0 flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the SCSTRCTL.ACKTWE bit. Reading the NTDTBP0 register at this time will produce the received data, and the RDBFF0 flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ACKCTL.ACKT bit. Furthermore, if the next byte to be received is the next to last byte, set the SCSTRCTL.RWE bit to 1 (for wait insertion) before reading the NTDTBP0 register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ACKCTL.ACKT bit to 1 (NACK) in step 6, due to other interrupts, etc., this fixes the SCLn line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a STOP condition is possible.
6. When the SCSTRCTL.ACKTWE bit = 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ACKCTL.ACKT bit to 1 (NACK).
7. After reading the byte before last from the NTDTBP0 register, if the value of the NTST.RDBFF0 flag is confirmed to be 1, write 1 to the CNDCTL.SPCND bit (STOP condition issuance request) and then read the last byte from the NTDTBP0 register. When 1 is written to the CNDCTL.SPCND bit, I3C is released from the wait state and issues

the STOP condition after low-level output in the ninth clock cycle is completed or the SCLn line is released from the low- hold state.

8. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the BST.SPCNDDF flag to 1.

9. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

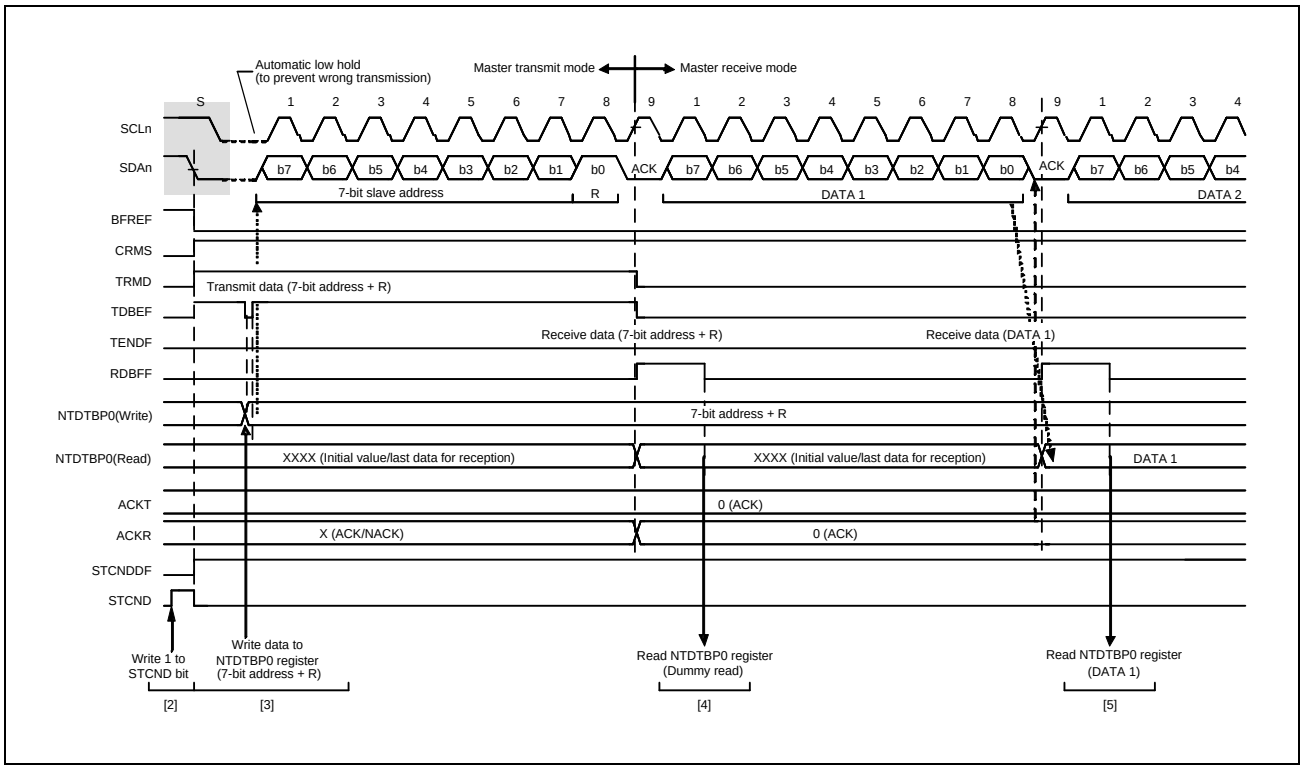

Figure 7.8-9 Master Receive Operation Timing (1) (7-bit Address Format, When ACKTWE = 0)

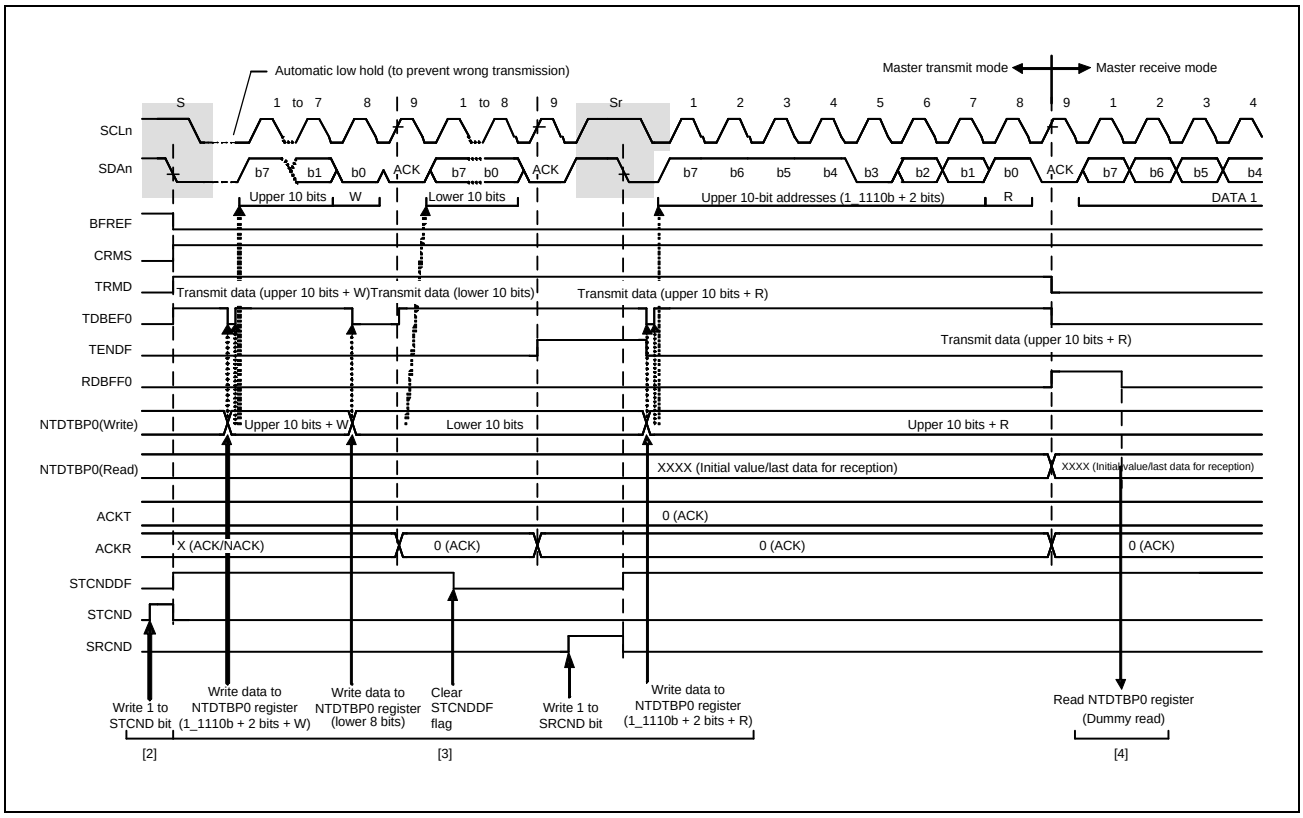

Figure 7.8-10 Master Receive Operation Timing (2) (10-bit Address Format, When ACKTWE = 0)

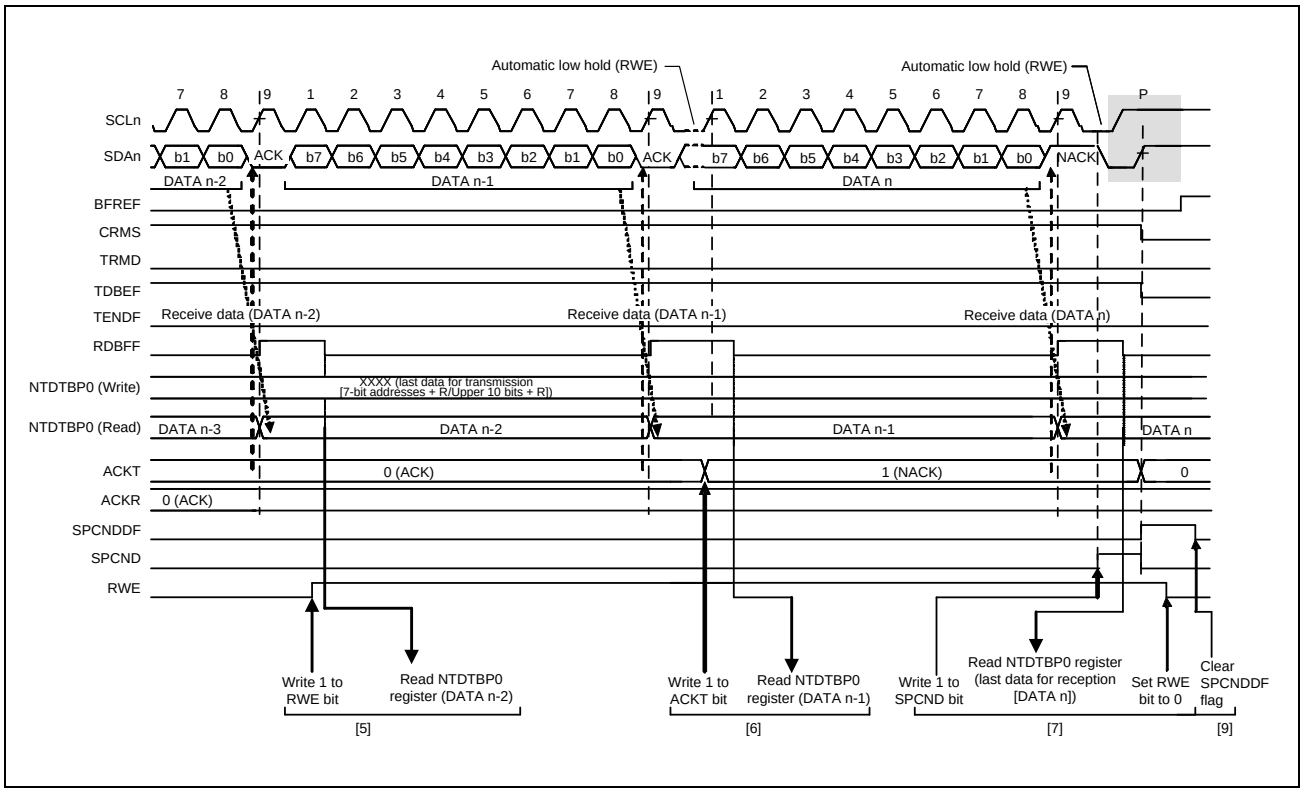

Figure 7.8-11 Master Receive Operation Timing (3) (When ACKTWE = 0)

(b) I3C Master Operation

1) Dynamic Address Assign Procedure

After initializing I3C, first execute Dynamic Address Assign Procedure for I3C Slave connected on the I3C Bus. The following describes the procedure.

1. Initial setting (refer to **7.8.3.3.1 (2) I3C Initial Setting Flow** for details)
2. Execute Dynamic Address Assign with ENTDAA or SETDASA Common Command Code (CCC) for I3C Slave set in DAT (DATBASm register).
   Write Command Descriptor (Address Assign Command) to Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, Transaction is issued on I3C Bus.
4. When ENTDAA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave for the number of DATs specified by DEV_COUNT[3:0] starting with DAT specified by DEV_INDEX[4:0] of Address Assign Command.
   When SETDASA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave indicated by DAT specified by DEV_INDEX[4:0] of Address Assign Command.
5. In case of ENTDAA, the Provisional ID, BCR, DCR transmitted from I3C Slave is stored in Receive Data Buffer (BCR is also automatically stored in the MSDCTm register).
   Read the Provisional ID, BCR, and DCR from the Receive Data Buffer via the NTDTBPn register with an interrupt by RDBFF0 = 1.
6. When execution of Dynamic Address Assign is completed, issue STOP condition and store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor via the NRSPQP register and check the status.
8. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor match the value of DEV_COUNT[3:0] of the Address Assign Command.

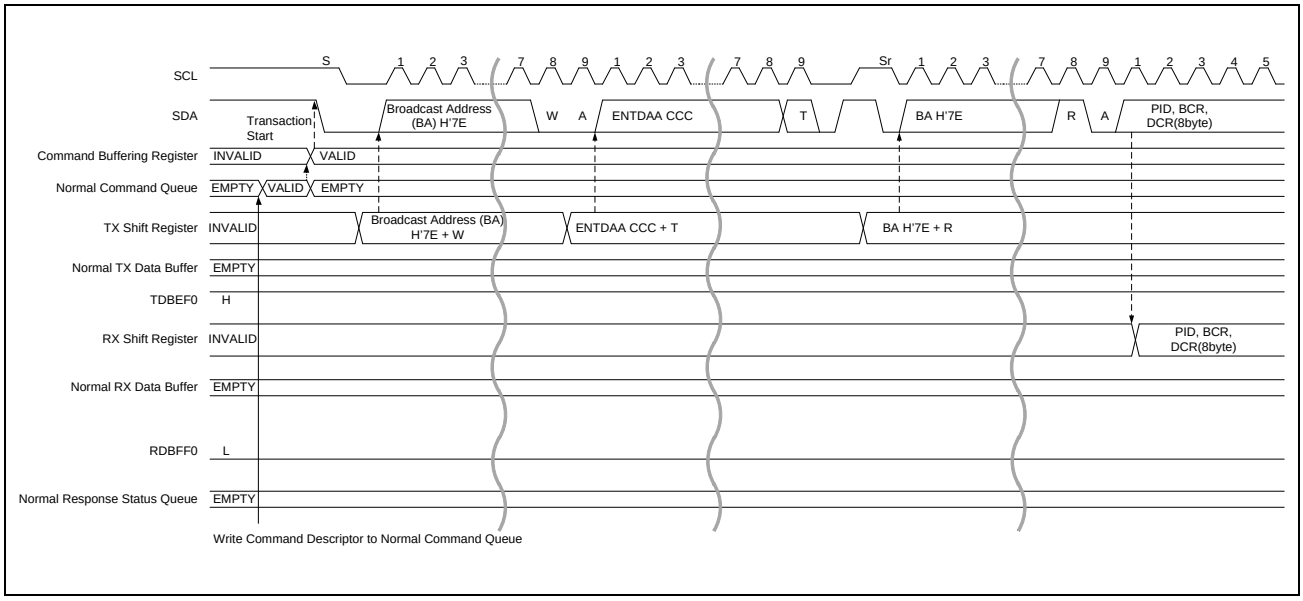

Figure 7.8-12 Dynamic Address Assign Procedure (ENTDAA CCC) Timing (1/3)

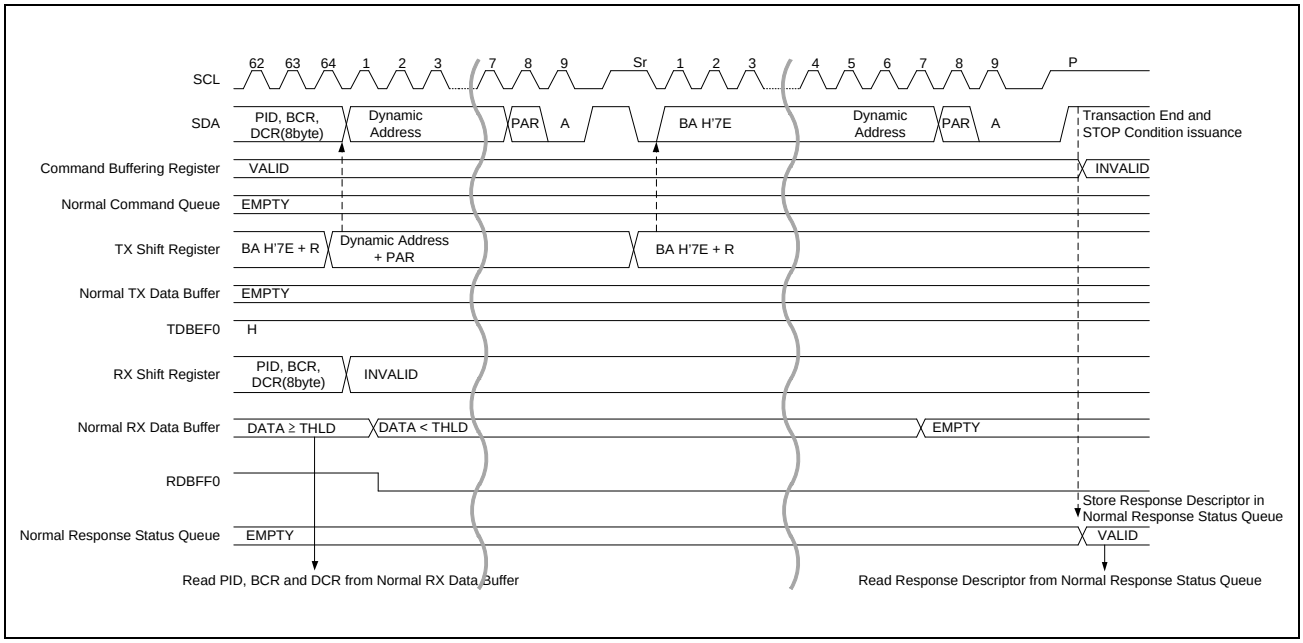

Figure 7.8-14 Dynamic Address Assign Procedure (ENTDAA CCC) Timing (3/3)

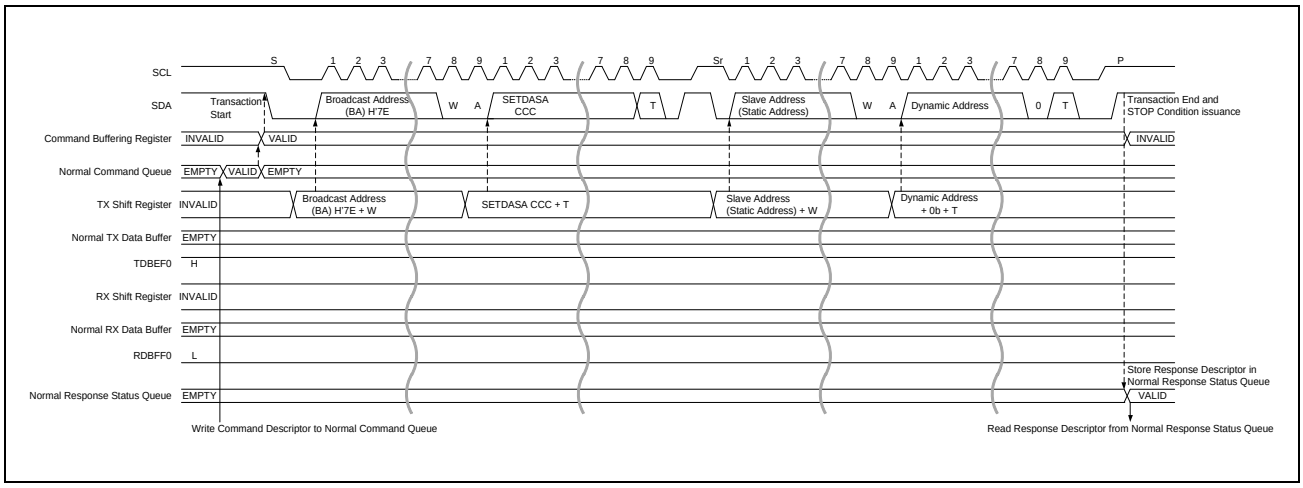

Figure 7.8-15 Dynamic Address Assign Procedure (SETDASA CCC) Timing

2) SDR Data Write Transfer

1. Write data for transmission to the Transmit Data Buffer via the NTDTBPn register.
2. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
4. If data for transmission still remain, write data for transmission by an interrupt with TDBEF0 = 1 to the Transmit Data Buffer via the NTDTBPn register.
5. When data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, the Repeated START condition or STOP condition is issued and the Response Descriptor is stored in the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check that the value of the DATA_LENGTH[15:0] bits of the Response Descriptor is 0.

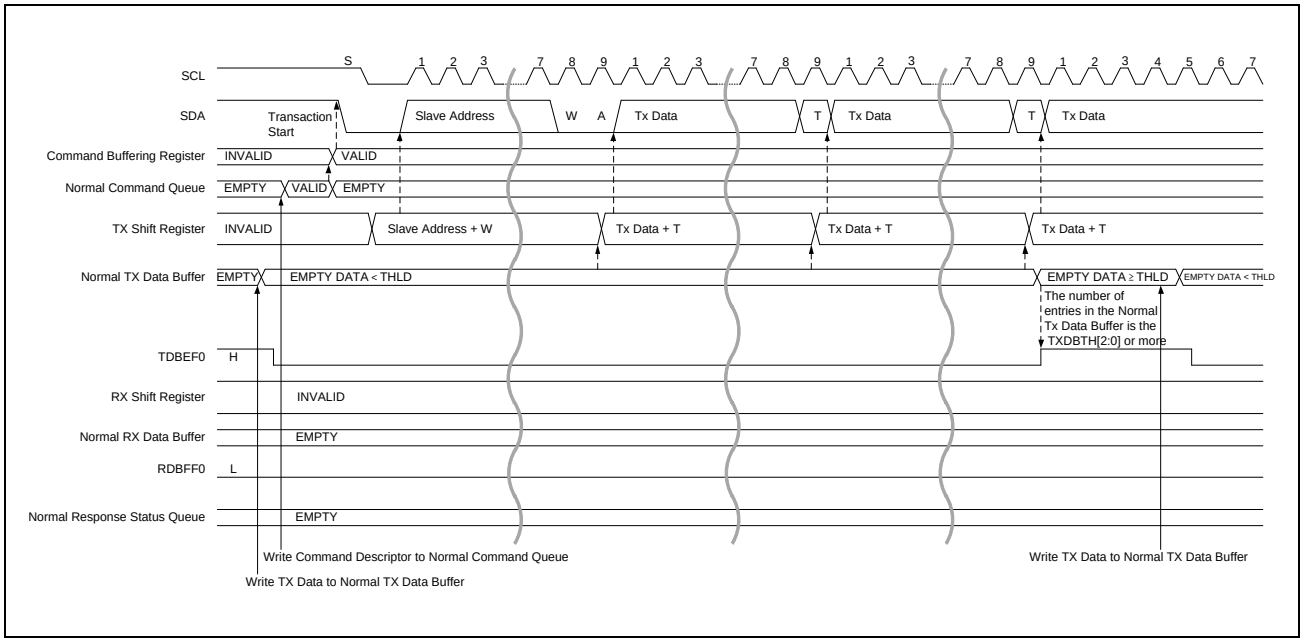

Figure 7.8-16 SDR Data Write Transfer Timing (1/2)

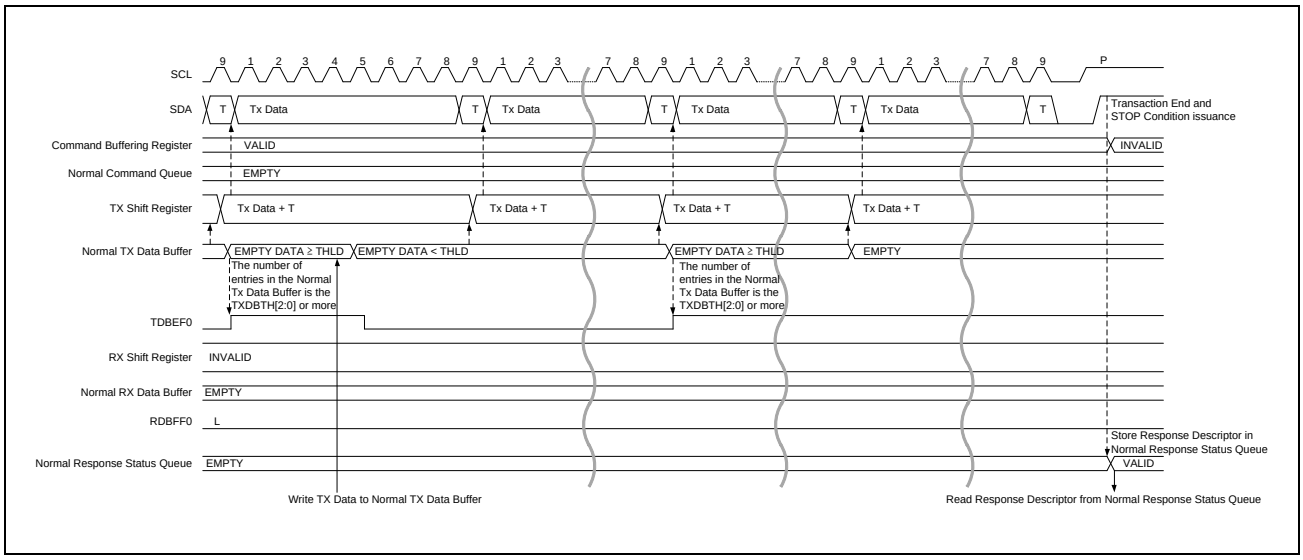

Figure 7.8-17 SDR Data Write Transfer Timing (2/2)

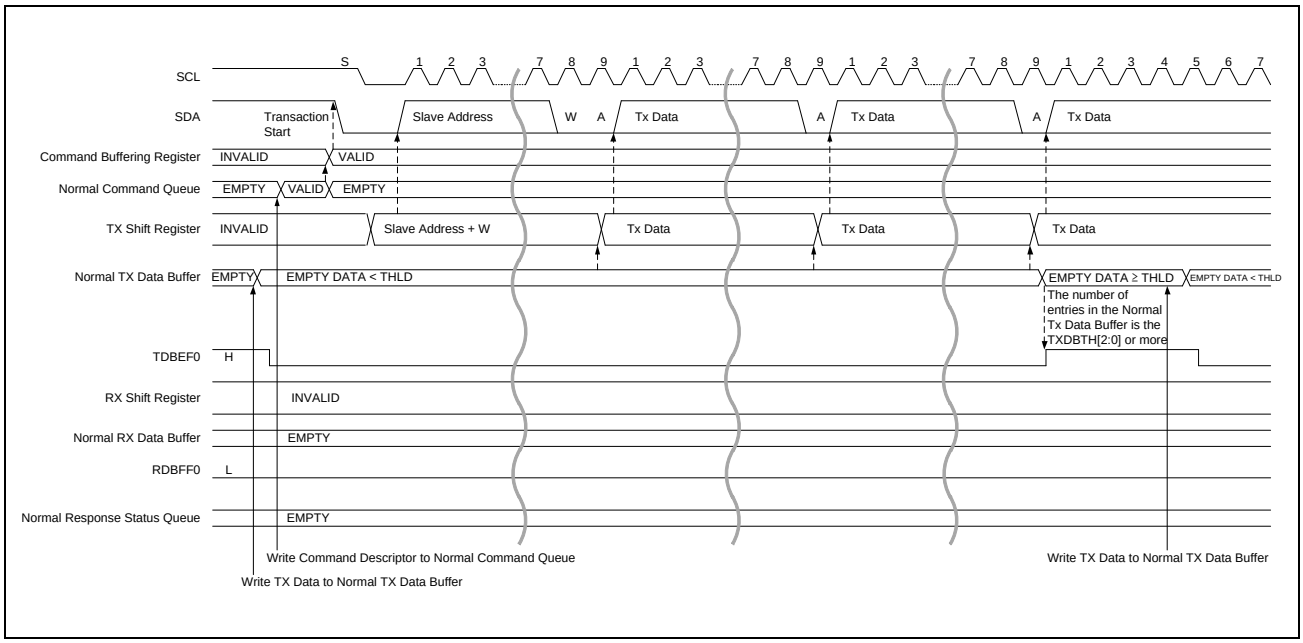

Figure 7.8-18 Legacy I²C Message Data Write Timing (1/2)

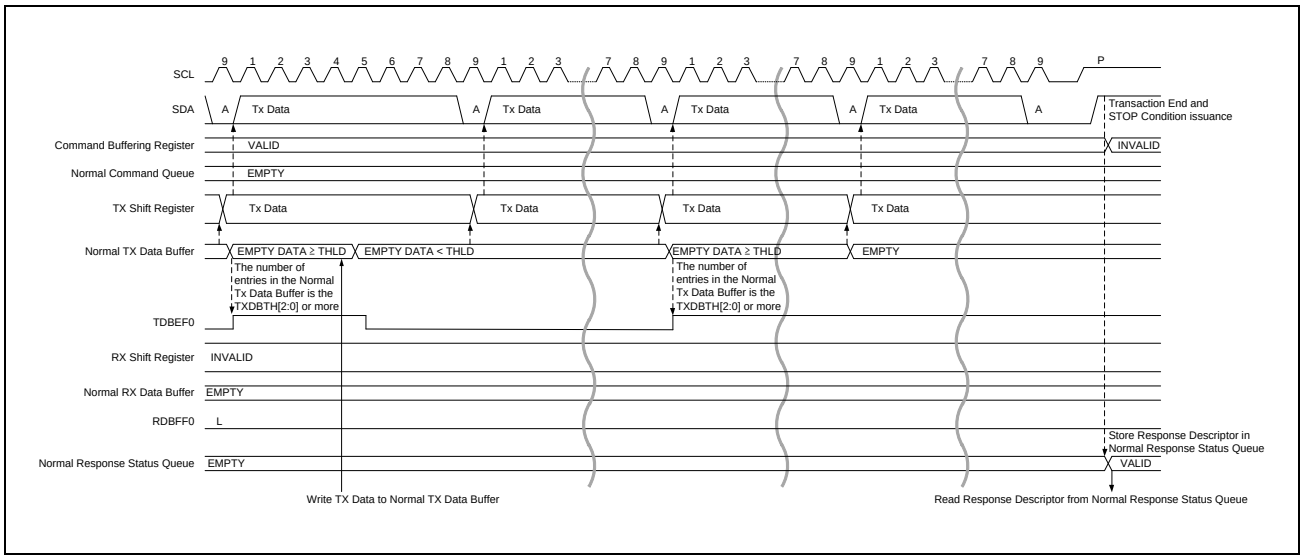

Figure 7.8-19 Legacy I²C Message Data Write Timing (2/2)

3) SDR Data Read Transfer

1. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
2. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
3. Data received from the I3C Slave is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
5. SDR:
   Detecting Low in T-bit or receiving Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, issue Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
   Legacy I^2C Message:
   When data reception for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, NACK is issued. After that, issue a Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor match the data length setting value of the Command Descriptor.

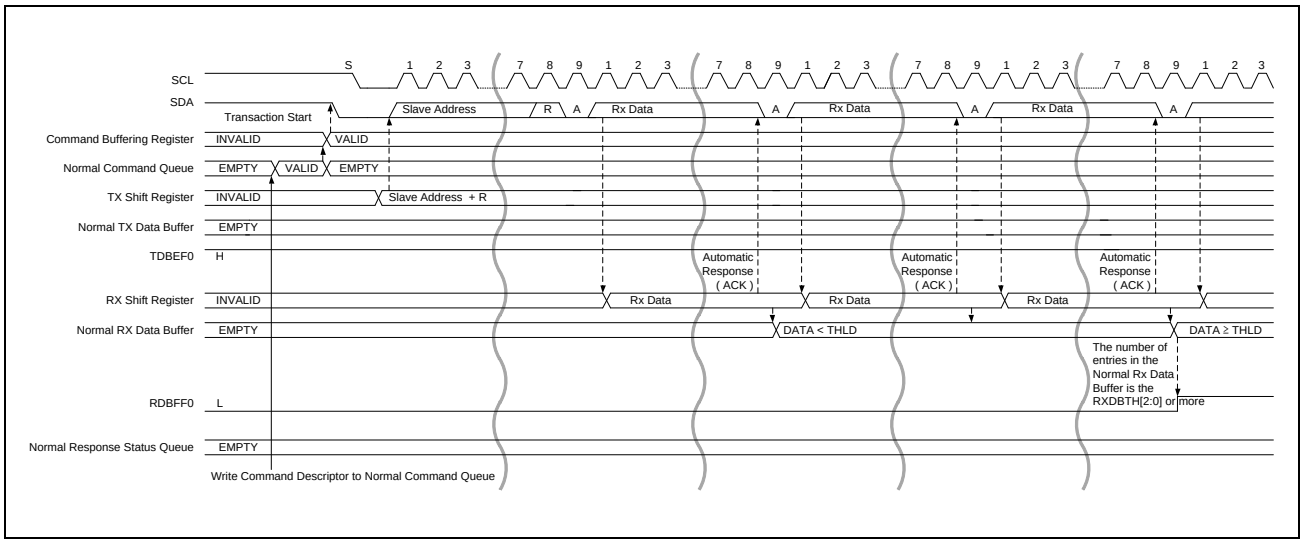

Figure 7.8-20 SDR Data Read Transfer Timing (1/2)

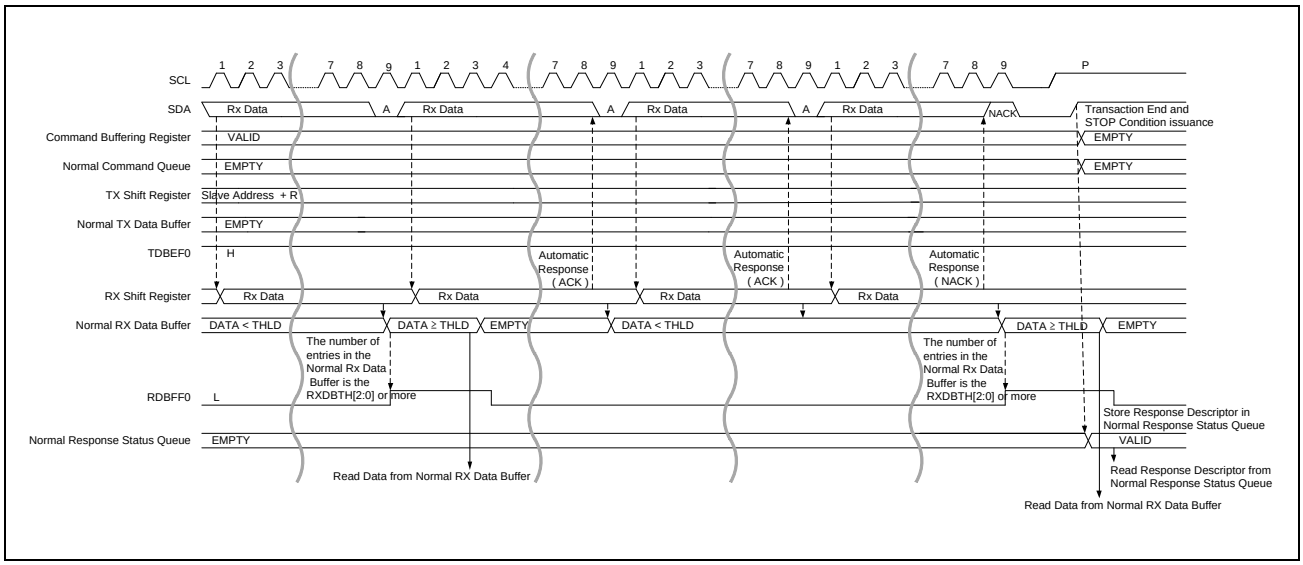

Figure 7.8-21 SDR Data Read Transfer Timing (2/2)

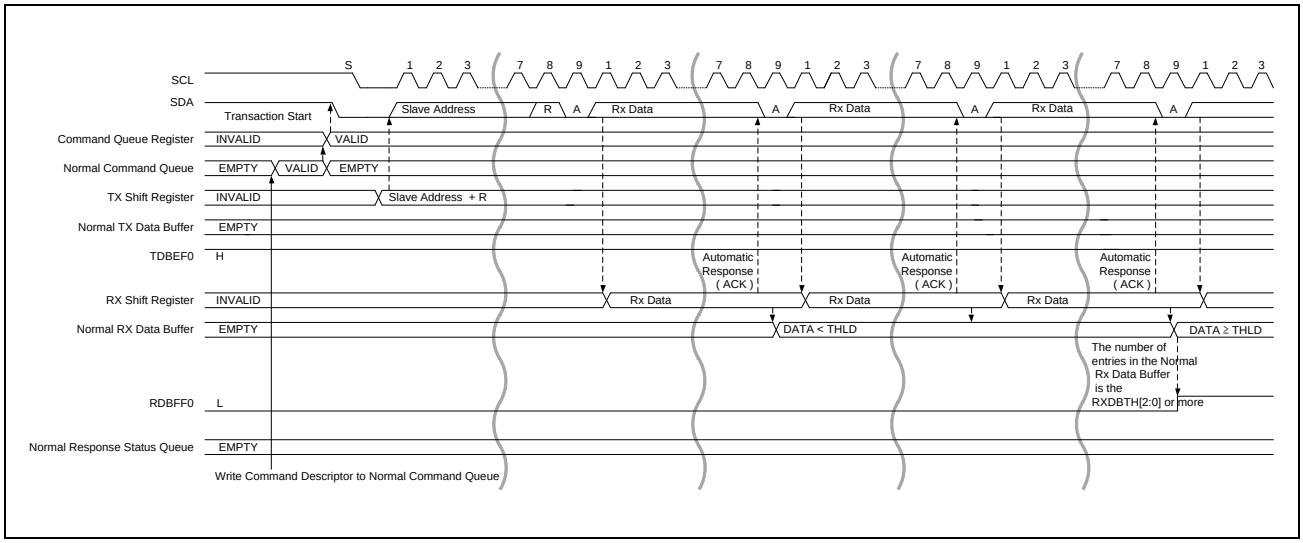

Figure 7.8-22 Legacy I²C Message Data Read Transfer Timing (1/2)

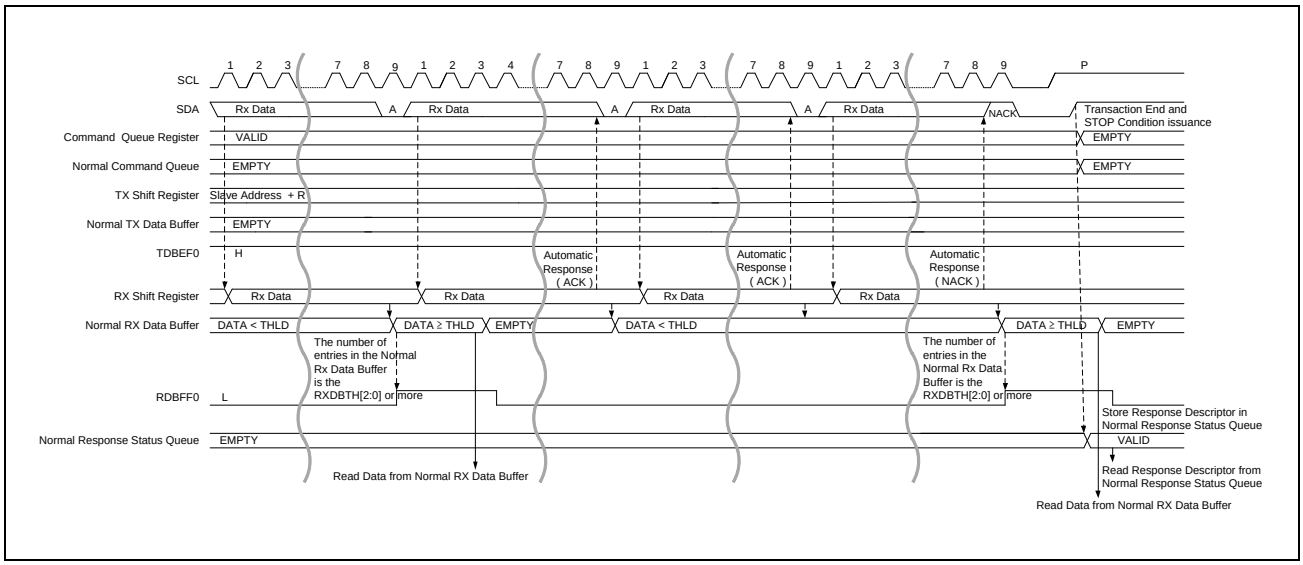

Figure 7.8.23 Legacy I²C Message Data Read Transfer Timing (2/2)

4) IBI Transfer

1. Write Command Descriptor to the Command Buffer and issue Transaction on I3C Bus.
   If START Request (SDA Low Drive) is issued from the slave device, I3C drives SCL to Low and completes START condition.
   Thereafter, the SCL is supplied, and In-Band Interrupt Request is received.
2. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing In-Band Interrupt from I3C Slave, stop issuing Transaction.
3. According to **7.8.3.2.3 (8) In-Band Interrupt [I3C mode]**, detect In-Band Interrupt and process.
4. In the interrupt with IBIQEFF = 1, read the IBI Status Descriptor from the IBI Status Buffer via the NIBIQP register and check the status.
   When detected a Slave Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the IBI Status Descriptor from the IBI Data Buffer via the NIBIQP register.
5. Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of In-Band Interrupt is shown below.

Processing procedure for detecting Mastership Request and transferring master right to Secondary Master

1. If the I3C Secondary Master wins the Arbitration, issue a DEFSLVS CCC and notify Slave information to Secondary Master.
2. Issue a GETACCMST CCC and complete CCC by a STOP condition.

NOTE

- After transferring master right to Secondary Master, to get master right again, issue a Mastership Request according to (f) IBI Transfer of **7.8.3.2.1(2) (b) I3C Slave Operation**.
- After Mastership Request is accepted by the Current Master, to get master right again at receiving the GETACCMST CCC and complete CCC by a STOP condition.

Processing procedure when Hot-Join Event is detected

1. Issue a Broadcast Command Code Enter Dynamic Address Assignment (ENTDAA) to start the Dynamic Address Assignment process.
2. Issue a DEFSLVS CCC and notify Slave information to Secondary Master.

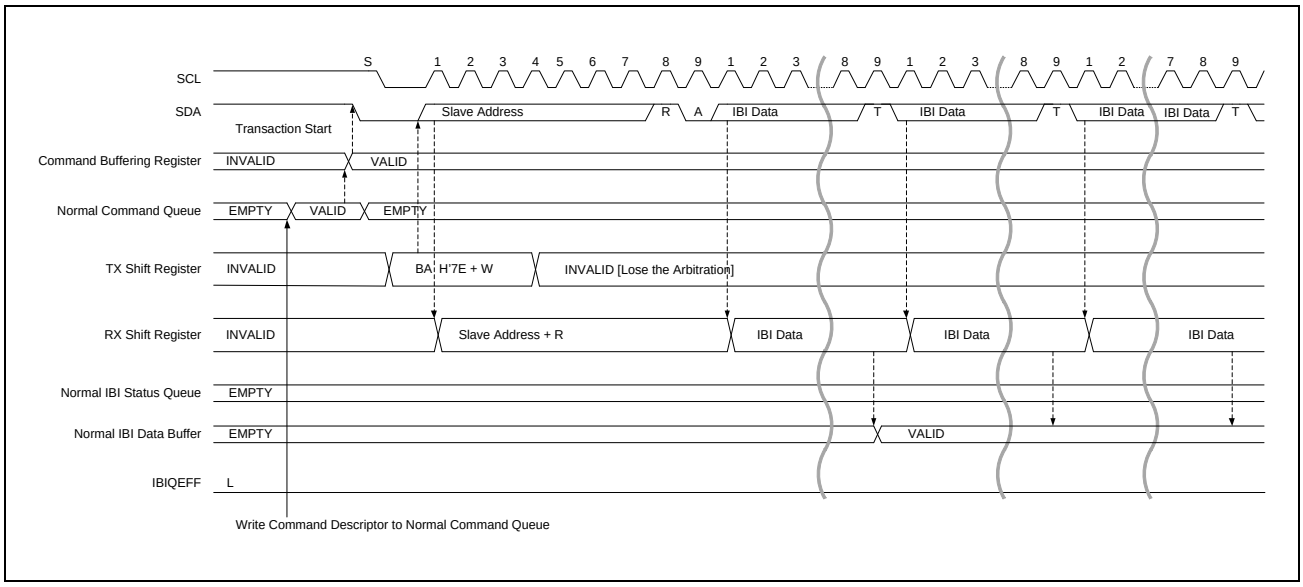

Figure 7.8-24 I3C Master IBI Transfer Timing (1/2)

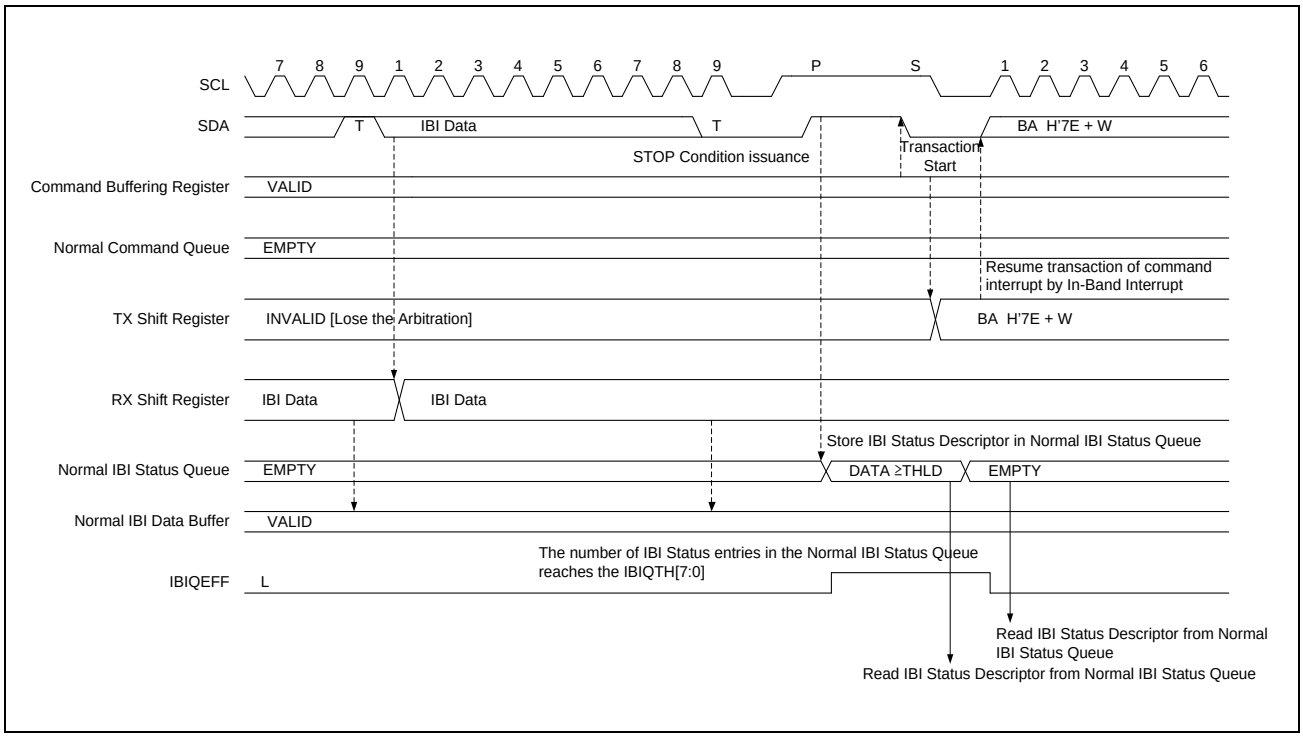

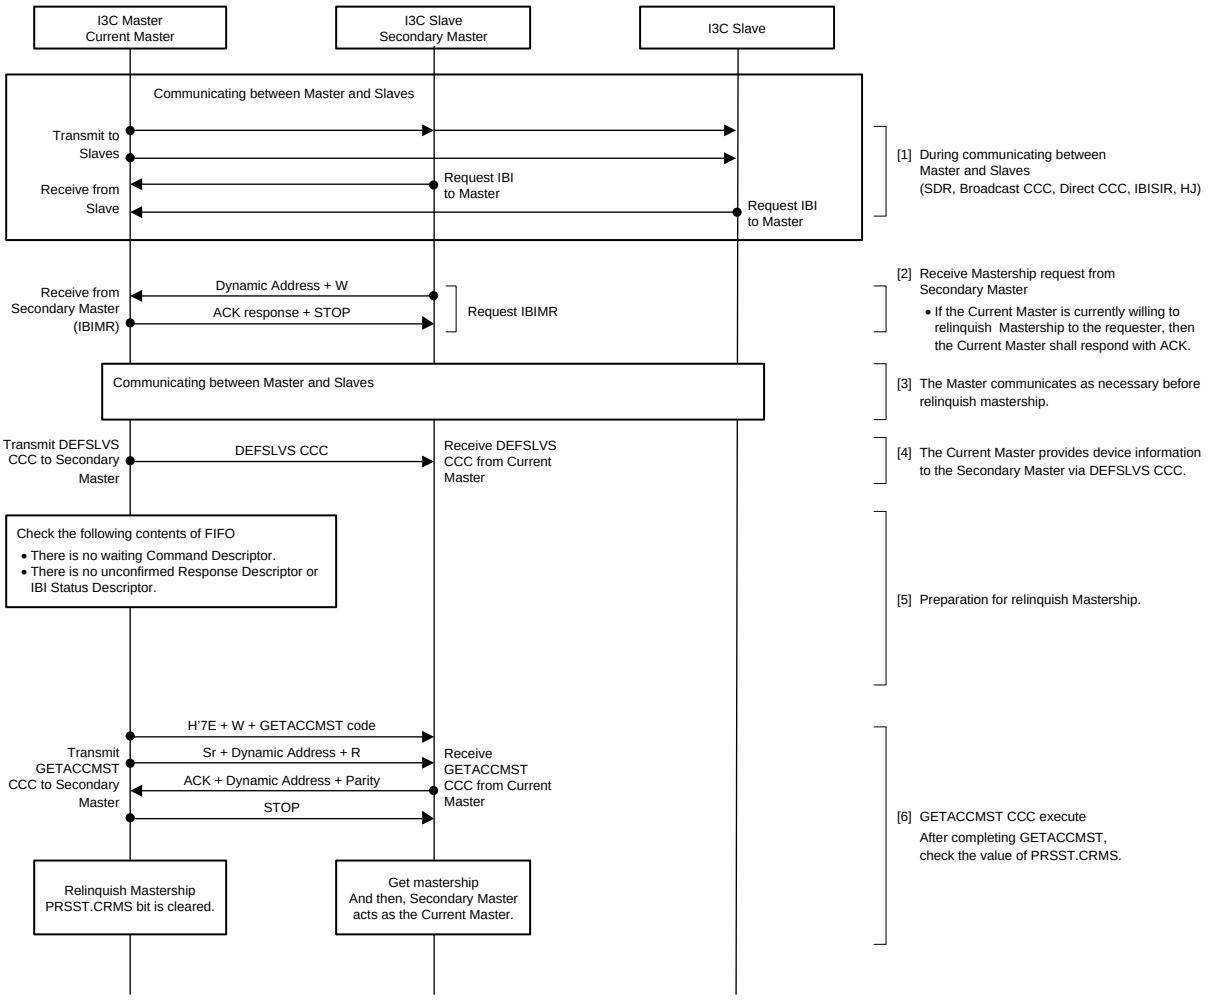

Figure 7.8-25 I3C Master IBI Transfer Timing (2/2)

Note: The Abort request during GETACCMST by BCTL.ABT setting are prohibited due to the transfer of Mastership.

Figure 7.8-26 I3C Master Mastership Processing Flow

(2) Slave Mode Operation

(a) I^2C Slave Operation

1) Data Write Transfer (Single Buffer Transfer)

In slave receive operation, the master device outputs the SCL clock and transmit data, and I3C returns acknowledgments as a slave device.

Figure 7.8-128 shows an example of usage of slave reception and **Figure 7.8-27** and **Figure 7.8-28** show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

1. Initial settings. For details, refer to **7.8.3.3.1 Initial Setting Flow**. After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, I3C continues to place itself in slave receive mode and sets the NTST.RDBFF0 flag to 1.
3. After the BST.SPCNDDF flag is confirmed to be 0 and the NTST.RDBFF0 flag to be 1, dummy read the NTDTBP0 register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
4. When the NTDTBP0 register is read, I3C automatically sets the NTST.RDBFF0 flag to 0. If reading of the NTDTBP0 register is delayed and a next byte is received while the RDBFF0 flag is still set to 1, I3C holds the SCLn line low from one SCL cycle before the timing with which RDBFF0 should be set. In this case, reading the NTDTBP0 register releases the SCLn line from being held at the low level. When the BST.SPCNDDF flag = 1 and the NTST.RDBFF0 flag is also 1, read the NTDTBP0 register until all the data is completely received.
5. Upon detecting the STOP condition, I3C automatically clears bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2) to 0.
6. After checking that the BST.SPCNDDF flag = 1, set the BST.SPCNDDF flag to 0 for the next transfer operation.

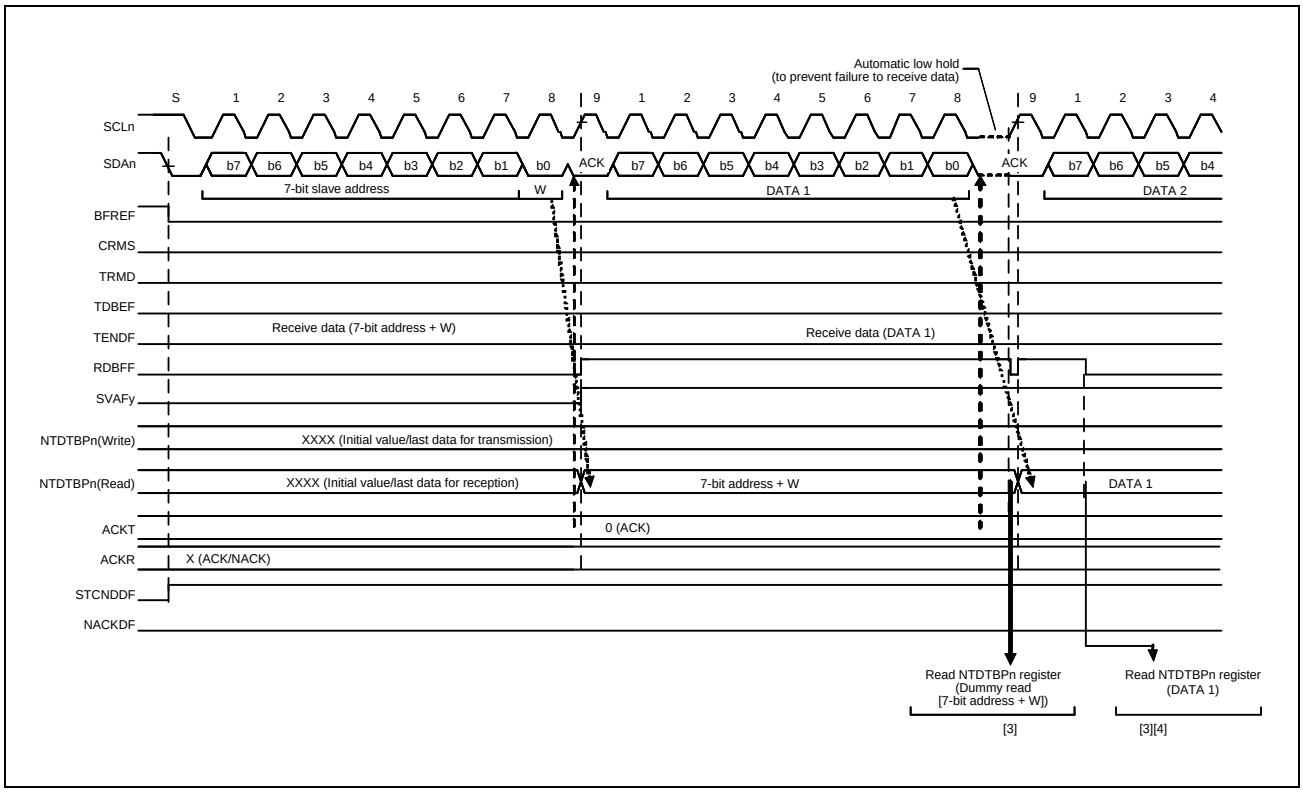

Figure 7.8-27 Slave Receive Operation Timing (1) (7-bit Address Format, When ACKTWE = 0)

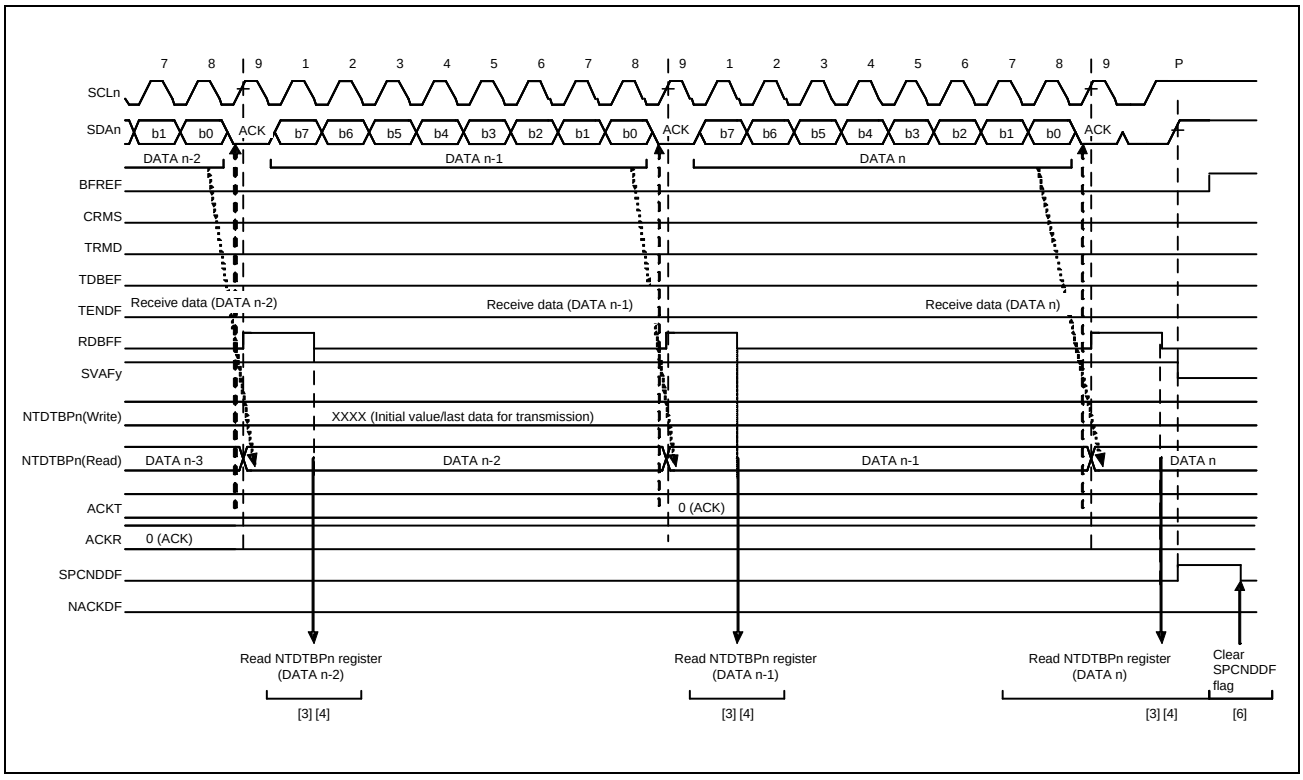

Figure 7.8-28 Slave Receive Operation Timing (2) (When ACKTWE = 0)

2) Data Read Transfer (Single Buffer transfer)

In slave transmit operation, the master device outputs the SCL clock, I3C transmits data as a slave device, and the master device returns acknowledgments.

Figure 7.8-127 shows an example of usage of slave transmission and **Figure 7.8-29** and **Figure 7.8-30** show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

1. Initial settings. For details, refer to **7.8.3.3.1 Initial Setting Flow**.
   After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, I3C automatically places itself in slave transmit mode by setting both the PRSST.TRMD bit and the NTST.TDBEF0 flag to 1.
3. After the NTST.TDBEF0 flag is confirmed to be 1, write the data for transmission to the NTDTBP0 register. At this time, if I3C does not receive acknowledge from the master device (receives an NACK signal) while the BSTE.NACKDE bit = 1, I3C aborts transfer of the next data.
4. Wait until the following (a) or (b) condition.
   (a) The BST.NACKDF flag is set to 1.
   (b) The BST.TENDF flag is set to 1 while the NTST.TDBEF0 flag = 1, after the last byte for transmission is written to the NTDTBP0 register.
5. When the BST.NACKDF flag or the BST.TENDF flag = 1, dummy read the NTDTBP0 register to complete the processing.
6. Upon detecting the STOP condition, I3C automatically sets bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2), flags NTST.TDBEF0 and BST.TENDF, and the PRSST.TRMD bit to 0, and enters slave receive mode.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

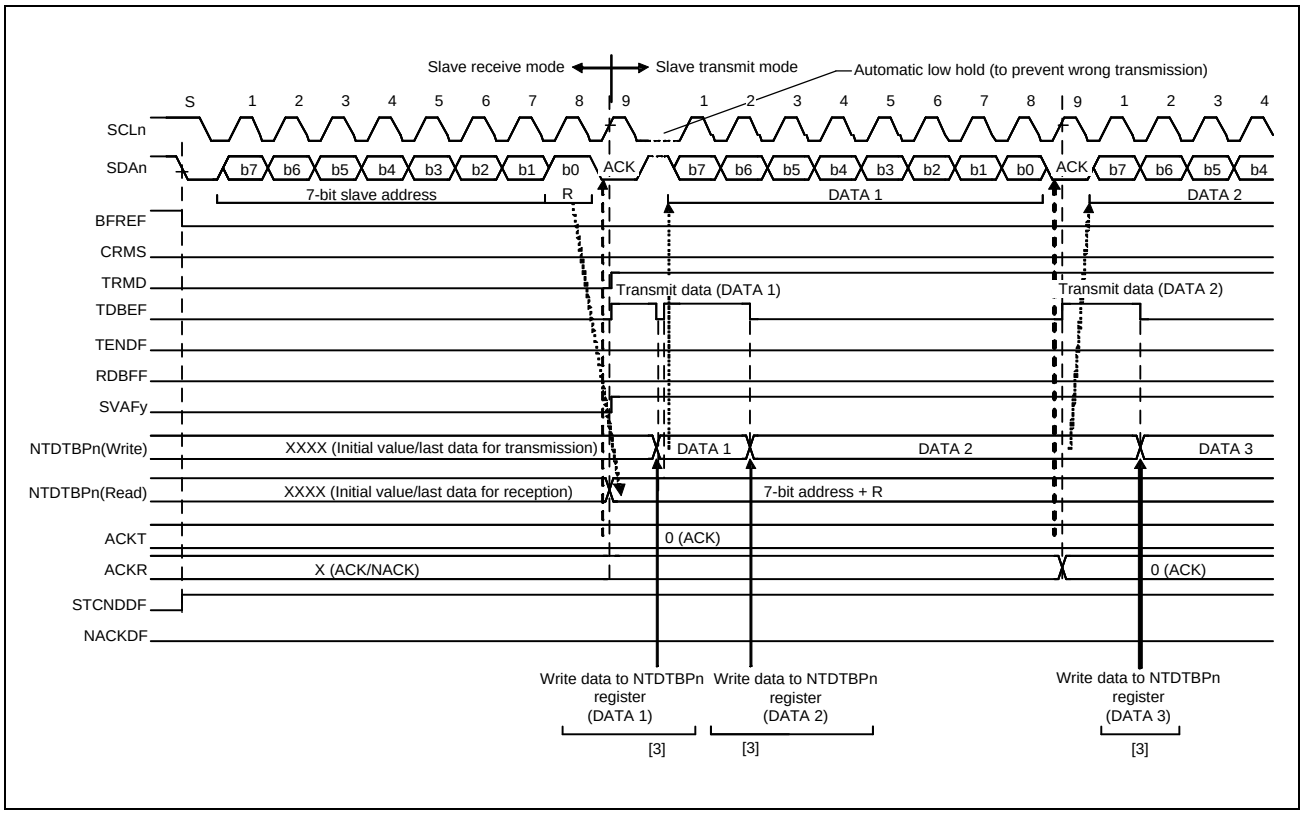

Figure 7.8-29 Slave Transmit Operation Timing (1) (7-bit Address Format)

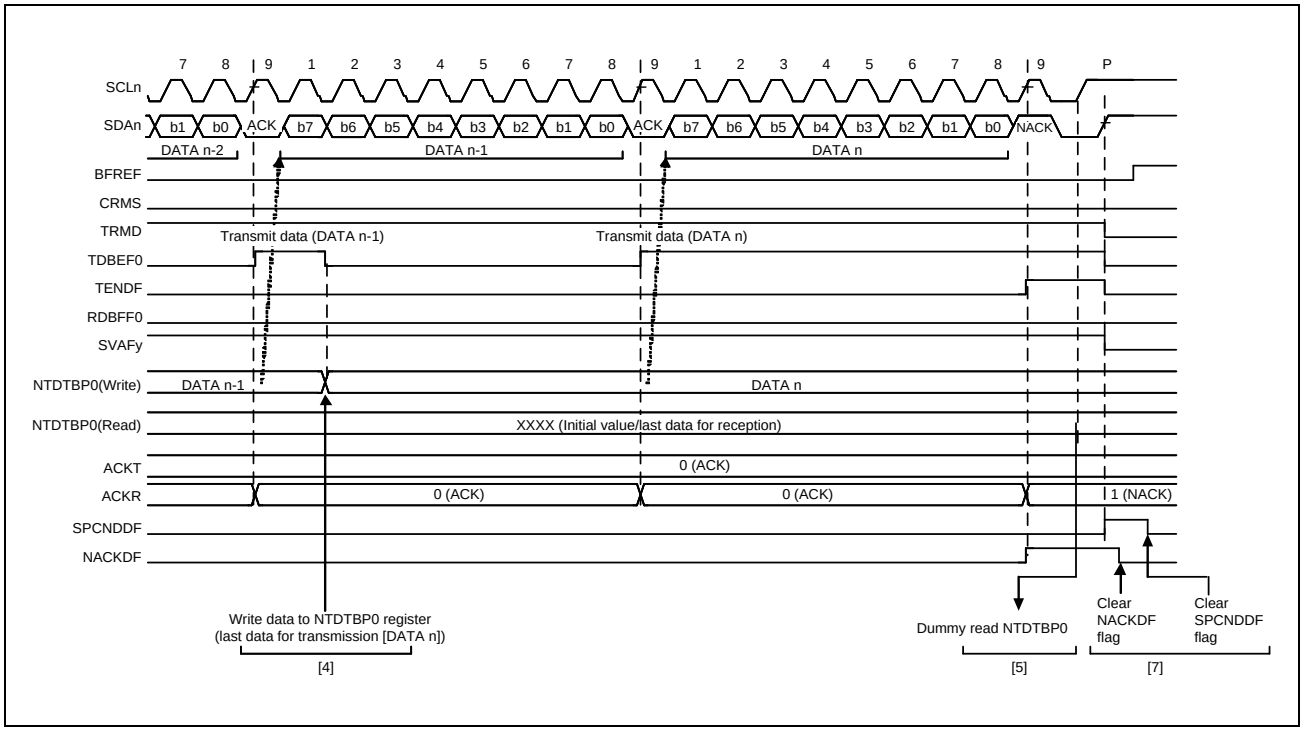

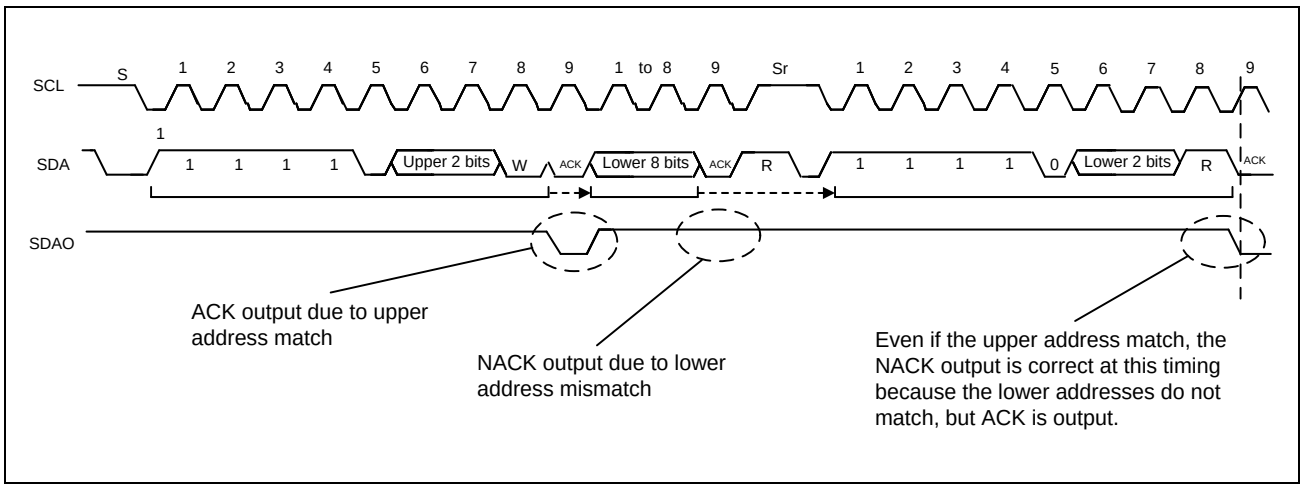

Figure 7.8-30 Slave Transmit Operation Timing (2)

NOTE

[10-bit address format Slave transmission]

When multiple I²C slaves are connected to the I²C bus and there is a possibility that an I²C Slave other than this module will NACK for the upper address/R after Repeated START, there are the following restrictions and workarounds.

- Work around: Set the upper 2 bits of the 10-bit address assigned to this module to a value different from other Slave. If the address is exhausted and cannot be set to a different value, use restriction (1).
- Restriction (1): 10-bit address not available.
- Restriction (2): After the ACK response in the red circle in the above figure, none of the slaves respond to data, so the SDA keeps the high level, and the I²C Master receives the H'FF data. In the case of a system that can handle H'FF as abnormal data, H'FF is read and discarded on the I²C Master side. If H'FF is valid data, use restriction (1).

3) Data Write Trans

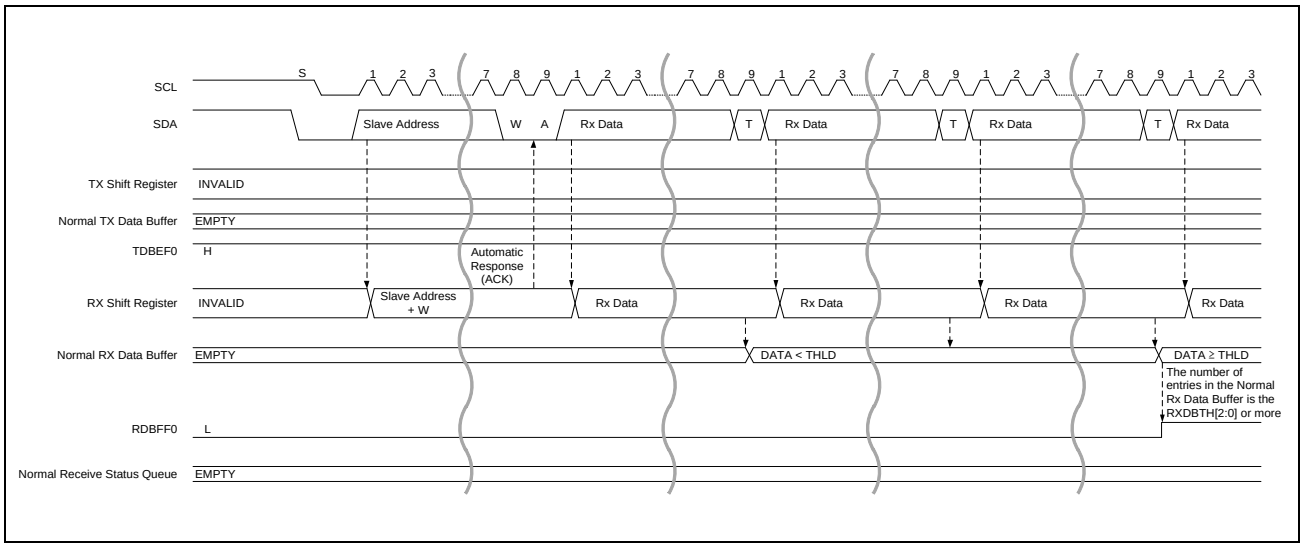

Figure 7.8-31 Data Write Transfer (FIFO Buffer Transfer) Timing (1)

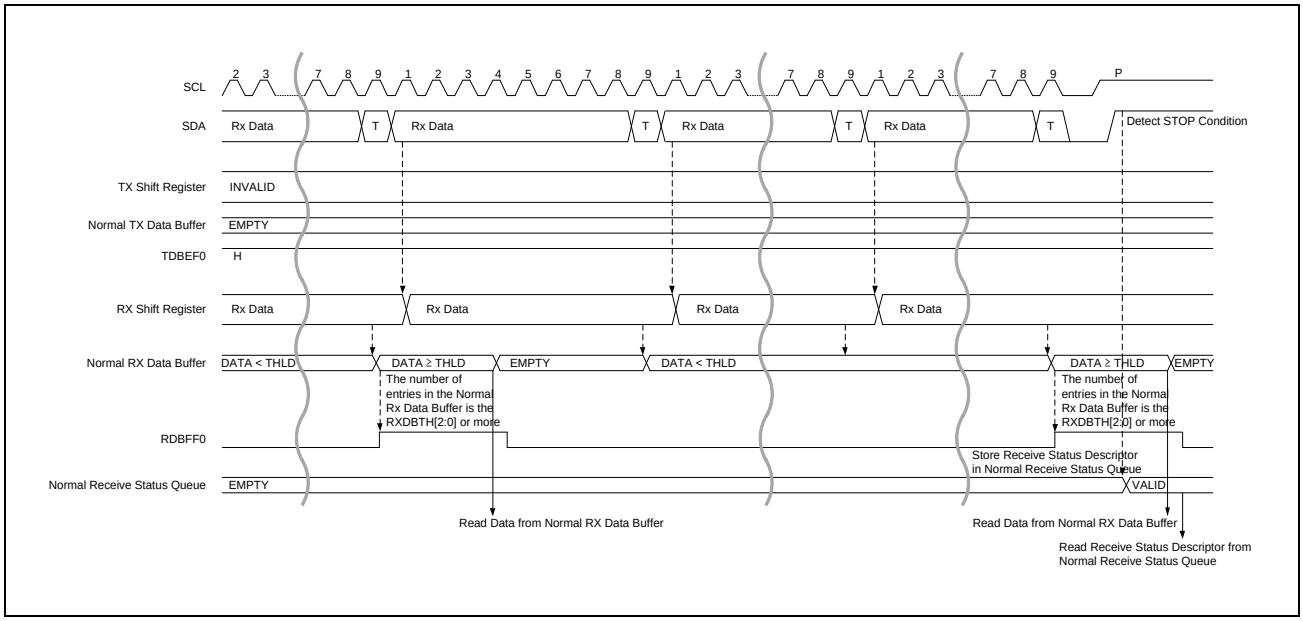

Figure 7.8-32 Data Write Transfer (FIFO Buffer Transfer) Timing (2)

(b) I3C Slave Operation

1) Dynamic Address Assign Procedure

After initializing I3C, the I3C master first performs Dynamic Address Assign Procedure.

The operation of R-I3 during the Dynamic Address Assign Procedure by ENTDAA CCC is described below.

1. Initial setting (For details, refer to **7.8.3.3.1(2) I3C Initial Setting Flow**)
2. When ENTDAA CCC is received, I3C transmits Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCR[7:0]), DCR (SVDCT.TDCR[7:0]) until a dynamic address is assigned. (For details, refer to "In case of Broadcast CCC (ENTDAA)" of **7.8.3.2.3(4) (e) CCC Detection Function [I3C mode]**.)
3. When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Buffer.
4. Read Receive Status Descriptor via NRSQP register and check the status.
5. Read the data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the Receive Status Descriptor from the Receive Data Buffer via the NTDTBP0 register.

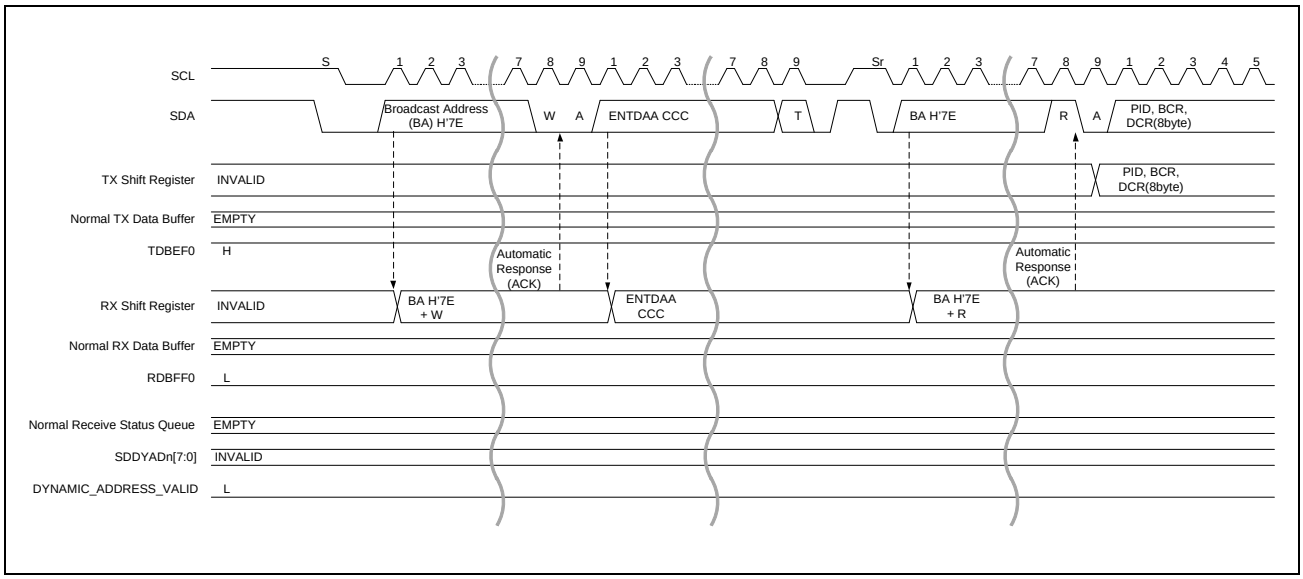

Figure 7.8-33 Dynamic Address Assign Procedure (ENTDAA CCC) Timing (1/3)

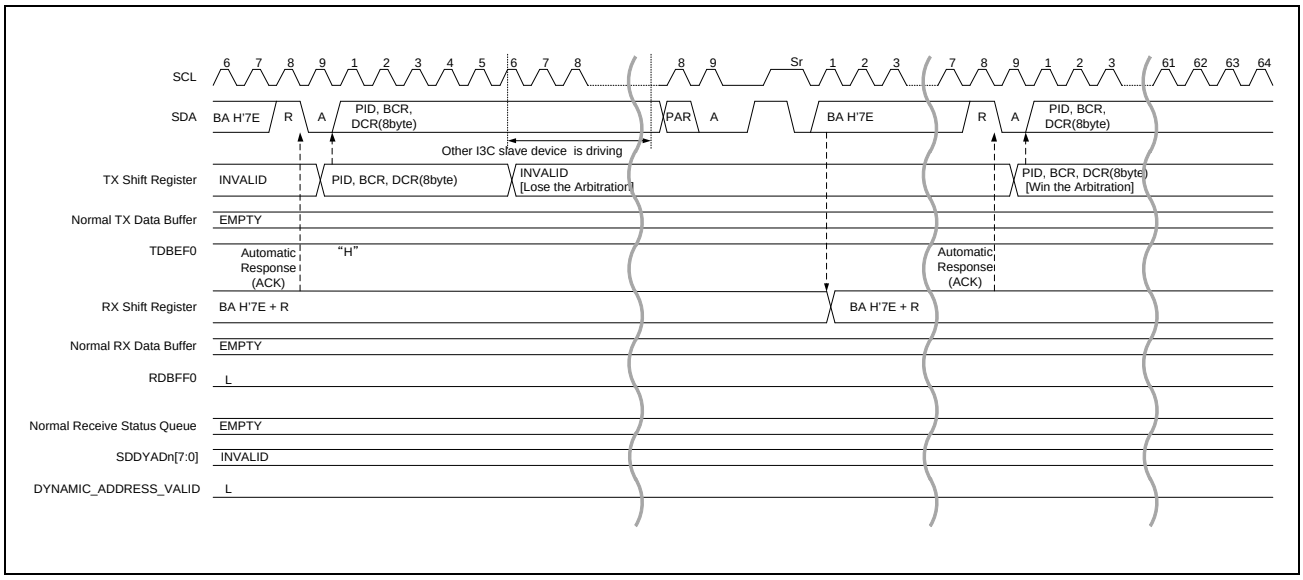

Figure 7.8-34 Dynamic Address Assign Procedure (ENTDAA CCC) Timing (2/3)

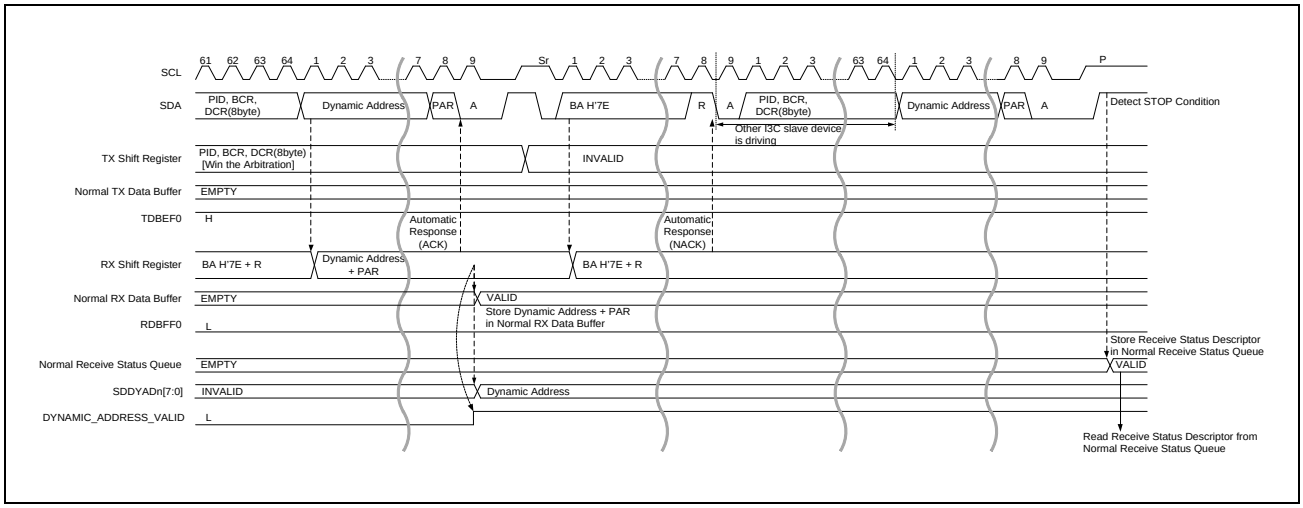

Figure 7.8-35 Dynamic Address Assign Procedure (ENTDAA CCC) Timing (3/3)

When communicating with a Static Address until the Dynamic Address is assigned from the I3C Master, by setting to the DVSTAD[6:0] bit of DAT (SDATBASn register), the SSTADV bit of the SVDVADn register is set to 1 and the Static Address Will be effective.

If the I3C Slave has a Static Address and the I3C Master executes the Dynamic Address Assign Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of I3C during SETDASA CCC Dynamic Address Assign Procedure is described below.

1. Initial setting (For details, refer to **7.8.3.3.1 (2) I3C Initial Setting Flow**)
2. When SETDASA CCC which agrees with its own Static Address is received, the SDDYAD[7:0] bit of DAT (SDATBAS0 register) is renewed and SDYADV bit of SVDVAD0 register is set in 1. (For details, refer to "In case of Direct Write CCC" of Section **7.8.3.2.3(4) (e) CCC Detection Function [I3C mode]**.)
3. When SETDASA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Buffer.

4. Read Receive Status Descriptor via NRSQP register and check the status.

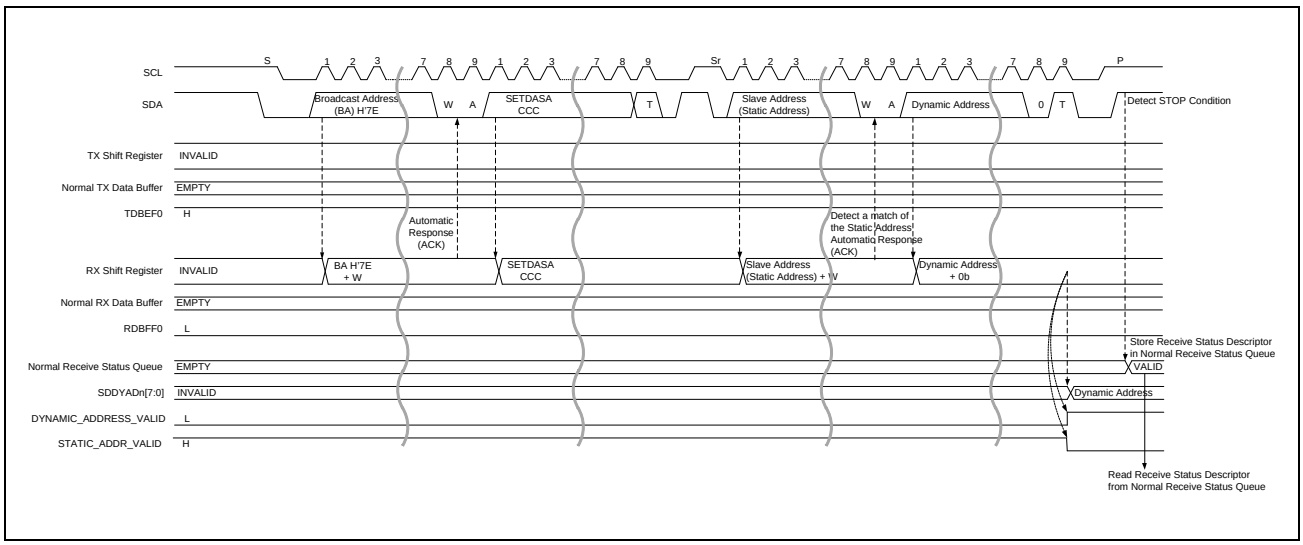

Figure 7.8-36 Dynamic Address Assign Procedure (SETDASA CCC) Timing

2) SDR Data Write Transfer

1. When Transaction is issued from the I3C Master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a Transaction is received, if the Receive Data Buffer is full, the I3C Slave will respond with NACK in the Address Header.
   In preparation for retrying the I3C Master, read the data from the Receive Data Buffer via the NTDTBPn register, and empty the Receive Data Buffer.
2. Data received from I3C Master is stored in the Receive Data Buffer.
3. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
4. When Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Buffer.
5. Read Receive Status Descriptor via NRSQP register and check the status.

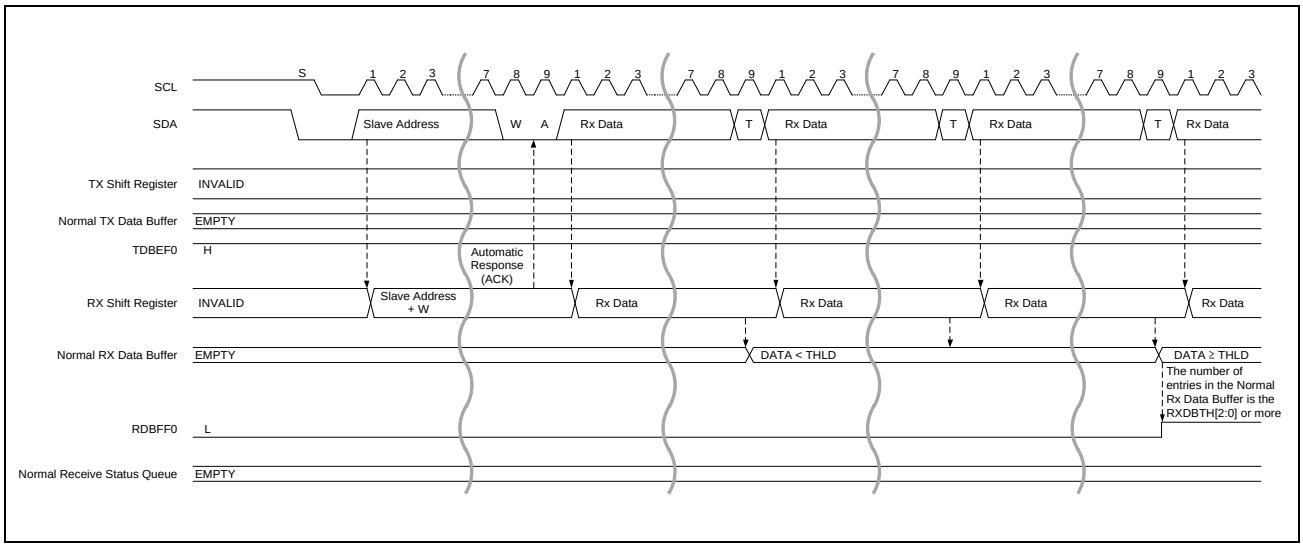

Figure 7.8-37 SDR Data Write Transfer Timing (1/2)

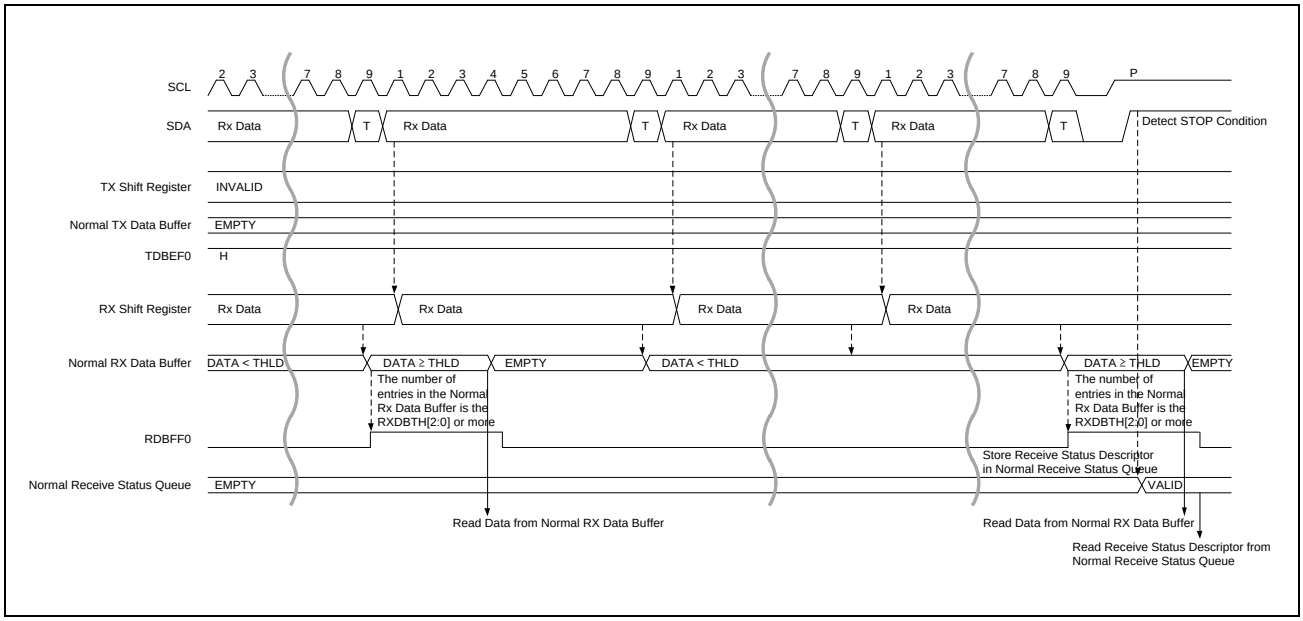

Figure 7.8-38 SDR Data Write Transfer Timing (2/2)

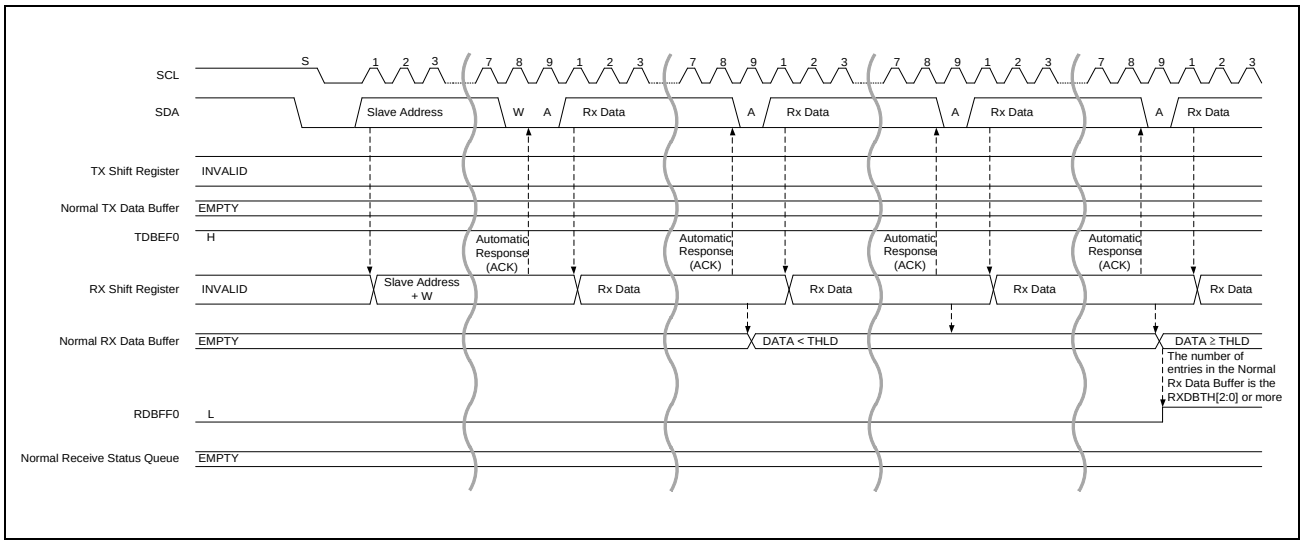

Figure 7.8-39 Legacy I²C Message Data Write Transfer Timing (1/2)

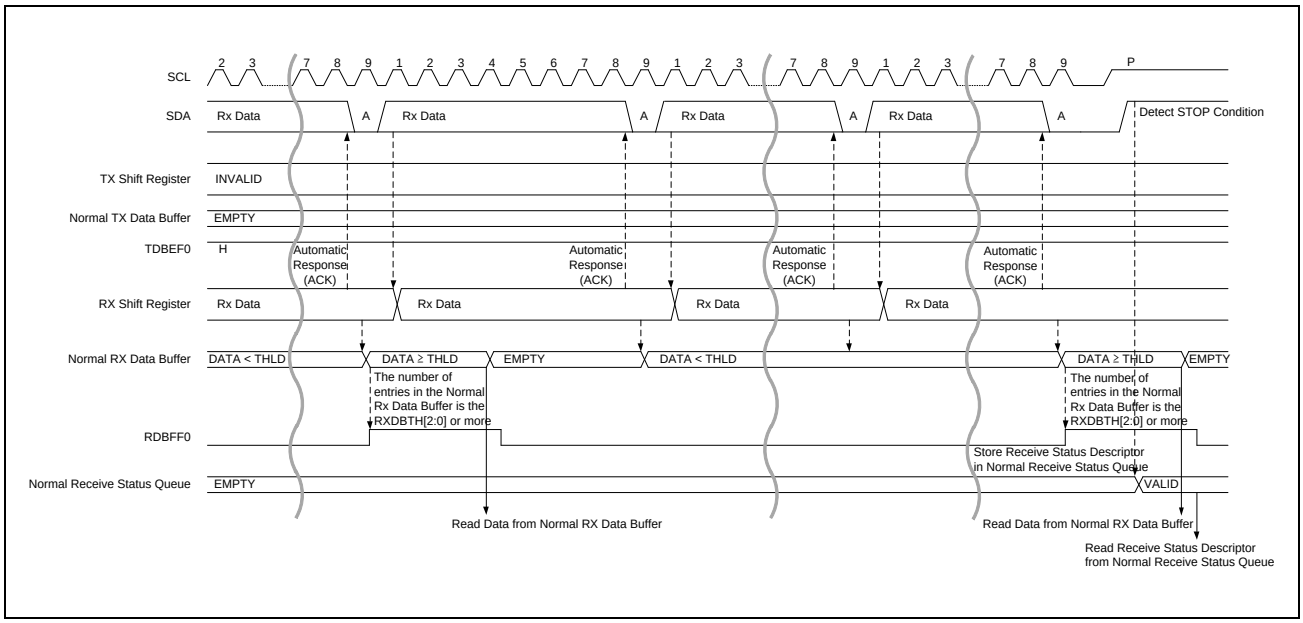

Figure 7.8-40 Legacy I²C Message Data Write Transfer Timing (2/2)

3) SDR Data Read Transfer

1. Write the data requested from the I3C Master to the Transmit Data Buffer via the NTDTBPn register.
2. When Transaction is issued from the I3C Master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a Transaction is received, if the Transmit Data Buffer is EMPTY, I3C Slave responds with NACK with the Address Header.
   In preparation for retrying the I3C Master, write data to the Transmit Data Buffer via the NTDTBPn register.
3. Transmit the data stored in the Transmit Data Buffer.
4. If data to be transmitted still remains, write the data to be transmitted with an interrupt by TDBEF0 = 1 to the Transmit Data Buffer via the NTDTBPn register.
5. SDR:
   When the transmission of the data stored in the Transmit Data Buffer is completed, Low is output to the T-bit following Data, and it is notified to the I3C Master that it is the final data.
   Legacy I^2C Message:
   When NACK is detected, data transmission is terminated.
6. When a Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Buffer.
7. Read the Receive Status Descriptor via NRSQP and check the status.
   If the data length does not match, set the RSTCTL.INTLRST bit to 1 and then reset the internal states of this module. For details, refer to **7.8.3.2.4 (6) Error Recovery Operation [I3C mode]**.

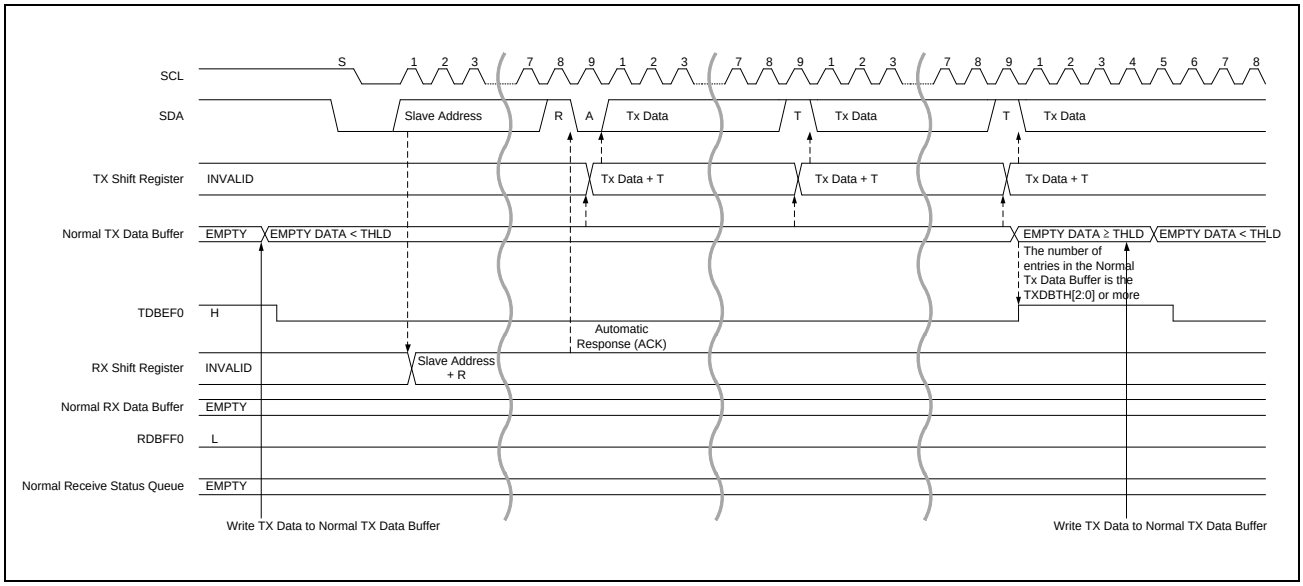

Figure 7.8-41 SDR Data Read Transfer Timing (1/2)

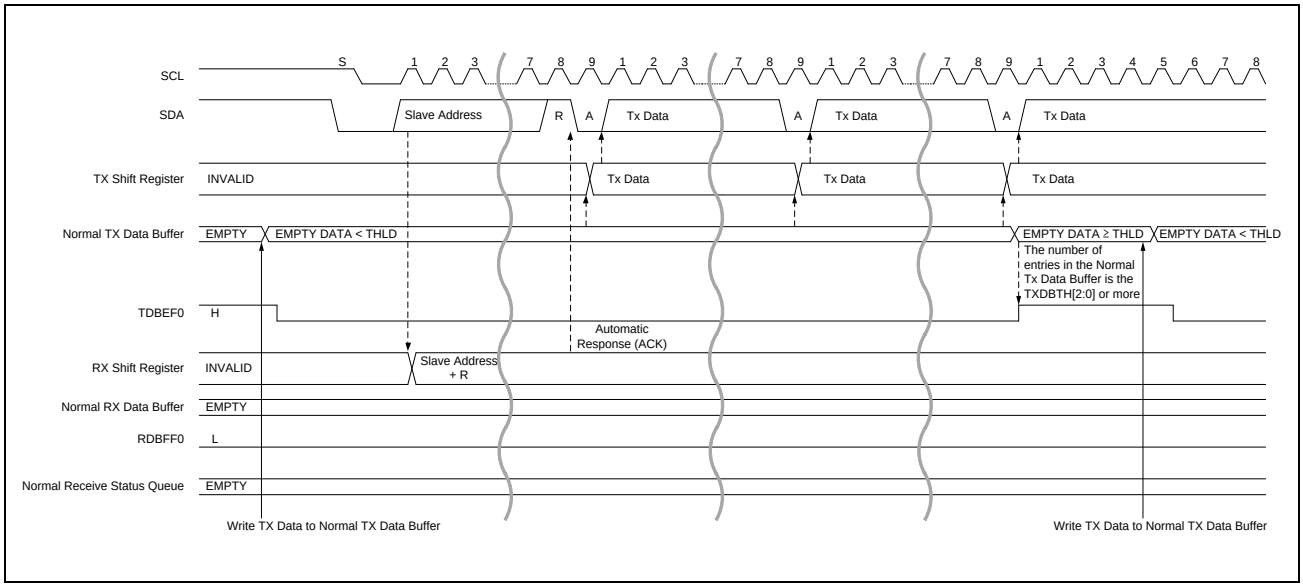

Figure 7.8-43 Legacy I^{2}C Message Data Read Transfer Timing (1/2)

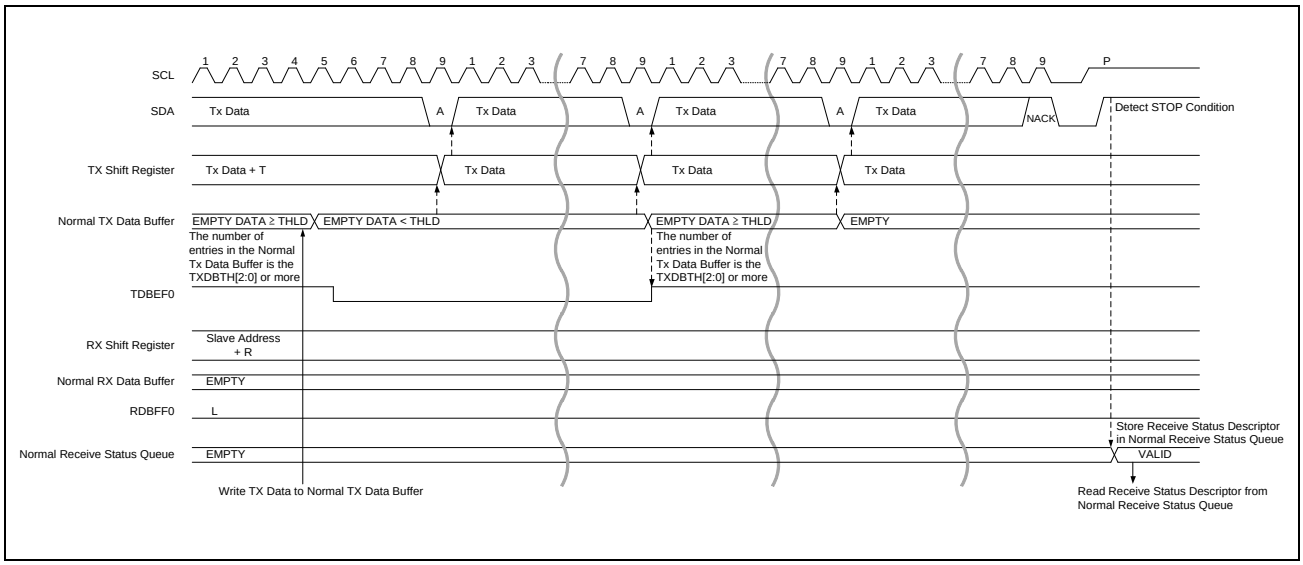

Figure 7.8-44 Legacy I²C Message Data Read Transfer Timing (2/2)

4) IBI Transfer

1. When sending Slave Interrupt Request.
   When transmitting IBI Data, write IBI Data to the IBI Data Buffer via the NIBIQP register.
2. Write Command Descriptor (Immediate Transfer Command or Regular Transfer Command) to the Command Buffer for IBI Transfer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, IBI Transaction is issued under the following conditions.
   - When START condition is detected in Slave Interrupt Request or Mastership Request. (Does not apply a Repeated START condition)
   - If no START is forthcoming within the following Bus Condition, then this module issue a START Request by pulling the SDA line Low.
     a) Slave Interrupt Request, Mastership Request: Bus Available
     b) Hot-Join Event: Bus Idle
4. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing a Transaction from I3C Master, stop issuing Transaction.
   When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
5. When sending Slave Interrupt Request:
   - When IBI data for transmission still remain, write IBI data with an interrupt by IBIQEFF = 1 to the IBI Data Buffer via the NIBIQP register.
   - When the transmission of IBI Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, output Low to the T-bit following IBI Data and notify the I3C Master that it is the final IBI Data.
6. When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor Form the Response Buffer with the NRSPQP register and check the status. If NACK is responded, repeat steps 1 to 7.
8. When sending Slave Interrupt Request:
   Check that the value of the DATA_LENGTH[15:0] bit of the Response Descriptor is 0.

The Mastership processing flow is shown in **Figure 7.8-47**. When joining the I3C Bus by Hot-Join after the I3C Bus has already been configured, issue the Hot-Join according to the flow shown in **Figure 7.8-133**.

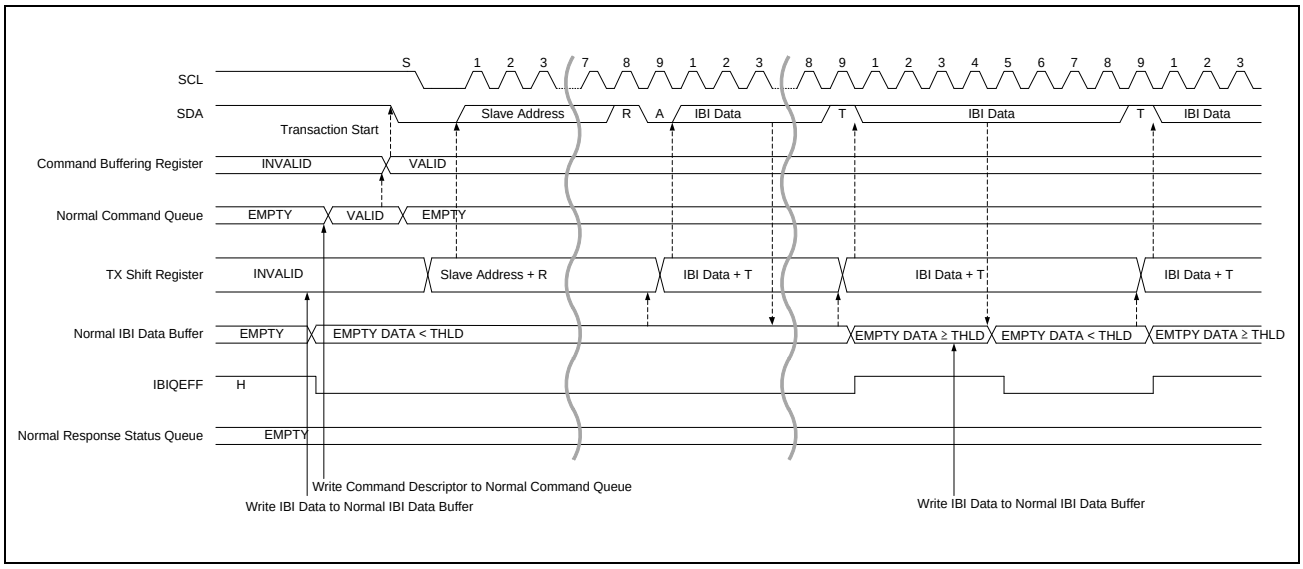

Figure 7.8-45 I3C Slave IBI Transfer Timing (1/2)

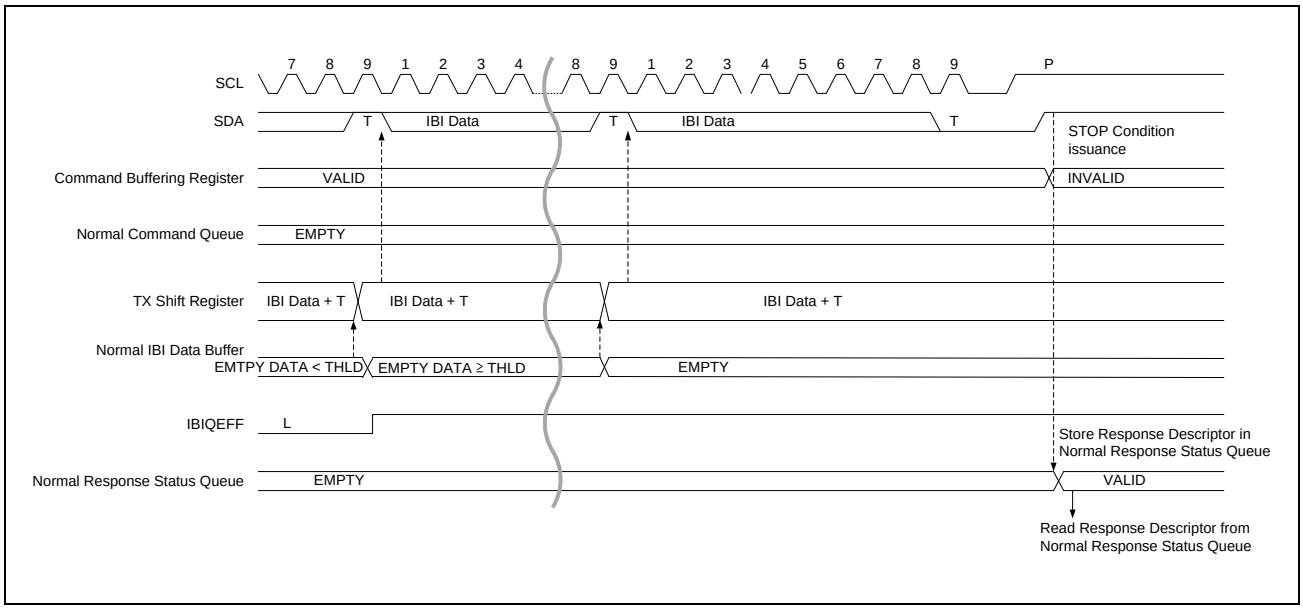

Figure 7.8-46 I3C Slave IBI Transfer Timing (2/2)

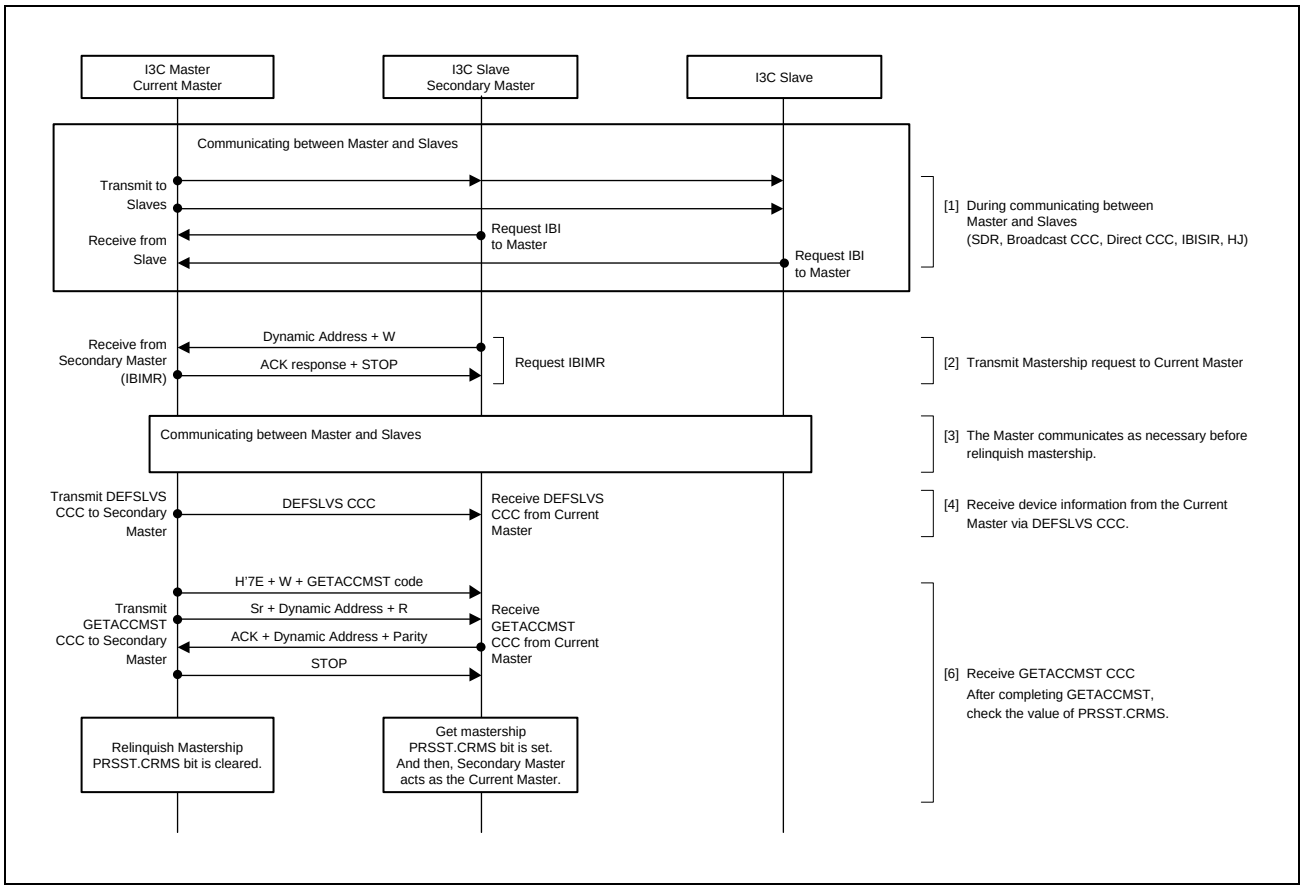

Figure 7.8-47 I3C Slave Mastership Processing Flow

7.8.3.2.2 Data Handler

The relationship between the transfer method and the queue is shown in **Table 7.8-11**.

Table 7.8-11 Transfer Method and Queue

Protocol	Transfer Method	Queue/Buffer	Size	Master	Slave	Secondary Master
I^2C Mode	Single buffer transfer	Normal Transmit Data	1 byte	✓	✓	—
		Normal Receive Data	1 byte	✓	✓	—
I3C Mode	Normal FIFO buffer transfer	Normal Command	4 QUEUEs	✓	✓	✓
		Normal Response Status	4 QUEUEs	✓	✓	✓
		Normal Transmit Data	16 DWORDs	✓	✓	✓
		Normal Receive Data	16 DWORDs	✓	✓	✓
		Normal Receive Status	2 QUEUEs	—	✓	✓
		Normal IBI Status	2 QUEUEs	✓	—	✓
		Normal IBI Data	8 DWORDs	✓	✓	✓

(1) Transfer Method in I²C Mode

(a) Single Buffer Transfer

Each process (condition issue, data transfer, ACK/NACK response) is controlled by software.

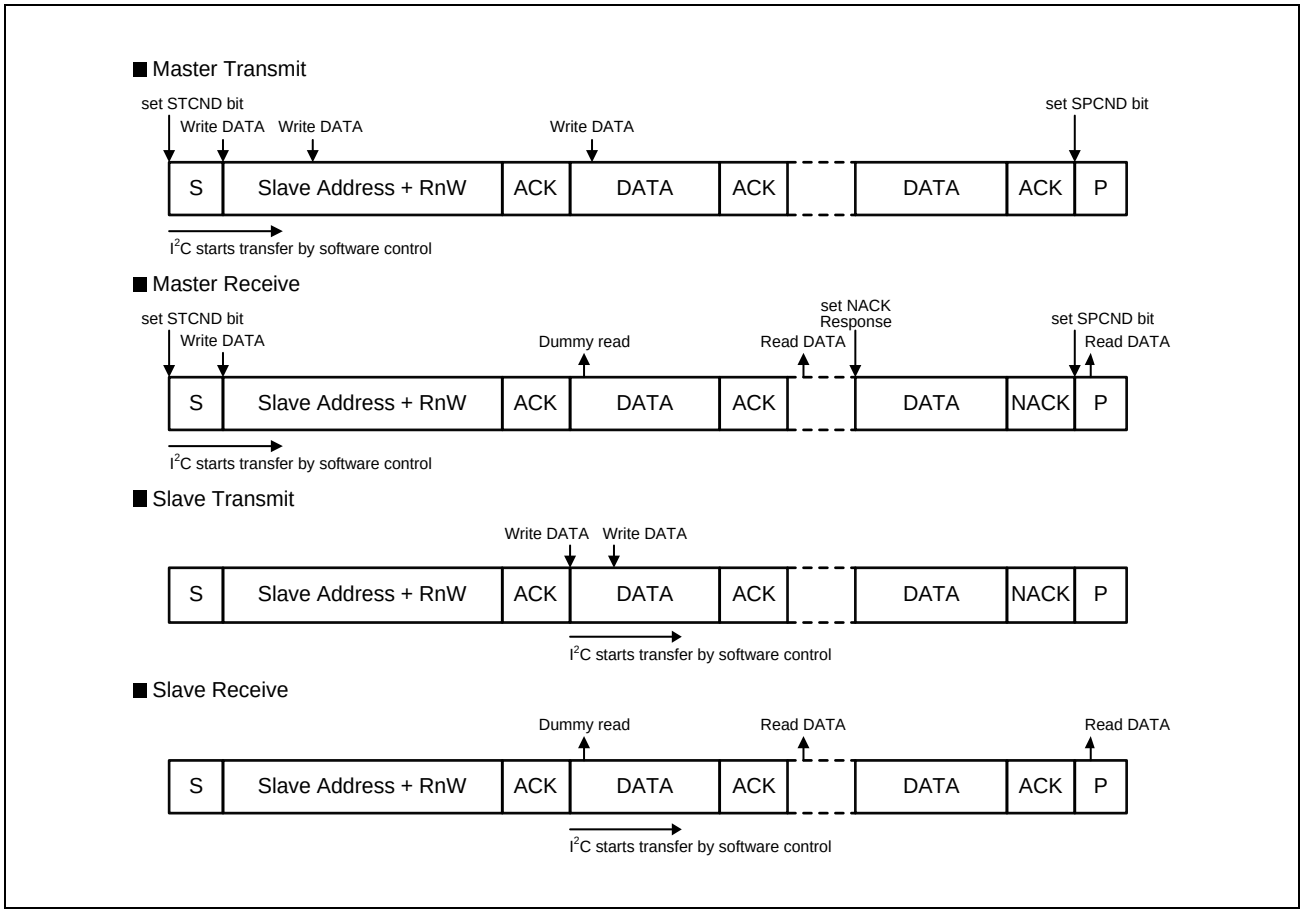

Figure 7.8-48 Data Handler with Single Buffer Transfer

(2) Transfer Method in I3C Mode

(a) Normal FIFO Buffer Transfer

I3C autonomously starts transfer when data and command are written.

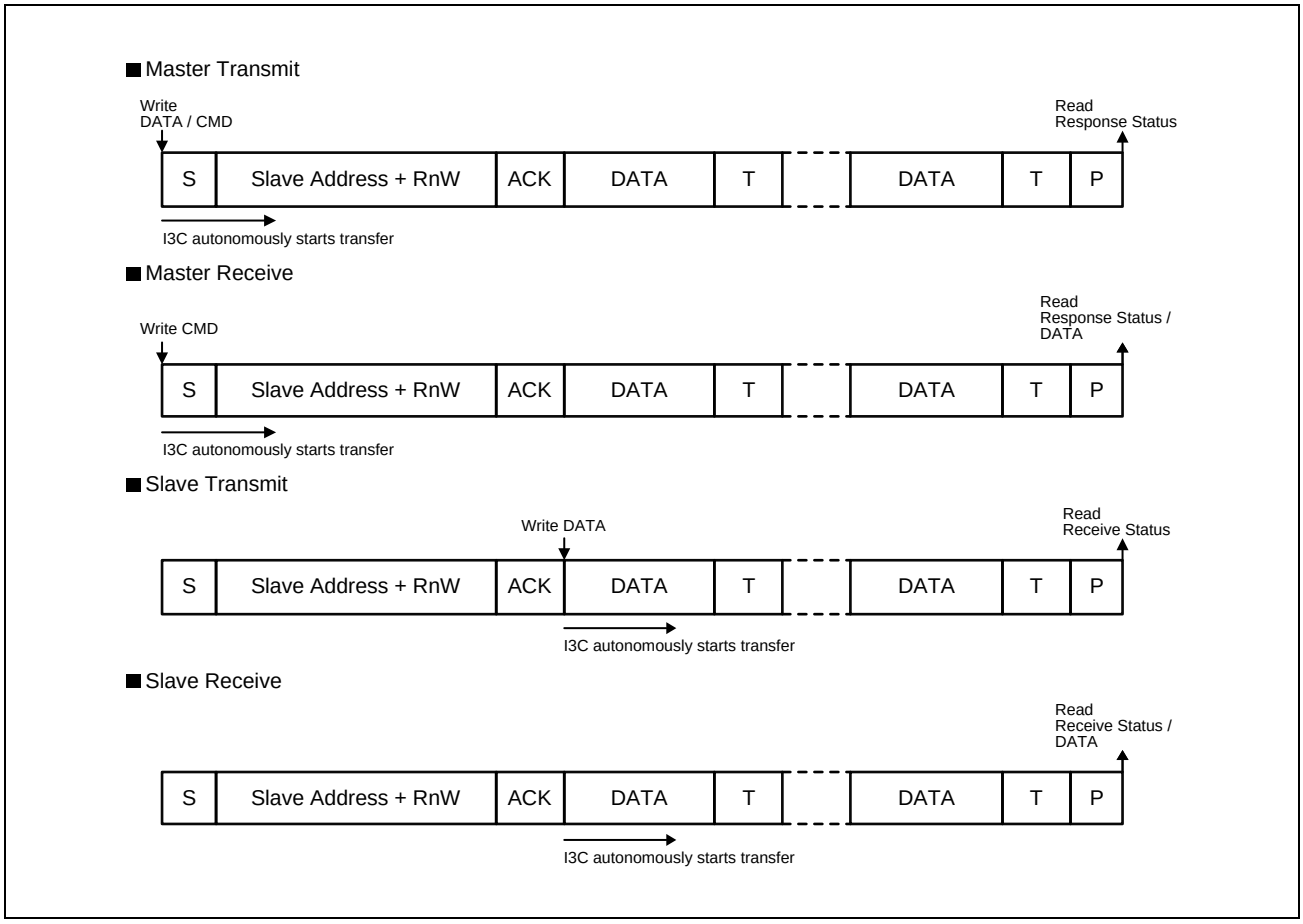

Figure 7.8-49 Data Handler with Normal FIFO Buffer Transfer

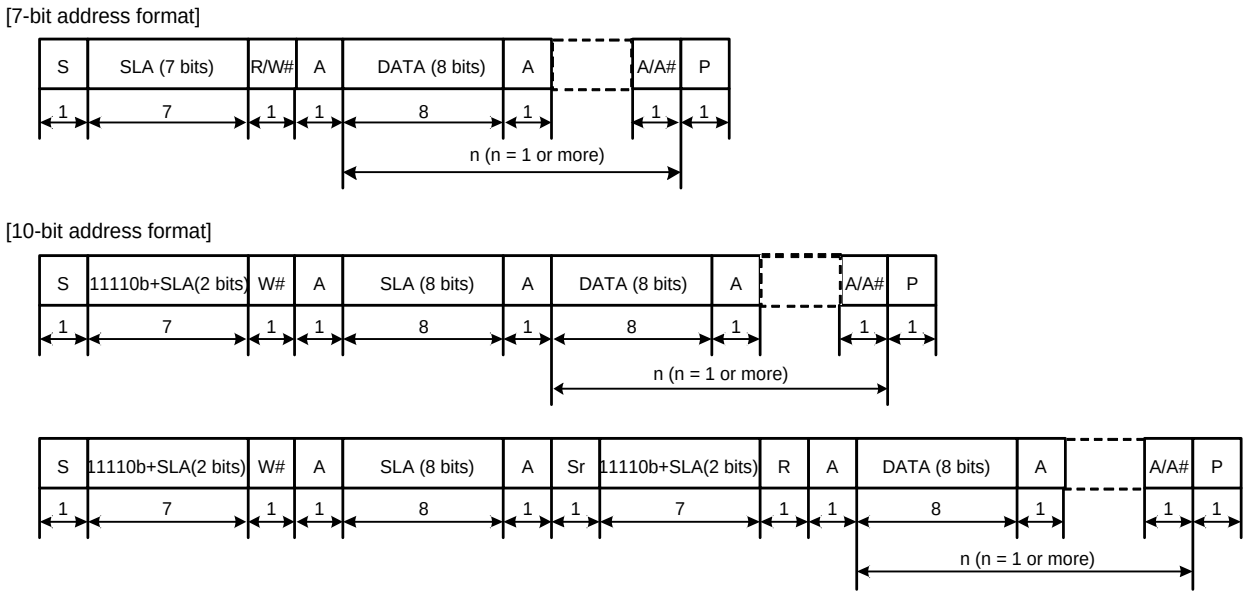
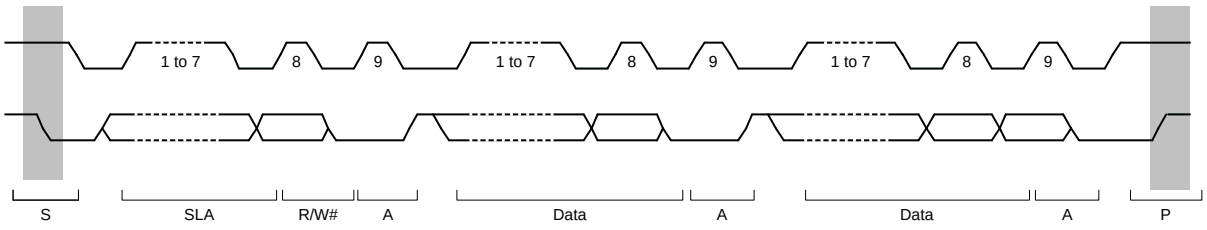


7.8.3.2.3 I²C/I3C Protocol

(1) Communication Protocol

(a) I²C Communication Data Format



The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a START condition or Repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is issued.

Figure 7.8-50 shows the I²C bus format, and **Figure 7.8-51** shows the I²C bus timing.

Note: n: Number of transmit DATA bytes

Figure 7.8-50 I²C Bus Format

S: START condition. The master device drives the SDAn line low from high level while the SCLn line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W = 1, or from the master device to the slave device when R/W = 0.

A: Acknowledge. The receive device drives the SDAn line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receive device drives the SDAn line high.

Sr: Repeated START condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line at the high level.

DATA: Transmitted or received data

P: STOP condition. The master device drives the SDAn line high from low level while the SCLn line is at a high level.

Figure 7.8-51 I^2C Bus Timing (SLA = 7 bits)

(b) I3C Communication Data Format

Figure 7.8-52 through illustrate a typical communication for each of the six I3C Protocols. While these diagrams do not exhaustively illustrate all possible I3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each I3C Protocol.

Figure 7.8-52 illustrates example communication using I3C Single Data Rate (SDR) coding with Broadcast (H'7E). It shows the Master reading a byte of data from the Slave at Address H'2B in SDR Mode. From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (H'7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain.

All Slaves ACK by pulling the SDA line Low (in the Figure, pink fill means the Slave is in control of the SDA line at this time). The Master then issues a Repeated START, then the Address of the Slave (H'2B) it wants to read followed by RnW (1 for Read). The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the SDA line Low. At this point, the Master continues to toggle the SCL line and release the SDA line, allowing the Slave to drive SDA to send one byte of data (H'4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pullup, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over. SDR Mode is backwards compatible with Legacy I^2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I^2C 50ns Spike Filter.

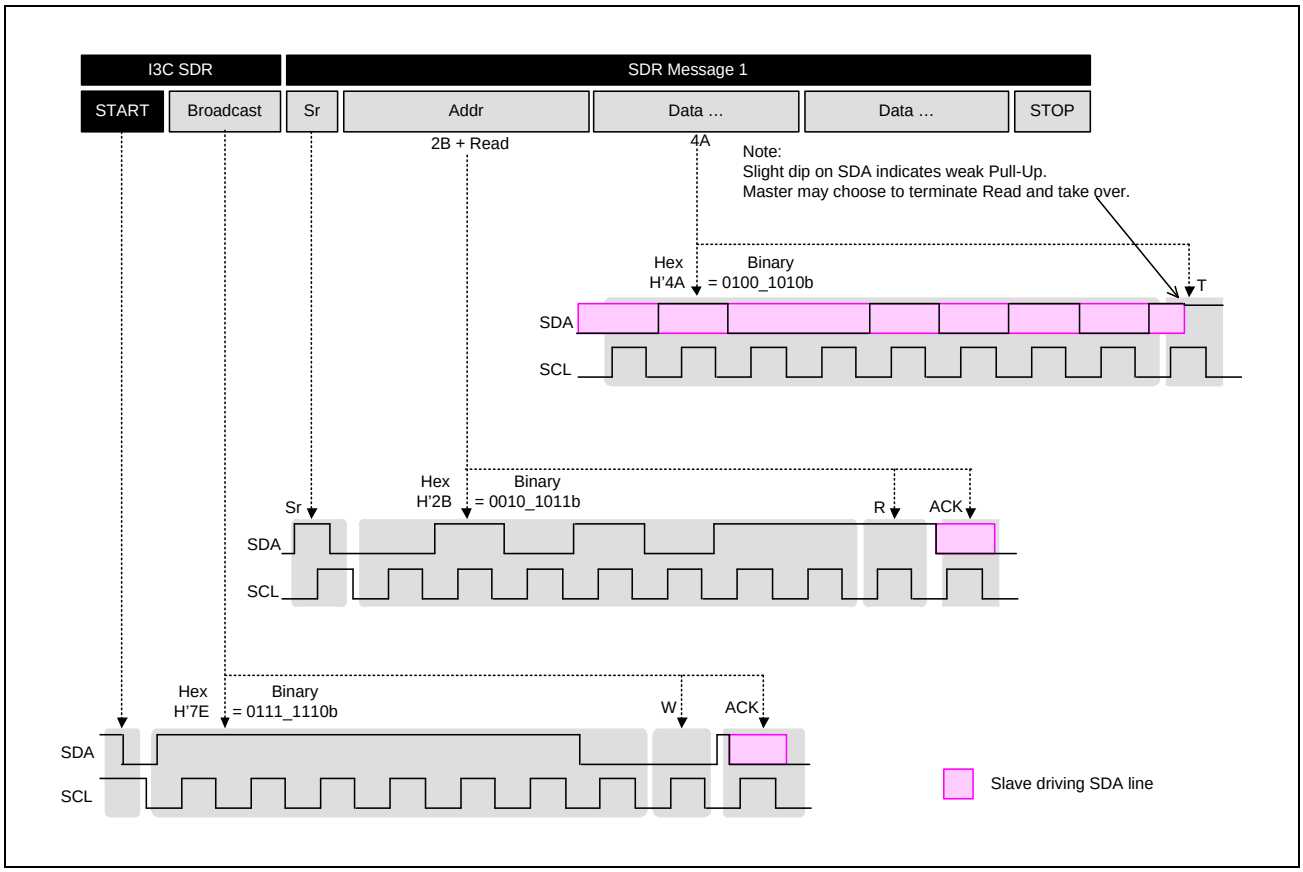


Figure 7.8-52 Example Communication Using I3C Coding SDR with Broadcast (H'7E)

Figure 7.8-53 illustrates example communication using I3C Single Data Rate (SDR) coding without Broadcast (H'7E). It shows the Master reading a byte of data from the Slave at Address H'2B in SDR Mode. From the Bus Free Condition, The Master then issues a START, then the Address of the Slave (H'2B) it wants to read followed by RnW (1 for Read).

The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the SDA line Low. At this point, the Master continues to toggle the SCL line and release the SDA line, allowing the Slave to drive SDA to send one byte of data (H'4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pull-up, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over. SDR Mode is backwards compatible with Legacy I^2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I^2C 50ns Spike Filter.

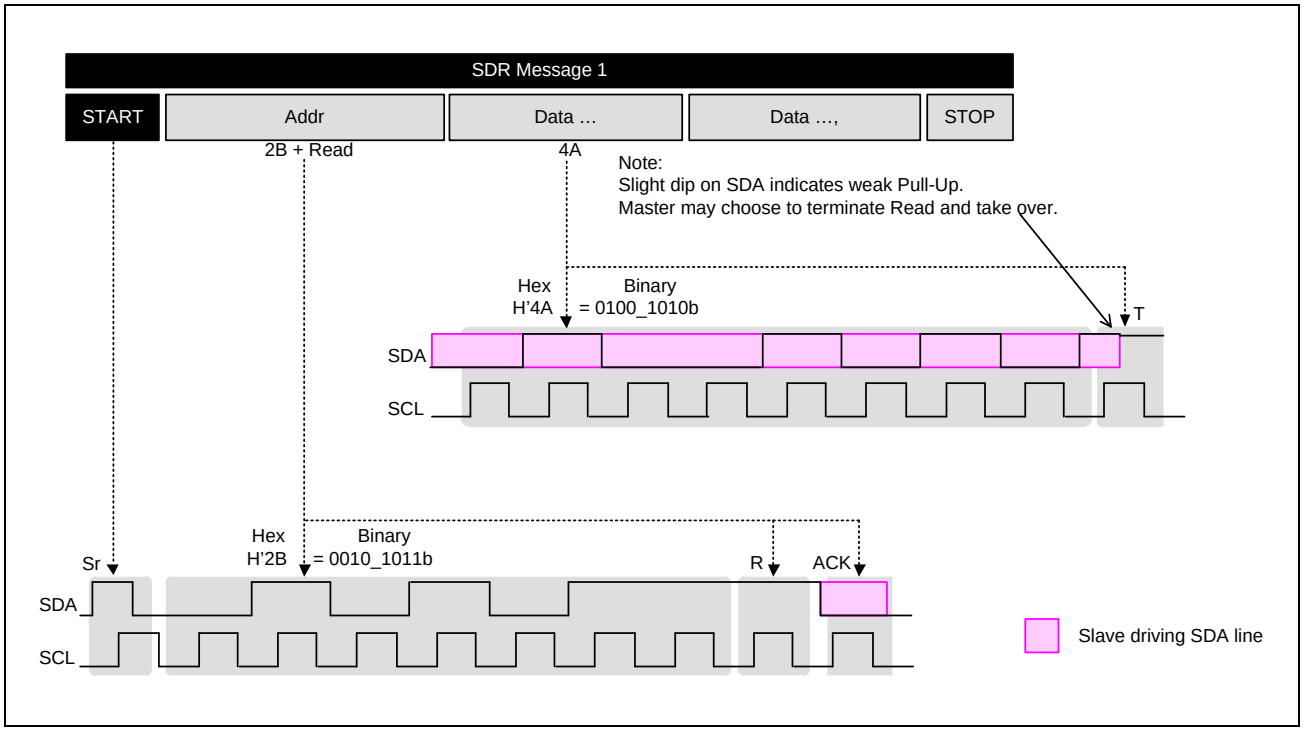

Figure 7.8-53 Example communication using I3C coding SDR without broadcast (H'7E)

Figure 7.8-54 shows the Master issuing a CCC Direct Command to a single Slave. This particular command (GETPID) reads the Provisional ID of a Slave.

From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (H'7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Direct Common Command Code for GETPID (H'8C) followed by parity bit T (odd parity = 0 for H'8C) then the 7-bit Dynamic Address of the Slave (chosen arbitrarily here to be H'2B) followed by a RnW bit (1 for Read). Then the Master turns on a pull-up resistor and goes to Open Drain, allowing the Slave at Address H'2B to ACK by pulling SDA Low, which tells the Master that the Slave Acknowledges the command and will comply. (Alternatively, the Slave may NACK by not pulling SDA Low, which would inform the Master that the Slave will not comply – in this case, that an error occurred.) Following the ACK, the Slave outputs its 48-bit PID one byte at a time, and then the Master issues a Repeated START (this part of the waveform sequence is not shown in the Figure).

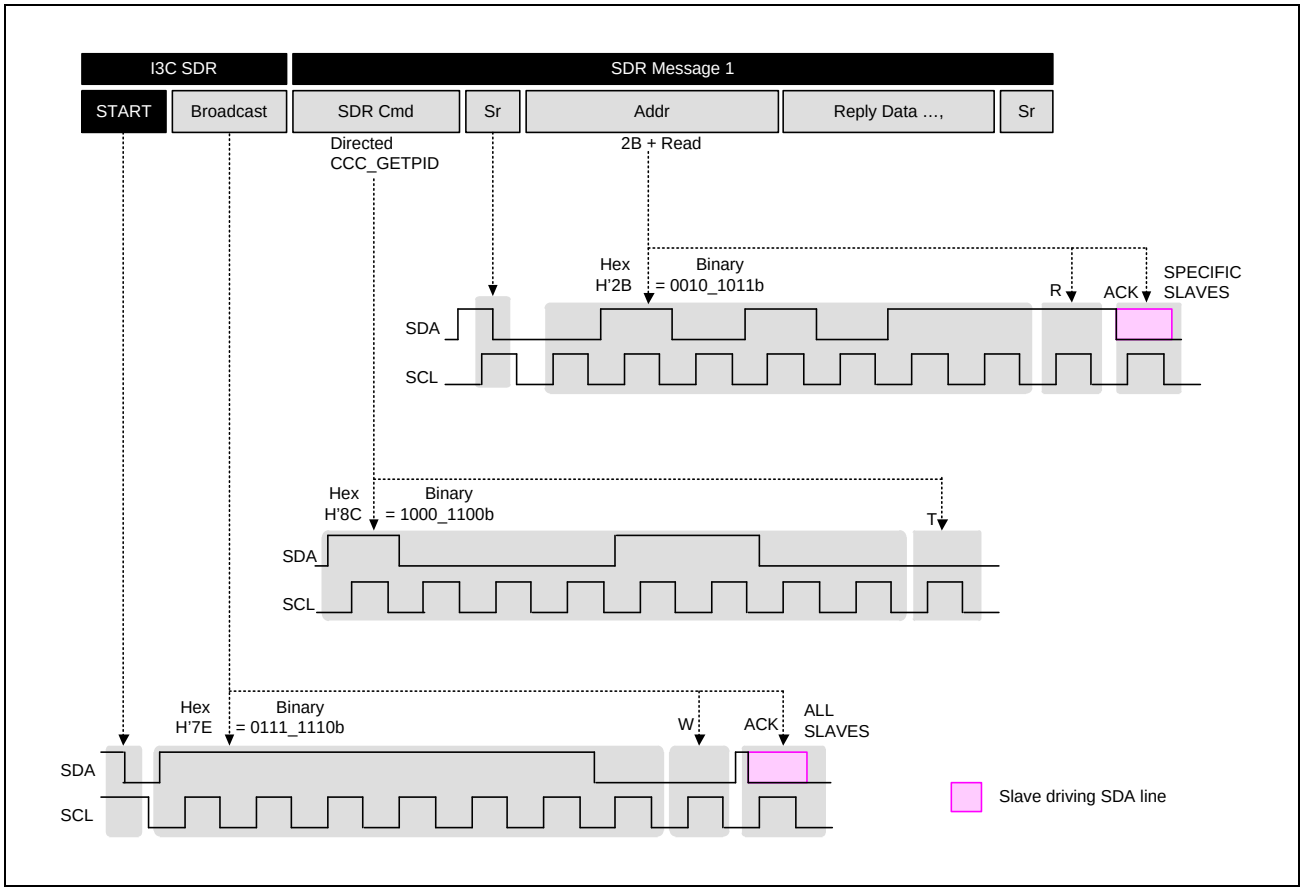

Figure 7.8-54 Example Communication Using I3C Coding SDR with CCC Direct Addressing

Figure 7.8-55 illustrates example SDR communication with a CCC Broadcast command. The command used in this example sets the Maximum Read Length of all Slaves to 43 bytes (H'2B).

From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (H'7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for SETMRL (H'09) followed by parity bit T (odd parity = 1 for H'09), and then 2 data bytes (MSB first) to define the maximum number of bytes which can be read from a Slave in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this the Master issues a Repeated START.

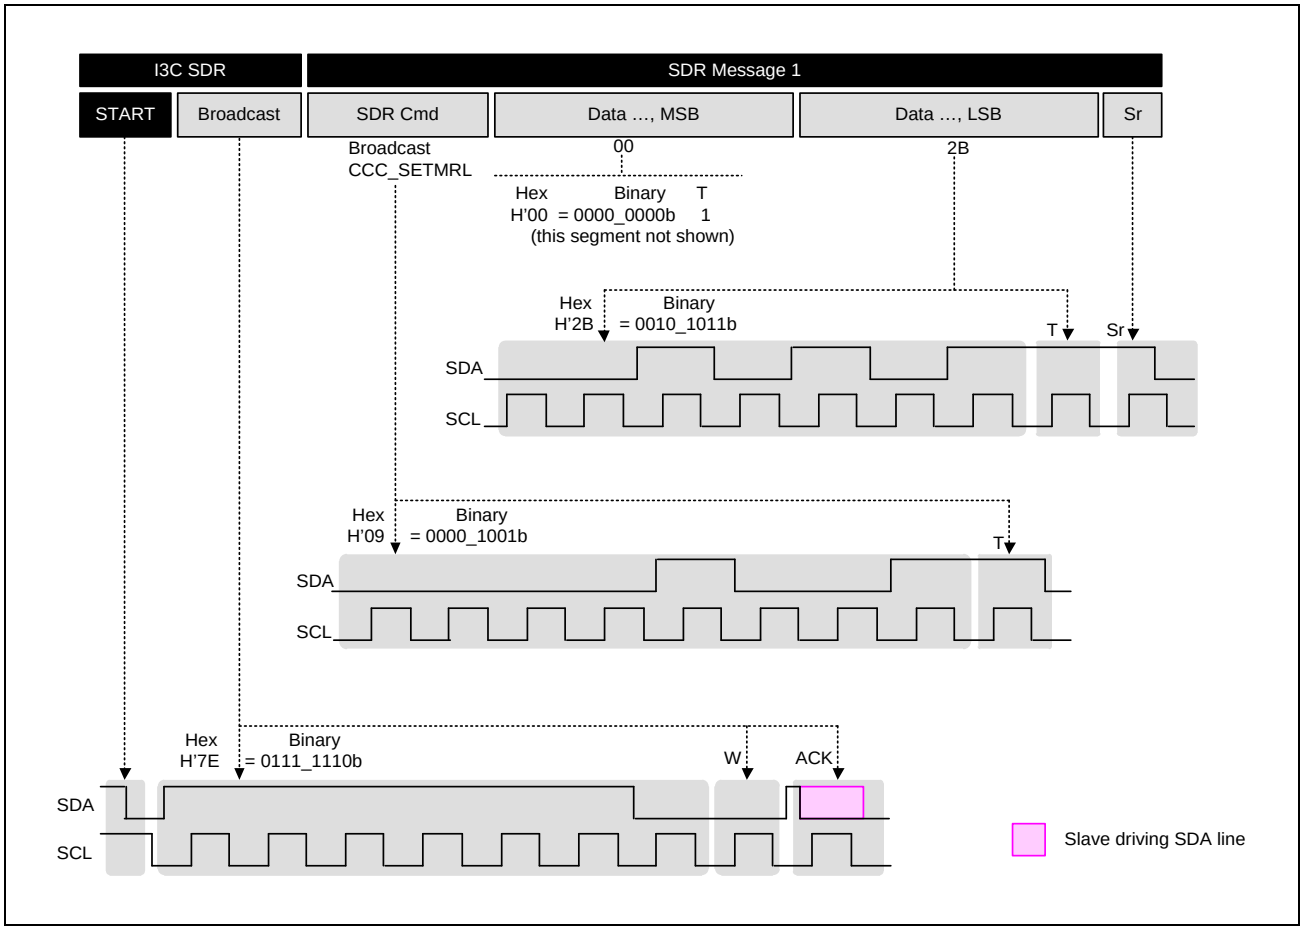

Figure 7.8-55 Example Communication Using I3C Coding SDR with CCC Broadcast

(2) Bus Conditions

I3C defines three distinct conditions in which the I3C Bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (refer to **Figure 7.8-56**).

(a) Bus Free Condition

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BFRECDT.FRECYC[8:0] bit.

(b) Bus Available Condition [I3C mode]

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BAVLCDT.AVLCYC[8:0] bit.

A Slave may only issue a START Request (For example, for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

(c) Bus Idle Condition [I3C mode]

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BIDLCDT.IDLCYC[17:0] bit.

A Slave may only issue a START Request (For example, for a Hot-Join) after a Bus Idle Condition. Specifications are as follows. IDLE needs to be the largest.

BFRECDT.FRECYC[8:0] < BAVLCDT.AVLCYC[8:0] < BIDLCDT.IDLCYC[17:0]

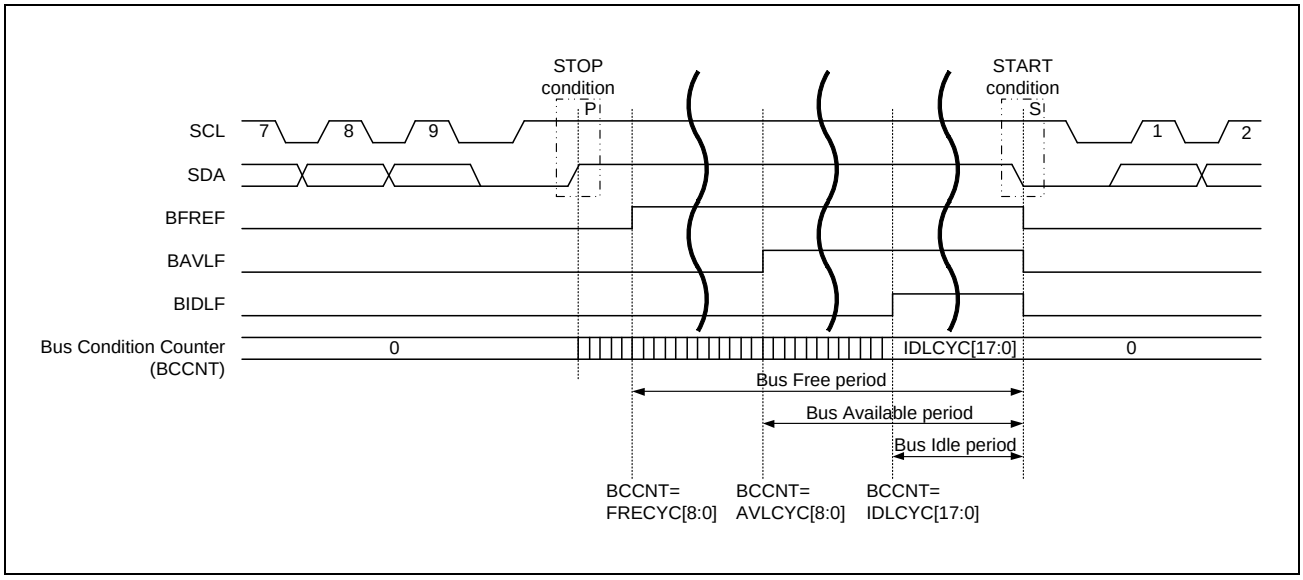

Figure 7.8-56 Bus Conditions

(3) START Condition / Repeated START Condition / STOP Condition Issuing Function

(a) Issuing a START Condition

I3C issues a START condition when the CNDCTL.STCND bit is set to 1.

Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).

I3C issues a START condition.

When a START condition is issued normally, I3C automatically shifts to the master transmit mode. A START condition is issued in the following sequence.

[START condition issuance]

- Drive the SDAn line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the START condition hold time.
- Drive the SCLn line low (high level to low level).
- Detect low level of the SCLn line and ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0].

(b) Issuing a Repeated START Condition

I3C issues a Repeated START condition when the CNDCTL.SRCND bit is set to 1.

When the SRCND bit is set to 1, a Repeated START condition issuance request is made and I3C issues a Repeated START condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.CRMS bit = 1 (master mode).

A Repeated START condition is issued in the following sequence. [Repeated START condition issuance]

- Release the SDAn line.
- Ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].
- Release the SCLn line (low level to high level).
- Detect a high level of the SCLn line and ensure the time set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] and the Repeated START condition setup time.
- Drive the SDAn line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the Repeated START condition hold time.
- Drive the SCLn line low (high level to low level).
- Detect a low level of the SCLn line and ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].

NOTE

When issuing Repeated START conditions request, please write the slave address to NTDTBP0 after confirming CNDCTL.SRCND = 0. Data written in the period of CNDCTL.SRCND = 1 is not forwarded because retransmission condition before the occurrence.

To issue a Repeated START condition in Hs-mode, follow the steps below.

1. Wait until PRSTDBG.SCOLV = 0b.
2. Set EXTBR.EBRHO[7:0] to satisfy the hold time of the Repeated START condition.
3. Set the CNDCTL.SRCND bit to 1b.
4. After confirming CNDCTL.SRCND = 0b, wait until PRSTDBG.SCOLV = 0b.
5. Set EXTBR.EBRHO[7:0] according to the High period of the SCL clock in Hs-mode.

6. Write the slave address to NTDTBP0.

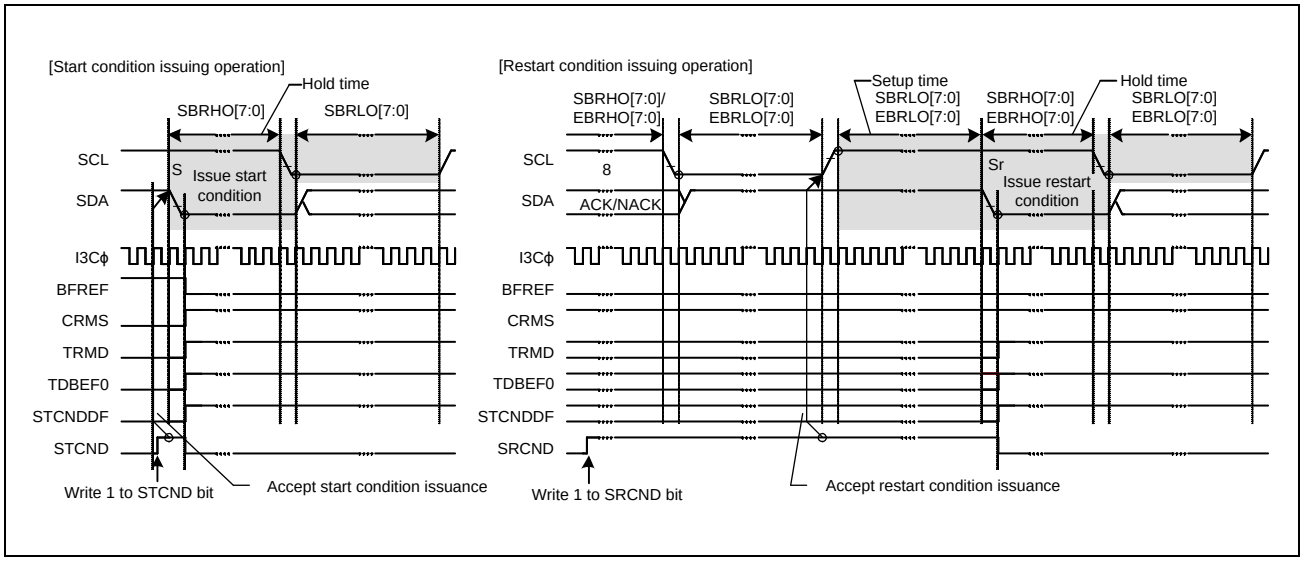

Figure 7.8-57 START Condition / Repeated START Condition Issue Timing (STCND and SRCND bits)

Figure 7.8-58 shows the operation to issue a Repeated START condition after the master transmission.

[Repeated START condition issuance after the master transmission]

- Initial setting. For details, refer to **7.8.3.3.1 Initial Setting Flow**.
- Read the BFREF flag in BCST to check that the bus is open, and then set the STCND bit in CNDCTL to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag is automatically set to 0 and the STCNDDF flag in BST is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and CRMS and TRMD bits in PRSST is automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
- Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to NTDTBP0. Once the data for transmission are written to NTDTBP0, the TDBEF0 flag is automatically set to 0, the data are transferred from NTDTBP0, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Since the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1_1110, the 2 higher-order bits of the slave address, and W to NTDTBP0 as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to NTDTBP0.
- After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the SCLn line low until the data for transmission are ready, a Repeated START condition is issued or a STOP condition is issued.

- After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then, after check that the BST.STCNDDF flag = 1, set the BST.STCNDDF flag to 0.
- Set the SRCND bit in CNDCTL to 1 (Repeated START condition issuance request). Upon receiving the request, I3C issues a Repeated START condition.
- After check that the BST.STCNDDF flag = 1, write the value for transmission (the slave address and the R/W# bit) to NTDTBP0.

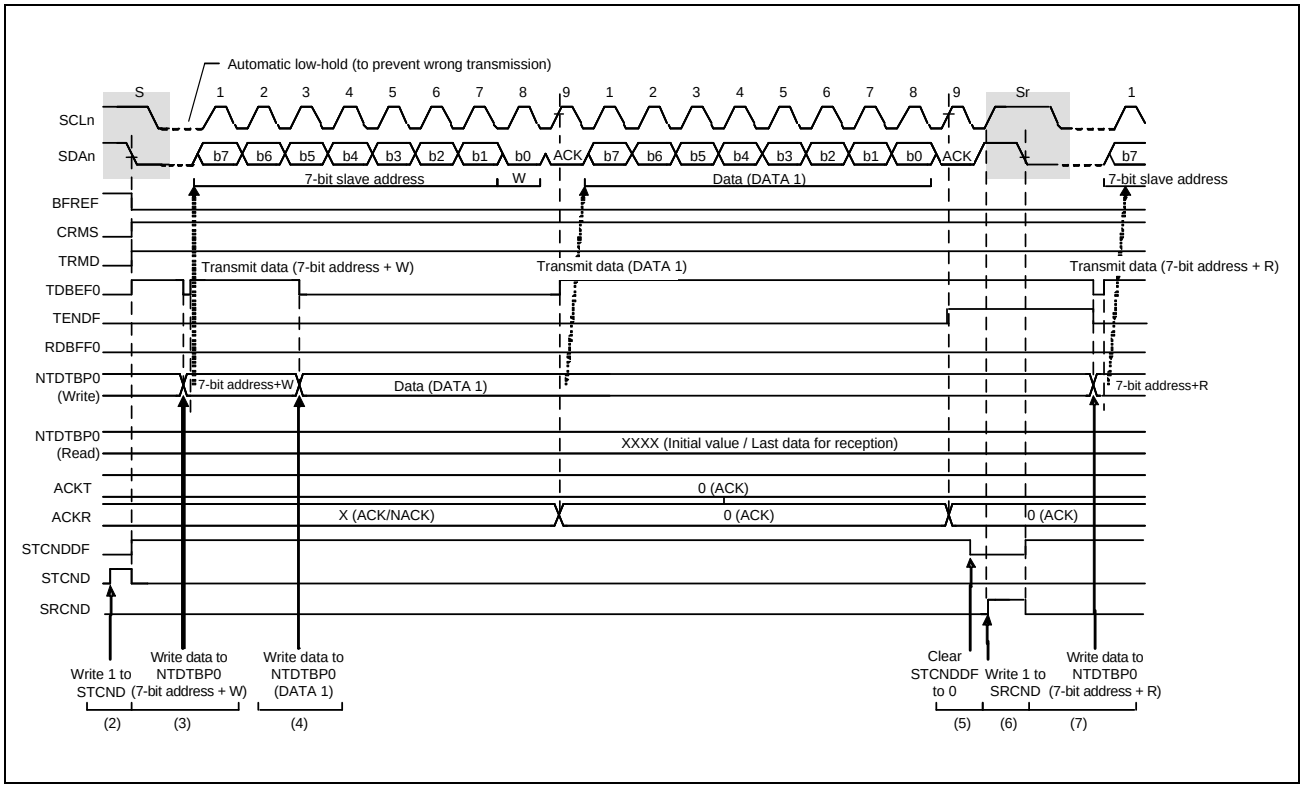

Figure 7.8-58 Repeated START Condition Issuance after the Master Transmission Timing

(c) Issuing a STOP Condition

I3C issues a STOP condition when the SPCND bit in CNDCTL is set to 1.

When the SPCND bit is set to 1, a STOP condition issuance request is made and I3C issues a STOP condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.MST bit = 1 (master mode).

A STOP condition is issued in the following sequence.

[STOP condition issuance]

- Drive the SDAn line low (high level to low level).
- Ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].
- Release the SCLn line (low level to high level).
- Detect a high level of the SCLn line and ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the STOP condition setup time.
- Release the SDAn line (low level to high level).
- Ensure the time set in BFRECDT.FRECYC[8:0] and the bus free time.
- Set the BFREF flag to 1 (to release the bus mastership).

NOTE

To issue a STOP condition in Hs-mode, follow the steps below

1. Wait until PRSTDBG.SCOLV = 0b
2. Set EXTBR.EBRHO[7:0] to satisfy the setup time for the STOP condition.
3. Set the CNDCTL.SPCND bit to 1b.
4. Wait until CNDCTL.SPCND = 0b.
5. Set EXTBR.EBRHO[7:0] according to the High period of the SCL clock in Hs-mode.

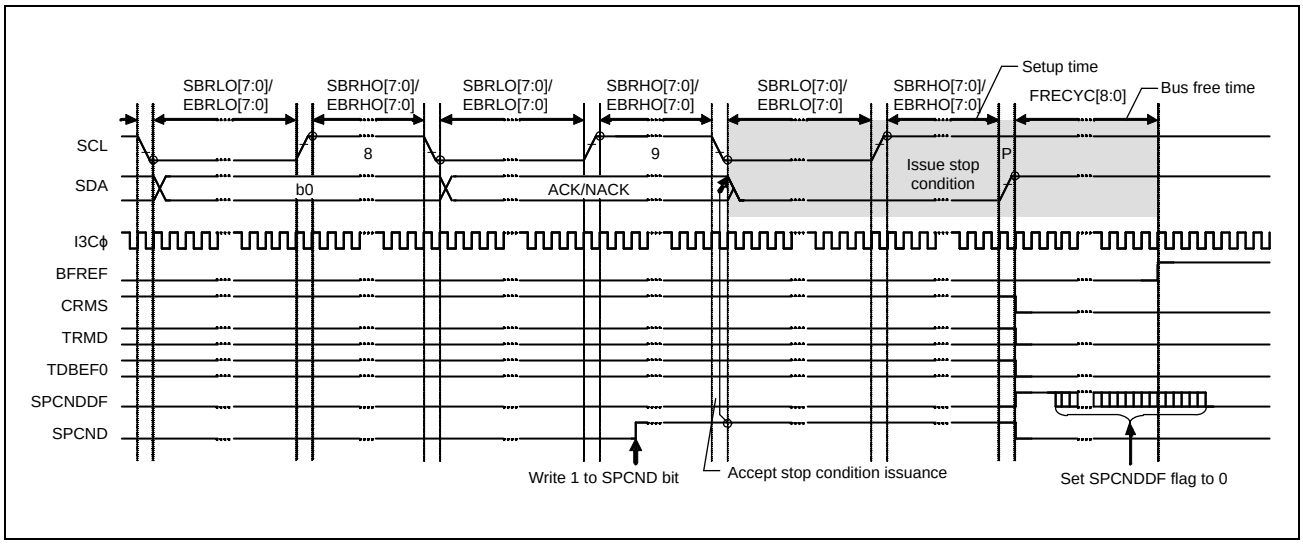

Figure 7.8-59 STOP Condition Issue Timing (SPCND bit)

(4) Address Match Detection

I3C can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10- bit slave addresses.

(a) Slave-Address Match Detection [I²C mode]

I3C can set three unique slave addresses and has a slave address detection function for each unique slave address.

When the SVCTL.SVAEy bit (y = 0 to 2) is set to 1, the slave addresses set in the SVDVADy register (y = 0) can be detected.

When I3C detects a match of the set slave address, the corresponding SVST.SVAFy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (I3Cn_RX) or transmit data empty interrupt (I3Cn_TX) to be generated. The SVAFy flag is used to identify which slave address has been specified.

Figure 7.8-60 to **Figure 7.8-62** show the SVAFy flag set timing in three cases.

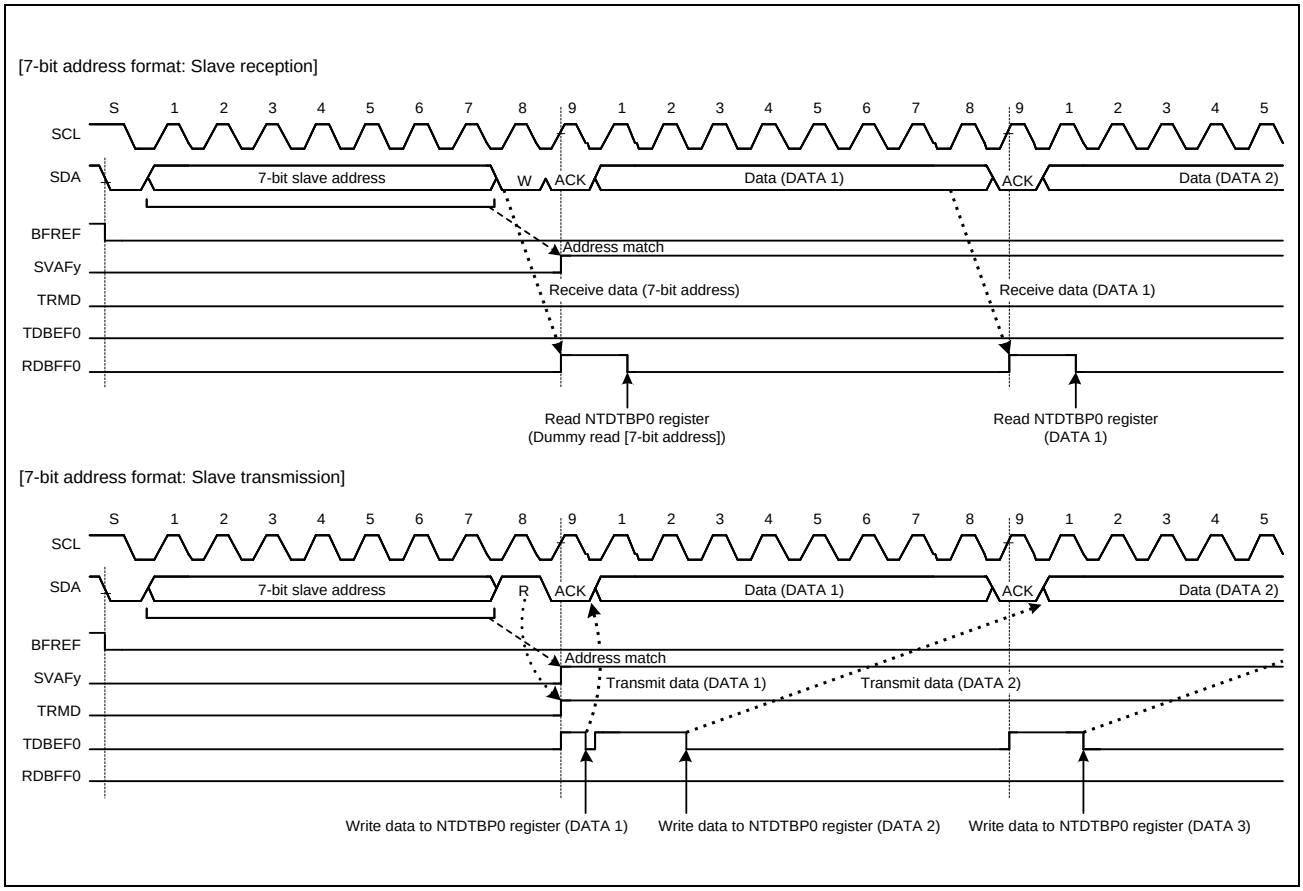

Figure 7.8-60 SVAFy Flag Set Timing with 7-bit Address Format Selected

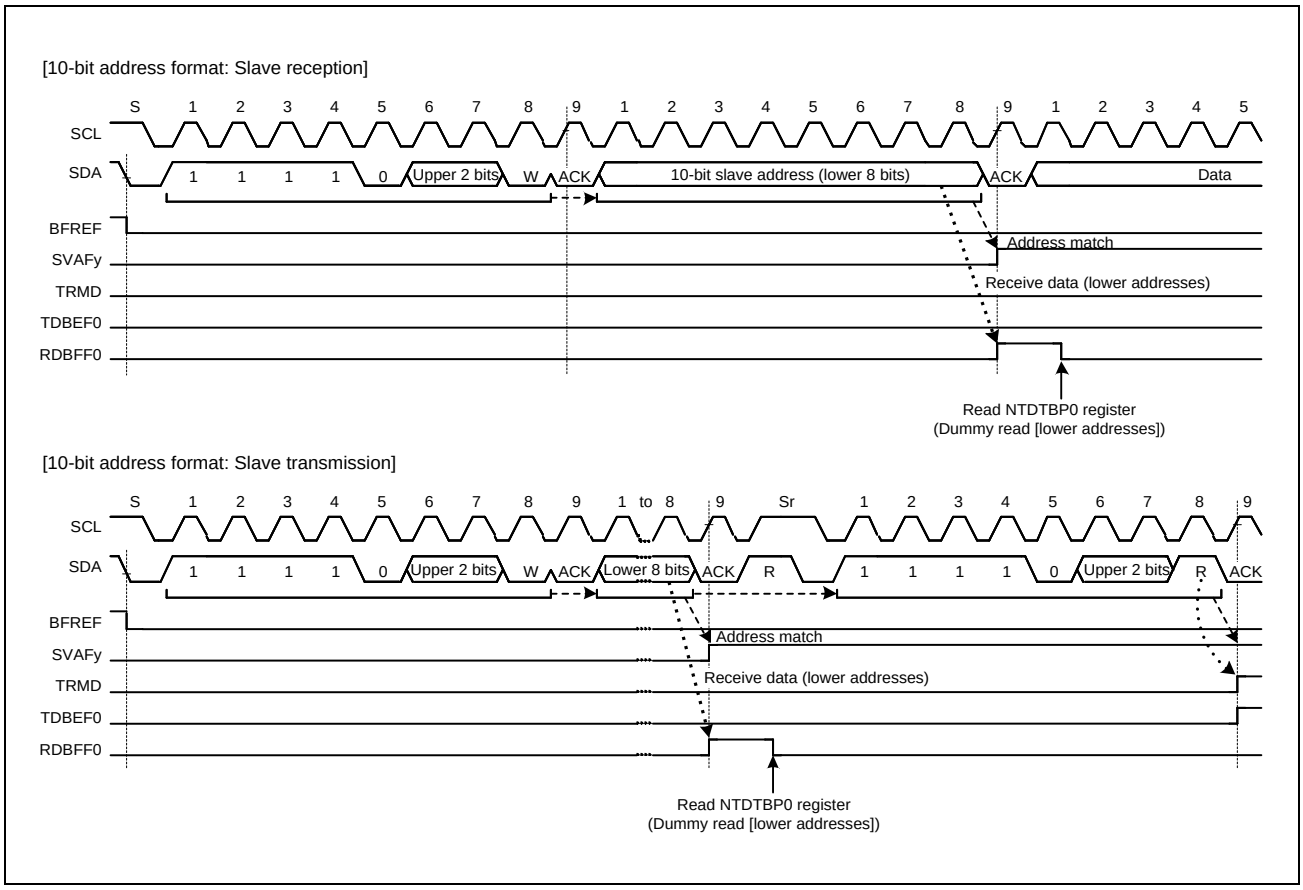

Figure 7.8-61 SVAFy Flag Set Timing with 10-bit Address Format Selected

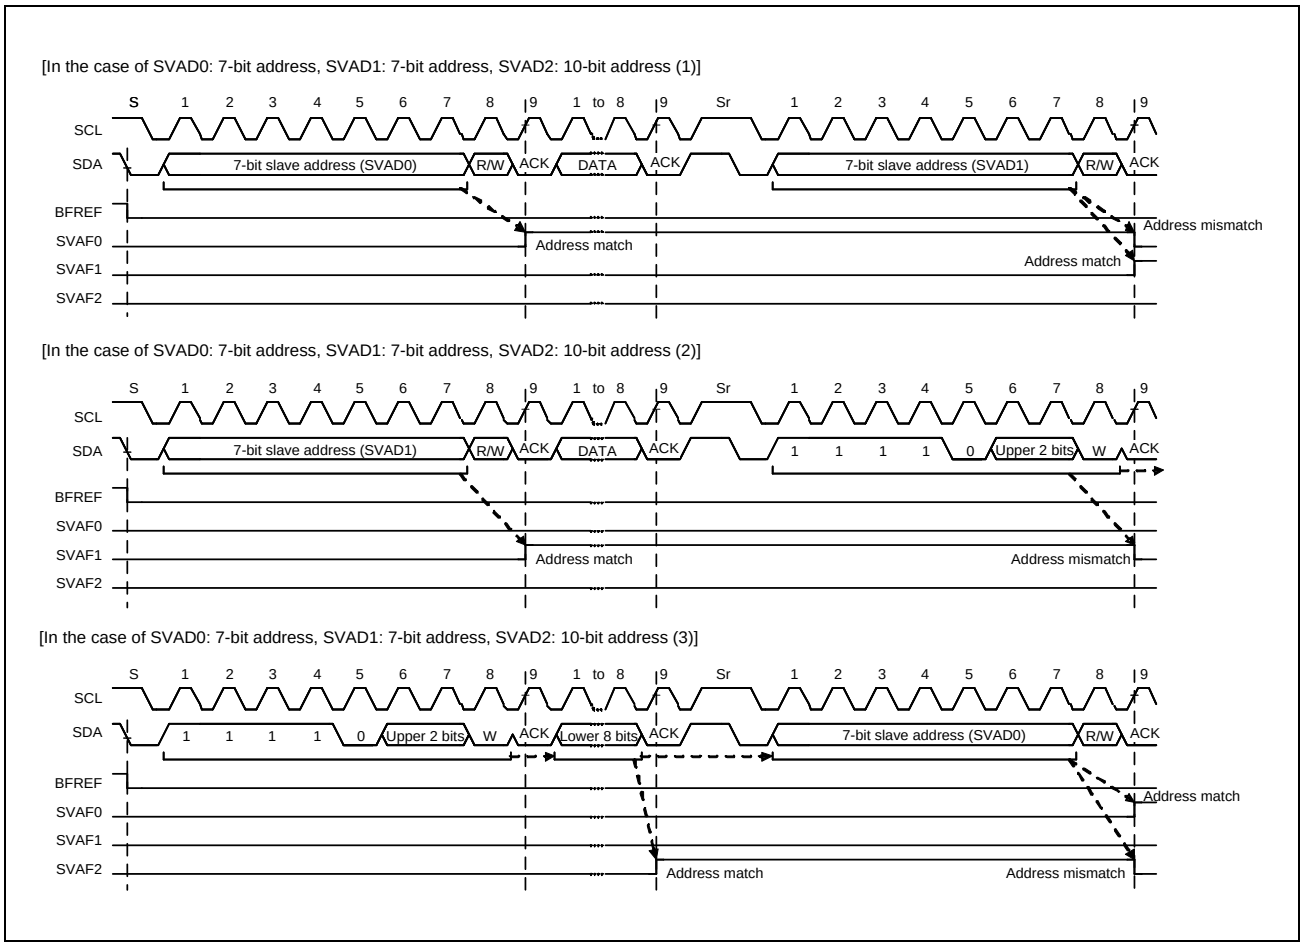

Figure 7.8-62 SVAFy Flag Set / Clear Timing with 7-bit/10-bit Address Formats Mixed

(b) Detection of the General Call Address [I²C mode]

I3C has a facility for detecting the general call address (000_0000 + 0 (write)). This is enabled by setting the SVCTL.GCAE bit to 1.

If the address received after a START or Repeated START condition is issued is 000_0000 + 1 (read) (start byte), I3C recognizes this as the address of a slave device with an all-zero address but not as the general call address.

When I3C detects the general call address, both the SVST.GCAF flag and the NTST.RDBFF0 flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (I3Cn_RX). The value of the GCAF flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

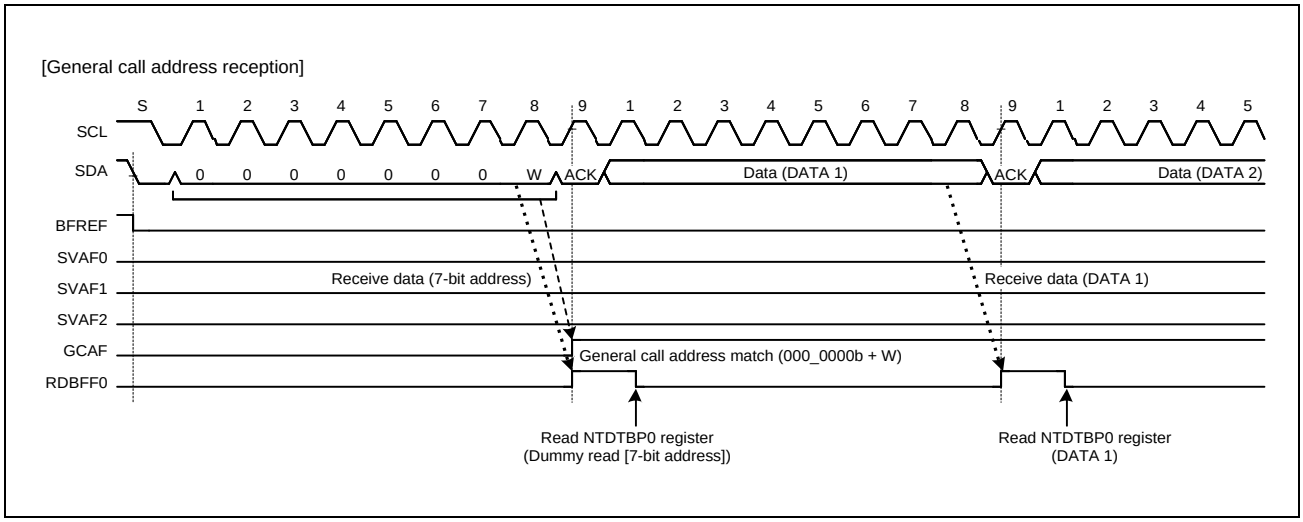

Figure 7.8-63 Timing of GCAF Flag Setting during Reception of General Call Address

(c) Device-ID Address Detection [I²C mode]

I3C module has a facility for detecting device-ID addresses conformant with the I²C-bus specification (Rev.03). When I3C receives 111_1100 as the first byte after a START condition or Repeated START condition was issued with the SVCTL.DVIDE bit set to 1, I3C recognizes the address as a device ID, sets the SVST.DVIDF flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit = 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, I3C sets the corresponding SVST.SVAFy flag (y = 0 to 2) to 1.

After that, when the first byte received after a START or Repeated START condition is issued matches the device ID address (111_1100) again and the following R/W# bit = 1, I3C does not compare the second and subsequent bytes and sets the NTST.TDBEF0 flag to 1.

In the device-ID address detection function, I3C sets the DVIDF flag to 0 if a match with I3C's own slave address is not obtained or a match with the device ID address is not obtained after a match with I3C's own slave address and the detection of a Repeated START condition. If the first byte after detection of a START or Repeated START condition matches the device ID address (111_1100) and the R/W# bit = 0, I3C sets the DVIDF flag to 1 and compares the second and subsequent bytes with I3C's slave address. If the R/W# bit = 1, the DVIDF flag holds the previous value and I3C does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DVIDF flag after confirming that TDBEF0 flag = 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

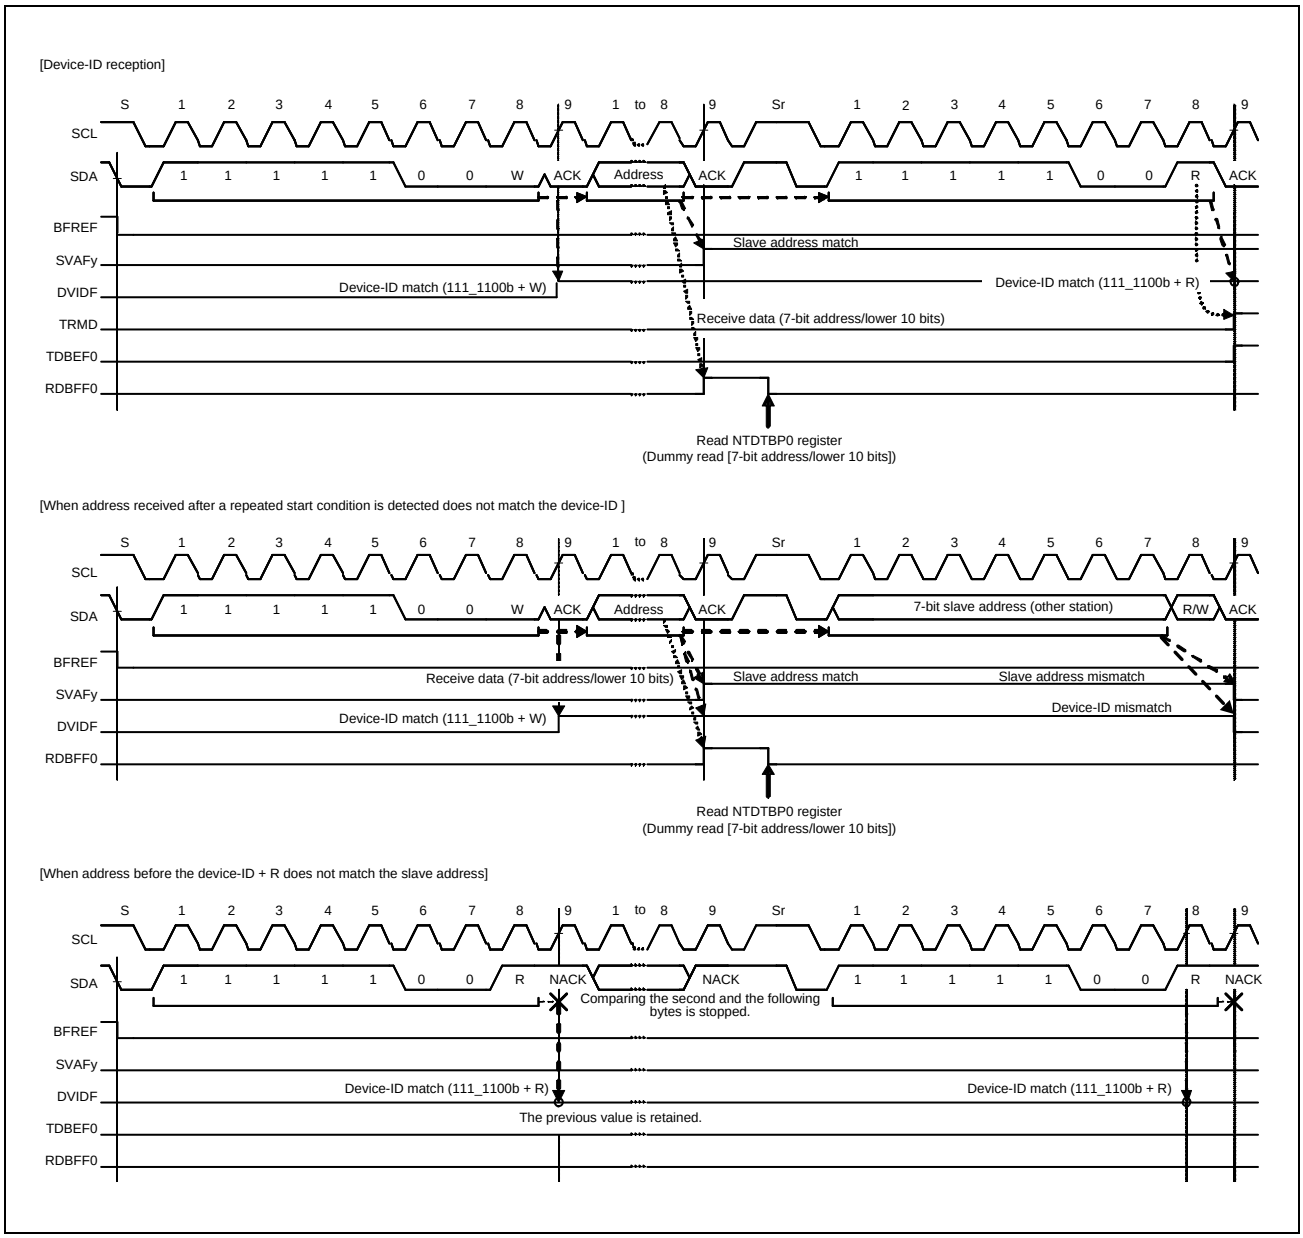

Figure 7.8-64 SVAFy/DVIDF Flag Set / Clear Timing during Reception of Device-ID

(d) Hs-Mode Master Code Detection [I²C mode]

IIC has a facility for detecting the Hs-mode master code (0000_1XXXb). When IIC receives the Hs-mode master code (0000_1XXXb) as the first byte after a START condition was issued with the SVCTL.HSMCE bit set to 1, this module recognizes the address as the Hs-mode master code, sets the SVST.HSMCF flag to 1 on the rising edge of the ninth SCL clock cycle. The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADy.SVAD[9:0] (y = 0 to 2). When IIC detects a match of the set slave address, the corresponding SVST.SVAFy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (IICn_RX) or transmit data empty interrupt (IICn_TX) to be generated. The SVAFy flag is used to identify which slave address has been specified. The SVST.HSMCF flag is cleared to 0 when the STOP condition is detected.

NOTE

If the Hs-mode master code (0000_1XXXb) is received with the SVCTL.HSMCE bit set to 0, other patterns are ignored until the STOP condition is detected.

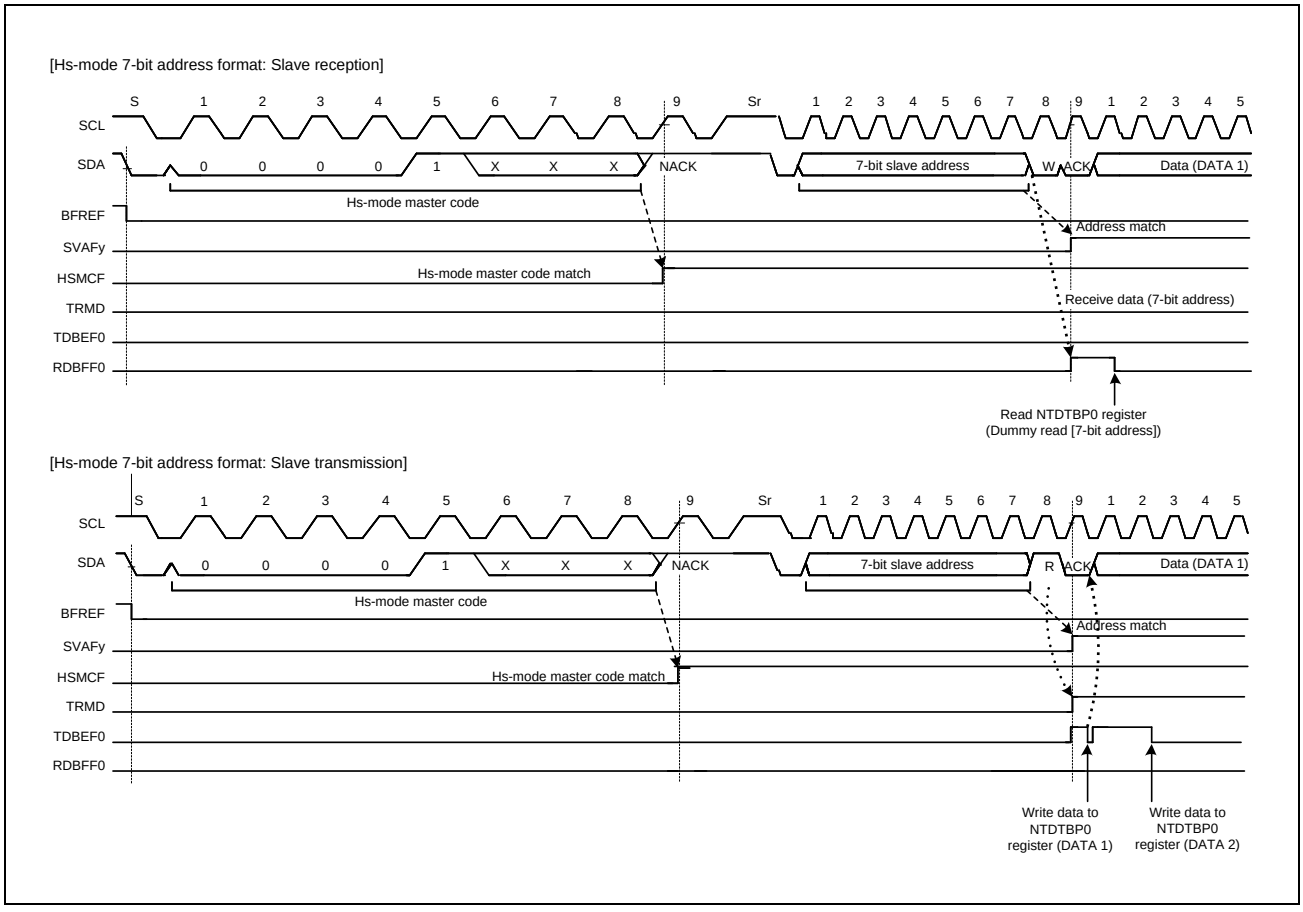

Figure 7.8-65 SVAFy/HSMCF Flag Set Timing during Reception of Hs-Mode Master Code

(e) CCC Detection Function [I3C mode]

- In case of Broadcast CCC

1. It receives Broadcast Address (H'7E) and R/W# = 0 after START condition or Repeated START.
2. Respond to ACK.
3. Receive Common Command Code (CCC).
4. In accordance with the CCC, the following data is stored. (Storage destination: refer to **Table 7.8-12**)
5. Store the Receive Status Descriptor into the Receive Status Queue.

- In case of Broadcast CCC (ENTDAA)

1. It receives Broadcast Address (H'7E) and R/W# = 0 after START condition.
2. Respond to ACK.
3. Receive ENTDAA.
4. If receives Broadcast Address (H'7E) and R/W# = 1 after Repeated START.
5. When the Dynamic Address is not assigned, ACK response is done.
6. This Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCR[7:0]) and DCR (SVDCT.TDCR[7:0]) are transmitted.
7. When winning the arbitration in a transmission of the above Step 6, the dynamic address following that is received. When losing arbitration in a transmission of the above Step 6, processing of Step 6 is repeated from Step 4.
8. When parity of the Dynamic Address is valid, ACK response is done.
9. When parity of the Dynamic Address is invalid, NACK replies, and repeat the process from Steps 4 to 7.
10. SDATBAS0.SDDYAD[7:0] is renewed and the SVDVAD0.SDYADV bit is set to 1.
11. Upon detecting the STOP condition, Store the Receive Status Descriptor into the Receive Status Queue.

- In case of Direct Write CCC

1. It receives Broadcast Address (H'7E) and R/W# = 0 after START condition or Repeated START.
2. Respond to ACK.
3. Receive Common Command Code (CCC).
4. Receive Dynamic Address and R/W# = 0 after Repeated START.
5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
   If they do not match, it responds with NACK and waits for Repeated START or STOP.
6. In accordance with the CCC, the following data is stored. (Storage destination: refer to **Table 7.8-12**)
7. Store the Receive Status Descriptor into the Receive Status Queue.

- In case of Direct Read CCC

1. It receives Broadcast Address (H'7E) and R/W# = 1 after START condition or Repeated START.
2. Respond to ACK.
3. Receive Common Command Code (CCC).
4. Receive Dynamic Address and R/W# = 1 after Repeated START.

5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
   If they do not match, it responds with NACK and waits for Repeated START or STOP.
6. Respond from SFR according to CCC. (Responding CCC: refer to **Table 7.8-12**)
7. Store the Receive Status Descriptor into the Receive Status Queue.

Table 7.8-12 Common Command Code Operation

Command Code	CCC Type	Command Name	With Data	Auto Response	Storage

(5) Arbitration-Lost Detection [I²C mode]

In addition to the normal arbitration-lost detection function defined by the I²C-bus specification, the I3C has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration- lost in slave transmit mode.

(a) Master Arbitration-Lost Detection (MALE Bit)

The I3C drives the SDAn line low to issue a start condition. However, if the SDAn line has already been driven low by another master device issuing a start condition, this module causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the CNDCTL.STCND bit is set to 1 while the BCST.BFREF flag is 0 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.

When a start condition is issued successfully, if the data for transmission including the address bits (the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output, that is, the SDA0 pin is in the high-impedance state) and the low level is detected on the SDAn line, the I3C loses in arbitration.

I3C detects master arbitration-lost when the following conditions are met while the BSTE.ALE bit = 1 and the BFCTL.MALE bit = 1 (master arbitration-lost detection enabled).

If arbitration of mastership is lost, I3C immediately enters slave receive mode.

If a slave address (including the general call address) matches its own address at this time, I3C continues in slave operation.

[Conditions for master arbitration-lost]

- Non-matching of the internal level for output on SDA and the level on the SDAn line after a START condition was issued by setting the CNDCTL.STCND bit to 1 while the BCST.BFREF flag was set to 1 (erroneous issuing of a START condition)
- Setting of the CNDCTL.STCND bit to 1 (START condition double-issue error) while the BFREF flag is set to 0

NOTE

I3C does not issue a START condition.

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (bits CRMS and TRMD in the PRSST register = 11)

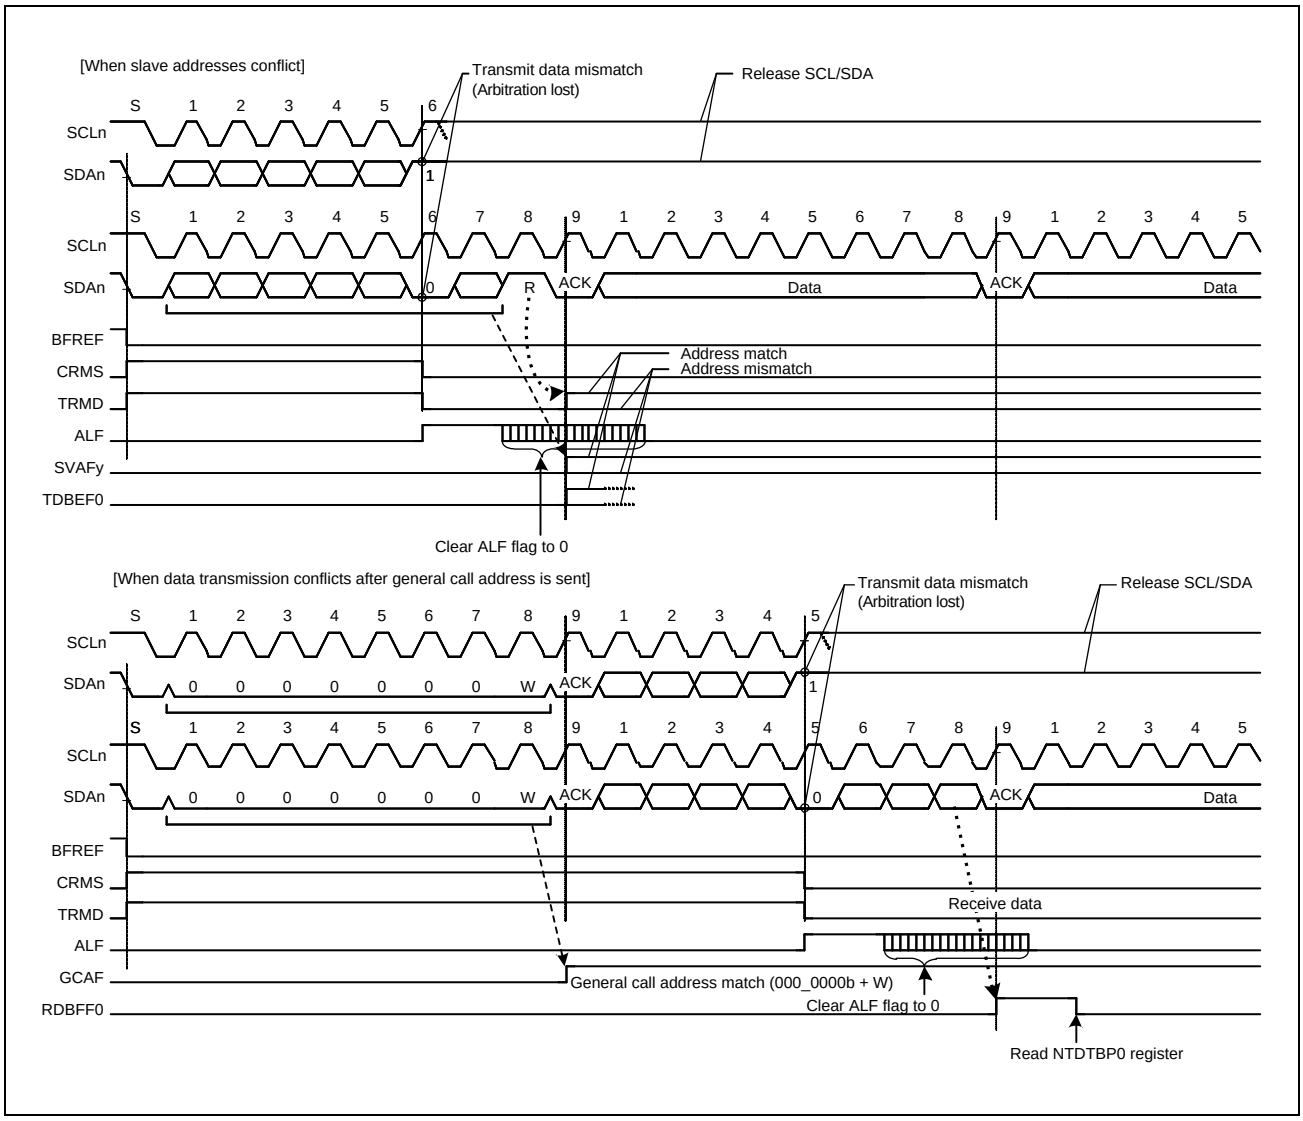

Figure 7.8-66 Examples of Master Arbitration-Lost Detection (MALE = 1)

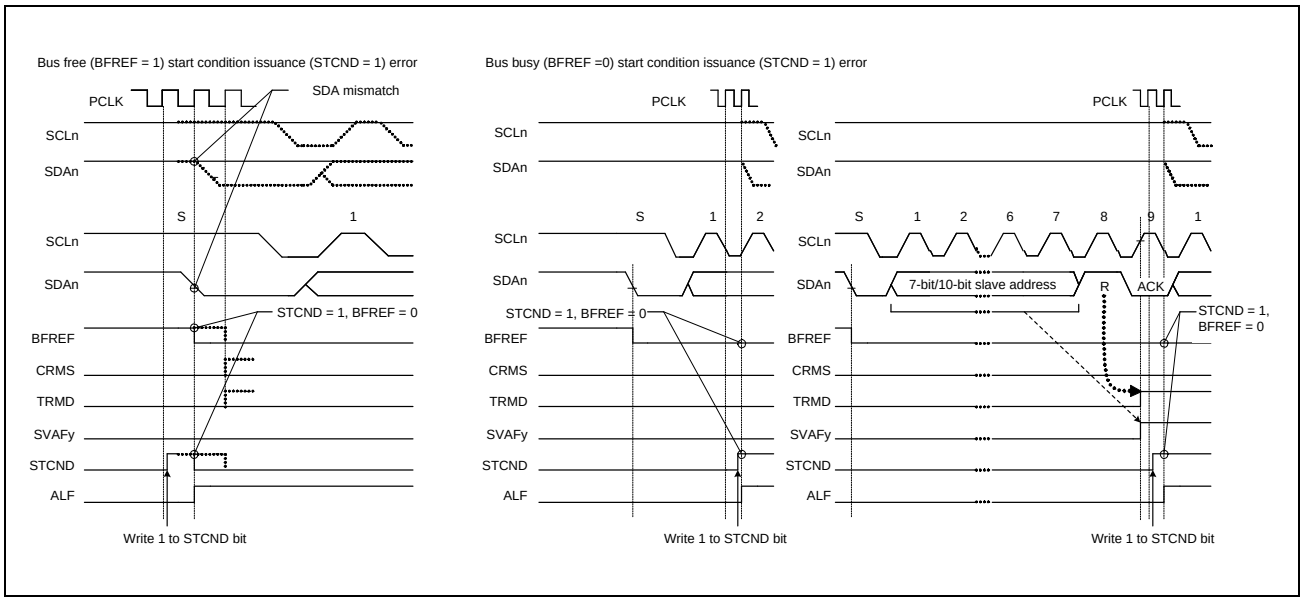

Figure 7.8-67 Arbitration-Lost Detection when a START Condition is Issued (MALE = 1)

(b) Arbitration-Lost Detection during NACK Transmission (NALE Bit)

The I3C has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (the high output as the internal SDA output, i.e., the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device.

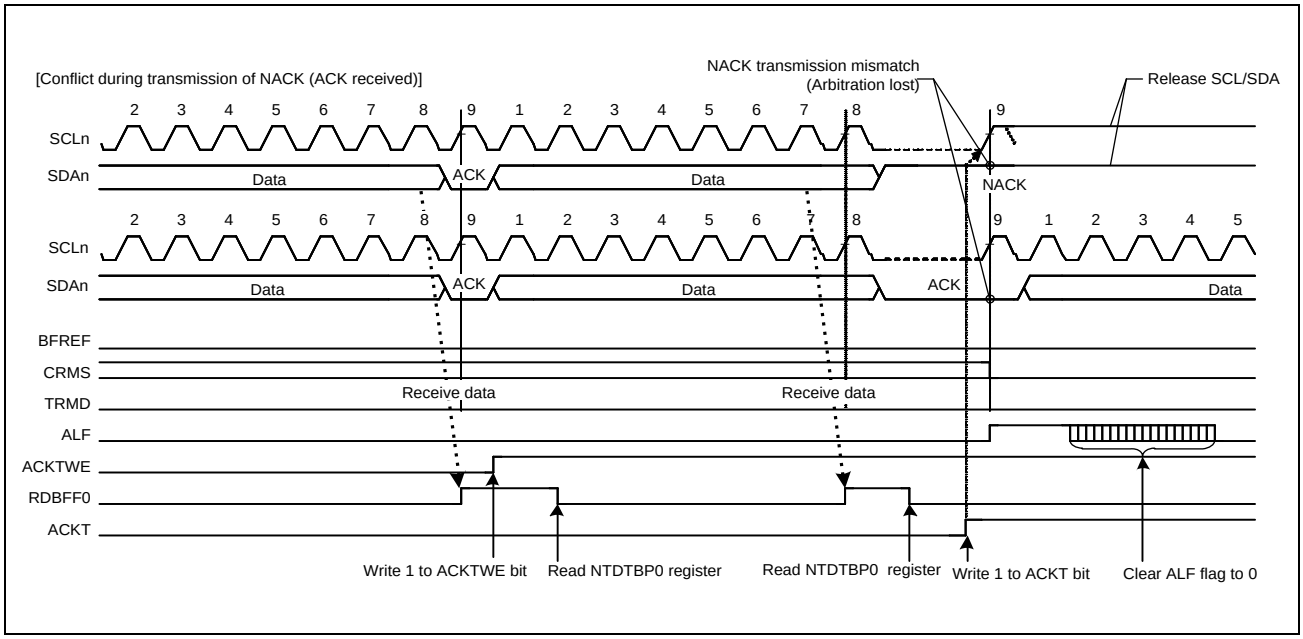

Figure 7.8-68 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following section explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. In this example, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When this module receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, this module is immediately released from the slave-matched state and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

The I3C detects arbitration-lost during transmission of NACK when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.NALE bit = 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKCTL.ACKT bit = 1)

(c) Slave Arbitration-Lost Detection (SALE Bit)

The I3C has a function to cause arbitration to be lost if the data for transmission (the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output, that is, the SDAn pin is in the high impedance state) and the low level is detected on the SDAn line in slave transmit mode.

If arbitration is lost during transmission of DATA, this module is immediately released from the slave-matched state and enters slave receive mode.

The I3C detects slave arbitration-lost when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.SALE bit = 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in slave transmit mode (bits CRMS and TRMD in the PRSST register = 01).

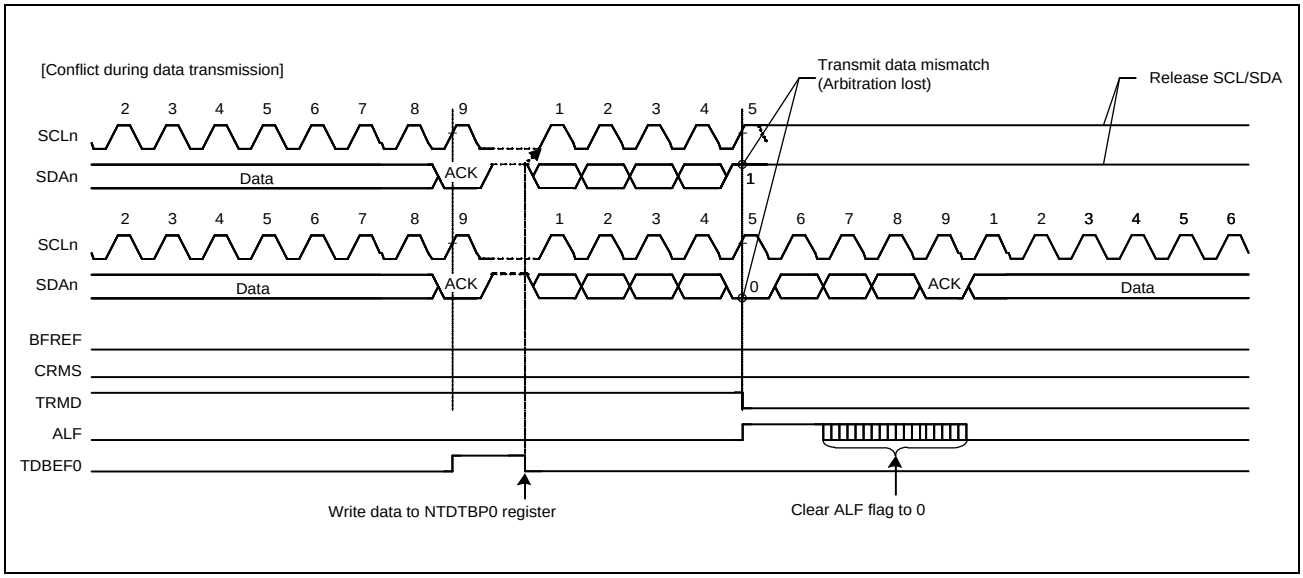

Figure 7.8-69 Example of Slave Arbitration-Lost Detection (SALE = 1)

(6) Clock Stretching [I²C mode]

(a) Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the I²C bus transmit data register (NTDTBP0) with I3C in transmission mode (PRSST.TRMD = 1), the SCLn line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a START condition or Repeated START condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

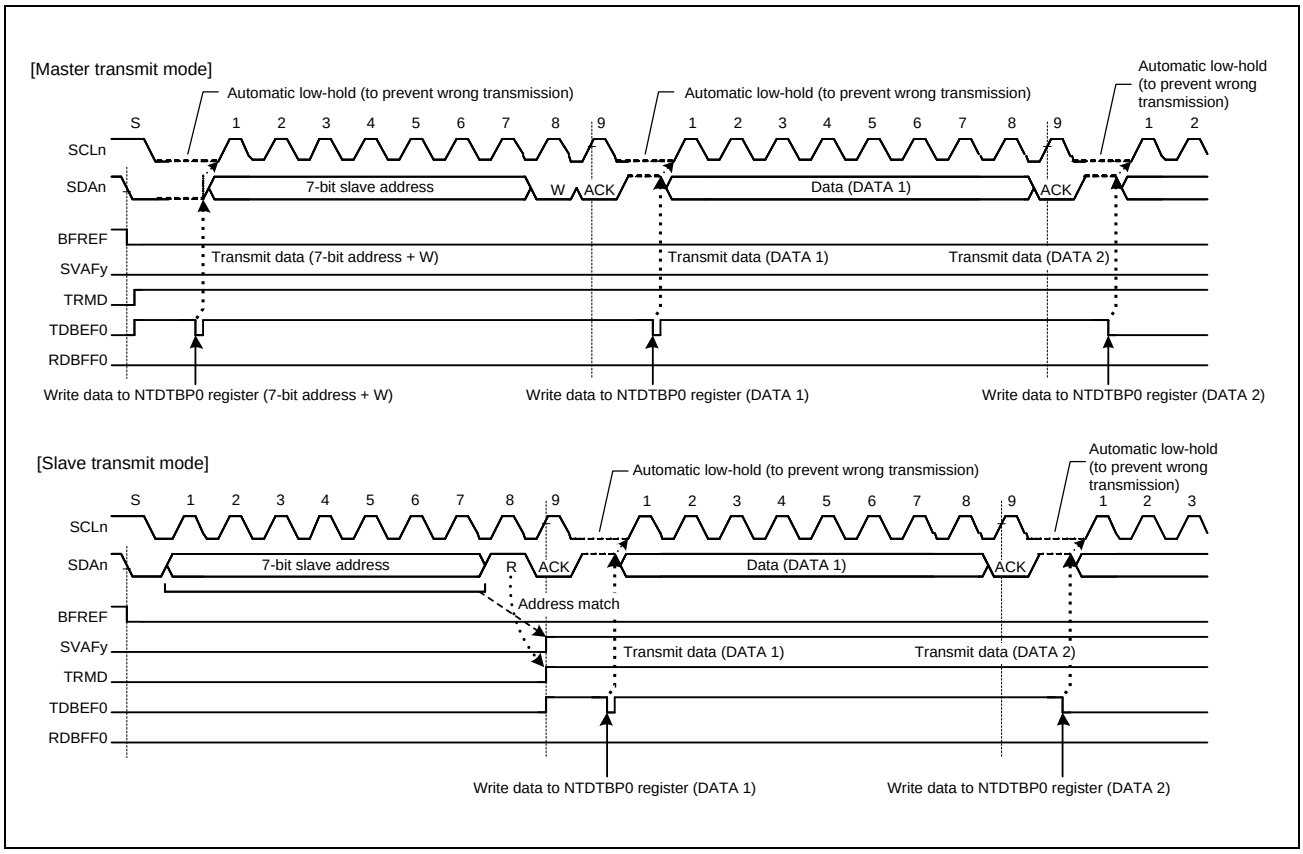

Figure 7.8-70 Automatic Low-Hold Operation in Transmit Mode

(b) NACK Reception Transfer Abort Function

I3C has a function to abort transfer operation when NACK is received in transmit mode (PRSST.TRMD = 1). This function is enabled when the BSTE.NACKDE bit is set to 1 (transfer abort enabled). If the next transmit data has already been written (NTST.TDBEF0 = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically aborted. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is aborted by this function (BST.NACKDF = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKDF flag to 0. In master transmit mode, restore operation using either of the methods below:

- After issuing a Repeated START condition, set the NACKDF flag to 0
- After issuing a STOP condition, set the NACKDF flag to 0 and then issue a START condition

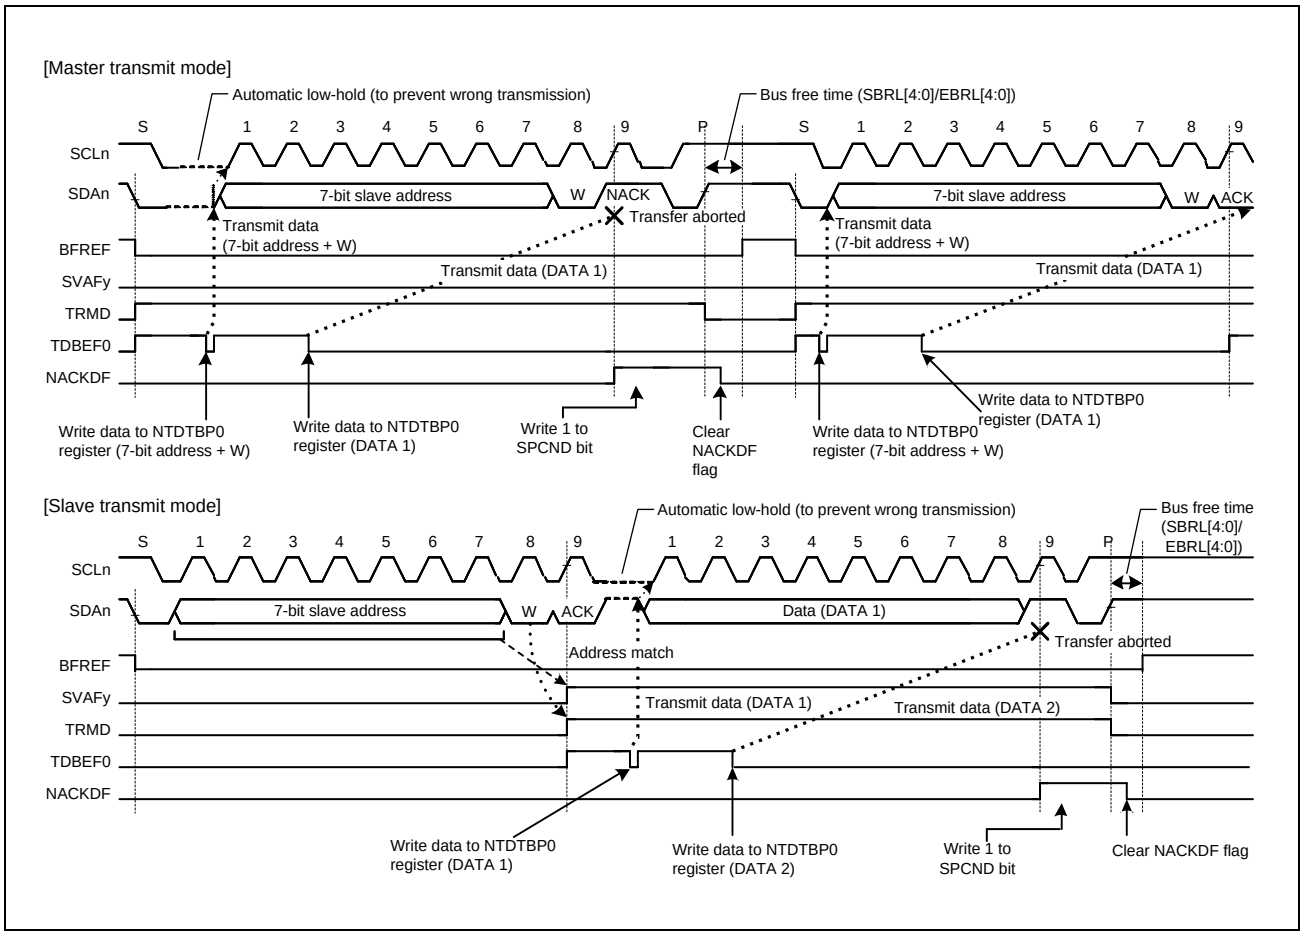

Figure 7.8-71 Abort of Data Transfer When NACK is Received (NACKE = 1)

(c) Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (NTDTBP0) read is delayed for a period of one transfer frame or more with receive data full (NTST.RDBFF0 = 1) in receive mode (PRSST.TRMD = 0), I3C holds the SCLn line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, I3C's own slave address or another slave address is received after a STOP condition is issued.

Sections in which the SCLn line is held low can be selected with a combination of the RWE and ACKTWE bits in SCSTRCTL.

1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the RWE Bit

When the SCSTRCTL.RWE bit is set to 1, I3C performs 1-byte receive operation using the RWE bit function.

Furthermore, when the SCSTRCTL.ACKTWE bit = 0, I3C automatically sends the ACKCTL.ACKT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCLn line low at the falling edge of the ninth SCL clock cycle using the RWE bit function. This low hold is released by reading data from NTDTBP0, which enables bytewise receive operation.

The RWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the ACKTWE Bit

When the SCSTRCTL.ACKTWE bit is set to 1, I3C performs 1-byte receive operation using the ACKTWE bit function.

When the ACKTWE bit is set to 1, the NTST.RDBFF0 flag (receive data full) is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low at the falling edge of the eighth SCL clock cycle. This lowhold is released by writing a value to the ACKCTL.ACKT bit, but cannot be released by reading data from NTDTBP0, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The ACKTWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

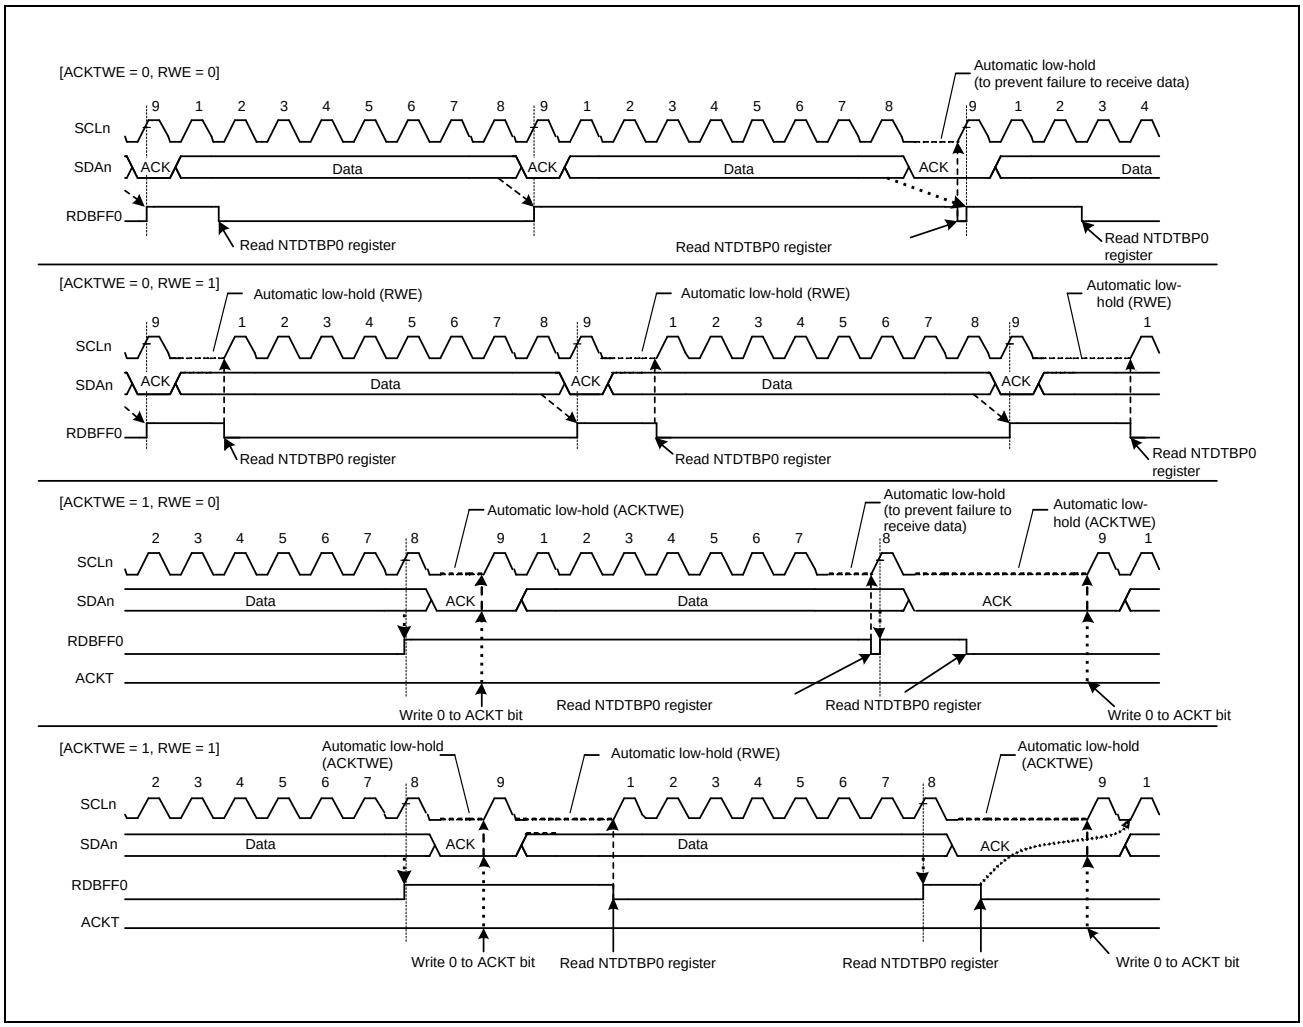

Figure 7.8-72 Automatic Low-Hold Operation in Receive Mode (using ACKTWE and RWE bits)

(7) Clock Stalling [I3C mode]

I3C has the function of stalling the SCL during the SCL Low period.

The SCL stall control is described in the table below.

Table 7.8-13 I3C clock stalling

Clock Stalling Condition	Clock Stalling Control	Clock Stalling Period
I3C Transfer, ACK/NACK Phase	SCSTLCTL.ACKPE bit setting	During the count period of SCSTLCTL.STLCYC[15: 0] value
	Transmit Data FIFO Empty	Until data is written to the TX FIFO
	Receive Data FIFO Full	Until data is read from the RX FIFO
I3C Write Data Transfer, Parity Bit	SCSTLCTL.PARPE bit setting	During the count period of SCSTLCTL.STLCYC[15: 0] value
	Transmit Data FIFO Empty	Until data is written to the TX FIFO
I3C Read Transfer, Transition Bit	Receive Data FIFO Full	Until data is read from the RX FIFO
Assigned Address Phase	SCSTLCTL.AAPE bit setting	During the count period of SCSTLCTL.STLCYC[15: 0] value
I3C Transfer, ACK/NACK Phase	SCSTLCTL.ACKPE bit setting	During the count period of SCSTLCTL.STLCYC[15: 0] value
	Transmit Data FIFO Empty	Until data is written to the TX FIFO
	Receive Data FIFO Full	Until data is read from the RX FIFO
I3C Write Data Transfer, Parity Bit	SCSTLCTL.PARPE bit setting	During the count period of SCSTLCTL.STLCYC[15: 0] value
	Transmit Data FIFO Empty	Until data is written to the TX FIFO
I3C Read Transfer, Transition Bit	Receive Data FIFO Full	Until data is read from the RX FIFO
Assigned Address Phase	SCSTLCTL.AAPE bit setting	During the count period of SCSTLCTL.STLCYC[15: 0] value

The following figure shows the stalling timing of each Condition.

(a) I3C Transfer, ACK/NACK Phase

(d) Dynamic Address Assignment, First Bit of Assigned Address

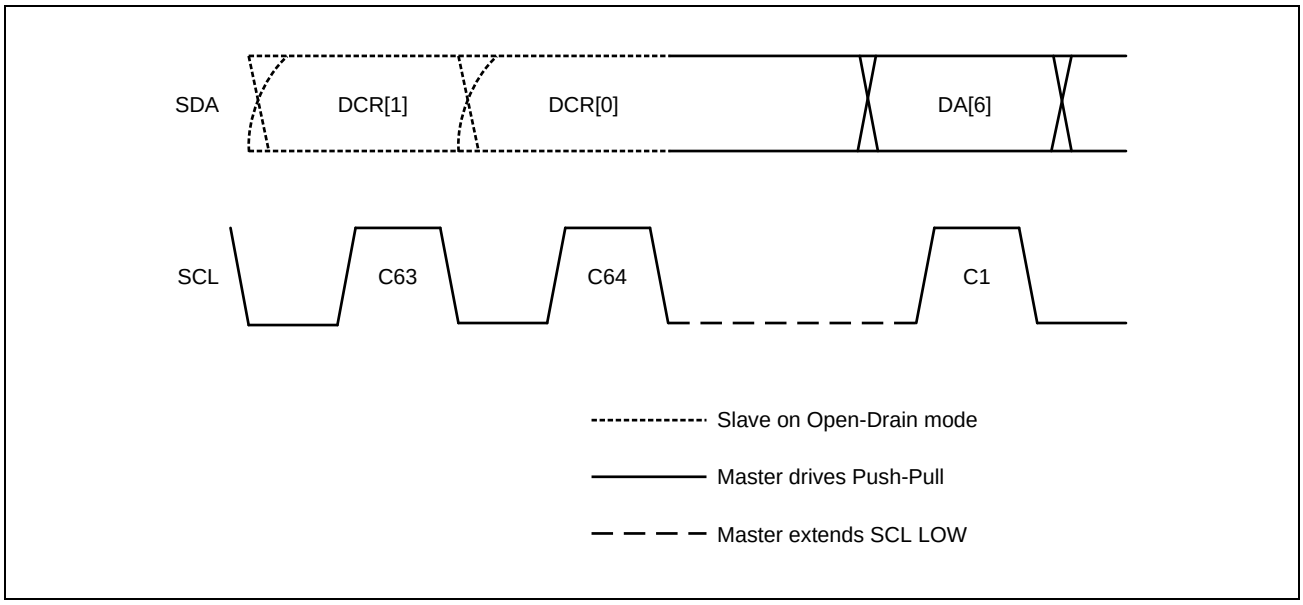

Figure 7.8-78 Master Clock Stalling in Dynamic Address First Bit

(8) In-Band Interrupt [I3C mode]

I3C detects In-Band Interrupt in the arbitrated Address Header following a START condition (but not following a Repeated START). If START Request (SDA Low Drive) is issued from Slave Device, I3C drives SCL low and completes START condition. After that, it supplies SCL and receives In-Band Interrupt Request.

The In-Band Interrupt to be detected is classified into the following three types.

- Slave Interrupt Request
- Mastership Request
- Hot-Join Event

The operation when detecting each In-Band Interrupt is described below.

(a) Slave Interrupt Request

1. Detect Slave Address with RnW bit High in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBASm register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 1:
   It operates in the following order:
   (a) Responds NACK.
   (b) Issues Repeated START condition, then automatically issues Direct DISEC CCC to the detected Slave.
   (c) Issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 0:
   Responds ACK.
4. When DAT.DVIBIPL = 0:
   Issues the STOP condition.
   When DAT.DVIBIPL = 1:
   Drives the SCL to receive the IBI Data from the Slave following the ACK response and receives IBI Data.
   It stores the received IBI Data into the IBI Data Queue.
   Each time IBI Data of the size set by the NQTHCTL.IBIDSSZ[7:0] bits is received, the IBI Status Descriptor is stored in the IBI Status Queue.
5. After detection of Low of T-bit following IBI Data, issues STOP condition.
6. After issues of STOP condition NACK response:
   – If IBINCTL.NRSIRCTL = 0, the IBI Status Descriptor is not stored into the IBI Status Queue.
   – If IBINCTL.NRSIRCTL = 1, the IBI Status Descriptor is stored into the IBI Status Queue.
   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

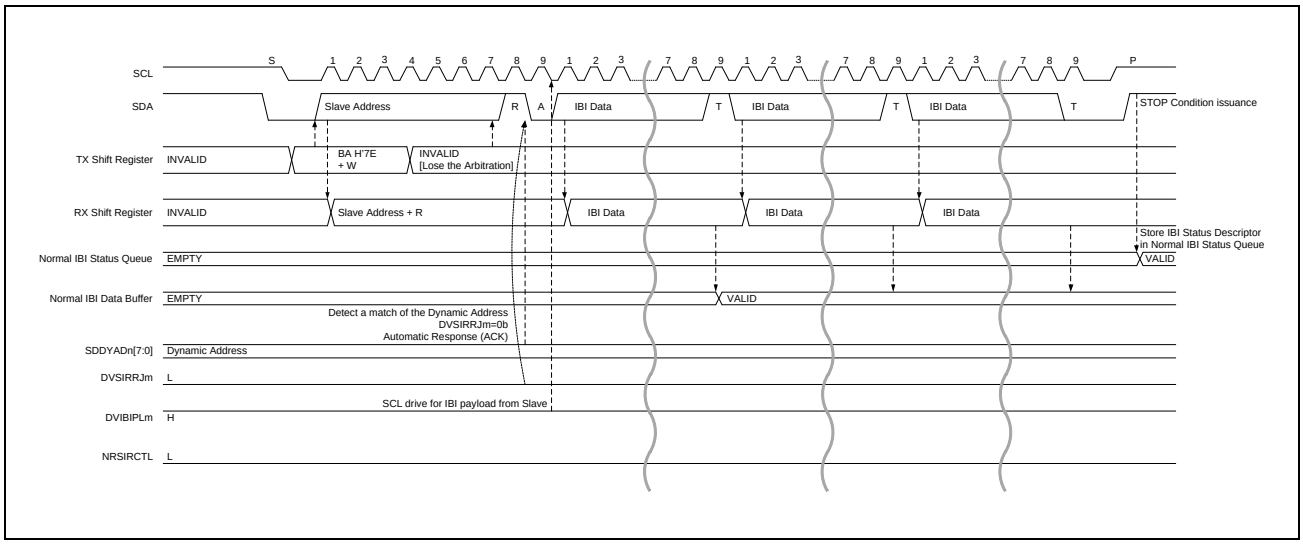

Figure 7.8-79 Slave Interrupt Request: ACK and DVIBIPL = 1

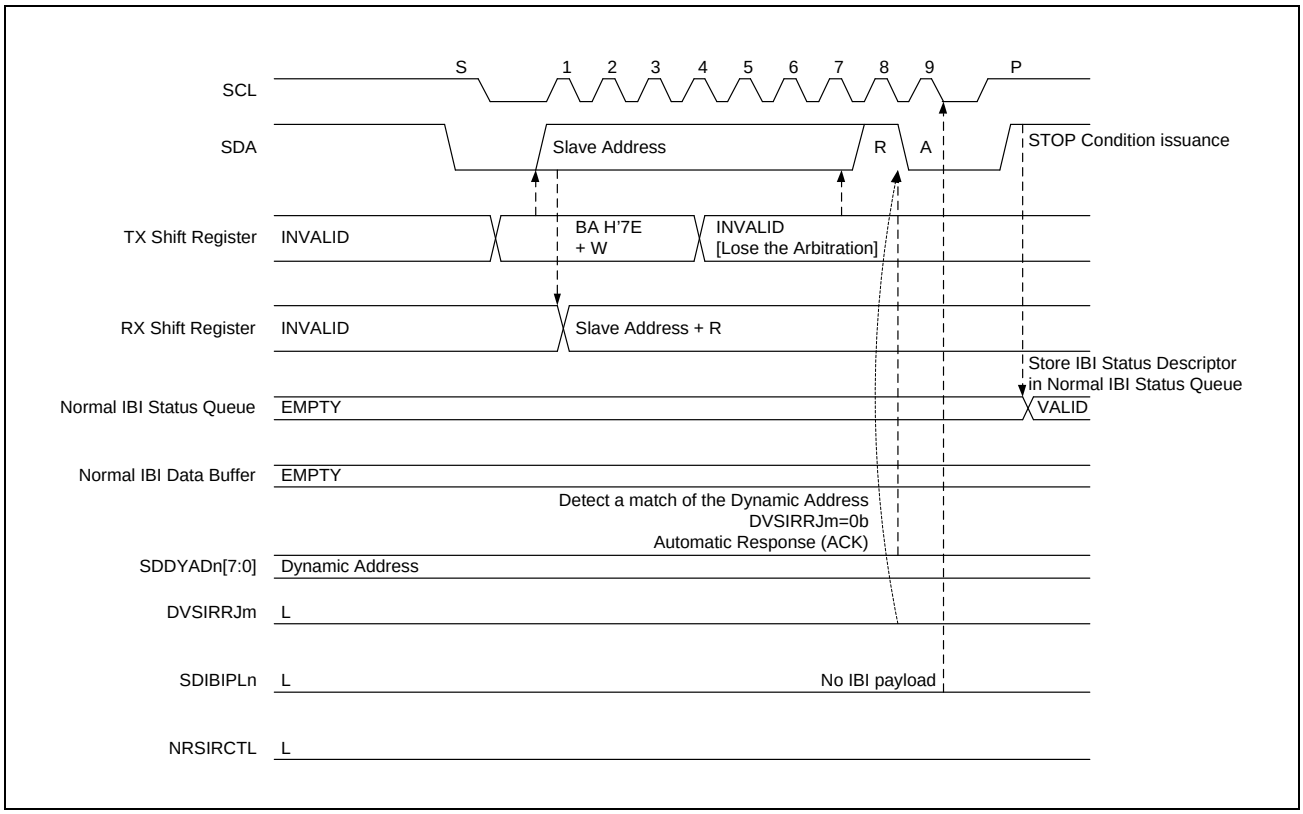

Figure 7.8-80 Slave Interrupt Request: ACK and DVIBIPL = 0

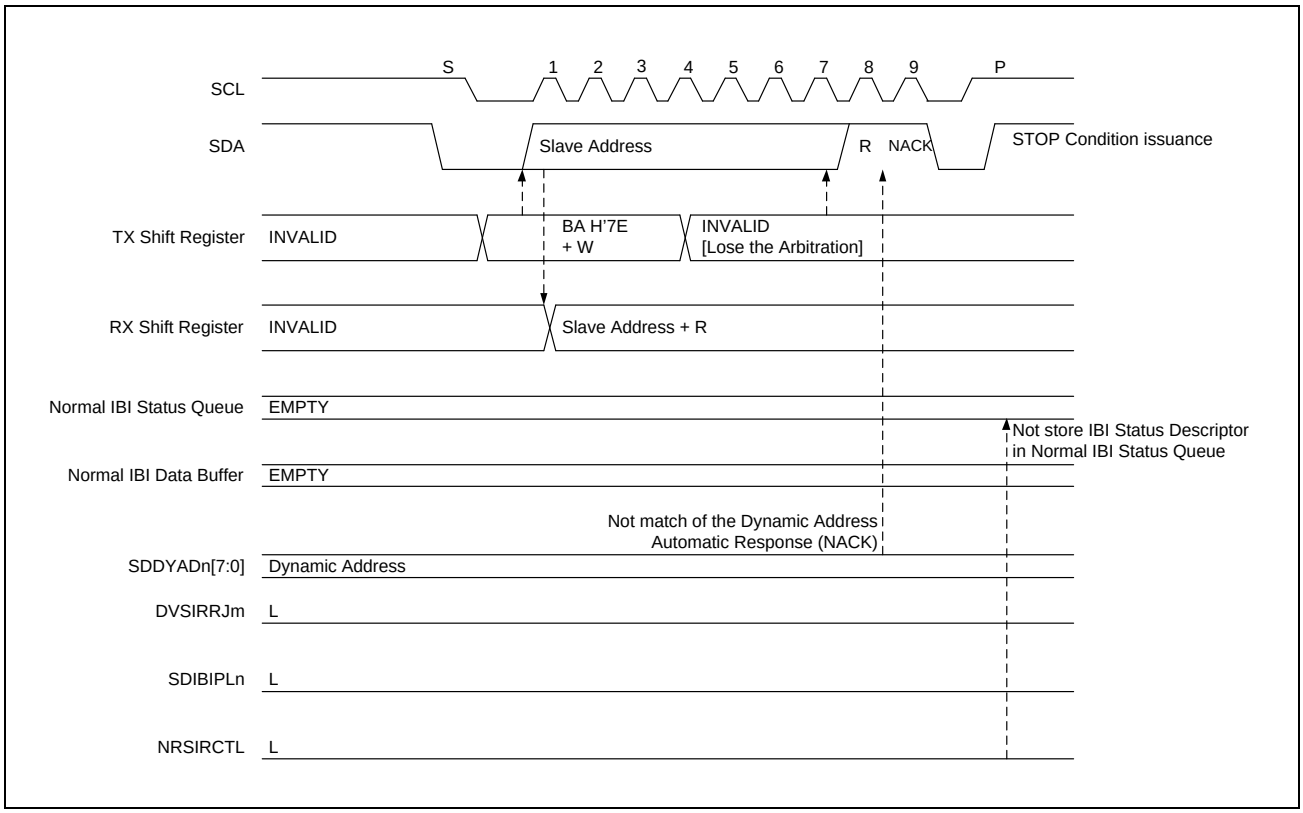

Figure 7.8-81 Slave Interrupt Request: NACK (not match the SDDYAD[7:0] of DAT) and NRSIRCTL = 0

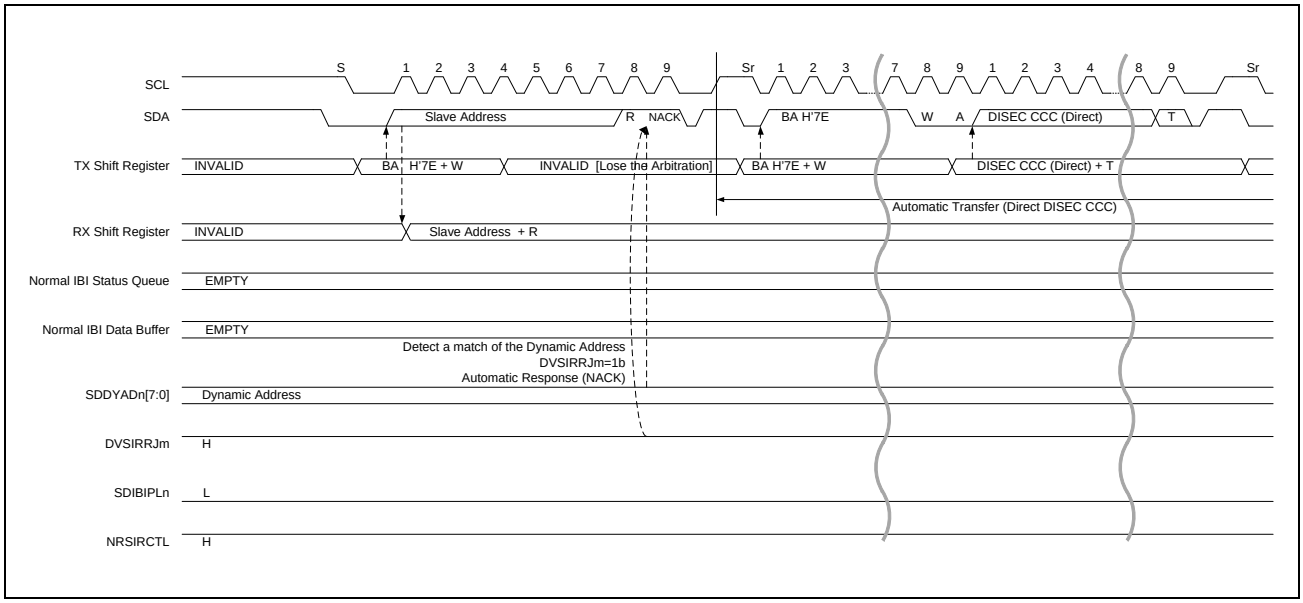

Figure 7.8-82 Slave Interrupt Request: NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (1/2)

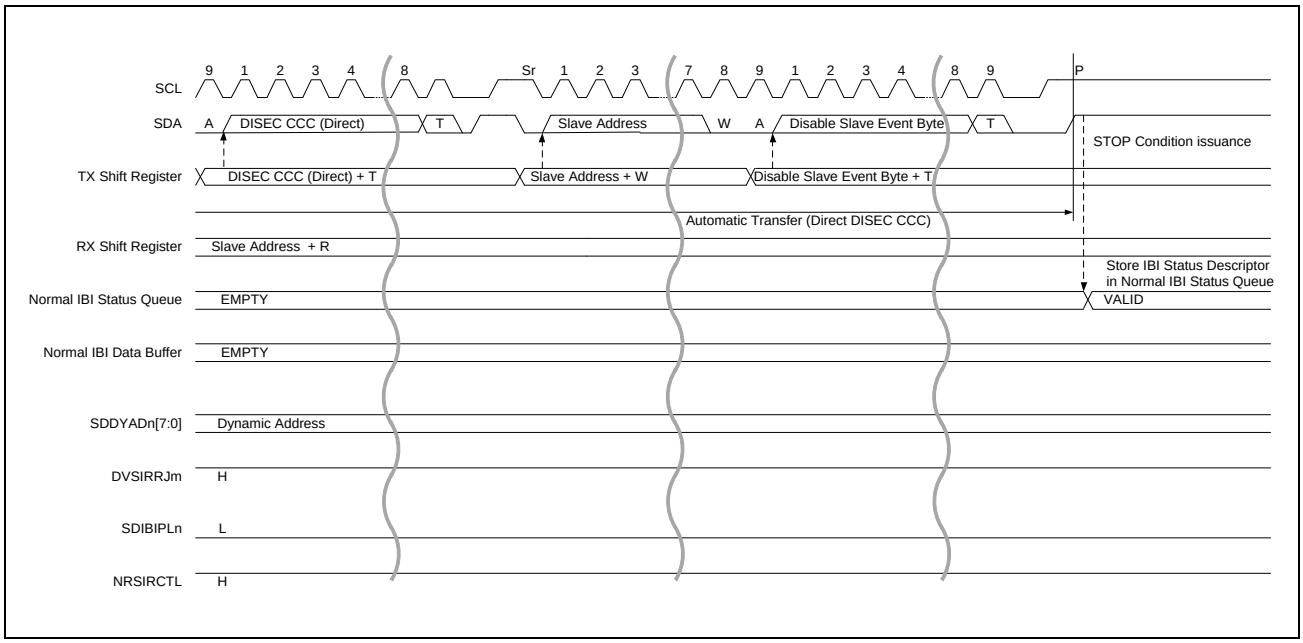

Figure 7.8-83 Slave Interrupt Request: NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (2/2)

(b) Mastership Request

1. Detect Slave Address with RnW bit Low in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBAS register).
3. When it does not match DAT.DVDYAD[7:0]:
   Rresponds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is other than I3C Master (01):
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is I3C Master (01):
   - When DAT.DVMRRJ = 1
     It operates in the following order.
     (a) Responds NACK.
     (b) Issued Repeated START condition and automatically issues Direct DISEC CCC to the detected Slave.
     (c) Issues the STOP condition.
   - When DAT.DVMRRJ = 0
     Responds ACK, then issues STOP condition.
4. After issues of STOP condition,
   NACK response:
   – If IBINCTL.NRMRCTL = 0, the IBI Status Descriptor is not stored into the IBI Status Queue.
   – If IBINCTL.NRMRCTL = 1, the IBI Status Descriptor is stored into the IBI Status Queue.
   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

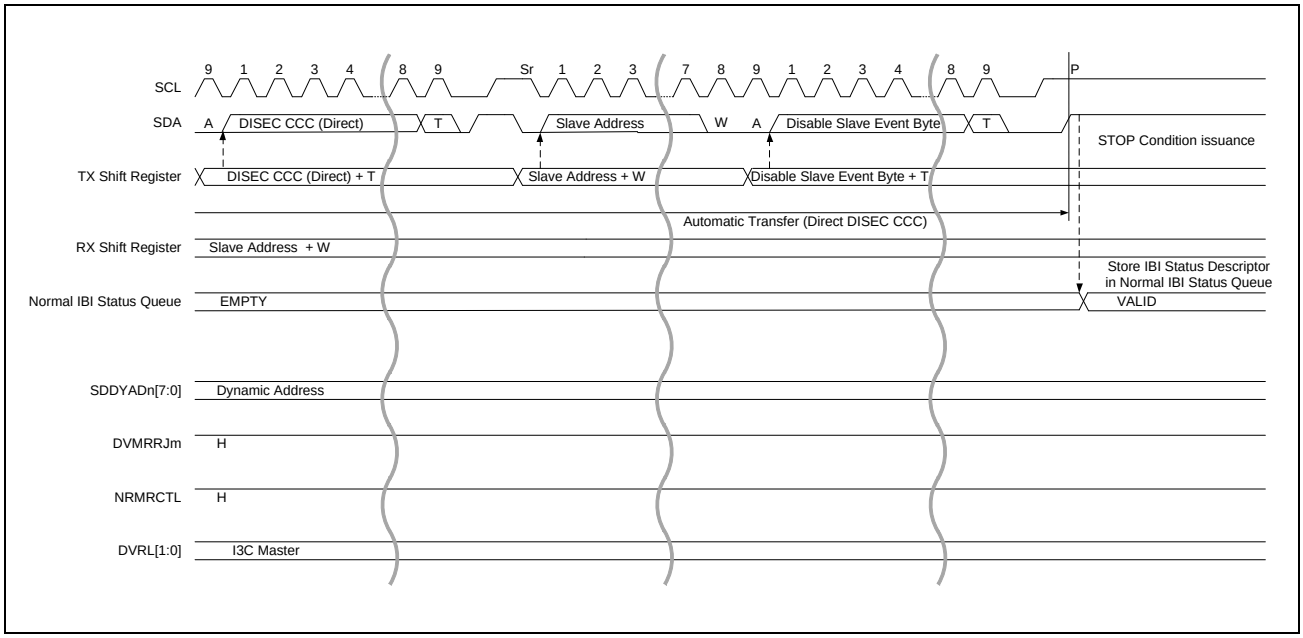

Figure 7.8-88 Mastership Request: NACK (DVMRRJ = 1) and NRMRCTL = 1 (2/2)

(c) Hot-Join Event

1. Detect the Hot-Join Address (H’02) with RnW bit Low in the Address Header.
2. When BCTL.HJACKCTL = 1,
   It operates in the following order.
   (a) Responds NACK.
   (b) Issues Repeated START condition and automatically issues Broadcast DISEC CCC.
   (c) Issues the STOP condition.
   When BCTL.HJACKCTL = 0,
   Responds ACK, then issues STOP condition.
3. After issues of STOP condition, NACK response:
   – If IBINCTL.NRHJCTL = 0, the IBI Status Descriptor is not stored into the IBI Status Queue.
   – If IBINCTL.NRHJCTL = 1, store the IBI Status Descriptor into the IBI Status Queue.
   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

(9) Timing Control [I3C mode]

I Timing Control is a function that enables Master to efficiently read data from Slave by controlling and grasping the timing at which the Slave Device samples the sensor value.

For details, refer to *5.1.8, Timing Control of MIPI I3C Specificaton v1.0*.

In this IP, timing Control supports the following three modes.

- Sync Mode
- Async Mode 0 (Asynchronous Basic Mode)
- Async Mode 1 (Asynchronous Advanced Mode)

The resources for realizing Timing Control in each mode are described below.

(a) Sync Mode

1) I3C Master

The measured value of Delay Time is sent as a DT message (SETXTIME CCC with DT subcommand) following the ST message.

2) I3C Slave

The sampling timing is recalculated by the corrected T_ph.

(b) Async Mode 0 (Asynchronous Basic Mode)

For timing control in Async Mode 0, set the ATCTL register if necessary.

1) I3C Master

This IP has counters of MREF (32bit) and MC2(16bit) for Async Mode 0.

- MREF Counter

  When ATCCNTE.ATCE is enabled, it starts counting.
  It captures as MREF on the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.

- MC2 Counter

  After enabling ATCCNTE.ATCE, it counts up from the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave to the SCL rise edge next to the Tbit after Mandatory Byte and capture it as MC2.

The MREF and MC2 capture values are stored next to the IBI Status Descriptor when IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1.
The MREF counter implemented in this IP is 32-bit counter.

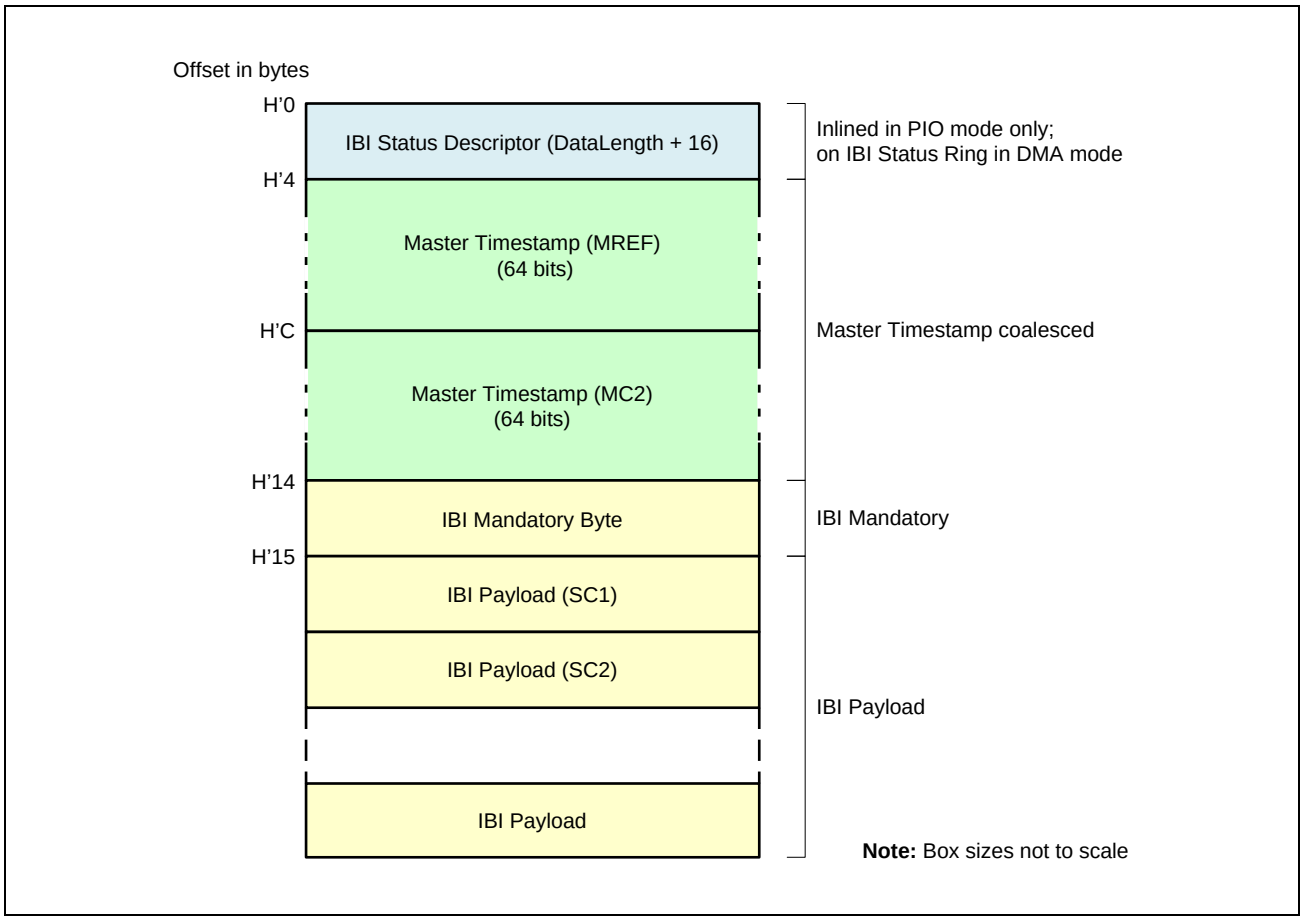

Figure 7.8-92 Master Timestamp Counters for IBI Event

2) I3C Slave

This IP has counters of SC1 (16 bits) and SC2 (8 bits) for Async Mode 0.

- SC1 Counter
  After enabling ATCCNTE.ATCE, it counts up from SC1 count trigger to SCL rise edge next to ACK for the IBI and capture it as SC1.
- SC2 Counter
  After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte and capture it as SC2.

When the CETSS.ASYNE[0] bit = 1 and the ITS bit in Command Descriptor for issuing IBI is 1, the SC1 and SC2 capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.

If the SC1 and SC2 counters overflow, H'FFFF and H'FF are captured and CETSS.ICOVF is set 1.

The DATA_LENGTH[15:0] bits value of the Command Descriptor sets a value obtained by adding the number of data of SC1 and SC2 to the number of transmission data.

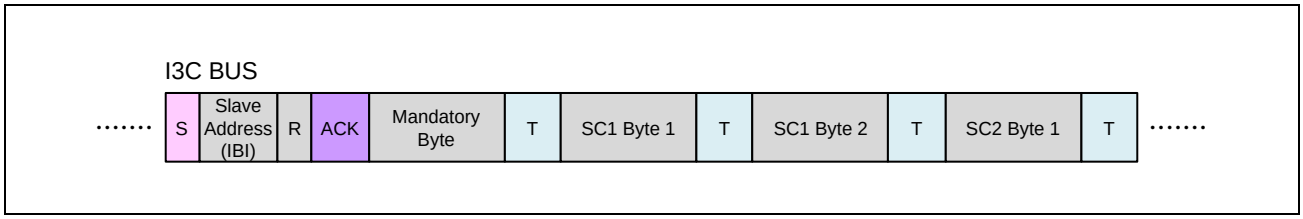

Figure 7.8-93 Example of Asynchronous Mode 0 Timestamp Data Transfer

(c) Async Mode 1 (Asynchronous Advanced Mode)

For timing control in Async Mode 1, set the ATCTL register if necessary.

1) I3C Master

This IP has counters of MREF (32 bits), MSyncCNT (32 bits) and MC2 (16 bits) for Async Mode 1.

- MREF Counter

  When ATCCNTE.ATCE is enabled, it starts counting.
  It captures as MREF at the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.
  The MREF extension method described in "1) I3C Master" of **7.8.3.2.3(9) (b) Async Mode 0 (Asynchronous Basic Mode)** is also possible in Async Mode 1.

- MSyncCNT Counter

  When ATCCNTE.ATCE is enabled, it starts counting.
  It captures as MSyncCNT for each aME (SDA falling edge of START condition) and store it in the capture register.

- MC2 Counter

  After enabling ATCCNTE.ATCE, it counts up from the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave to the SCL rise edge next to the Tbit after Mandatory Byte and capture it as MC2.

The MREF and MC2 capture values are stored next to the IBI Status Descriptor when the IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1. (Same as Async Mode 0)

2) I3C Slave

This IP has counters of SC1 (16 bits), SC2 (8 bits) and aME_TICK (8 bits) for Async Mode 1.

- SC1 Counter

  After enabling ATCCNTE.ATCE, it counts up from SC1 count trigger to the first aME and capture it as SC1.

- SC2 Counter

  After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte and capture it as SC2.

- aME_TICK Counter

  After enabling ATCCNTE.ATCE, it counts every aME, and capture it as aME_TICK at the SCL rise edge next to ACK for the IBI.
  The aME_TICK counter is cleared on the first aME after the SC1 count trigger.

When the CETSS.ASYNE[1] bit = 1 and the ITS bit in Command Descriptor for issuing IBI is 1, the SC1, SC2 and aME_TICK capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.

If the SC1 and SC2 counters overflow, H’FFFF and H’FF are captured and CETSS.ICOVF is set 1.

The DATA_LENGTH[15:0] bits value of the Command Descriptor sets a value obtained by adding the number of data of SC1, SC2 and aME_TICK to the number of transmission data.

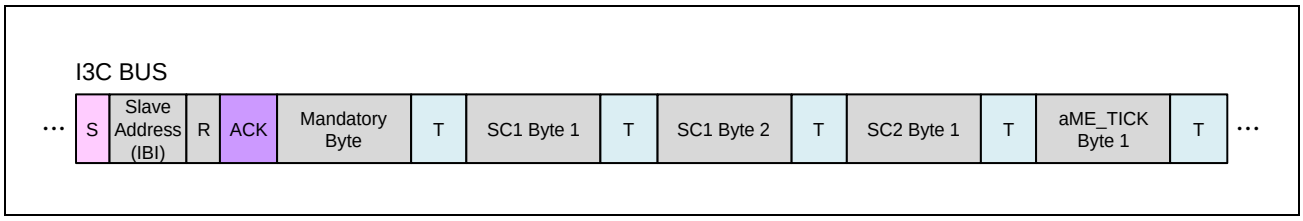

Figure 7.8-94 Example of Asynchronous Mode 1 Timestamp Data Transfer

(10) Port Control

(a) Extra SCL Clock Cycle Output Function

In master mode, I3C module has a facility for the output of extra SCL clock cycles to release the SDAn line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDAn line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from I3C with single cycles of the SCL clock as the unit in the case of a bus error where I3C cannot issue a Repeated START condition or a STOP condition because the slave device is holding the SDAn line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the OUTCTL.EXCYC bit is set to 1, an additional clock pulse at the frequency set by the REFCKCTL.IREFCKS[2:0] bits and the STDBR.SBRHO[7:0] and STDBR.SBRLO[7:0] registers is output from the SCLn pin. After output of this clock pulse, the EXCYC bit automatically becomes 0. After confirming that the EXCYC bit is 0, wait for the setup time of the Repeated START condition or STOP condition, and then confirm the detection of the Repeated START condition or STOP condition. If the Repeated START condition or STOP condition is not detected, consecutive additional clock pulses can be output by writing 1 to the EXCYC bit again.

When I3C module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a Repeated START condition or a STOP condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDILV bit in PRSTDBG. After the SDAn line has been released by the slave device, the preset of a Repeated START condition or a STOP condition is issued.

Use this function with the BFCTL.MALE bit set to 0 (master arbitration-lost detection is disabled).

[Output conditions for using the EXCYC bit in OUTCTL]

- When the bus is free (BFREF flag in BCST = 1) or in master mode (CRMS bit = 1 in PRSST and BFREF flag = 0 in BCST)
- When the communication device does not hold the SCLn line low

Figure 7.8-95 shows the operation timing of the extra SCL clock cycle output function (EXCYC bit).

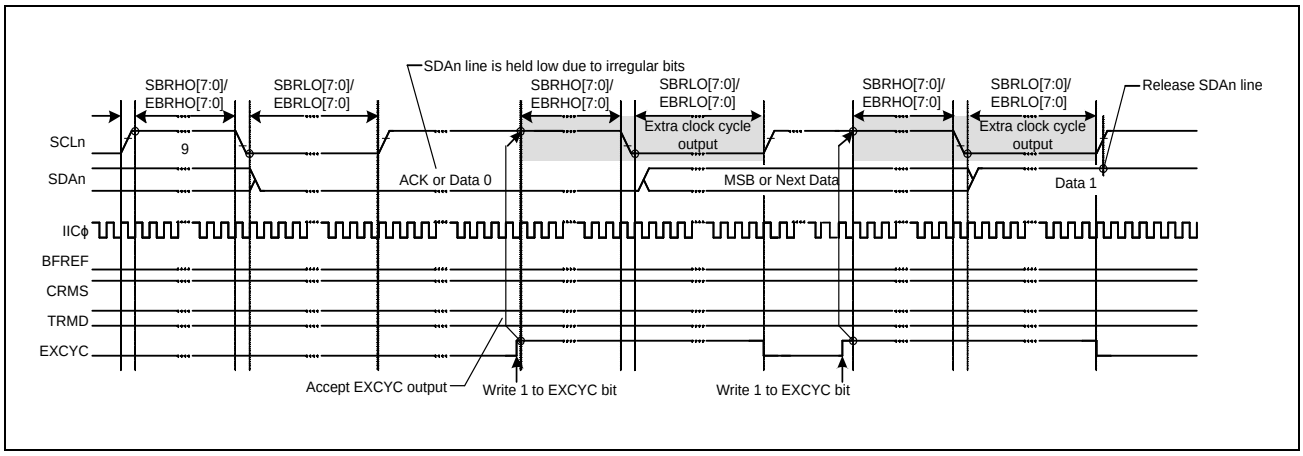

Figure 7.8-95 Extra SCL Clock Cycle Output Function (EXCYC Bit)

(11) Common Command Codes (CCC) [I3C mode]

Command Code H’E0 to H’FE Vendor Extension-Direct CCCs defined are not supported. The MIPI reserved area and Vendor Extension area of Command Code are not supported. Do not use an unsupported CCC when using this module with I3C Slave.

If the I3C Master must use an unsupported CCC, use the added CCC after using ENTASx CCC to put this module to Sleep mode.

7.8.3.2.4 Error Detection

(1) SDR Error Detection for I3C Slave Devices [I3C mode]

The seven error types summarized in **Table 7.8-14** are supported for all I3C slave devices. Each error type is further explained below the table.

Table 7.8-14 SDR Slave Error Types

Error Type	Description	Error Detection Method
S0	Broadcast address/W (= H'7E/W) or Dynamic address/RW	Detect any of the following: H'3E/W H'5E/W H'6E/W H'76/W H'7A/W H'7C/W H'7F/W H'7E/R
S1	CCC code	Parity check, using T-Bit
S2	Write data	Parity check, using T-Bit
S3	Assigned address during Dynamic address arbitration	Parity check, using PAR Bit
S4	H'7E/R after Sr during Dynamic address arbitration	Detect any value other than H'7E/R after Sr during Dynamic Address Arbitration
S5	Transaction after detecting CCC	Detect illegally formatted CCC
S6 (optional)	Monitoring error	Slave detects (through monitoring) that transmitted Data differs from what it intended to transmit (Does not apply during Dynamic address arbitration)

(2) SDR Error Detection for I3C Master Devices [I3C mode]

The two error types summarized i0n **Table 7.8-15** are supported for all I3C master devices. Each error type is further explained below the table.

Table 7.8-15 SDR Master Error Types

Error Type	Description	Error Detection Method
M0	Transaction after sending CCC	Detect illegally formatted CCC
M1 (optional)	Monitoring error	Master detects (through monitoring) transmitted data different from what it intended to transmit (Does not apply during Dynamic address arbitration)
M2	No response to Broadcast address (H'7E)	Master detects NACK after Broadcast address (H'7E) transmission

(3) Timeout Error Detection

I3C includes a timeout function for detecting when the SCLn line has been stuck longer than the predetermined time. I3C can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rising or falling), but continues to count unless the SCLn line changes. If the internal counter overflows due to no SCLn line change, I3C can detect the timeout and report the bus hung state.

This timeout function is enabled when BSTE.TODE = 1. It detects a hung state that the SCLn line is stuck low or high during the following conditions: (When TMOCTL.TOMDS[1:0] = 00b)

- The bus is busy (BCST.BFREF = 0) in master mode (PRSST.CRMS = 1).
- I3C's own slave address is detected (SVST register is not H'0000) and the bus is busy (BCST.BFREF = 0) in slave mode (PRSST.CRMS = 0).
- The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1).

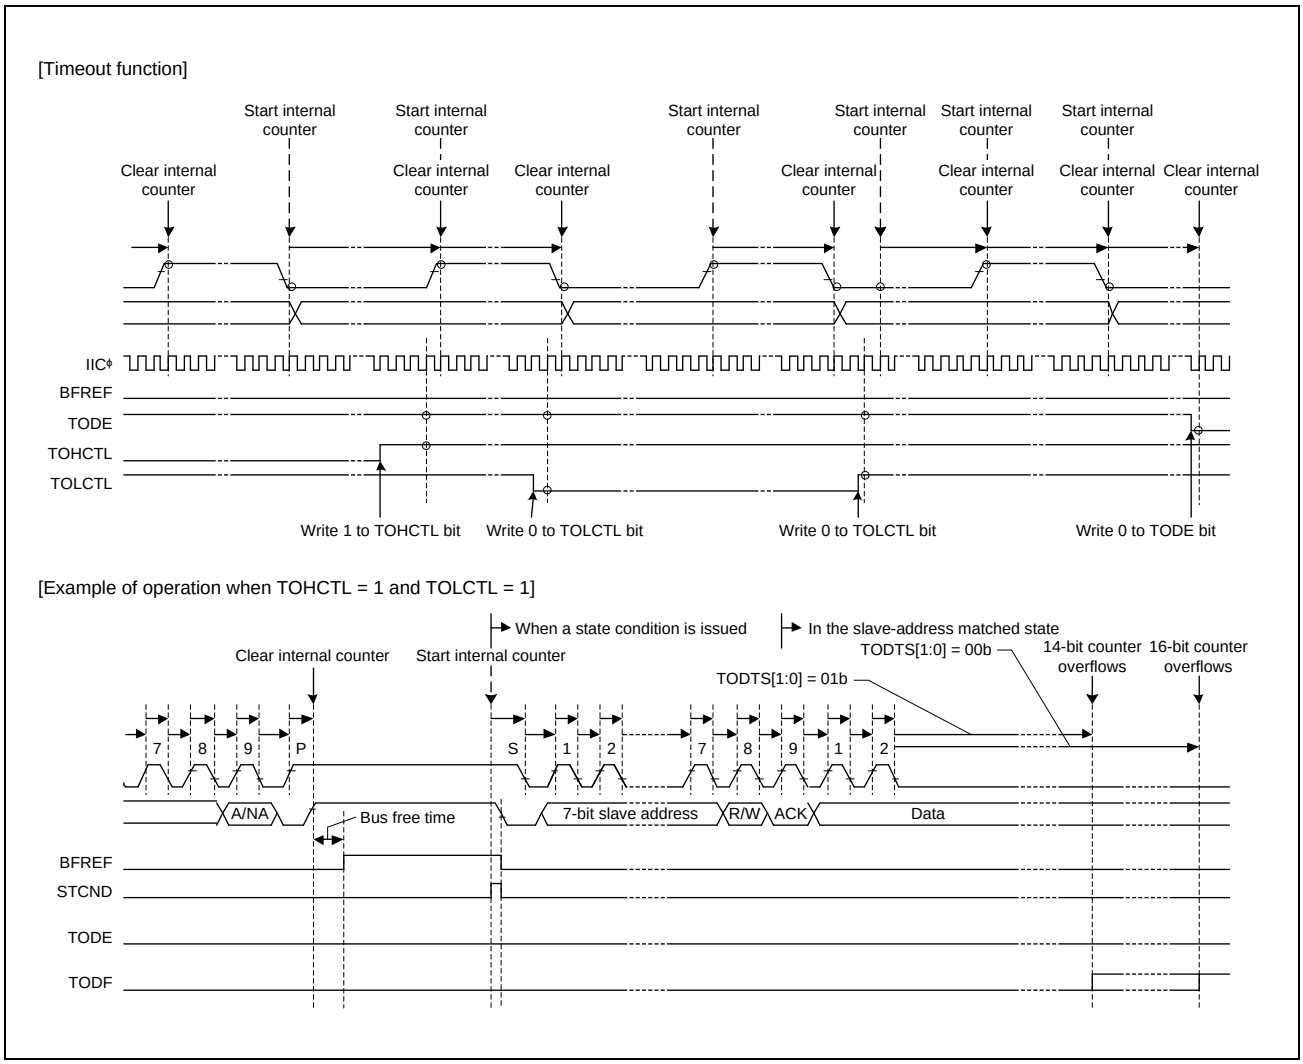

Figure 7.8-96 Timeout Error Detection (TODE, TODTS[1:0], TOHCTL, and TOLCTL bits)

(4) Resume Operation [I3C mode]

I3C enters the Halt state as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After I3C has entered the Halt state, the user must write the value 1 to the RSM bit to resume operation. I3C shall auto clear the RSM bit once it has initiated the next Command transfer or detected the START condition.

(5) Abort Operation [I3C mode]

When the BCTL.ABT bit is set to 1, I3C relinquish control of the bus before completing the currently issued transfer. In response to an abort request, I3C issues the STOP condition on the bus after the complete data byte is transferred or received. After I3C has aborted, the user shall clear the BCTL.ABT bit to allow operation on the bus.

NOTE

For Read transaction, when BCTL.ABT is set to 1, that receive data is stored in Receive data buffer.

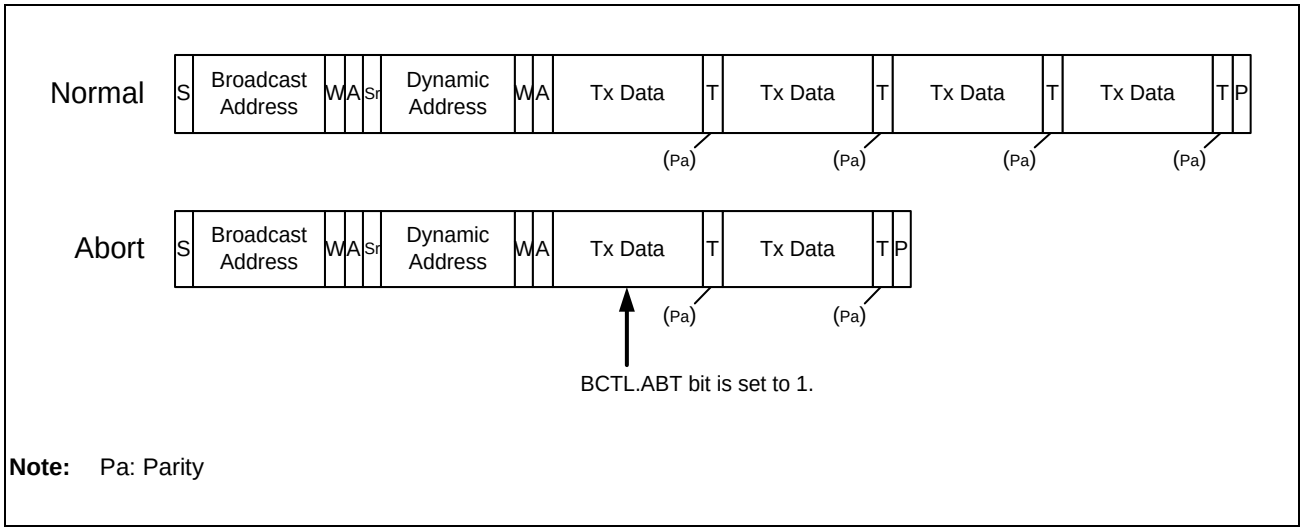

Figure 7.8-97 Abort Operation of SDR Write Transfer

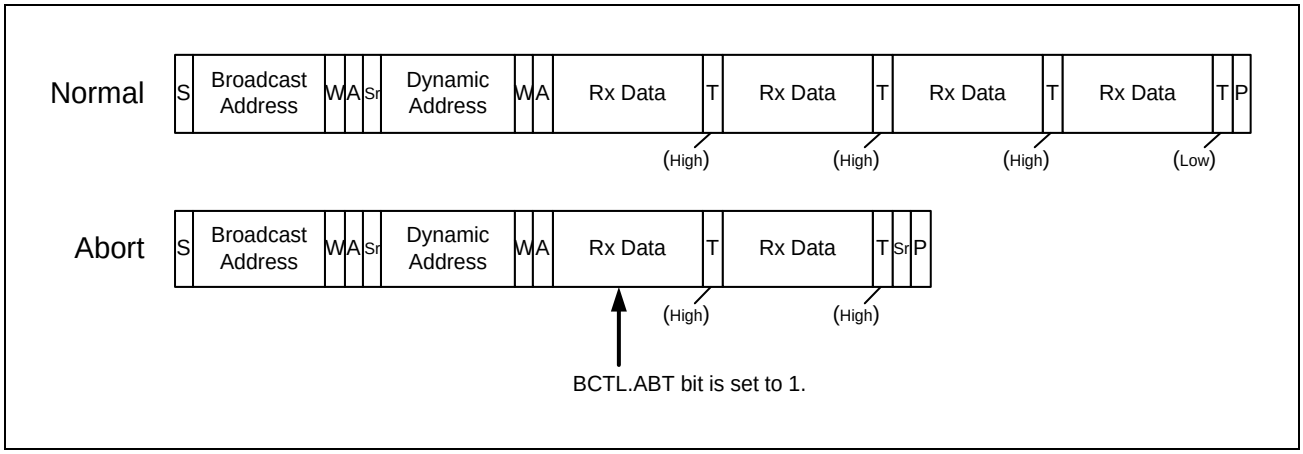

Figure 7.8-98 Abort Operation of SDR Read Transfer

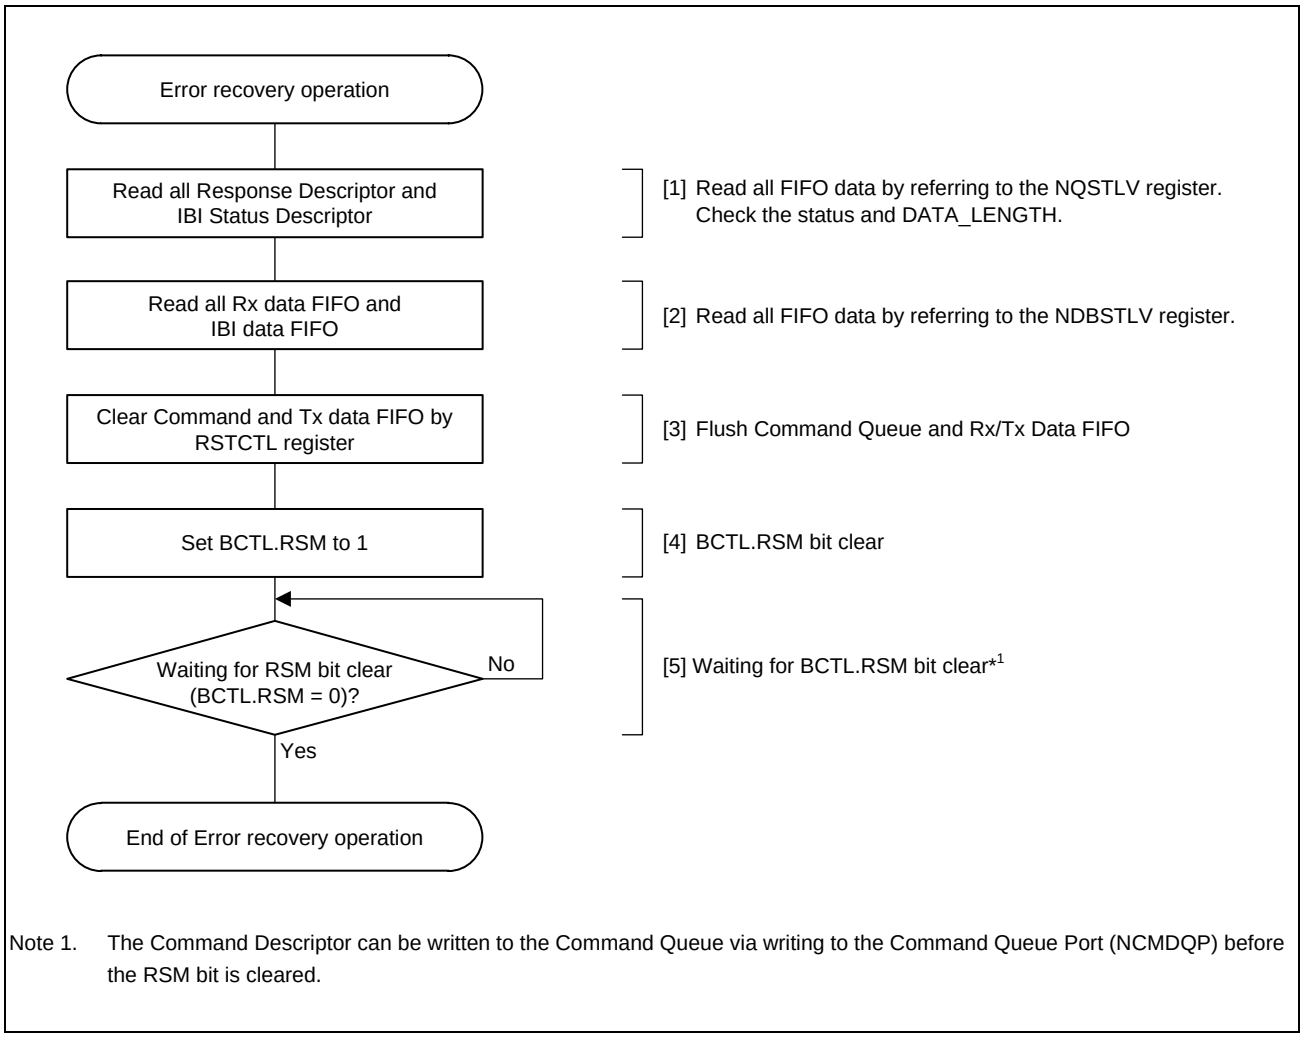
(6) Error Recovery Operation [I3C mode]

(a) Error Recovery Operation



When an error occurs, the flags of INST.INEF, NTST.TEF, HSTS.TEF and NTST.TABTF are set to 1b according to the cause of the error.

Or the interrupts INT_n3c_ierr_n, INT_n3c_terr_n and INT_ri3c_abort_n associated with each flag are asserted. (When detection and interrupts are enabled.)

There is a possibility of communication error or I3C internal error.

If an error occurs, I3C will be suspended. (BCTL.RSM becomes 1b.) After I3C is suspended, the application must write the value 1b to the BCTL.RSM bit to resume I3C operation and recover from the suspended state.

The error recovery flow is shown **Figure 7.8-99** and **Figure 7.8-100**.

Note 1. The Command Descriptor can be written to the Command Queue via writing to the Command Queue Port (NCMDQP) before the RSM bit is cleared.

Figure 7.8-99 Example of Error Recovery Operation Flowchart for I3C Master

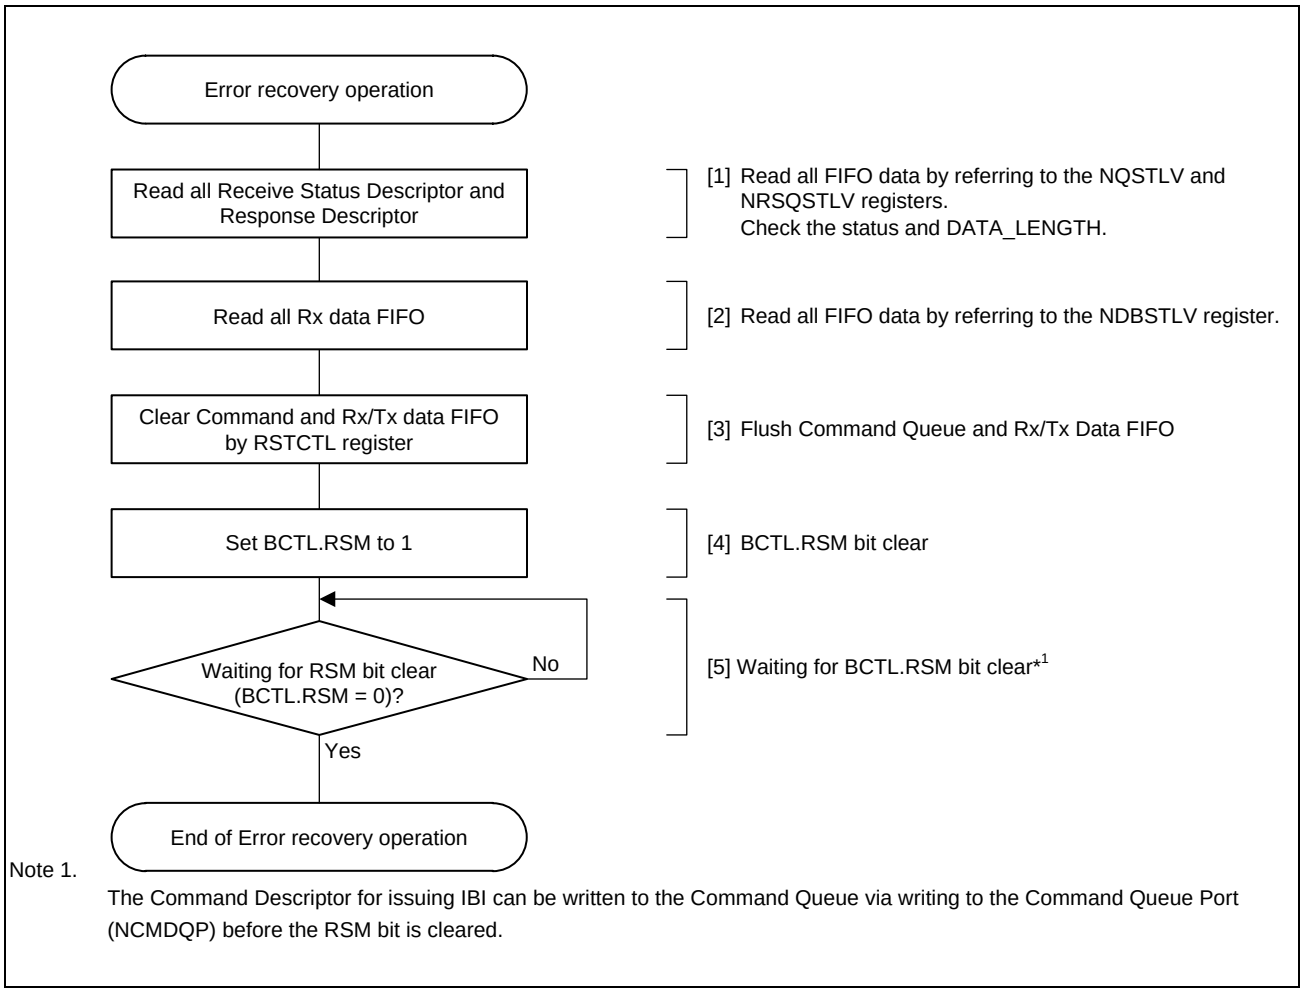


Figure 7.8-100 Example of Error Recovery Operation Flowchart for I3C Slave

When I3C Slave recovers from an error according to the error recovery flow, after setting BCTL.RSM to 1b, BCTL.RSM becomes 0b after detecting a state in which Bus Available period communication is not performed on I3C Bus.

If communication occurs on the I3C bus within the Bus Available period, BCTL.RSM will not be set to 0b and error recovery will not be completed, and a NACK response will be transmitted.

(b) Master Error Detection and Escalation Handling

If the Master does not receive an ACK of a transmitted private Message to a Slave and Steps 1 and 2 described in *Chapter 5.1.10.2.4* of *MIPI I3C Spec v1.0* fail, the processing flow of Step 3 shown in **Figure 7.8-101** and **Figure 7.8-102** is followed.

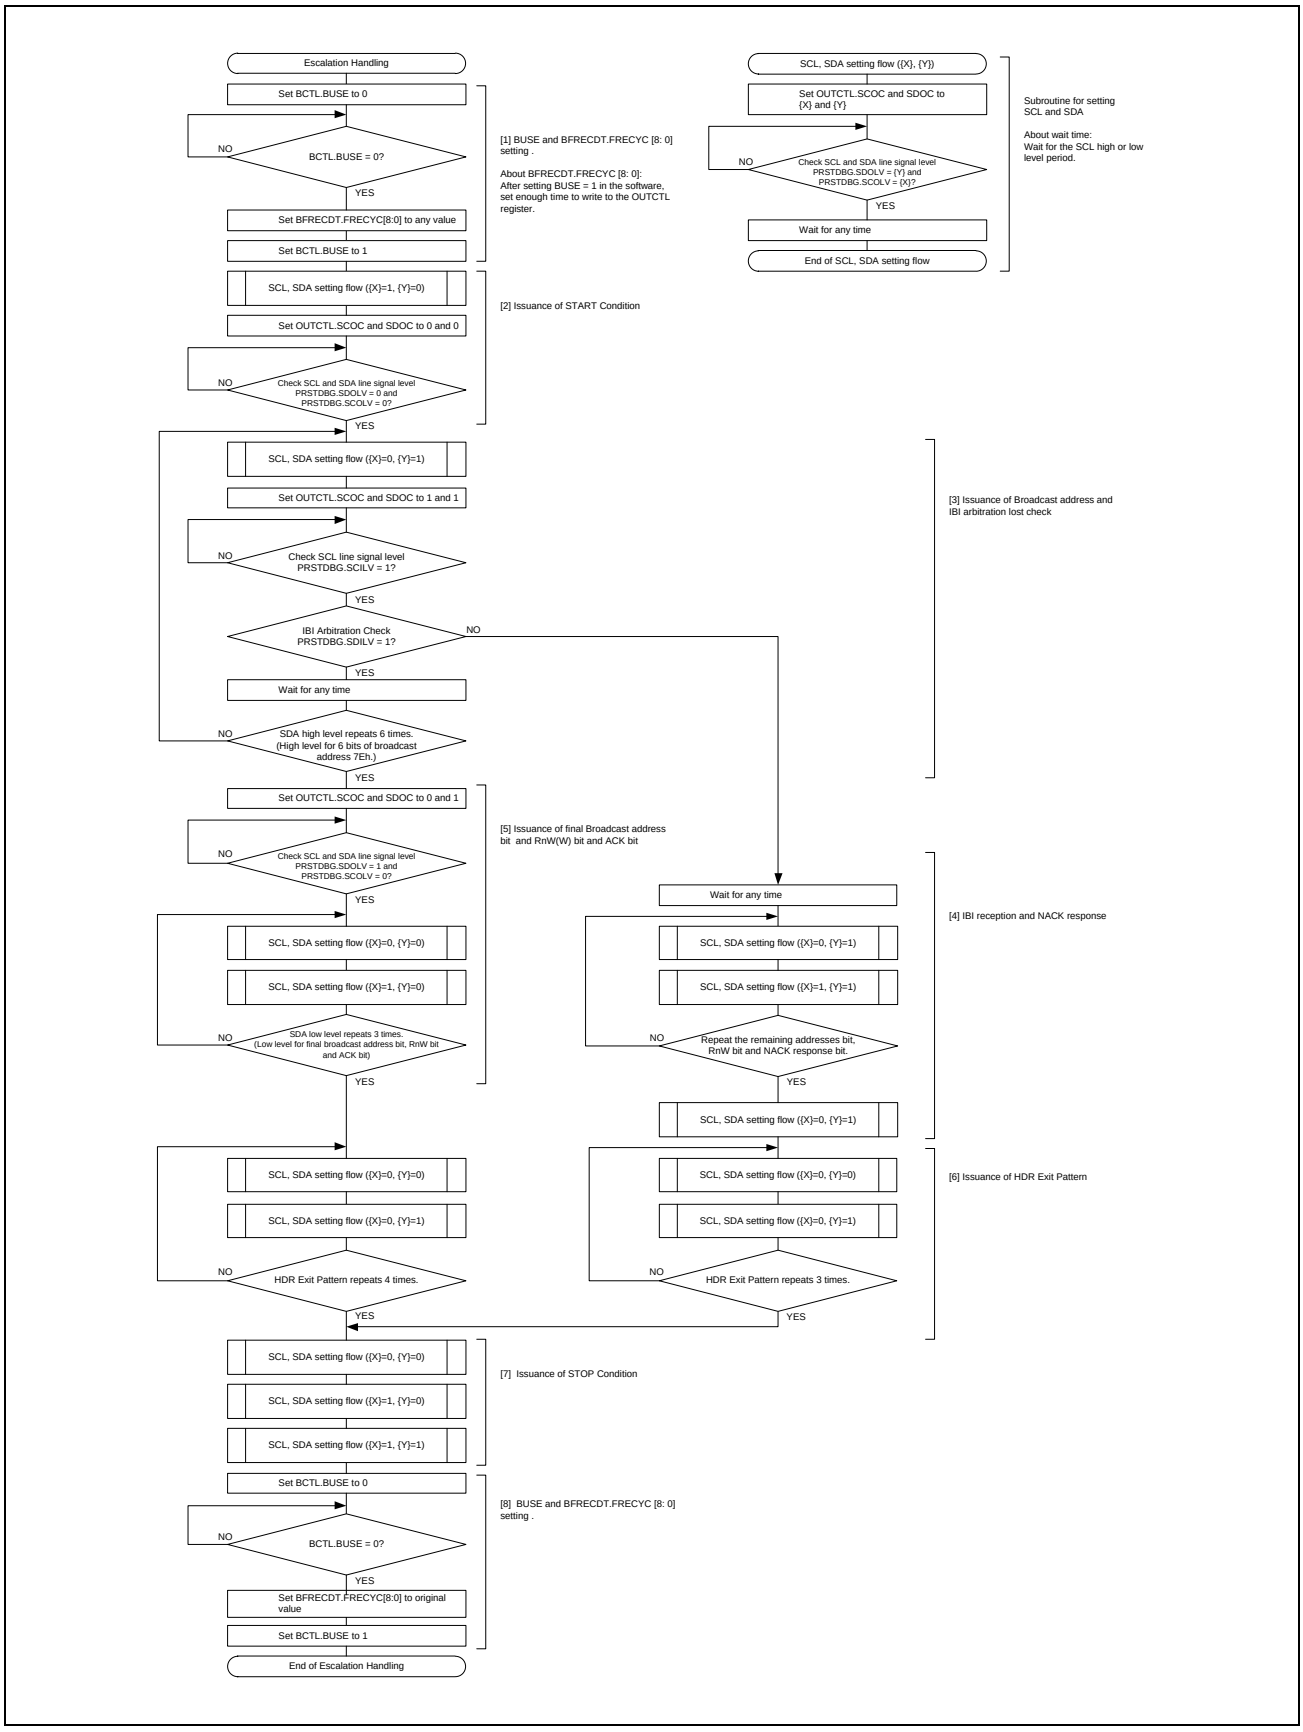

Figure 7.8-101 Escalation Handling Flowchart for I3C Master

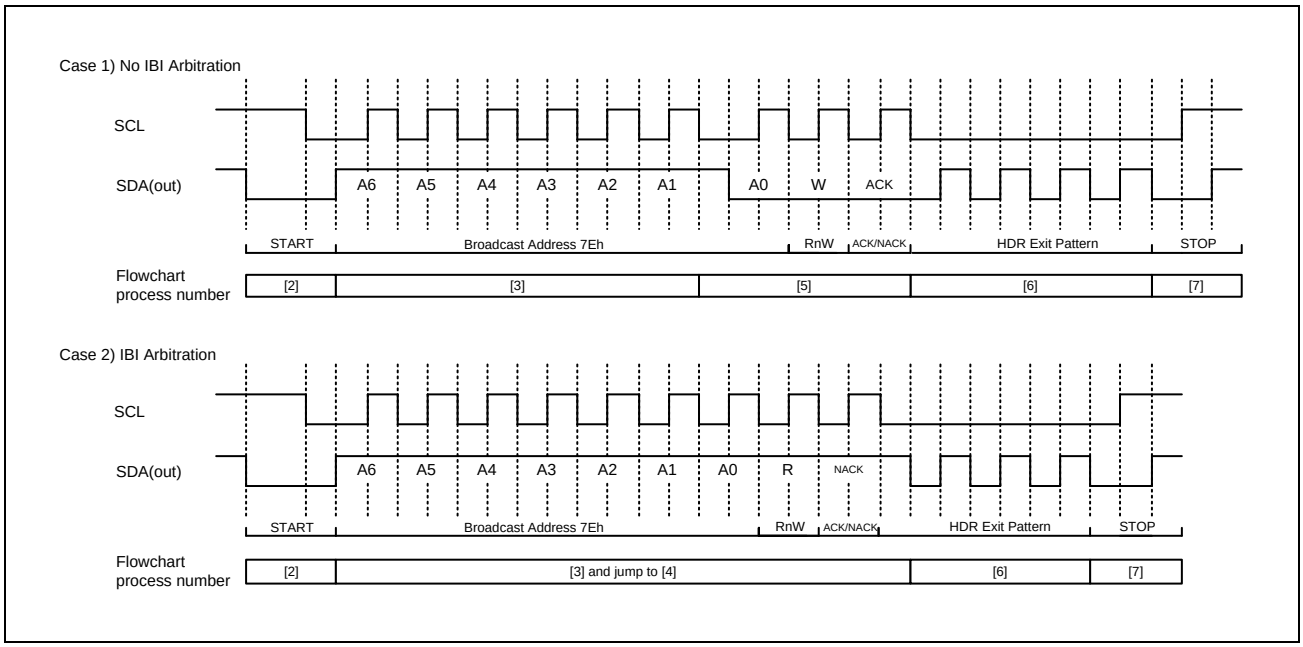

Figure 7.8-102 Escalation Handling timing chart for I3C Master

7.8.3.2.5 Low Power Function [I²C/I3C common]

(1) Wake Up function [I²C mode]

This IP is equipped with the Wake-up function that causes the microcomputer to transition from low power consumption mode with system clock is stopped (software standby mode, snooze, etc.) to the normal operation. The Wake-up function is used to generate a Wake-Up interrupt signal when the received data matches the address set to Wake-Up interrupt factor also receives data in a state where the operating clock (PCLK/TCLK) is stopped (PCLK/TCLK asynchronous operation). This wake-up interrupt signal causes the microcomputer to transition to the normal operation. After Wake-Up interrupt occurs, switch this IP to PCLK/TCLK synchronous operation, it will be able to continue the communication operation.

The Wake-up function has four wake-up operation modes (normal WU mode 1, normal WU mode 2, command recovery mode, and EEP response mode). The table below describes the behavior in these four wake-up operation modes.

Table 7.8-16 Wake-Up Operation Mode

	ACK Response Timing	ACK Type Responded before Recovery to PCLK/TCLK Synchronous Operation	SCL State before Recovery to PCLK/TCLK Synchronous Operation
Normal WU mode 1	Before recovery to PCLK/TCLK synchronous operation*1	ACK	Fixed to “L”
Normal WU mode 2	After recovery to PCLK/TCLK synchronous operation*2	Before recovery: no response (NACK level retained) After recovery: ACK response	Fixed to “L”
Command recovery mode	Before recovery to PCLK/TCLK synchronous operation*1	ACK	Open
EEP response mode	Before recovery to PCLK/TCLK synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK Synchronous operation is the fall of the 9th clock of SCL.

Note 2. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK Synchronous operation is the fall of the 8th clock of SCL.

The following is able to select as Wake-Up interrupt factor.

- Host address detection (valid when SVCTL.HOAE = 1)
- General call address detection (valid when SVCTL.GCAE = 1)
- Slave address 0*1 detection (valid when SVCTL.SVAE0 = 1)
- Slave address 1*1 detection (valid when SVCTL.SVAE1 = 1)
- Slave address 2*1 detection (valid when SVCTL.SVAE2 = 1)

Note 1. 7-bit address only can be set. Please set SDADLS bit to “0” in SDATBASn.

(a) Normal Wake-Up mode 1

This section describes the behavior, the timing, and a use case of normal WU mode 1.

1. A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in **Figure 7.8-105**.

   Before Wake-Up recovery: ACK is sent in response to the data received with its own slave address.

   During Wake-Up recovery: ACK response is made at the 9th clock cycle of SCL, and the SCL is held low afterwards.*1

   After Wake-Up recovery: Normal operation continues.

   If the slave address does not match, the SCL line is not held low after the fall of the 9th clock cycle of SCL, and the slave operation continues.

Note 1. Between ninth clock cycle and first clock cycle during Wake-Up recovery, SCSTRCTL.RWE = 1 does not work.

Refer to **Figure 7.8-103** “Use Case of Normal WU Mode 1” below for a use case.

2. A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to **Figure 7.8-104**.

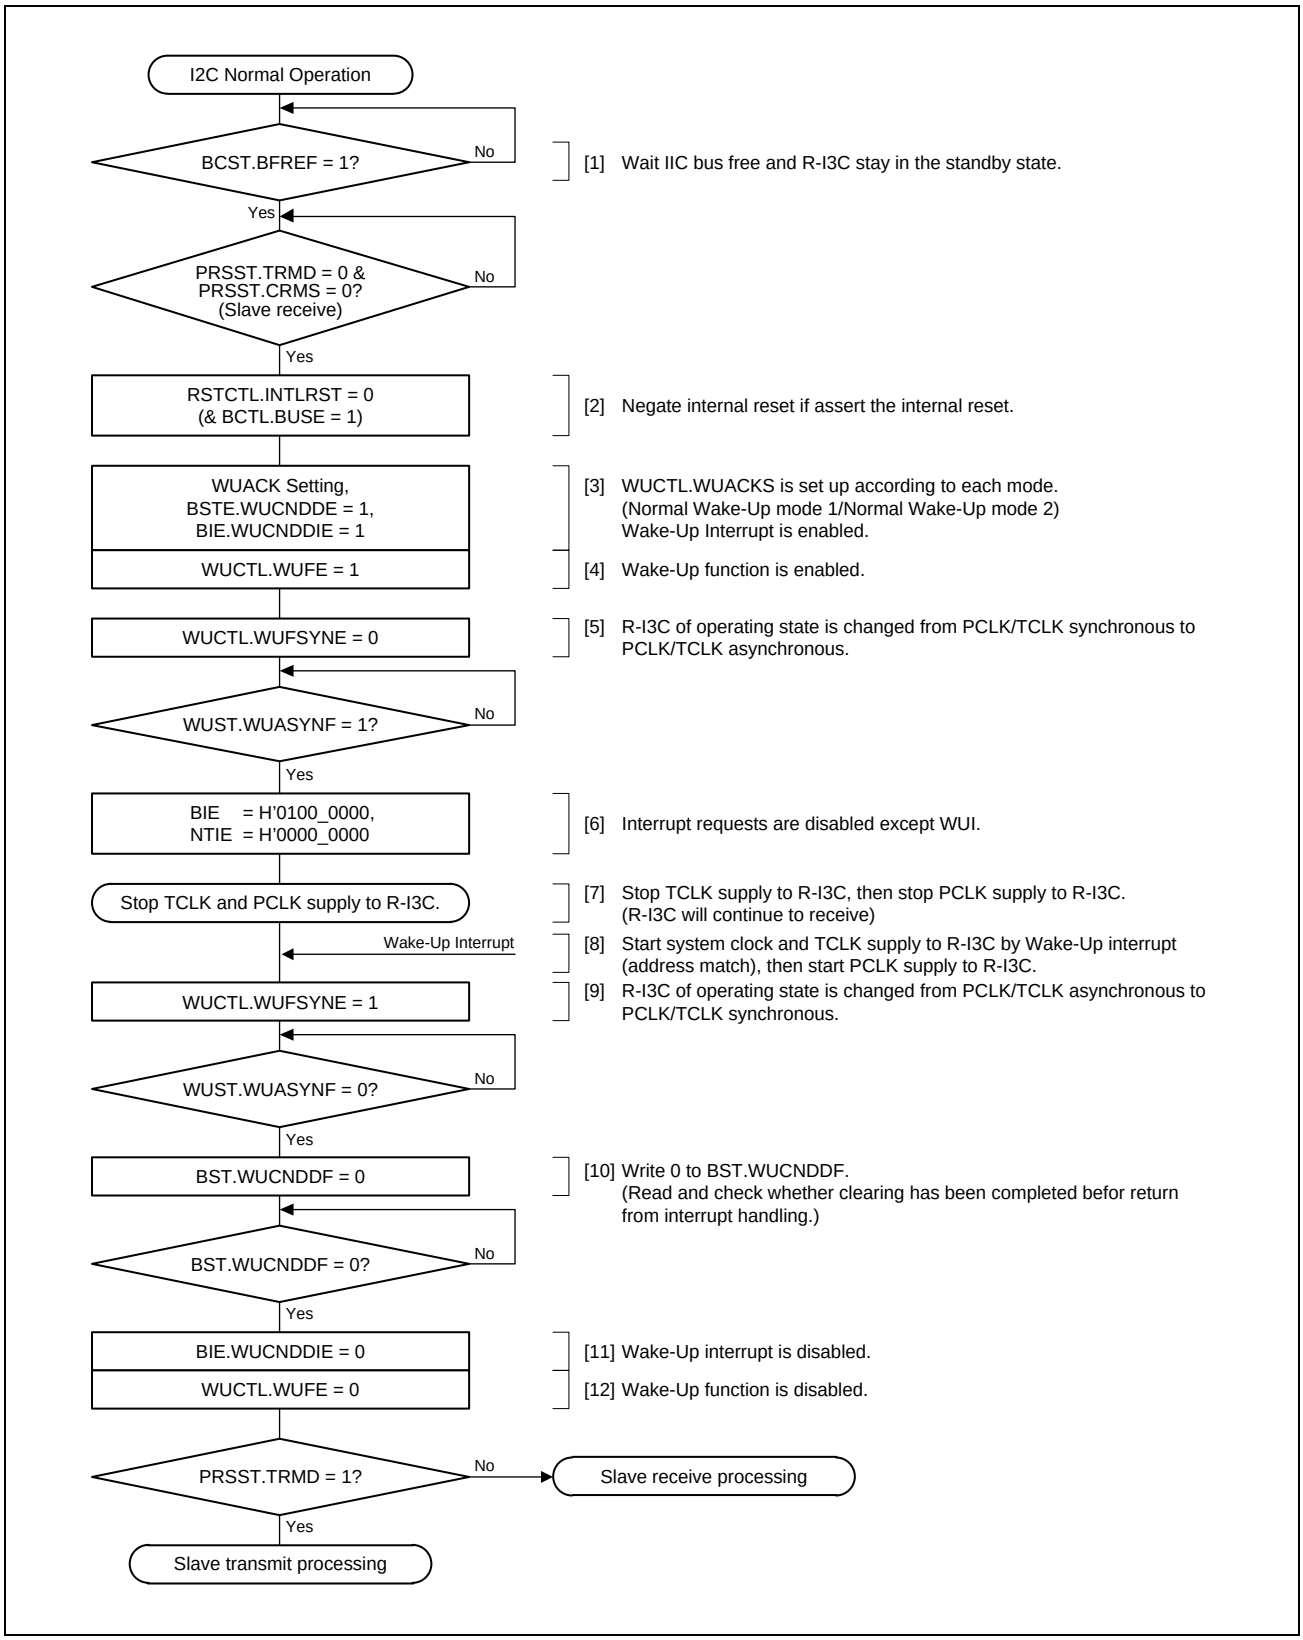

Figure 7.8-103 Use Case of Normal WU Mode 1
(Wake-Up Recovery by a Wake-Up Interrupt Triggered by the Match of the Slave Address)

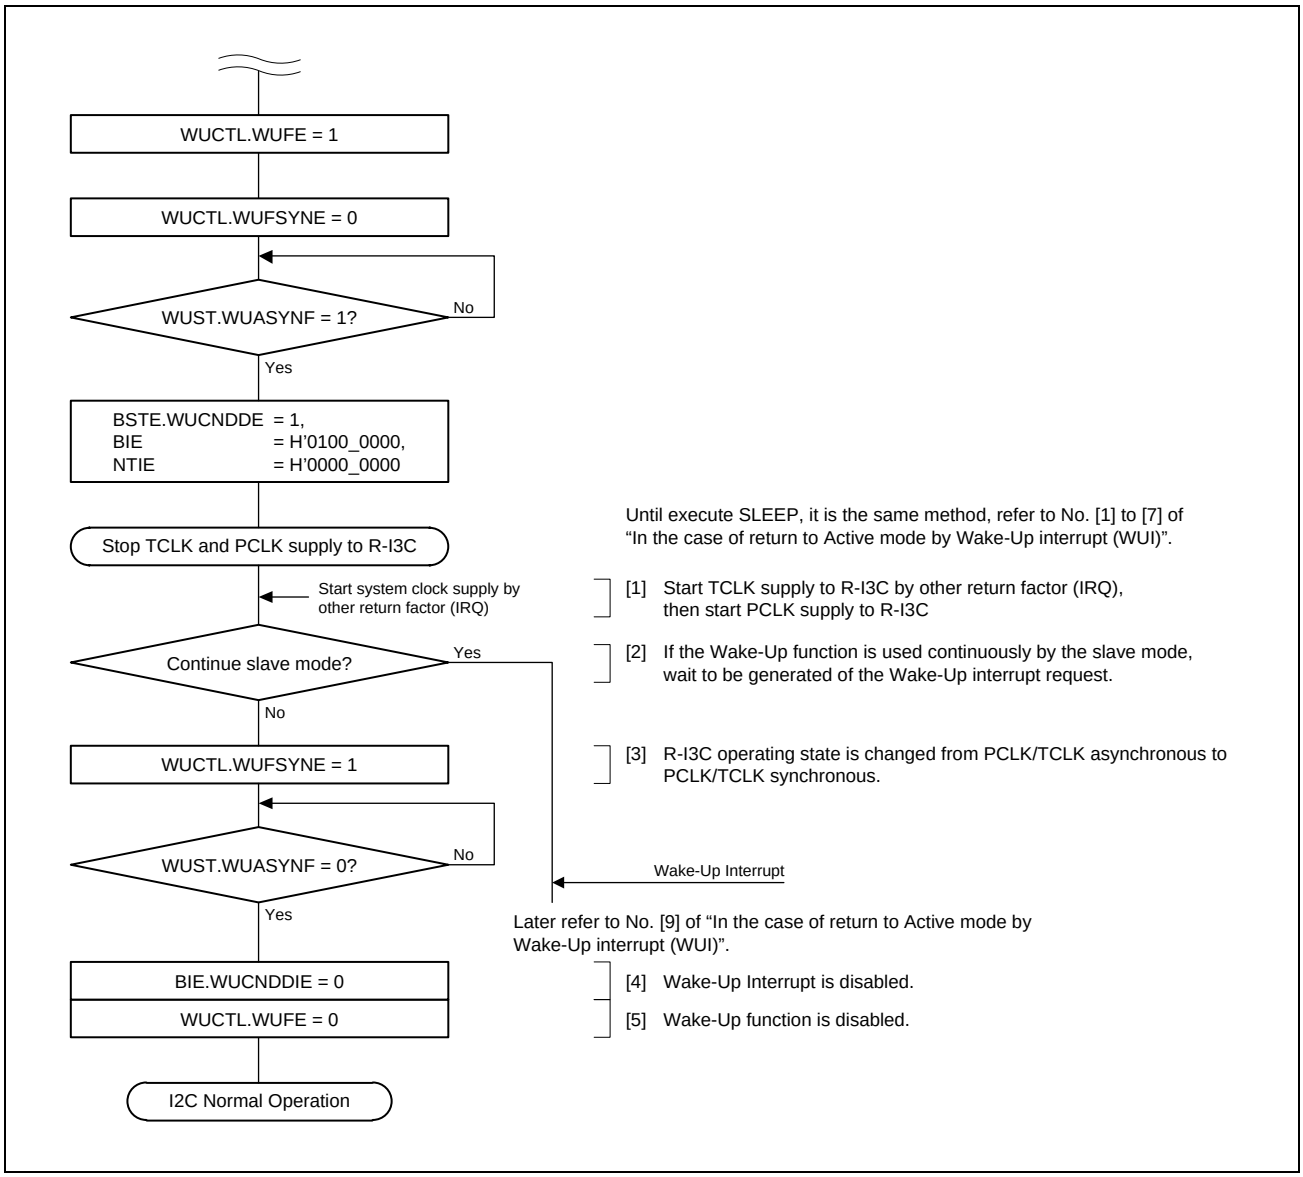

Figure 7.8-104 Use Case of Normal WU Modes 1 and 2
(Wake-Up Recovery by Other Recovery Causes (IRQ))

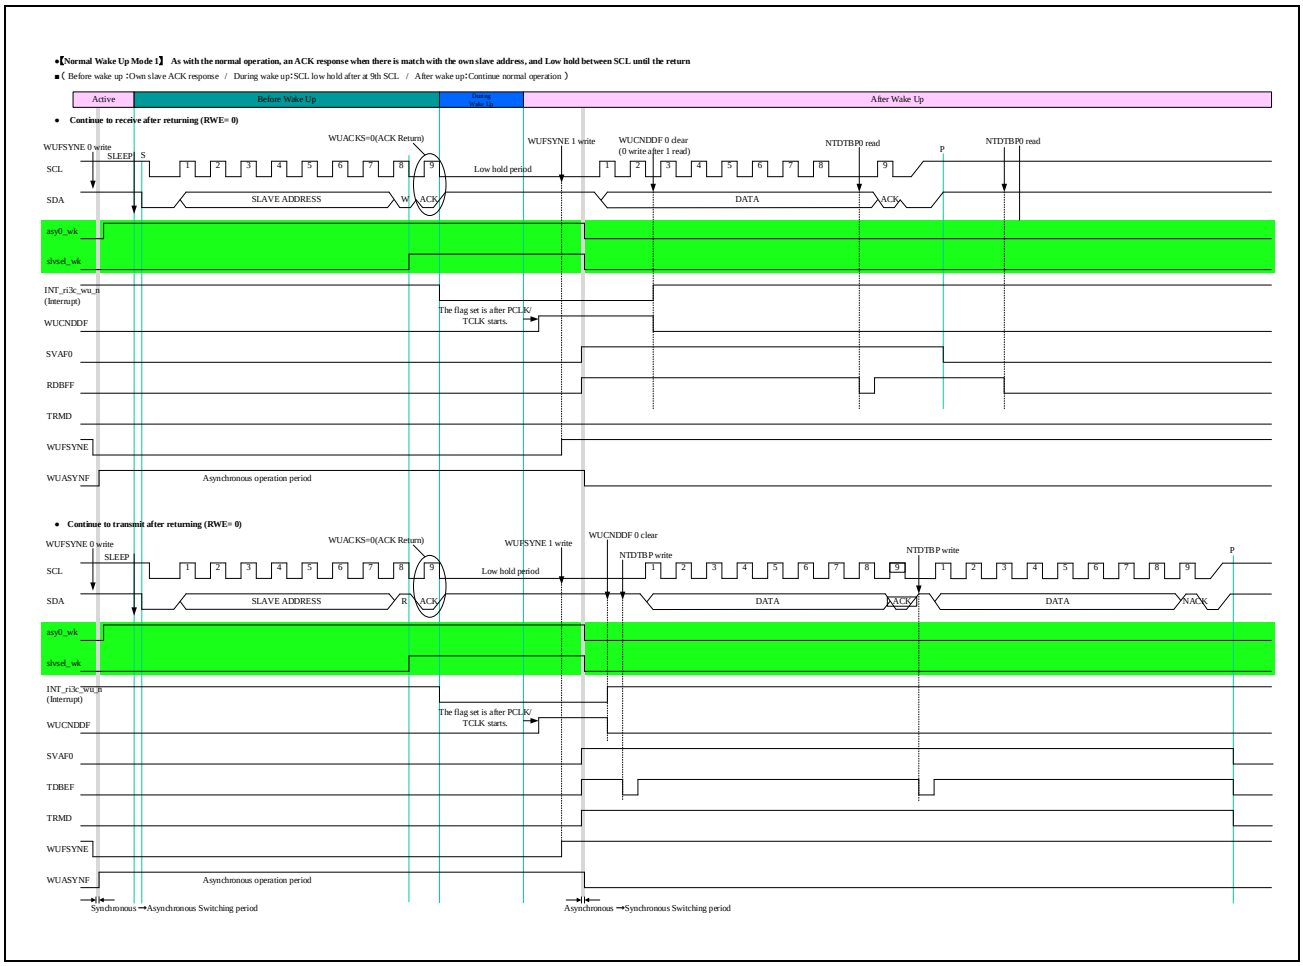

Figure 7.8-105 Timing of Normal Wake Up Mode 1

(b) Normal Wake Up mode 2

This section describes the behavior, the timing, and a use case of normal WU mode 2.

1. A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in **Figure 7.8-107**.

   Before Wake-Up recovery: No response to the data received with its own slave address (until 8th SCL cycle end)

   During Wake-Up recovery: Holding the SCL line low during the 8th and 9th clock cycles

   After Wake-Up recovery: Returning ACK at the 9th clock cycle of SCL, and continuing the normal operation

If the slave address does not match, the SCL line is not held low after the fall of the 8th SCL v clock cycle. The slave operation continues.

Refer to **Figure 7.8-106** “Use Case of Normal WU Mode 2” below for a use case.

2. A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to **Figure 7.8-104**.

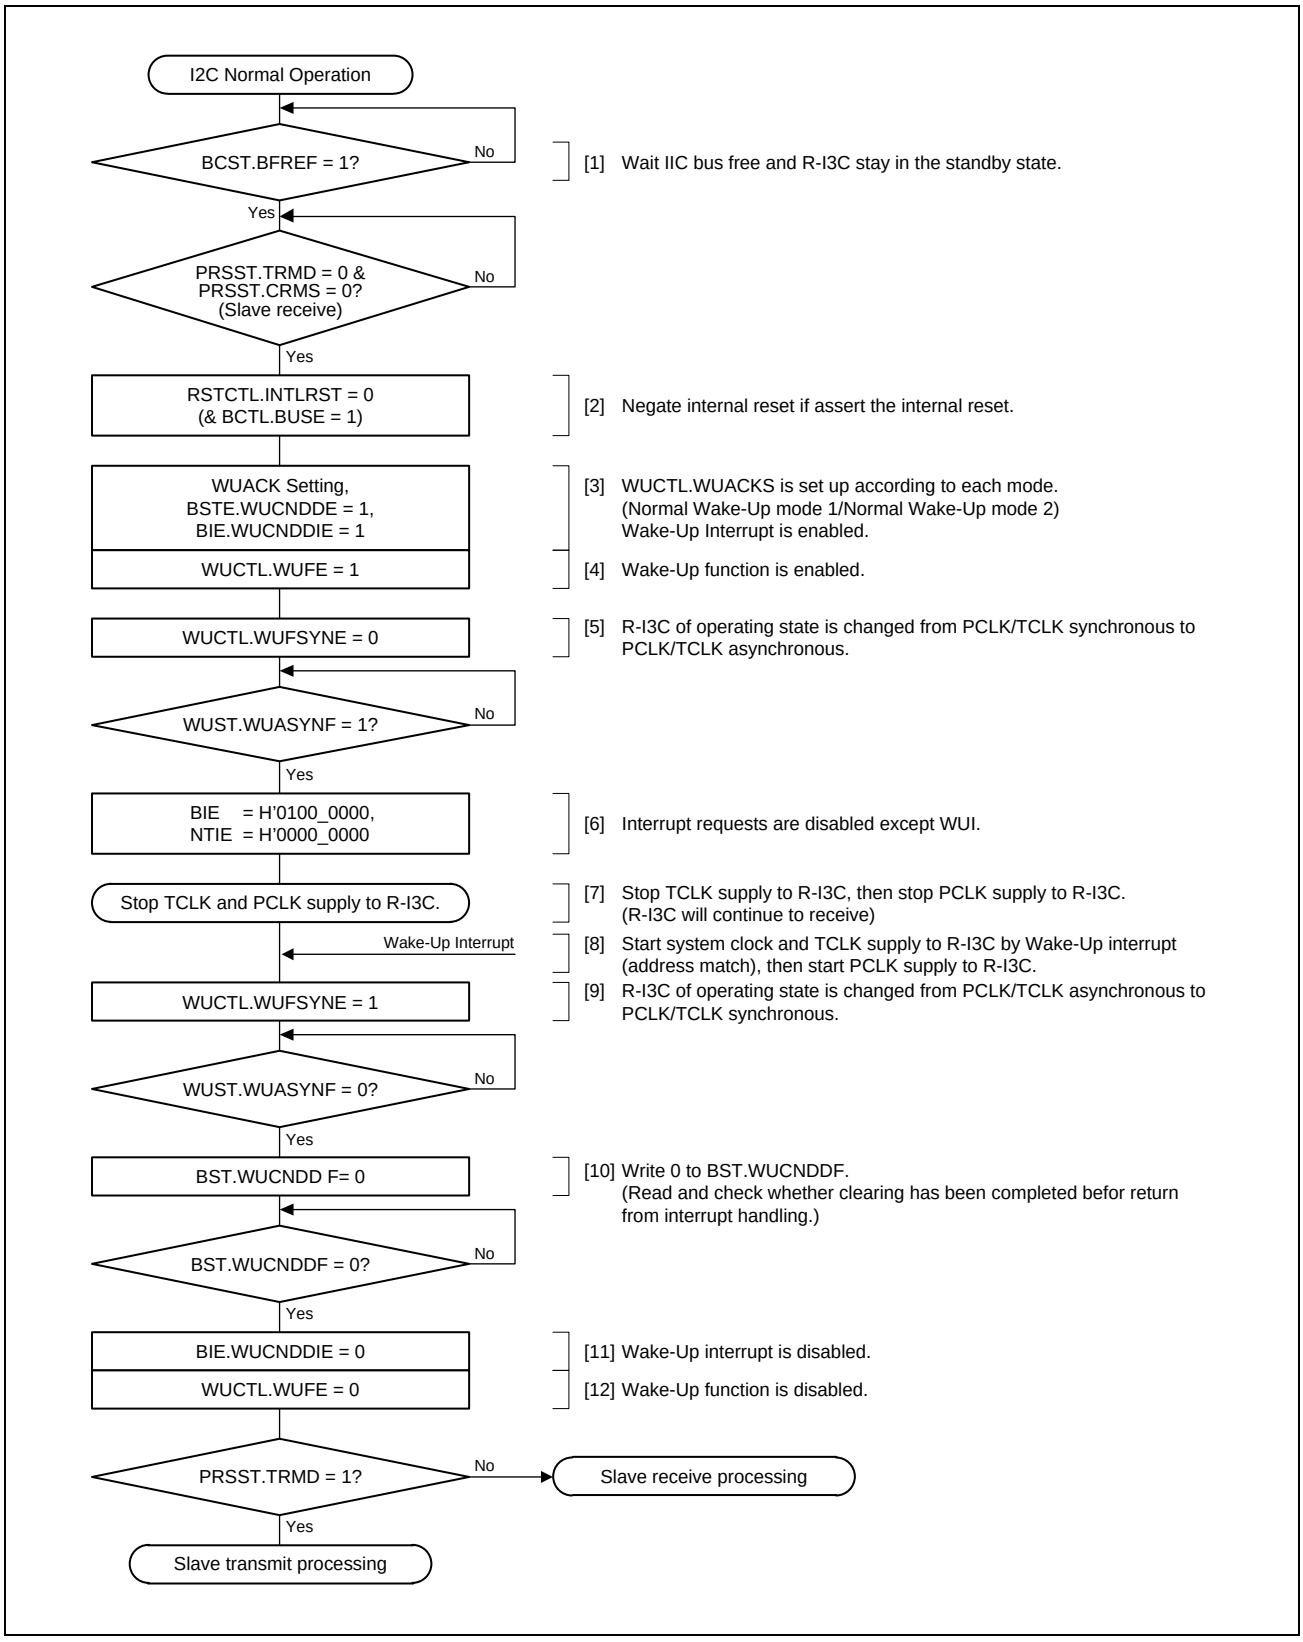

Figure 7.8-106 Use Case of Normal WU Mode 2
(Wake-Up Recovery by a Wake-Up Interrupt Triggered by the Match of the Slave Address)

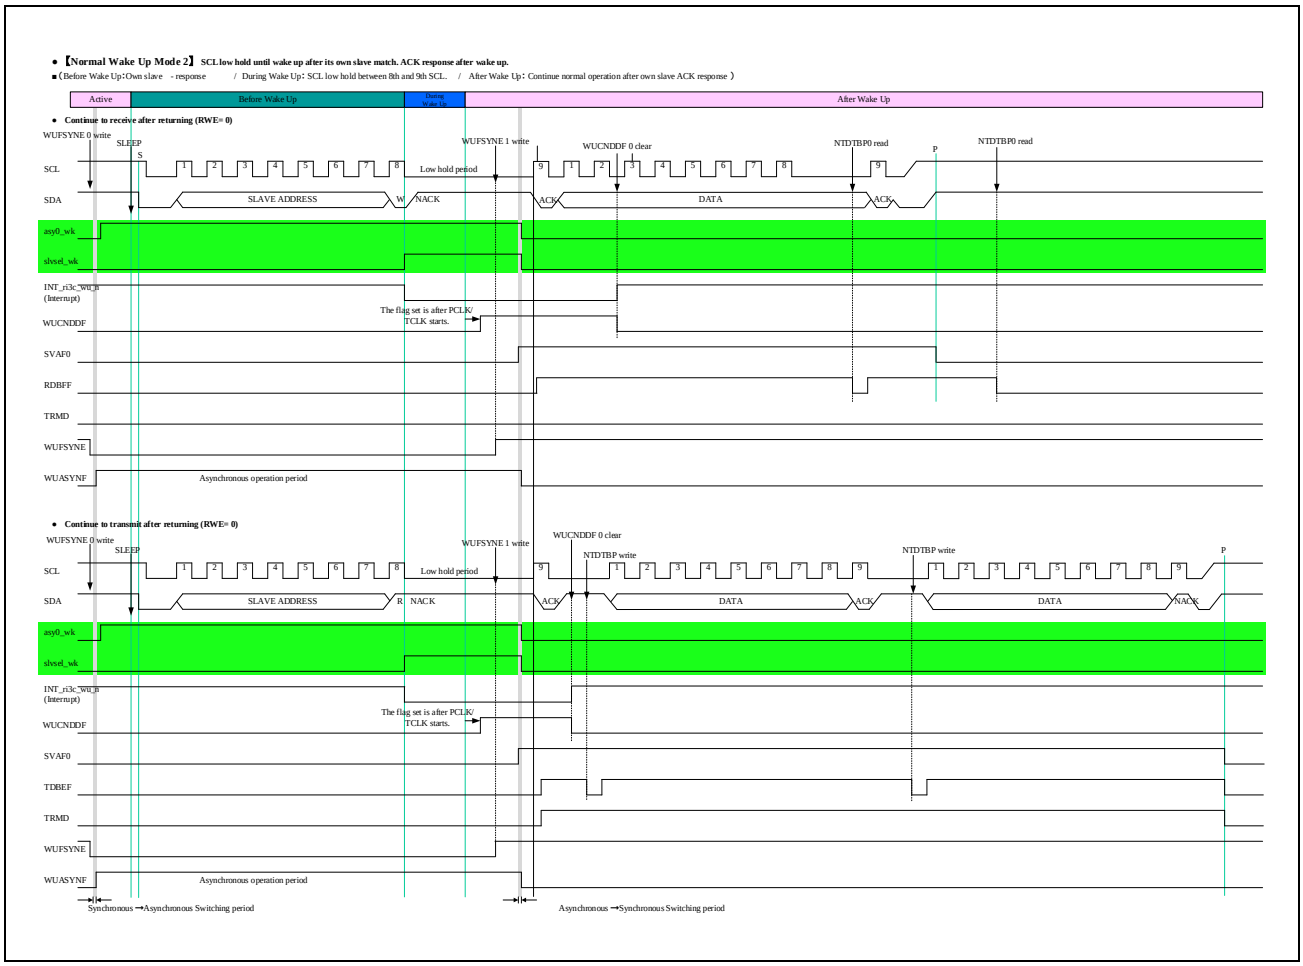

Figure 7.8-107 Timing of Normal Wake Up Mode2

(c) Command Recovery mode/EEP Response mode (Special Wake Up mode)

In the command recovery mode and EEP response mode, the SCL line is not held low during the wake-up recovery period (after the rise of the 9th clock cycle of SCL), so other I^2C/I3C devices can use the I^2C bus during this period.

This section describes the behavior, the timing, and use cases of the command recovery mode and the EEP response mode.

1. A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in **Figure 7.8-110**.

   Before Wake-Up recovery: In response to the data received with its own slave address, ACK (command recovery mode) or NACK (EEP response mode) is returned.

   During Wake-Up recovery: The SCL line is not held low.

   After Wake-Up recovery: Normal operation continues after this IP initial setting.

If the slave address does not match, the slave operation continues.

NOTES

1. Because the SCL line is not held low during wake-up recovery, the transmission/reception of the data that follows the slave address is not possible.
2. The command recovery mode and the EEP response mode are internal reset (RSTCTL.INTLRST= 1) states. Therefore, the match of the slave address does not set the SVST flags (HOAF, GCAF, and SVAF2, SVAF1, SVAF0).

Refer to **Figure 7.8-108** “Use Case of Command Recovery Mode and EEP Response Mode” below for a use case.

2. A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to **Figure 7.8-109**.

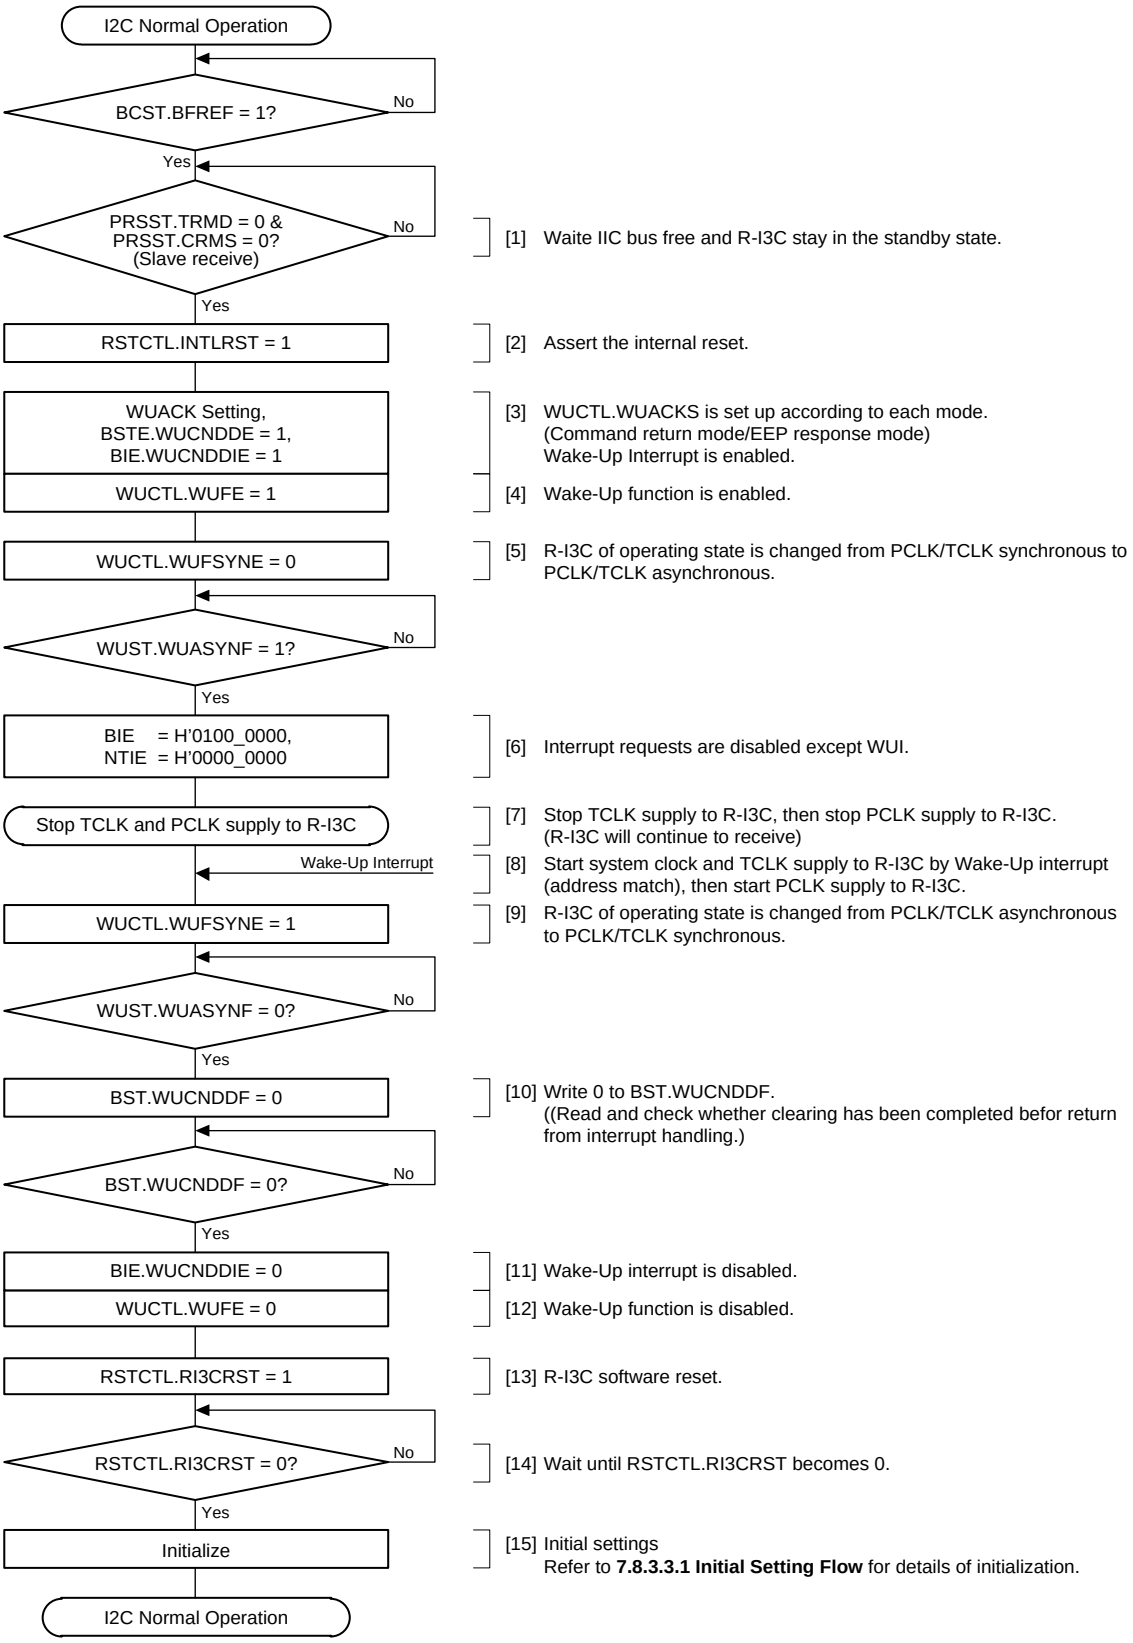

Figure 7.8-108 Use Case of Command Recover Mode and EEP Response Mode
(Wake-Up Recovery by a Wake-Up Interrupt Triggered by the Match of the Slave Address)

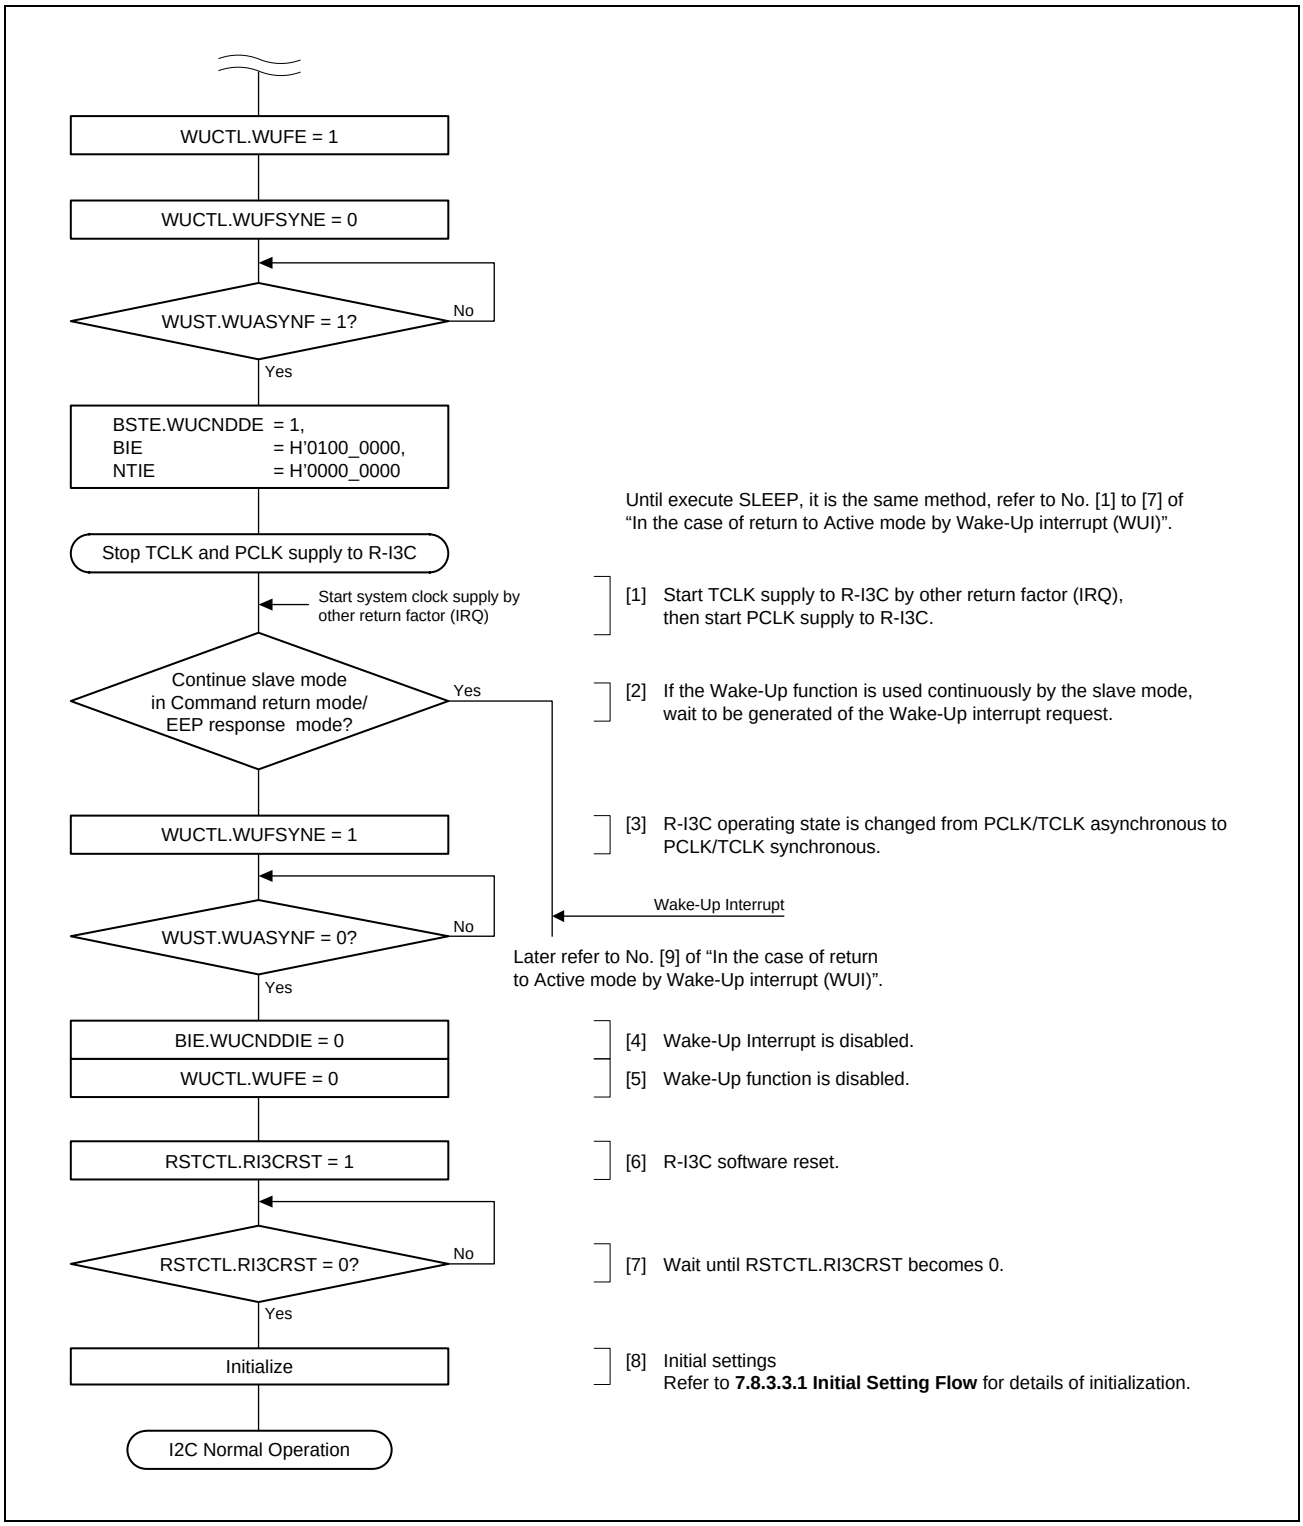

Figure 7.8-109 Use Case of Command Recover Mode and EEP Response Mode
(Wake-Up Recovery by Other Recovery Causes (IRQ))

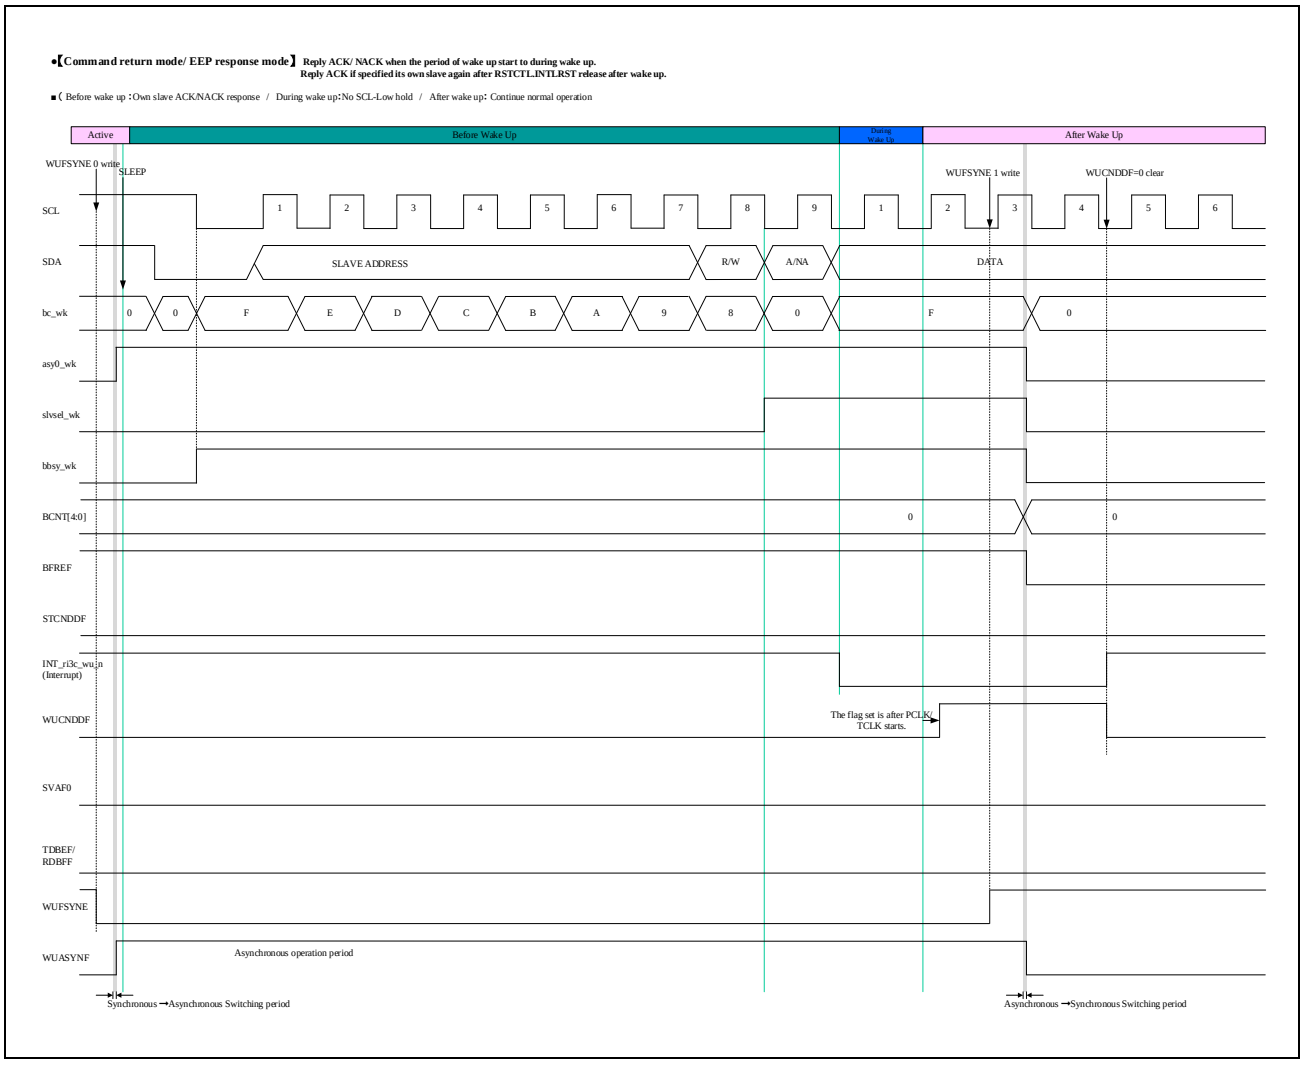

Figure 7.8-110 Timing of Command Recovery Mode/EEP Response Mode

(d) Precautions on the Use of the Wake-Up Function

Precautions on the use of the Wake-Up function is shown below.

1. Do not change the registers in this IP except the WUCTL.WUFSYNE bit while the WUST.WUASYNF flag = 1 (while PCLK/TCLK asynchronous operation).
2. Set WUCTL.WUFE = BSTE.WUCNDDE = BIE.WUCNDDIE = 1 and PRSST.CRMS = PRSST.TRMD = 0 (slave reception mode) before switching PCLK/TCLK asynchronous mode.
3. Can not select the device ID and the 10-bit slave address for Wake-Up interrupt factor. Set the DVIDE bit in SVCTL and SDADLS bit in SDATBAS2 to 0.
4. Sets all bits in BIE (TENDIE, NACKDIE, SPCNDDIE, STCNDDIE, ALIE, TODIE) to 0 (Interrupt disabled) before switching the asynchronous operation.
5. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).
6. Wake-up interrupt is generated while PCLK/TCLK asynchronous operation (when WUST.WUASYNF = 1). In case of detecting slave address matching, the case of detect slave address match in PCLK/TCLK synchronous mode (WUST.WUASYNF = 0), does not occur Wake-Up interrupt, and BST.WUCNDDF flag will be not set also.
7. If WUCTL.WUFSYNE bit to “0” write timing and START condition of detecting a conflict, this IP might start the next reception in PCLK/TCLK synchronous operation mode. In this case, WUST.WUASYNF flag becomes 1 (switch to PCLK/TCLK asynchronous mode) when data communication is finished and detected STOP condition and starts the Wake-Up event detection.
8. If you want to switch from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation without address match detection, it will switch in the STOP condition detection. When the WUCTL.WUFSYNE bit was set to 1 in a bus free state, it is continued PCLK/TCLK asynchronous operation (Reception operation: waiting communication frame). WUST.WUASYNF flag becomes to 0 when this IP detect the STOP condition of the next communication frame, and this IP switches to PCLK/TCLK synchronous operation.
9. After writing 0 to WUFSYNE bit in WUCTL, do not change this IP operation mode setting register (BFCTL, SCSTRCTL, ACKCTL, INCTL, SVCTL, SDATBASn) until switched to the PCLK/TCLK asynchronous operation from PCLK/TCLK synchronous operation (while WUST.WUASYNF flag = 1). If register value changes by the interrupt processing etc. in this period, this IP might malfunction without succeeding to the setting to the asynchronous operation.
10. During PCLK/TCLK asynchronous operation (WUST.WUASYNF = 1), do not refer to each flag of SVST, BST register and BCST.BFREF flag.
11. Do not set ACKCTL.ACKT = 1 in order to make an ACK response in the synchronization unit when Wake-Up is performed by slave address match in Normal Wake-Up Mode 2.

(2) Wake Up function [I3C mode]

(a) I3C Master Wake-Up

Wake-Up interrupt causes of I3C Master are shown below.

1. SDA Low detection (IBI request from I3C Slave)

   The operation when transitioning to active mode (normal operation) by Wake-Up interrupt of SDA Low detection is shown below.

   Before Wake-Up recovery: SDA Low Drive is detected and the INTWU interrupt is asserted.

   During Wake-Up recovery: Keep SCL Line High.

   After Wake-Up recovery: Drive SCL Low and complete START condition. SCL is supplied on the I3C Bus and IBI from I3C Slave is received.

If transition to active mode (normal operation) due to other factors, disable the Wake-Up function as necessary.

After confirming PRSTDBG.SDILV = 1, set WUCTL.WUFE = 0.

Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

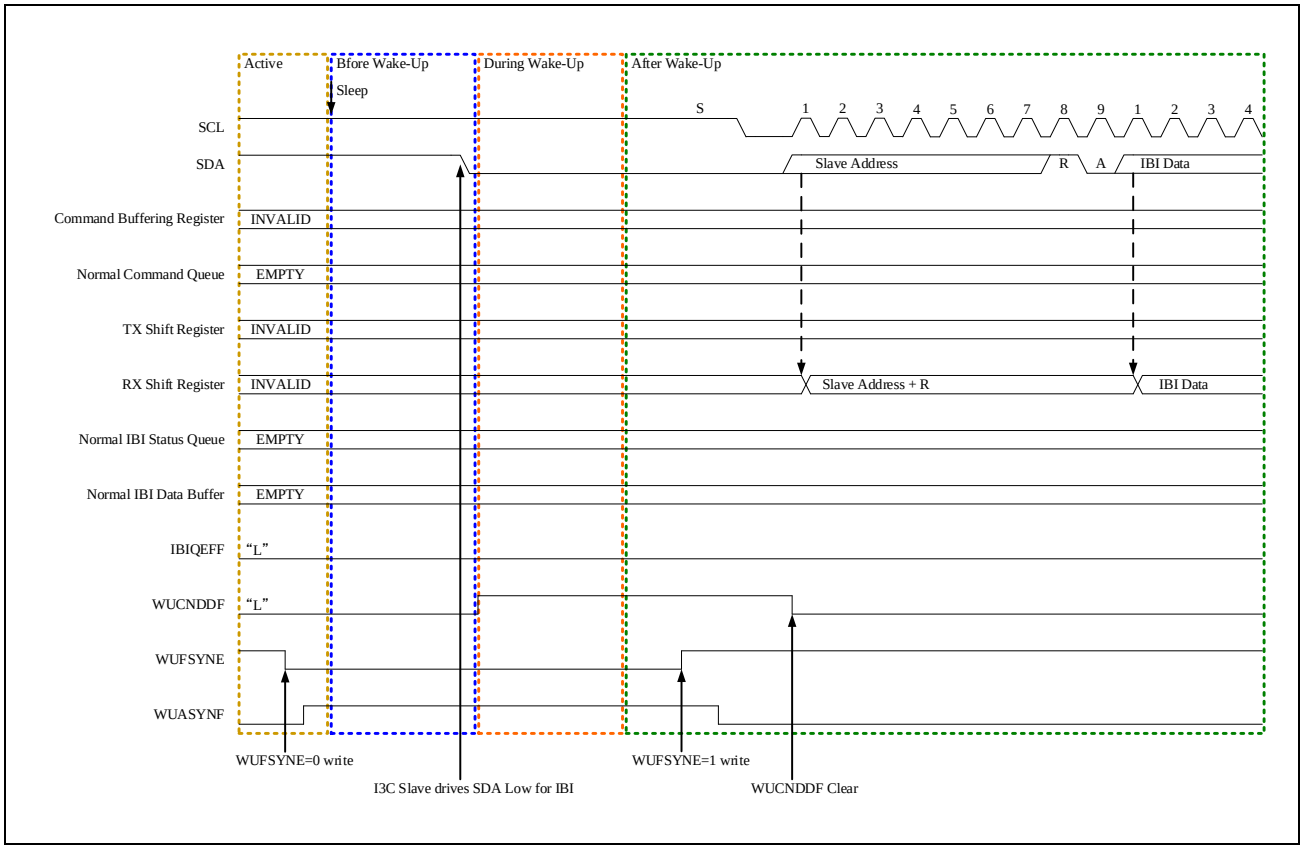

Figure 7.8-111 I3C Master Wake-Up Operation

(b) I3C Slave Wake-Up

Wake-Up interrupt causes of I3C Slave are shown below.

1. Broadcast Address (H'7E) and detects its own Slave Address match

   The operation when the Broadcast Address (H'7E) and transition to active mode (normal operation) by Wake-Up interrupt by detecting its own Slave Address match is shown.

   Before Wake-Up recovery:

   [Step 1]
   If this IP detects BA (H'7E/W) following a START (or Repeated START) Condition, then this IP shall generate ACK (after H'7E/W).

   [Step 2]

   If this IP detects its own Dynamic Address after a Repeated START condition following Step1, then this IP shall generate NACK (after its own Dynamic Address) and then issues a INTWU interrupt.

   During Wake-Up recovery: This IP always generates NACK.

   After Wake-Up recovery: Normal operation continues.

If transition to active mode (normal operation) due to other factors, disable the Wake-Up function as necessary.

Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

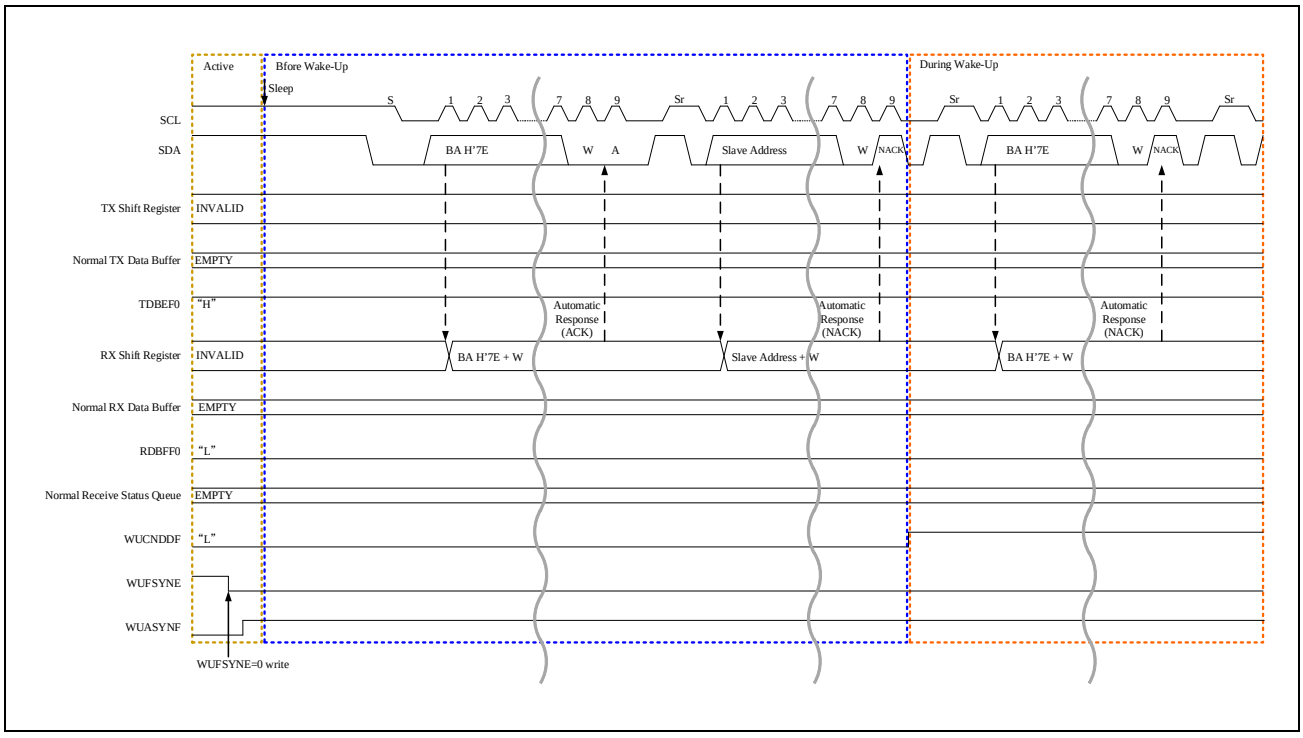

Figure 7.8-112 I3C Slave Wake-Up Operation (1/2)

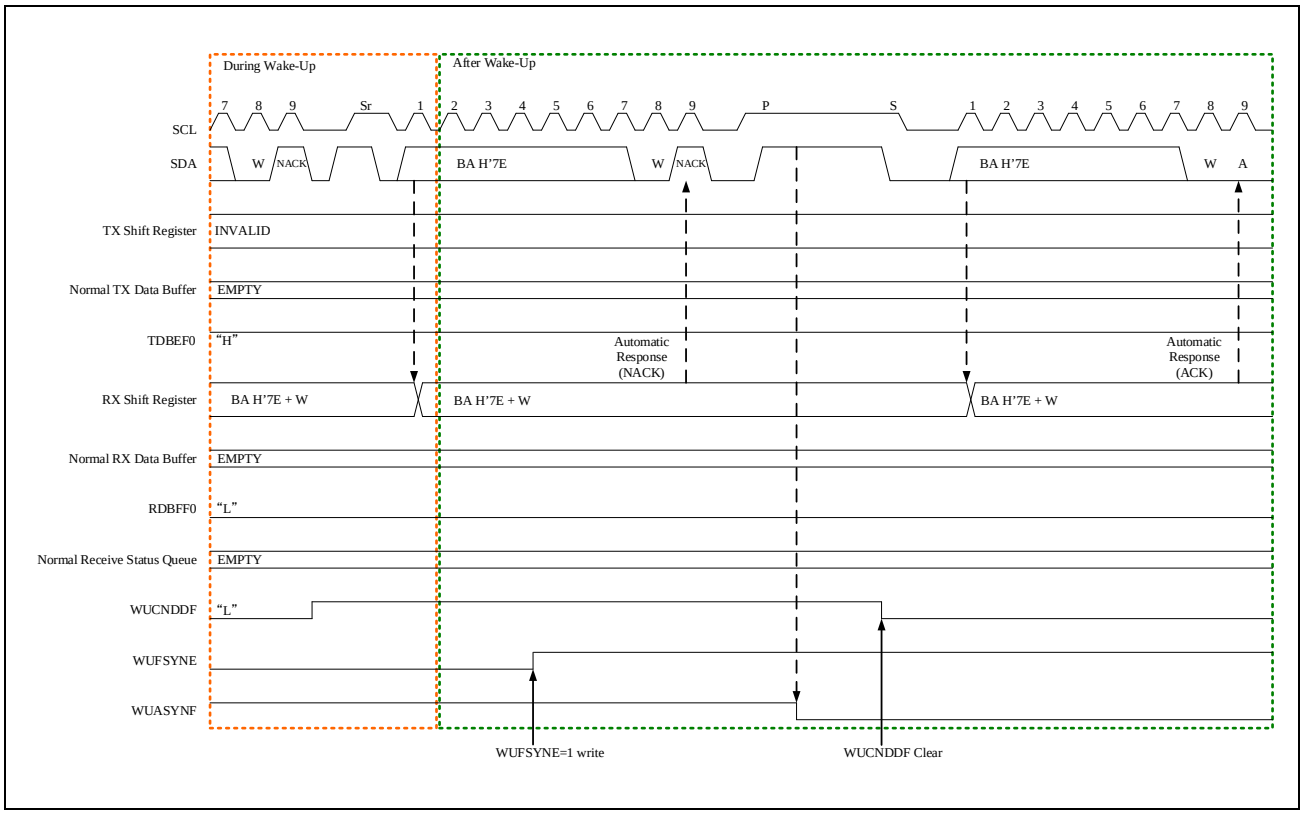

Figure 7.8-113 I3C Slave Wake-Up Operation (2/2)

7.8.3.2.6 Other

(1) SCL Synchronization Circuit [I²C mode]

This function is enabled while the PRTS.PRTMD bit is set to 1.

In generation of the SCL clock, I3C starts counting out the value for width at high level specified in STDBR.SBRHO[7:0] when it detects a rising edge on the SCLn line and drives the SCLn line low once counting of the width at high level is complete.

When I3C detects the falling edge of the SCLn line, it starts counting out the width at low level period specified in STDBR.SBRLO[7:0], and then stops driving the SCLn line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the I²C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, I3C is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When I3C has detected a rising edge on the SCLn line and thus started counting out the width at high level specified in STDBR.SBRHO[7:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, I3C stops counting when it detects the falling edge, drives the level on the SCLn line low, and starts counting out the width at low level specified in STDBR.SBRLO[7:0]. When I3C finishes counting out the width at low level, it stops driving the SCLn line to the low level (releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in this module, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCLn line has been released. When I3C finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCSYNE bit in BFCTL is set to 1.

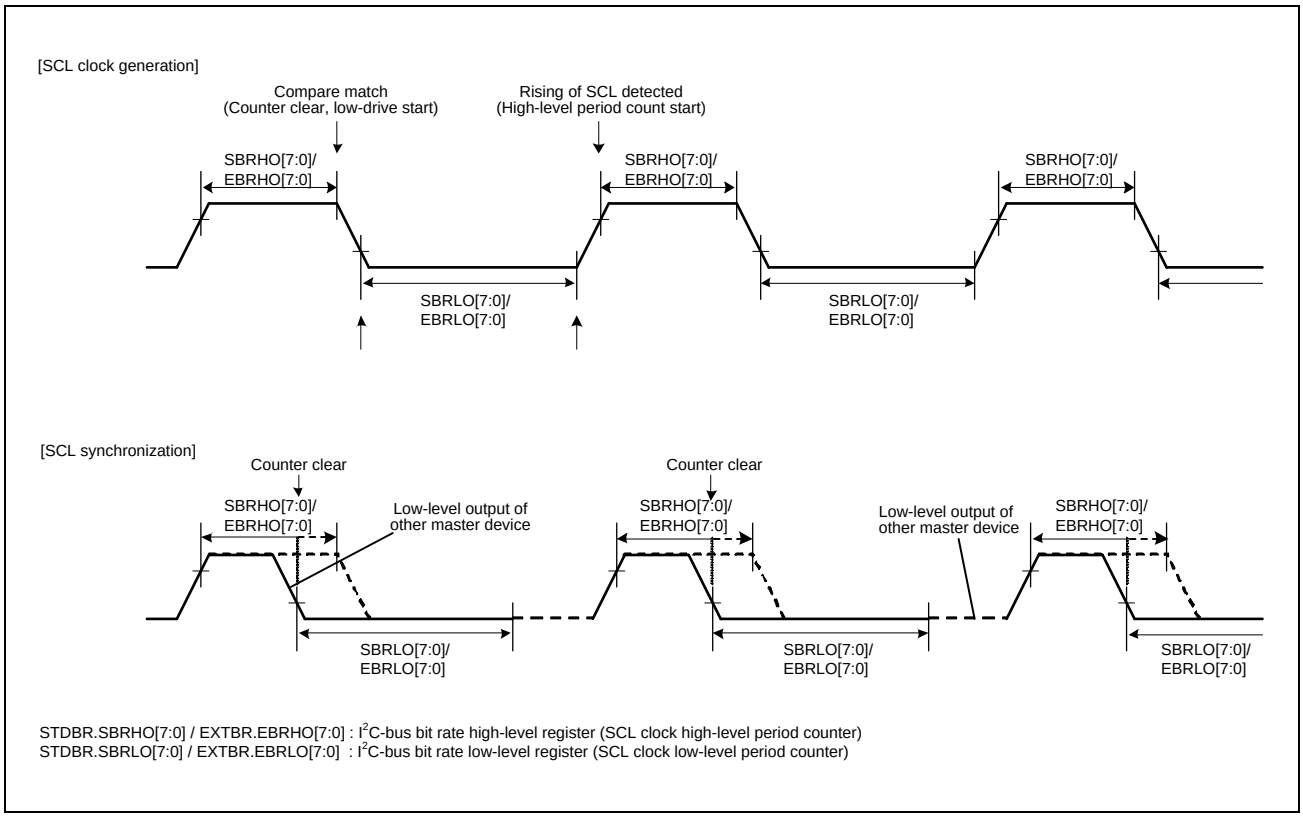

Figure 7.8-114 Generation and Synchronization of the SCL Signal

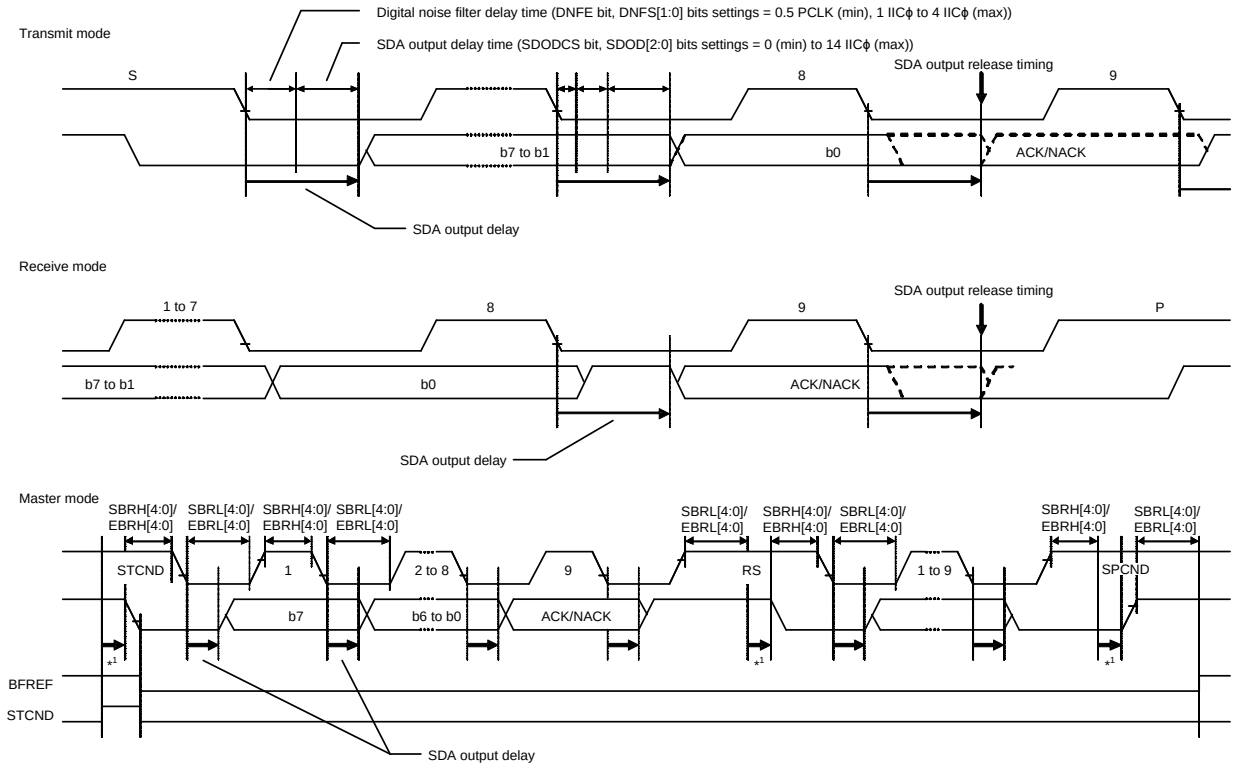


(2) Facility for Delaying SDA Output [I²C mode]

I3C module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the START, Repeated START, and STOP conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level.

The output delay facility is enabled by setting the SDOD[2:0] bits in OUTCTL to any value other than 000b, and disabled by setting the same bits to 000b.

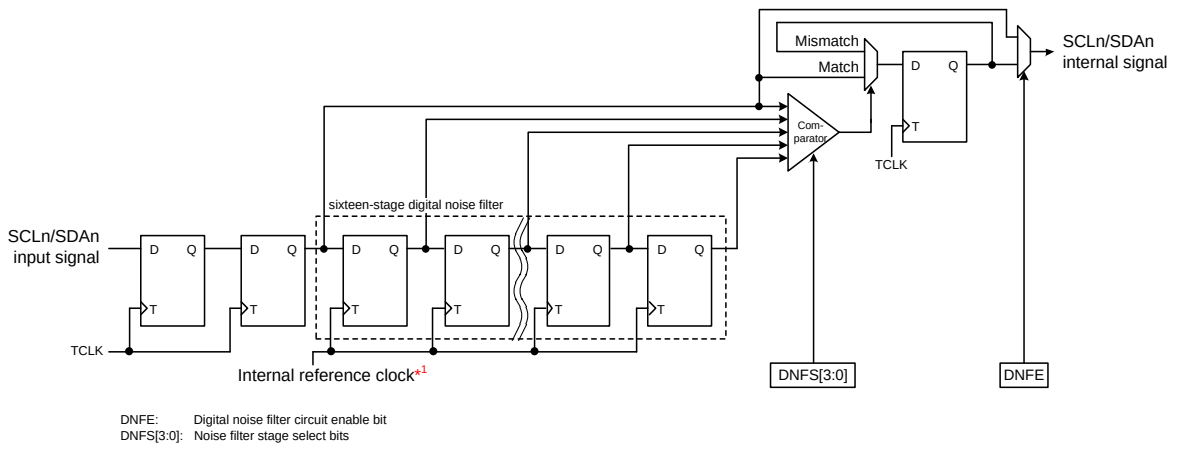
While the SDA output delay facility is enabled (while the SDOD[2:0] bits in OUTCTL are set to any value other than 000b), the SDODCS bit in OUTCTL selects the clock source for counting by the SDA output delay counter as the internal base clock (I3Cϕ) for I3C module or as a clock signal derived by dividing the frequency of the internal base clock by two (I3Cϕ/2). The counter counts the number of cycles set in the SDOD[2:0] bits in OUTCTL. After counting of the set number of cycles of delay is completed, I3C module places the required output (START, Repeated START, or STOP condition, data, or an ACK or NACK signal) on the SDA line.

Note: PCLK = PCLKB

Note 1. The output delay function is set by the SDODCS and SDOD[2:0] bits when a start (STCND), repeated start (SRCND), or stop (SPCND) condition is issued.

Figure 7.8-115 SDA Output Delay Facility

(3) Digital Noise-Filter Circuits [I²C mode]



The states of the SCLn and SDAn pins are conveyed to the internal circuitry through digital noise-filter circuits. **Figure 7.8-116** is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of I3C consists of 16 flip-flop circuit stages connected in series and a match detection circuit. When HS mode is selected, only the first four flip-flop circuits stages are enabled.

The number of effective stages in the digital noise filter is selected by the INCTL.DNFS[3:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to sixteen I3Cϕ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on rising edges of the I3Cϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the INCTL.DNFS[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLKD) and the transfer rate is small (For example, data transfer at 400 kbps with PCLKD = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.

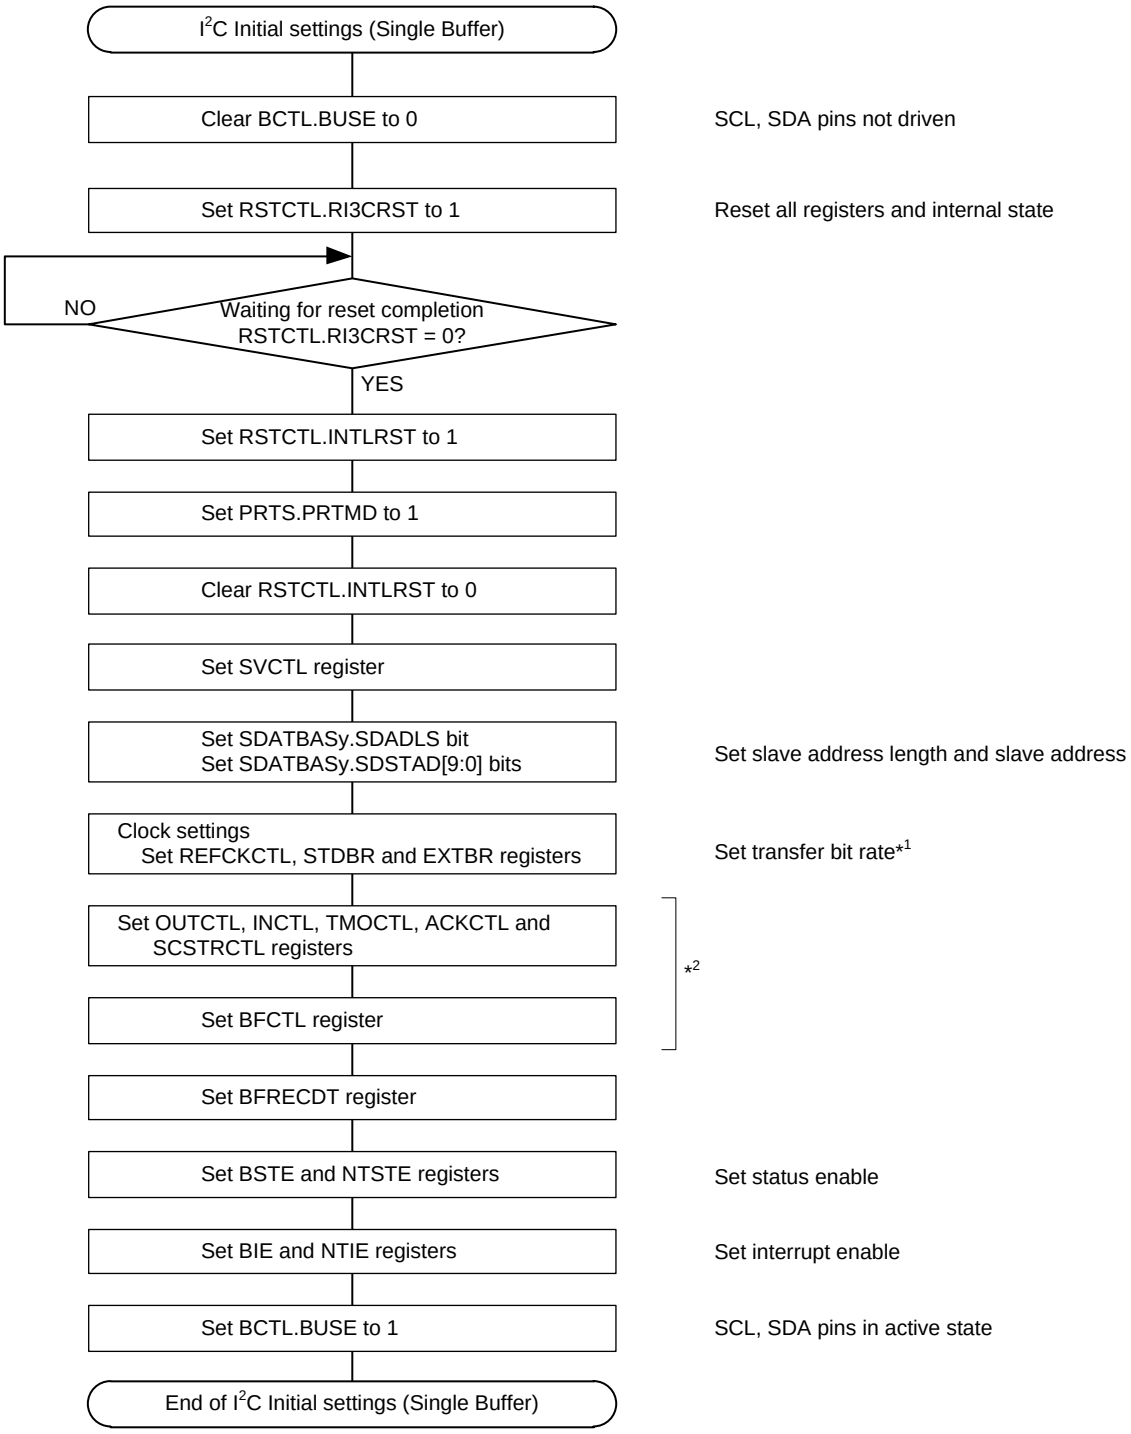
Note: TCLK = PCLKD

Note 1. Internal reference clock = I3Cϕ

Figure 7.8-116 Block Diagram of Digital Noise Filter Circuit

7.8.3.3 Operation

7.8.3.3.1 Initial Setting Flow



(1) I^2C Initial Setting Flow (Single Buffer Transfer)

Before starting data transmission and reception, initialize I3C according to the procedure in **Figure 7.8-117**. First, set the BCTL.BUSE bit to 0 (SCLn, SDAn pins not driven).

Next, set the RSTCTL.RI3CRST bit to 1 (I3C reset). This initializes all registers and internal state. Then, waits for RI3CRST to become 0.

This initializes the various flags and some registers. Refer to **7.8.5 Reset Descriptions**.

After that, set registers SDATBAS.SDADLS, SDATBAS.SDATAD[9:0], STDBR, INCTL, OUTCTL, TMOCTL, TMOCNT, SCSTRCTL, ACKCTL, and BFCTL, then set the other registers as necessary (for initial settings of I3C, refer to **Figure 7.8-117**).

Note: n = 0

Note 1. When the I3C is used only in slave mode, set the STDBR register to a value longer than the data setup time.

Note 2. Set these registers as necessary.

Figure 7.8-117 Example of I2C Initialization Flowchart (Single Buffer Transfer)

(2) I3C Initial Setting Flow

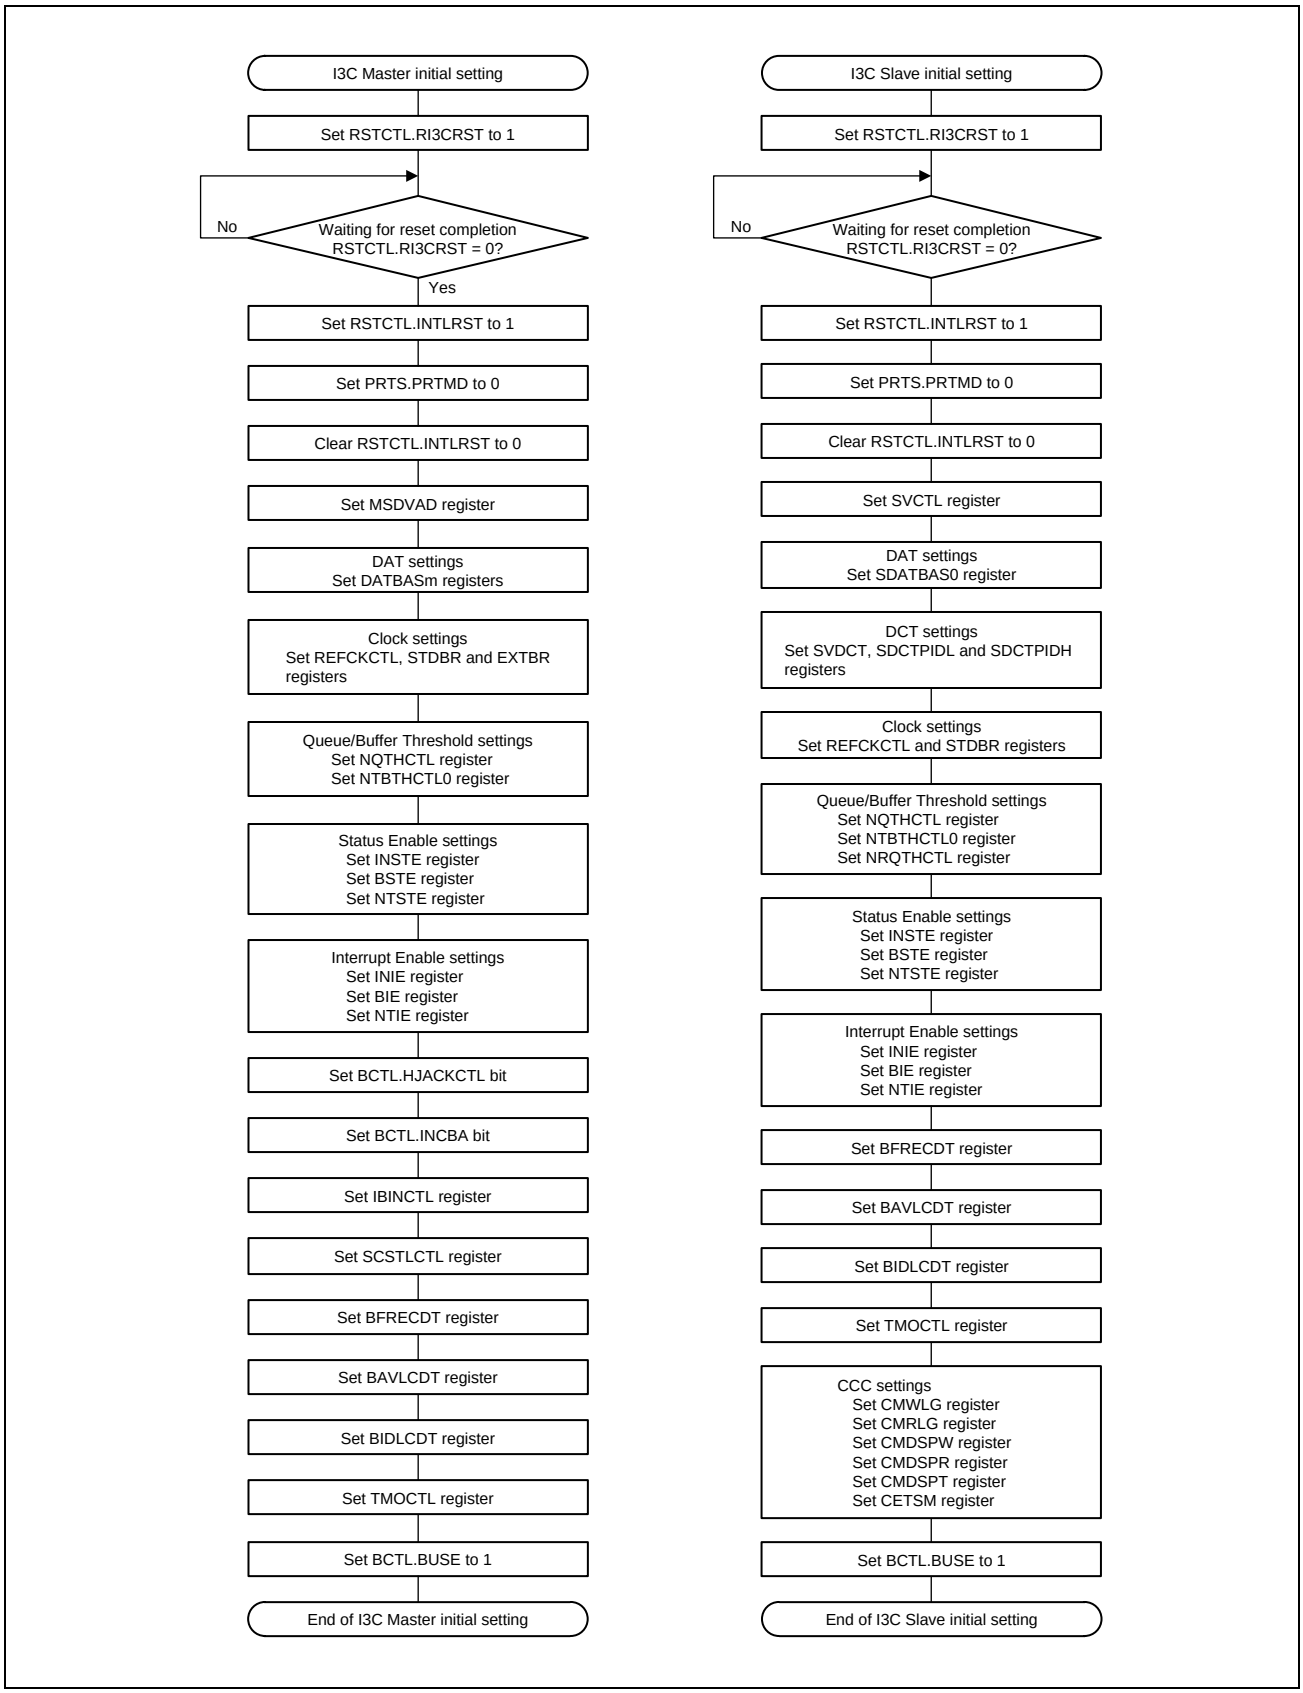


Figure 7.8-118 Example of I3C Initialization Flowchart

7.8.3.3.2 I3C Communication Flow

Figure 7.8-119 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START, followed by one or more transfers, and a STOP.

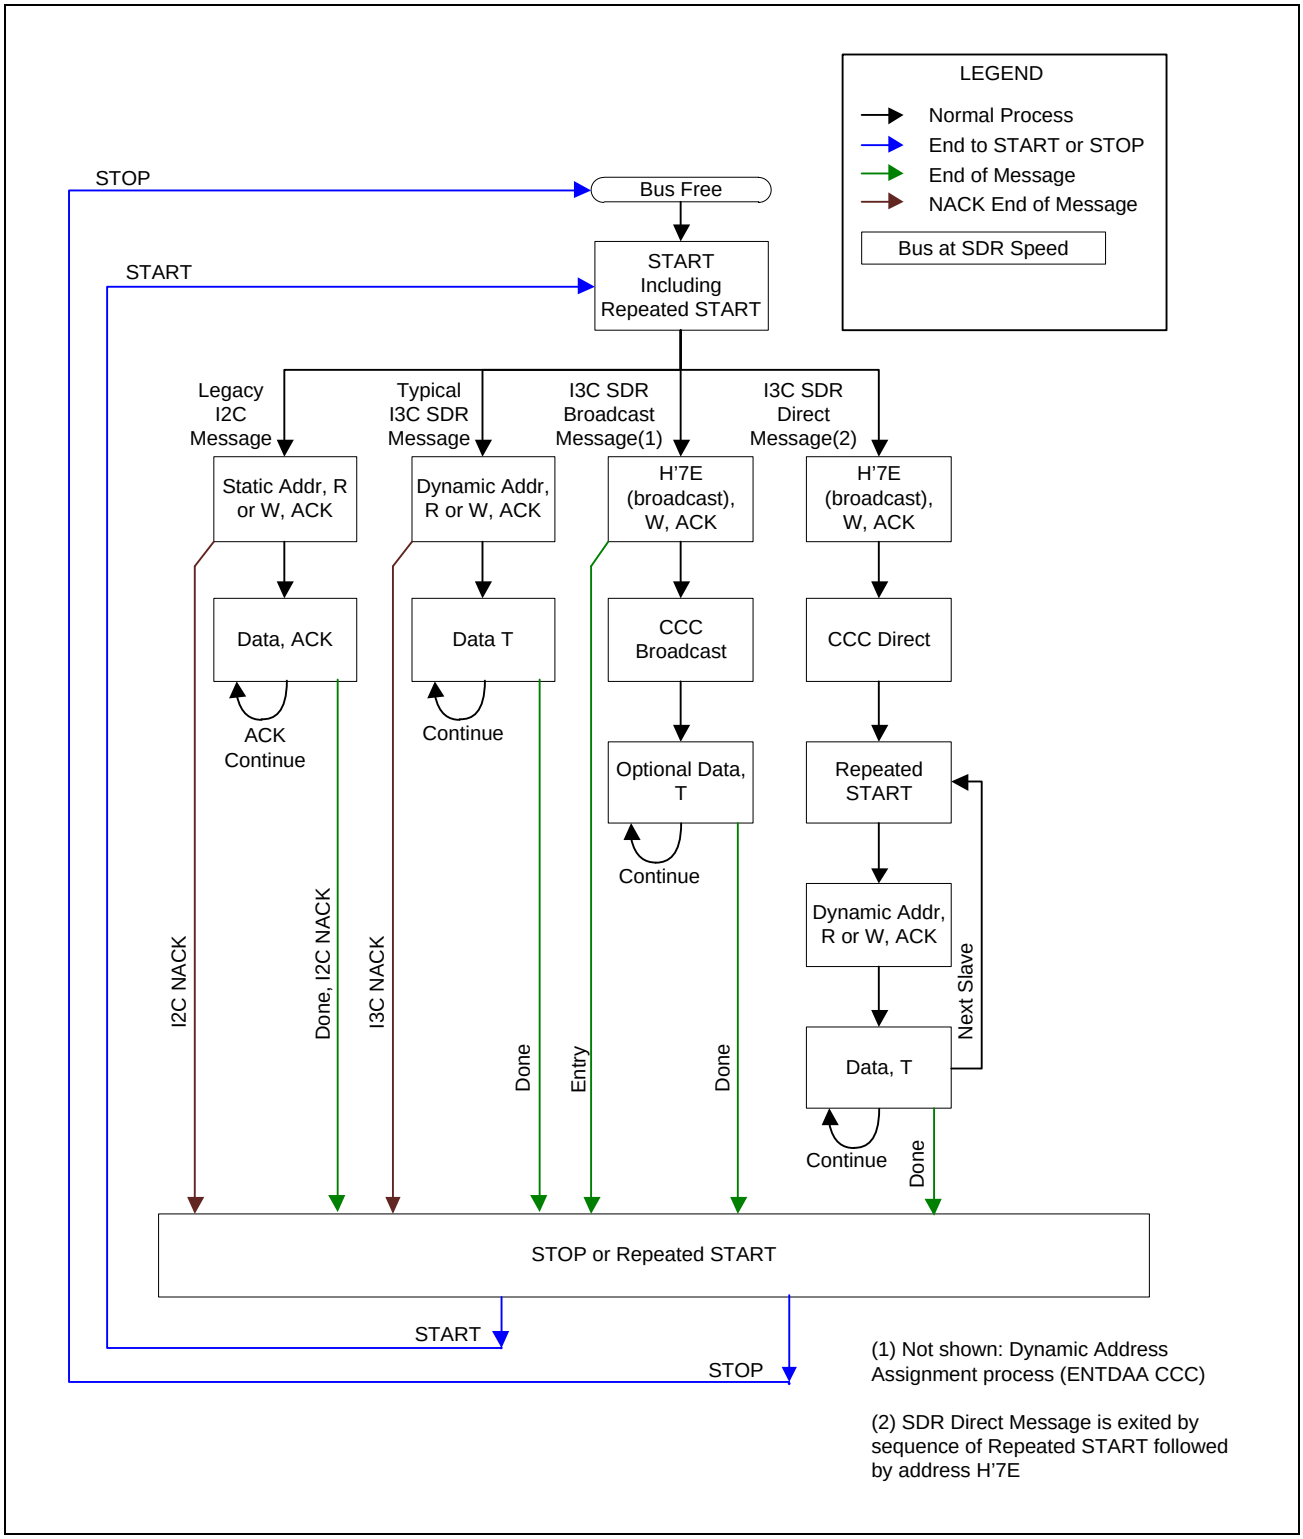

Figure 7.8-119 I3C Communication Flow

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is either SDR. Frames are bordered by I^2C-like bus management.

The I3C frame always includes at least the START, the Header, the Data, and the STOP. The Header following a START allows for Bus Arbitration. The Master uses the Header to address Slave device (s). Slave devices (s) may use the Header Arbitration for multiple purposes: for In-Band Interrupt, for Hot-Join, and for Secondary Master functionality.

I3C allows only one Master to have control of the I3C bus at a time. Mechanisms for handoff of the Master role from one device to another device are provided.

7.8.3.3.3 Master Mode Communication Flow

(1) I²C Master Transmission Flow (Single Buffer Transfer)

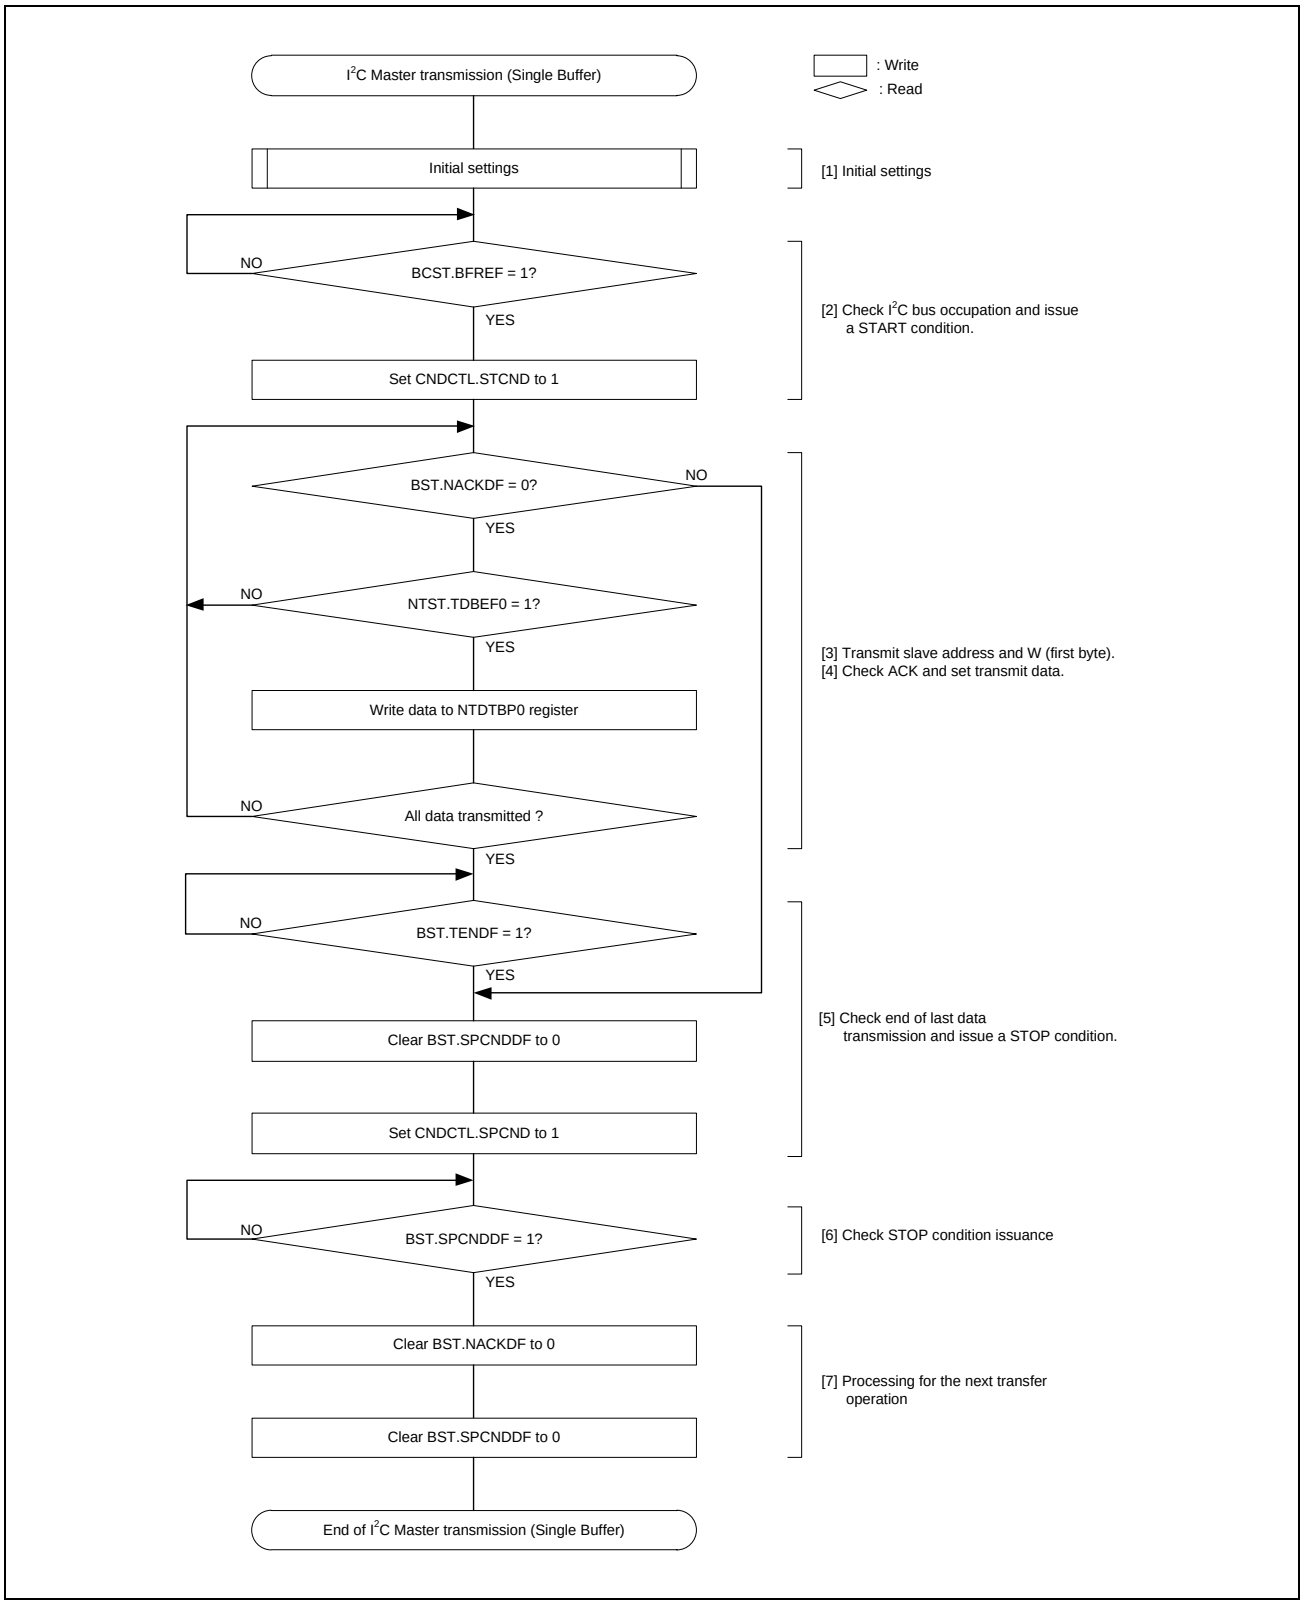

Figure 7.8-120 Example of I²C Master Transmission Flowchart (Single Buffer Transfer)

NOTE

The following processing is required when checking NTST.TDBEF0 = 1 in Steps [3] and [4] of the I^2C master transmission flowchart as shown in **Figure 7.8-120**.

- When sending a slave address:
  After confirming NTST.TDBEF0 = 1, confirm that PRSTDBG.SCILV = 0 (check the status of SCL) before writing the transmission data.
- When sending data:
  - If BITCNT.BCNT = other than 0 after confirming NTST.TDBEF0 = 1, write the transmission data immediately
  - If BITCNT.BCNT = 0 after confirming NTST.TDBEF0 = 1, check that BST.TENDF = 1 and PRSTDBG.SCILV = 0 (check the status of SCL) before writing the transmission data.

(2) I²C Master Reception Flow (Single Buffer Transfer)

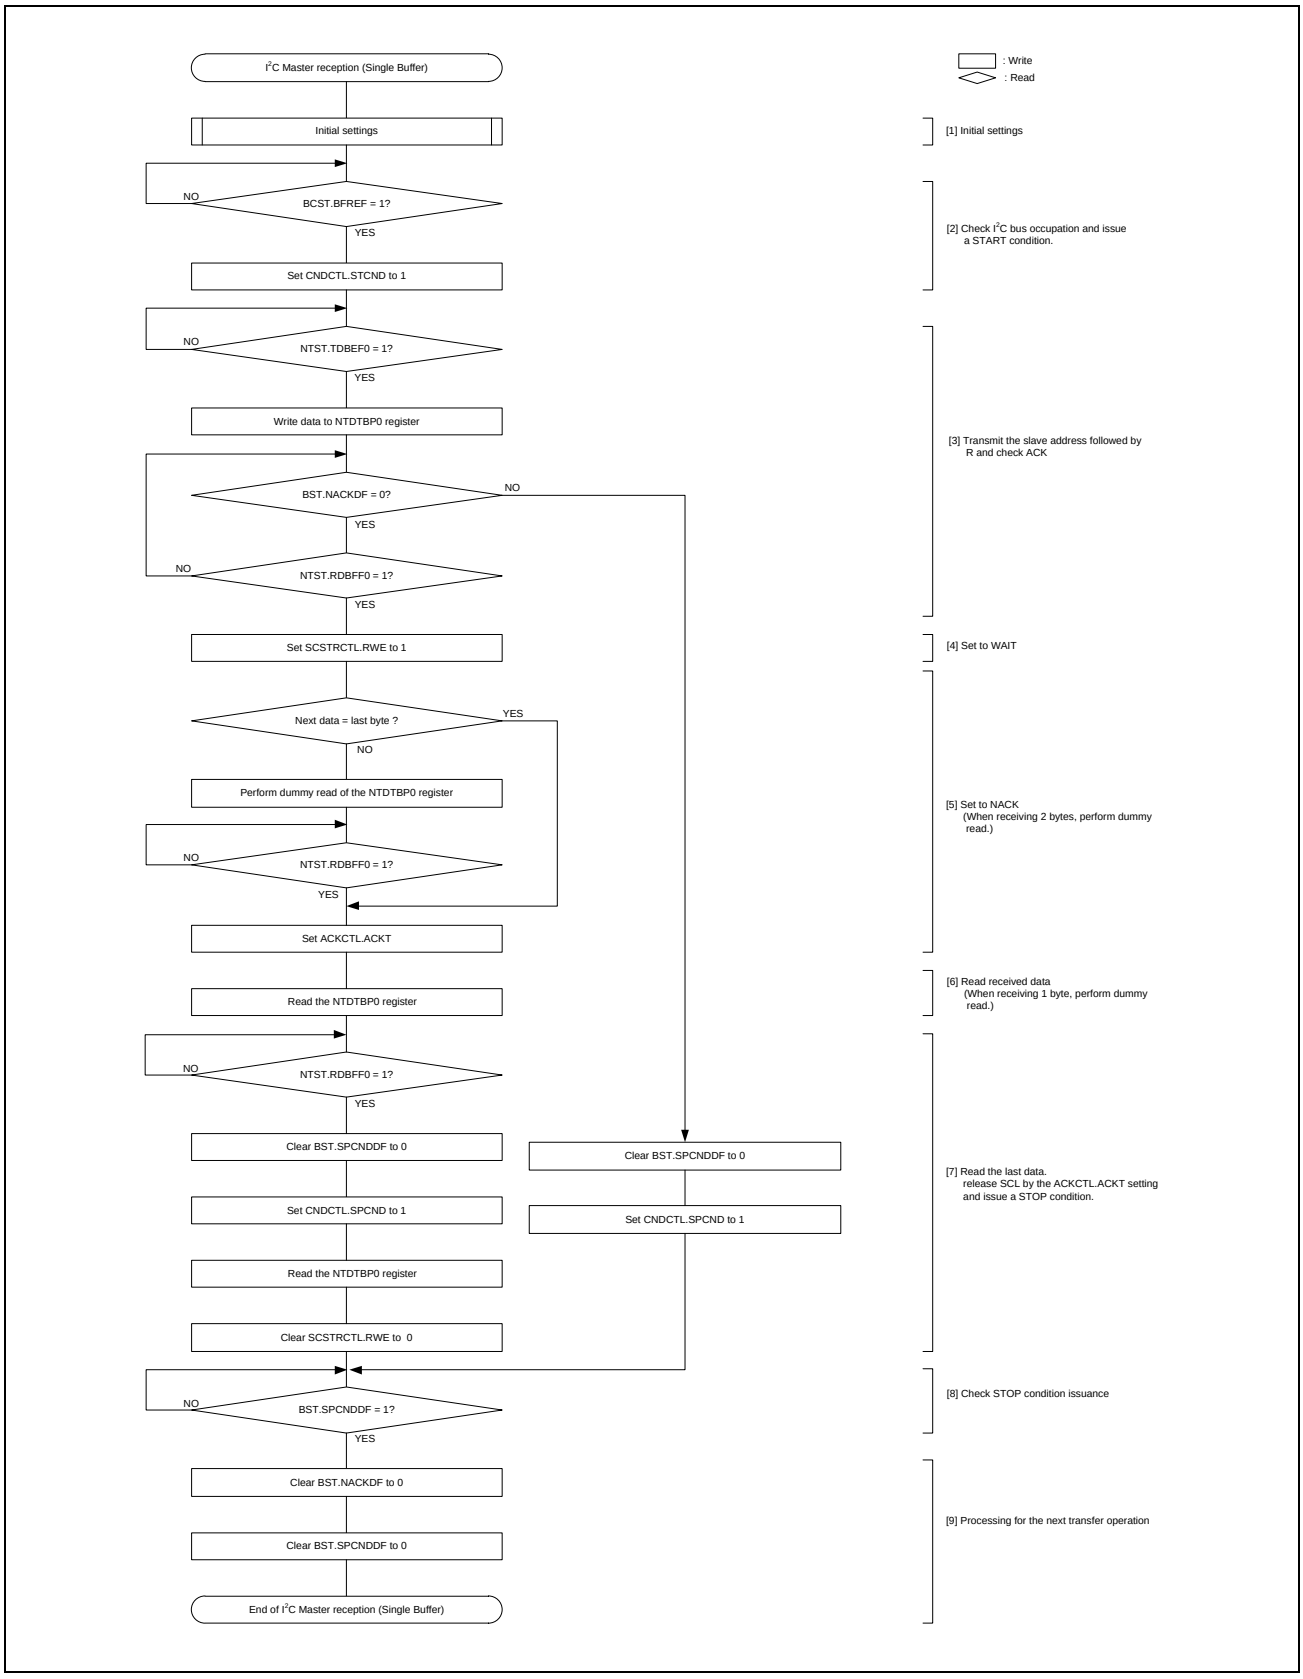

Figure 7.8-121 Example of I²C Master Reception Flowchart (7-bit Address Format, 1 or 2 bytes)

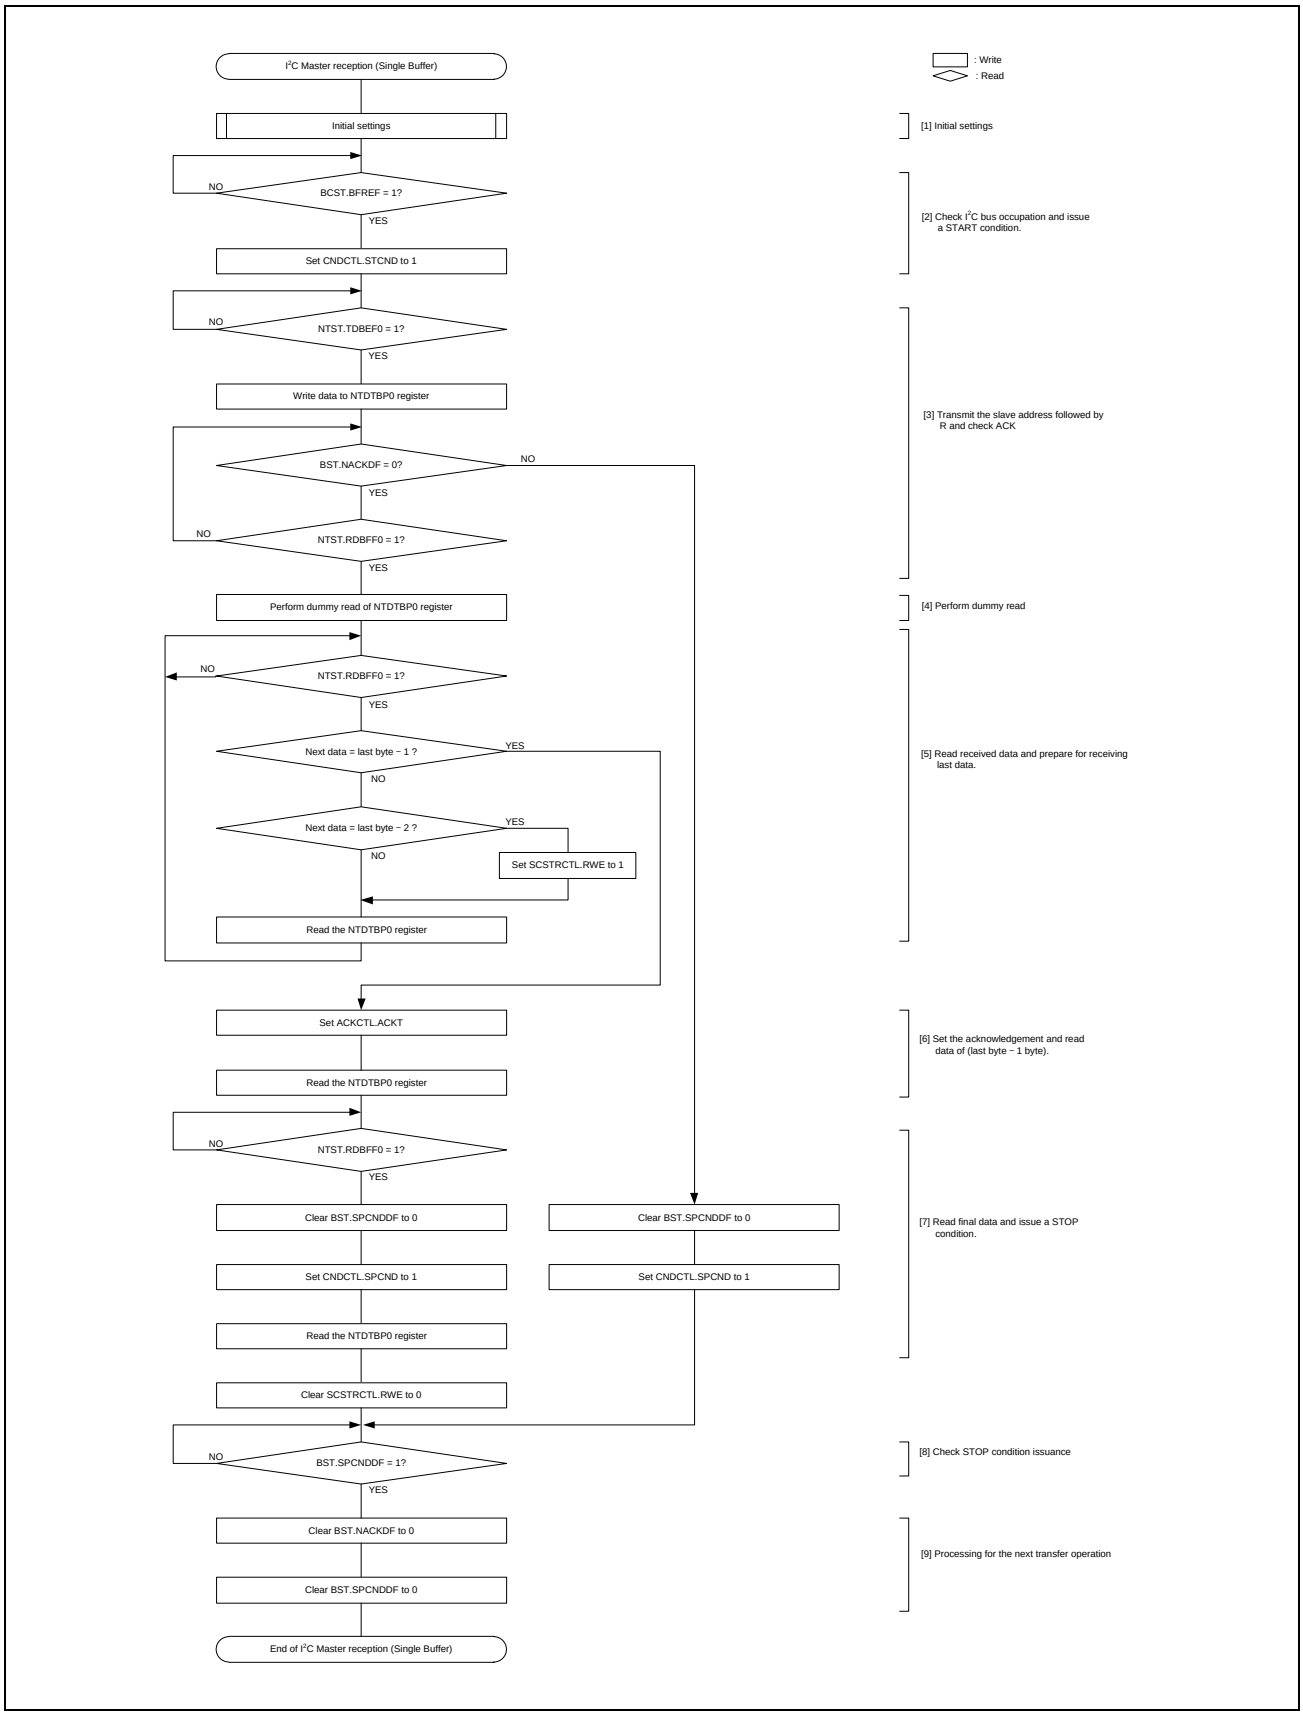

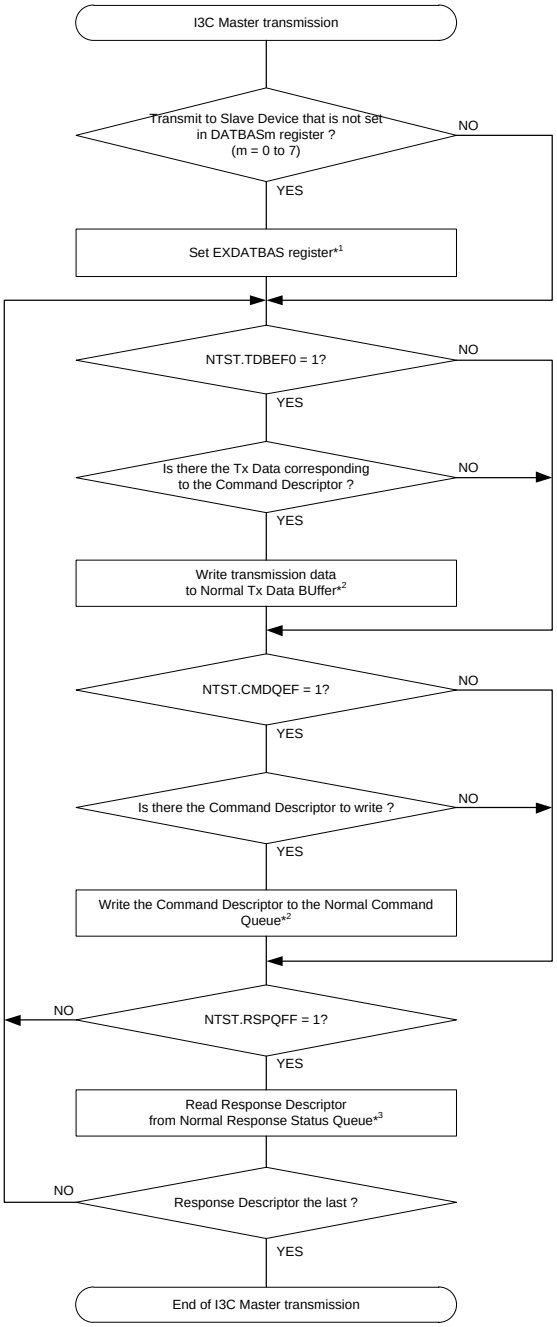

Figure 7.8-122 Example of I²C Master Reception Flowchart (7-bit Address Format, 3 bytes or more)

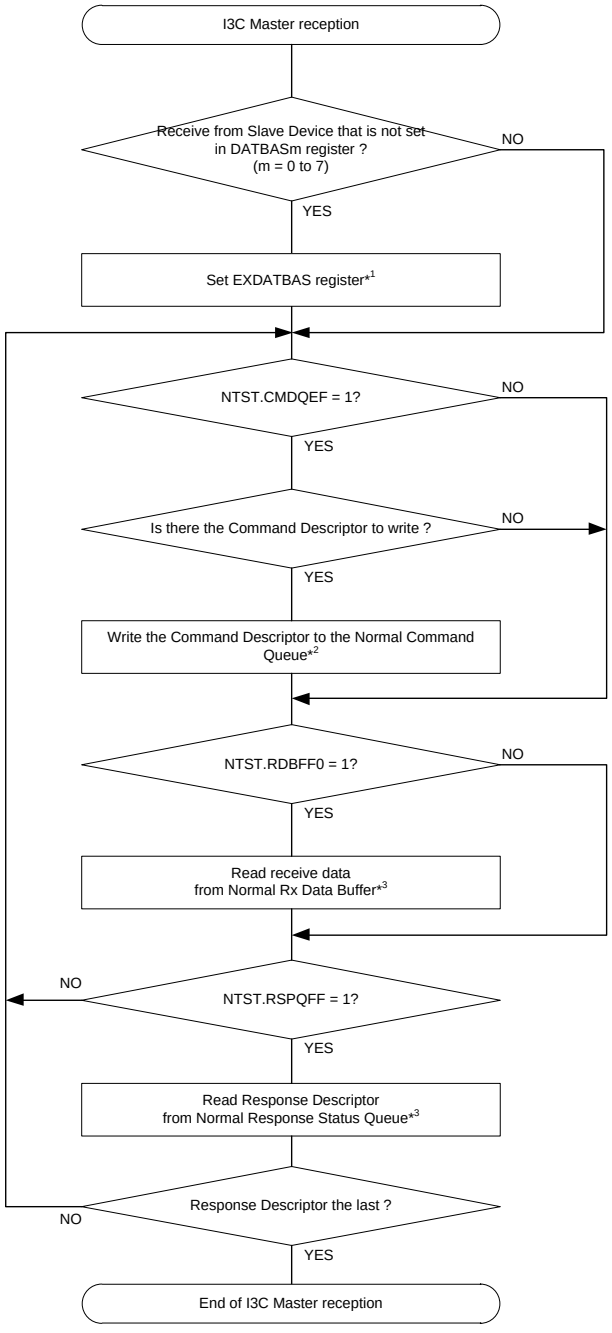
(3) I3C Master Transmission Flow (Normal FIFO Buffer Transfer)

Master transmission flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.



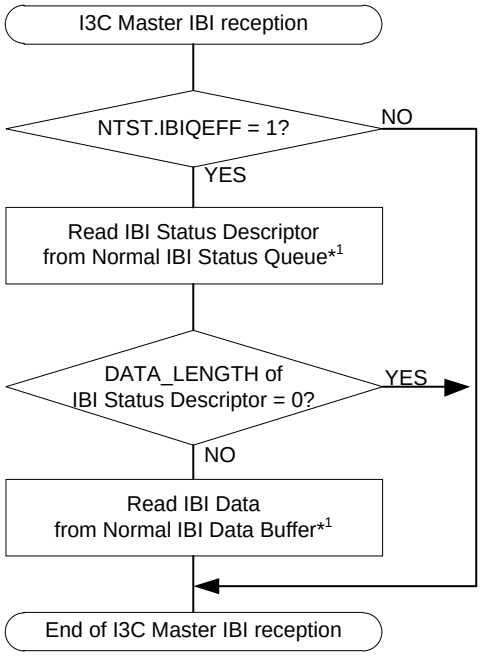
Note 2. In the case the register is write by away other than DTC, clear corresponding flags after write access.

Note 3. In the case the register is read by away other than DTC, clear corresponding flags after read access.

Figure 7.8-123 Example of I3C Master Transmission Flowchart (Normal FIFO Buffer Transfer)

(4) I3C Master Reception Flow (Normal FIFO Buffer Transfer)

Master reception flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).



Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.

Note 2. In the case the register is write by away other than DTC, clear corresponding flags after write access.

Note 3. In the case the register is read by away other than DTC, clear corresponding flags after read access.

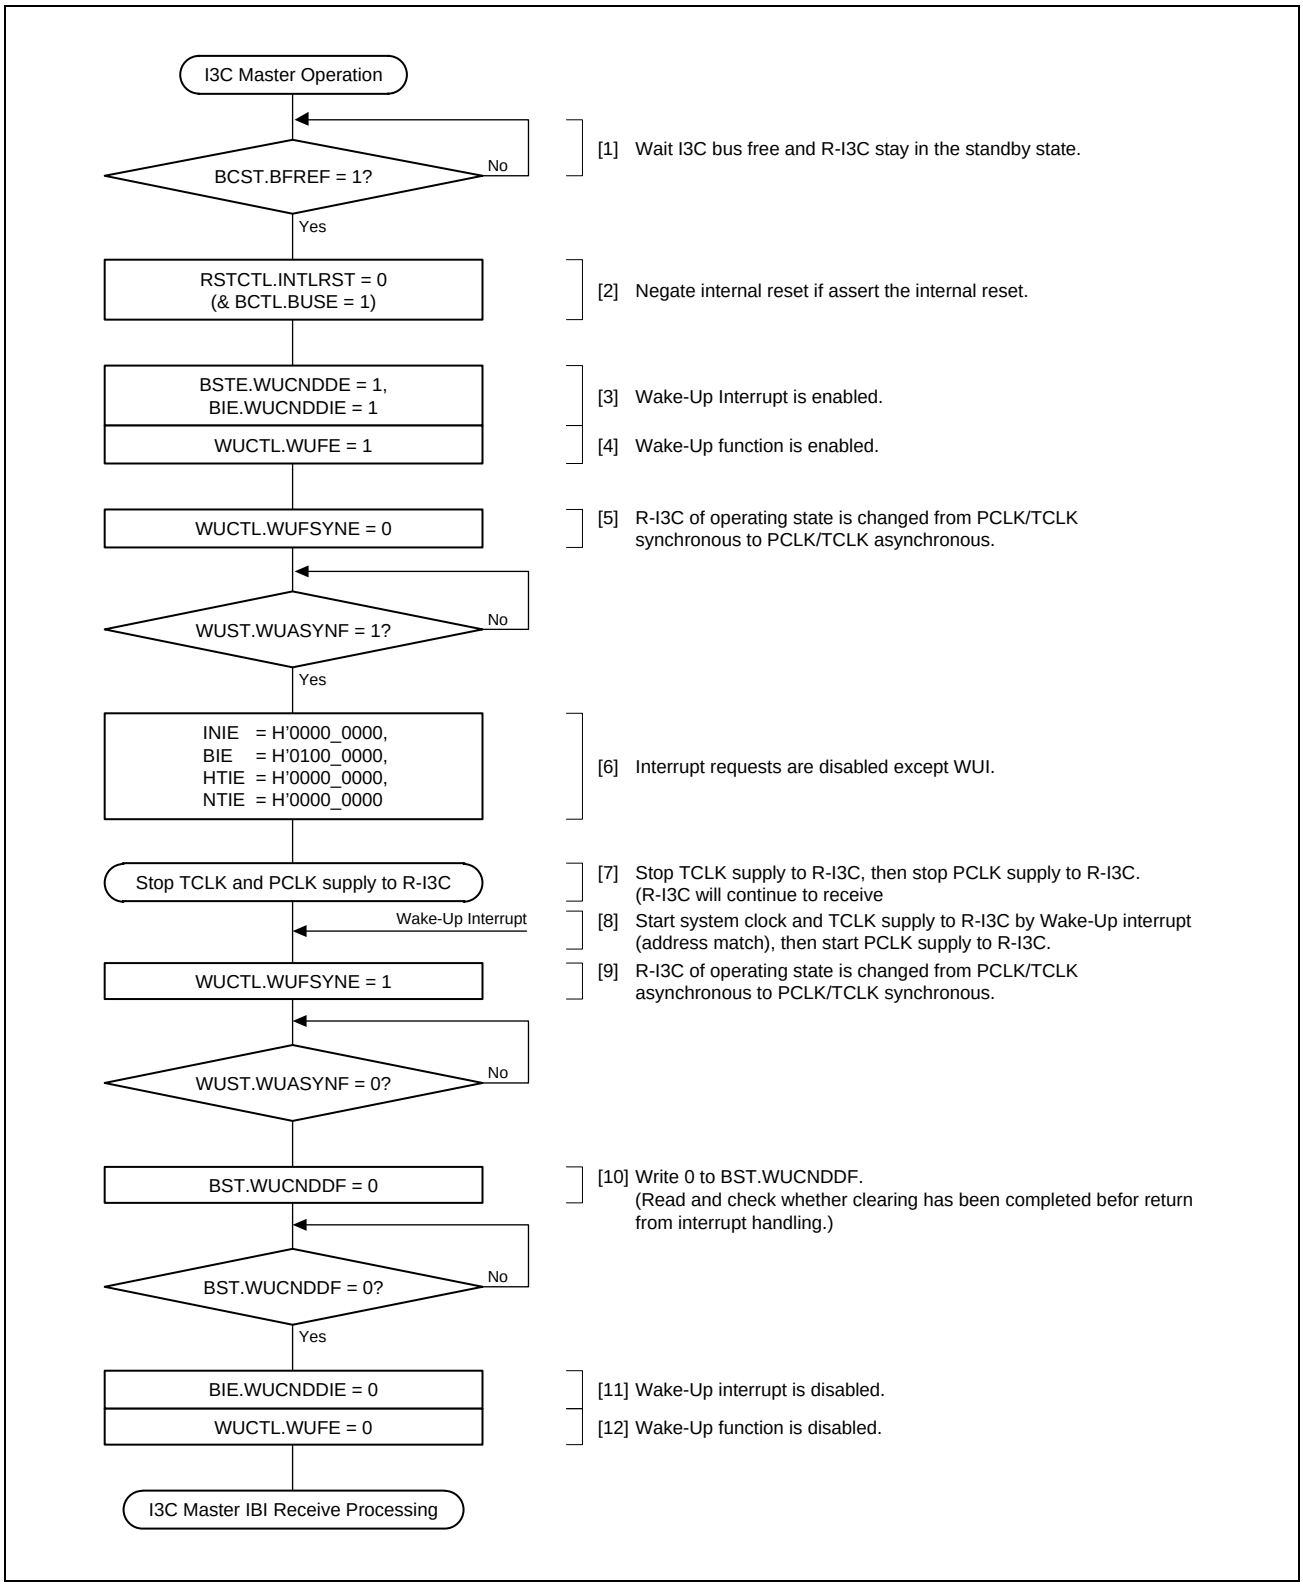
Figure 7.8-124 Example of I3C Master Reception Flowchart (Normal FIFO Buffer Transfer)

(5) I3C Master IBI Reception Flow

Note 1. In the case the register is read by a way other than DTC, clear corresponding flags after read access.

Figure 7.8-125 Example of I3C Master IBI Reception Flowchart

(6) I3C Master Wake-Up Flow



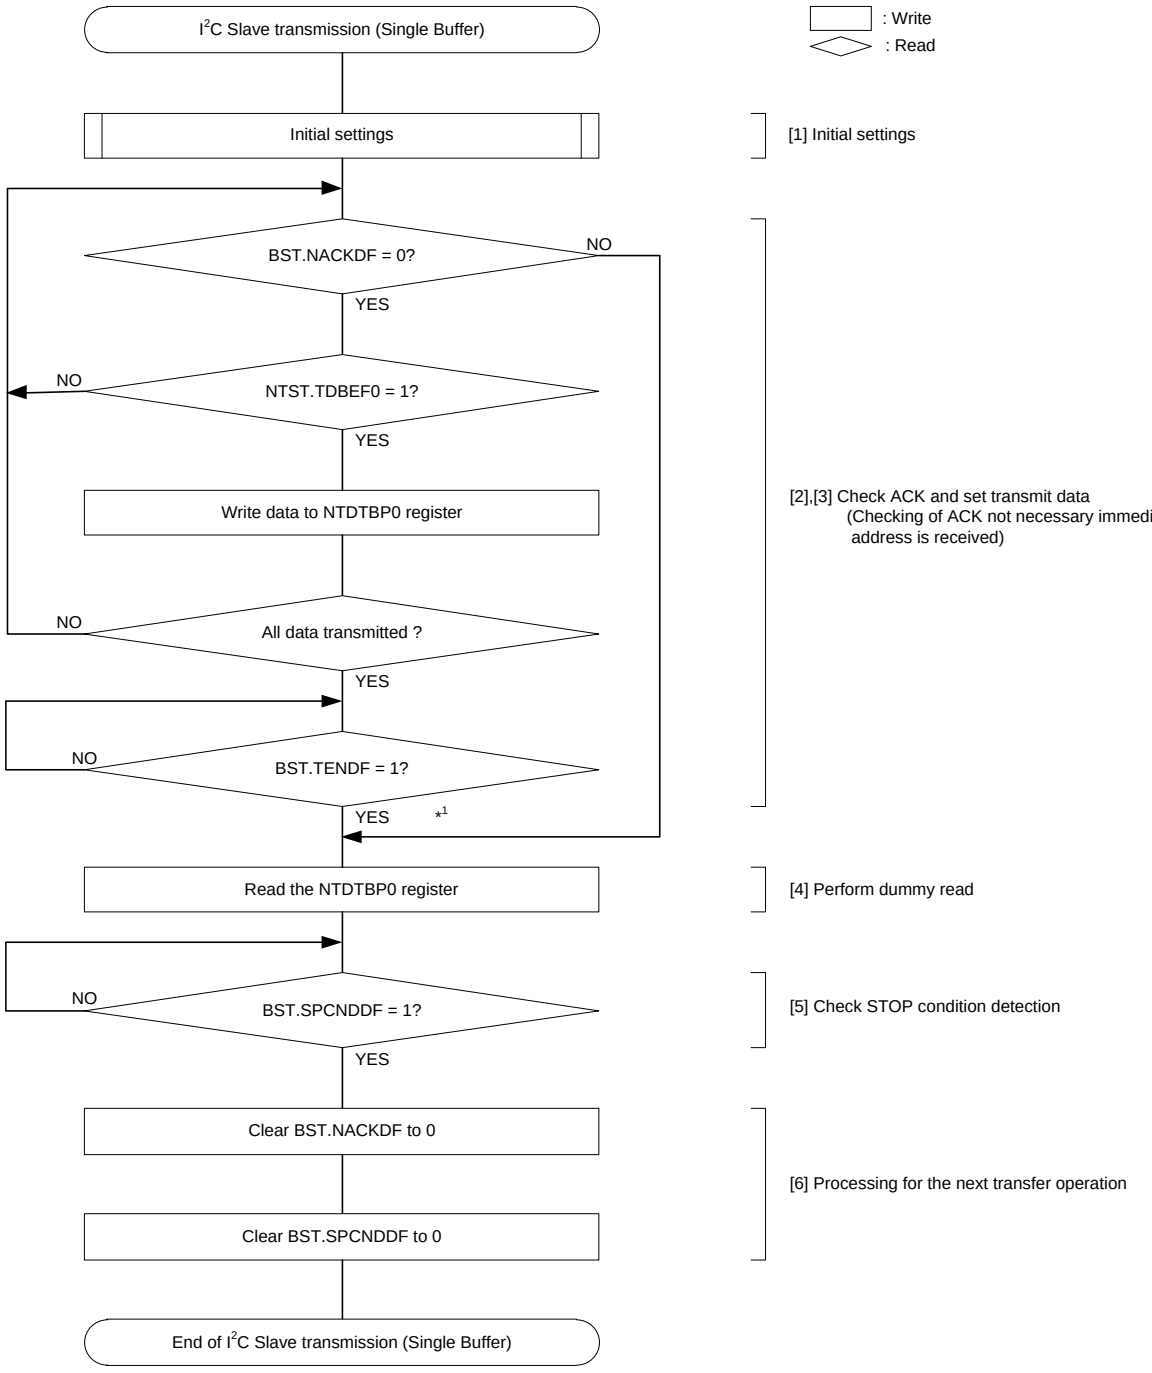


Figure 7.8-126 Use Case of I3C Master Wake-Up
(Wake-Up Recovery by a Wake-Up Interrupt Triggered by the Match of the Slave Address)

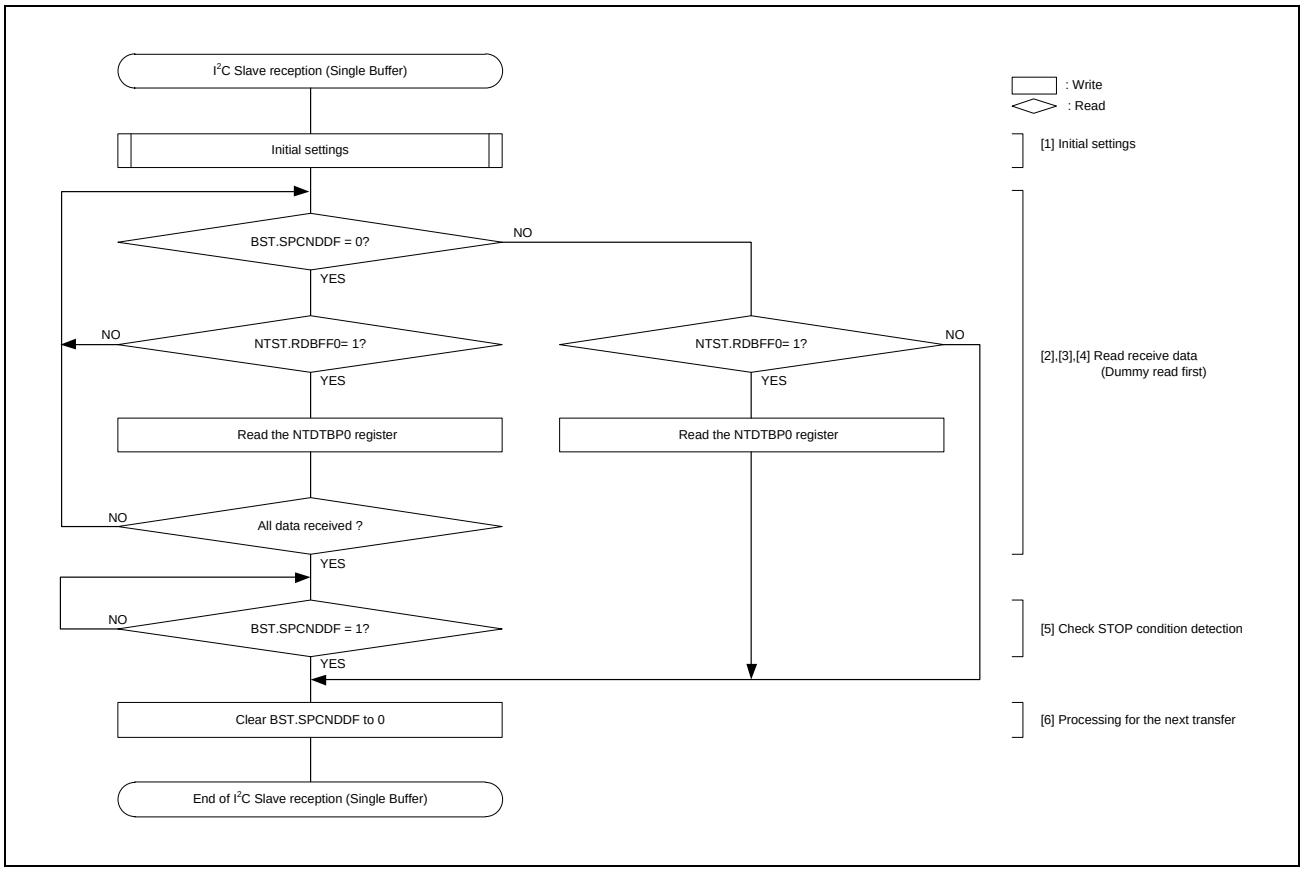
7.8.3.3.4 Slave Mode Communication Flow

(1) I²C Slave Transmission Flow (Single Buffer Transfer)

Note 1. Normally, Master responds to the last byte with NACK, so when BST.TENDF=1, BST.NACKDF will also 1.
If BST.NACKDF is 0 after BST.TENDF=1, the master may be hung up, so reset I3C with RSTCTL.INTLRST.

Figure 7.8-127 Example of I²C Slave Transmission Flowchart (Single Buffer Transfer)

(2) I²C Slave Reception Flow (Single Buffer Transfer)



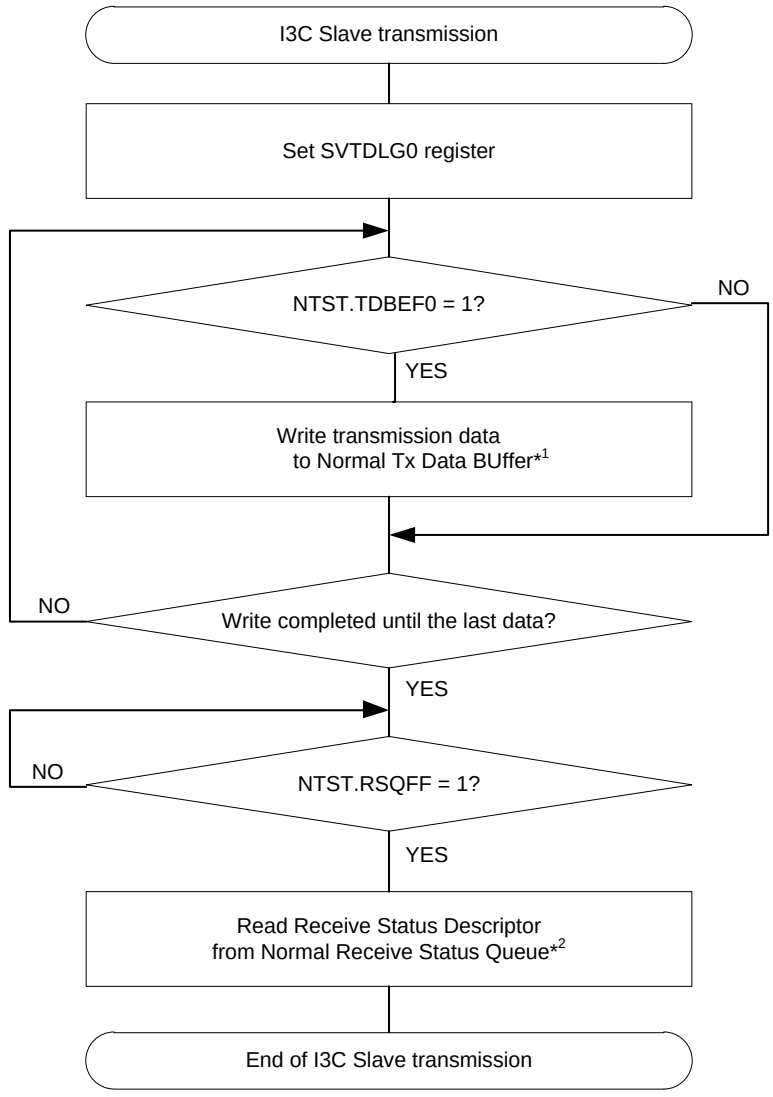


Figure 7.8-128 Example of I²C Slave Reception Flowchart (Single Buffer Transfer)

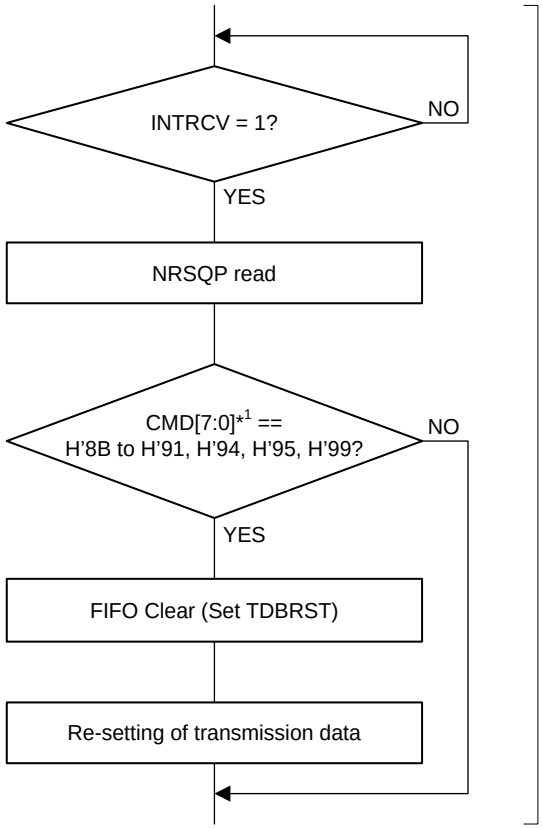
(3) I3C Slave Transmission Flow (Normal FIFO Buffer Transfer)

Slave Transmission Flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

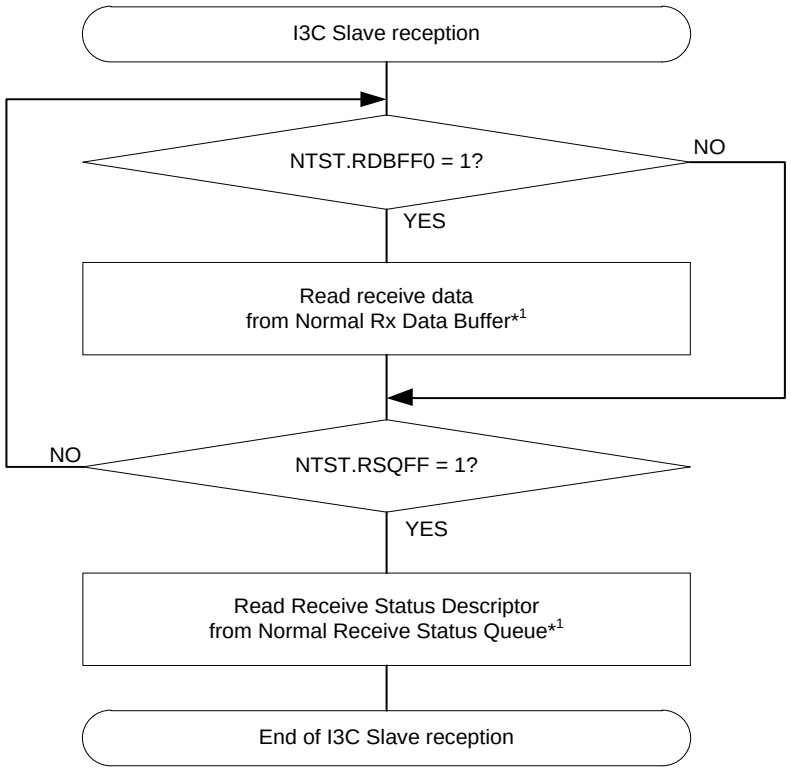


Note 1. In the case the register is write by away other than DTC, clear corresponding flags after write access.

Note 2. In the case the register is read by away other than DTC, clear corresponding flags after read access.

Figure 7.8-129 Example of I3C Slave Transmission Flowchart (Normal FIFO Buffer Transfer)

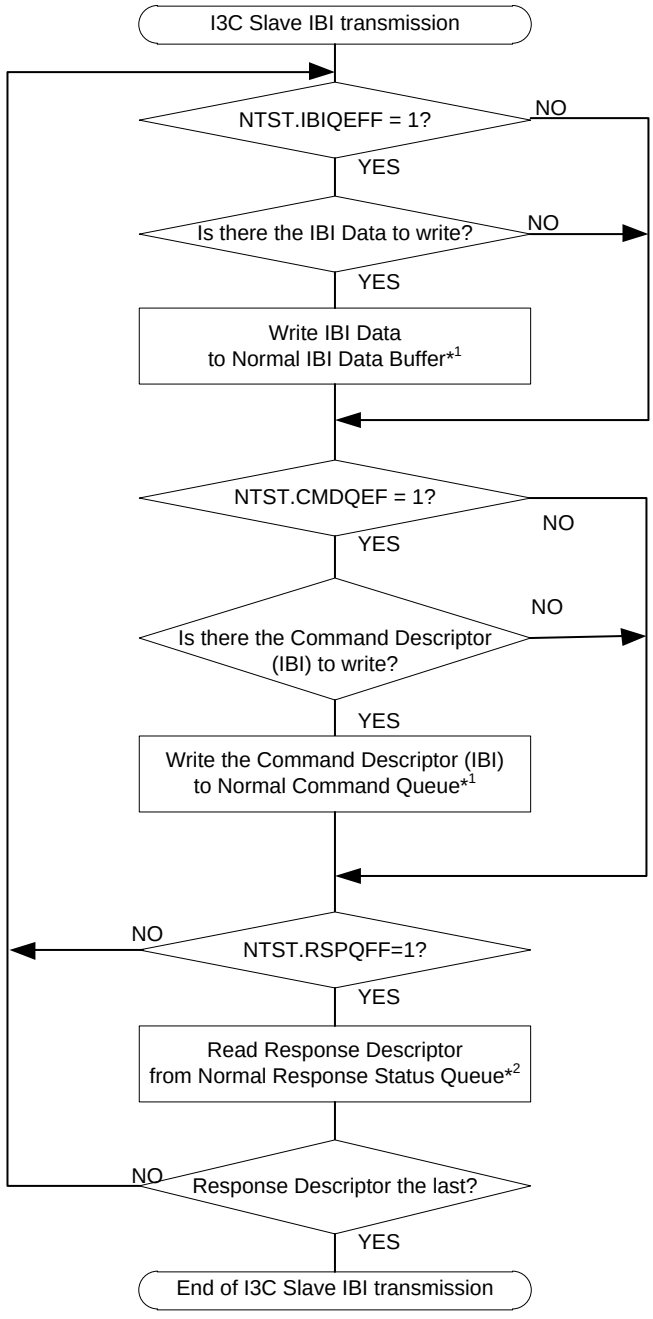
When using the I3C as an I3C slave, if I3C slave receives GET CCC while data exists by writing from the NTDTBP0 register to the transmission buffer, follow the flow below.



Note 1. CMD[7:0] is the bit field [23:16] of NRSQP (Receive Status Descriptor). GET CCC is when CMD[7:0] is H'8B to H'91, H'95, or H'99.

Figure 7.8-130 I3C Slave Receives GET CCC while Data Exists by Writing from the NTDTBP0 Register to the Transmission Buffer

(4) I3C Slave Reception Flow (Normal FIFO Buffer Transfer)



Slave Reception Flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

Note 1. In the case the register is read by away other than DTC, clear corresponding flags after read access.

Figure 7.8-131 Example of I3C Slave Reception Flowchart (Normal FIFO Buffer Transfer)

(5) I3C Slave IBI Transmission Flow

Note 1. In the case the register is write by away other than DTC, clear corresponding flags after write access.

Note 2. In the case the register is read by away other than DTC, clear corresponding flags after read access.

Figure 7.8-132 Example of I3C Slave IBI Transmission Flowchart

(6) I3C Slave Wake-Up Flow

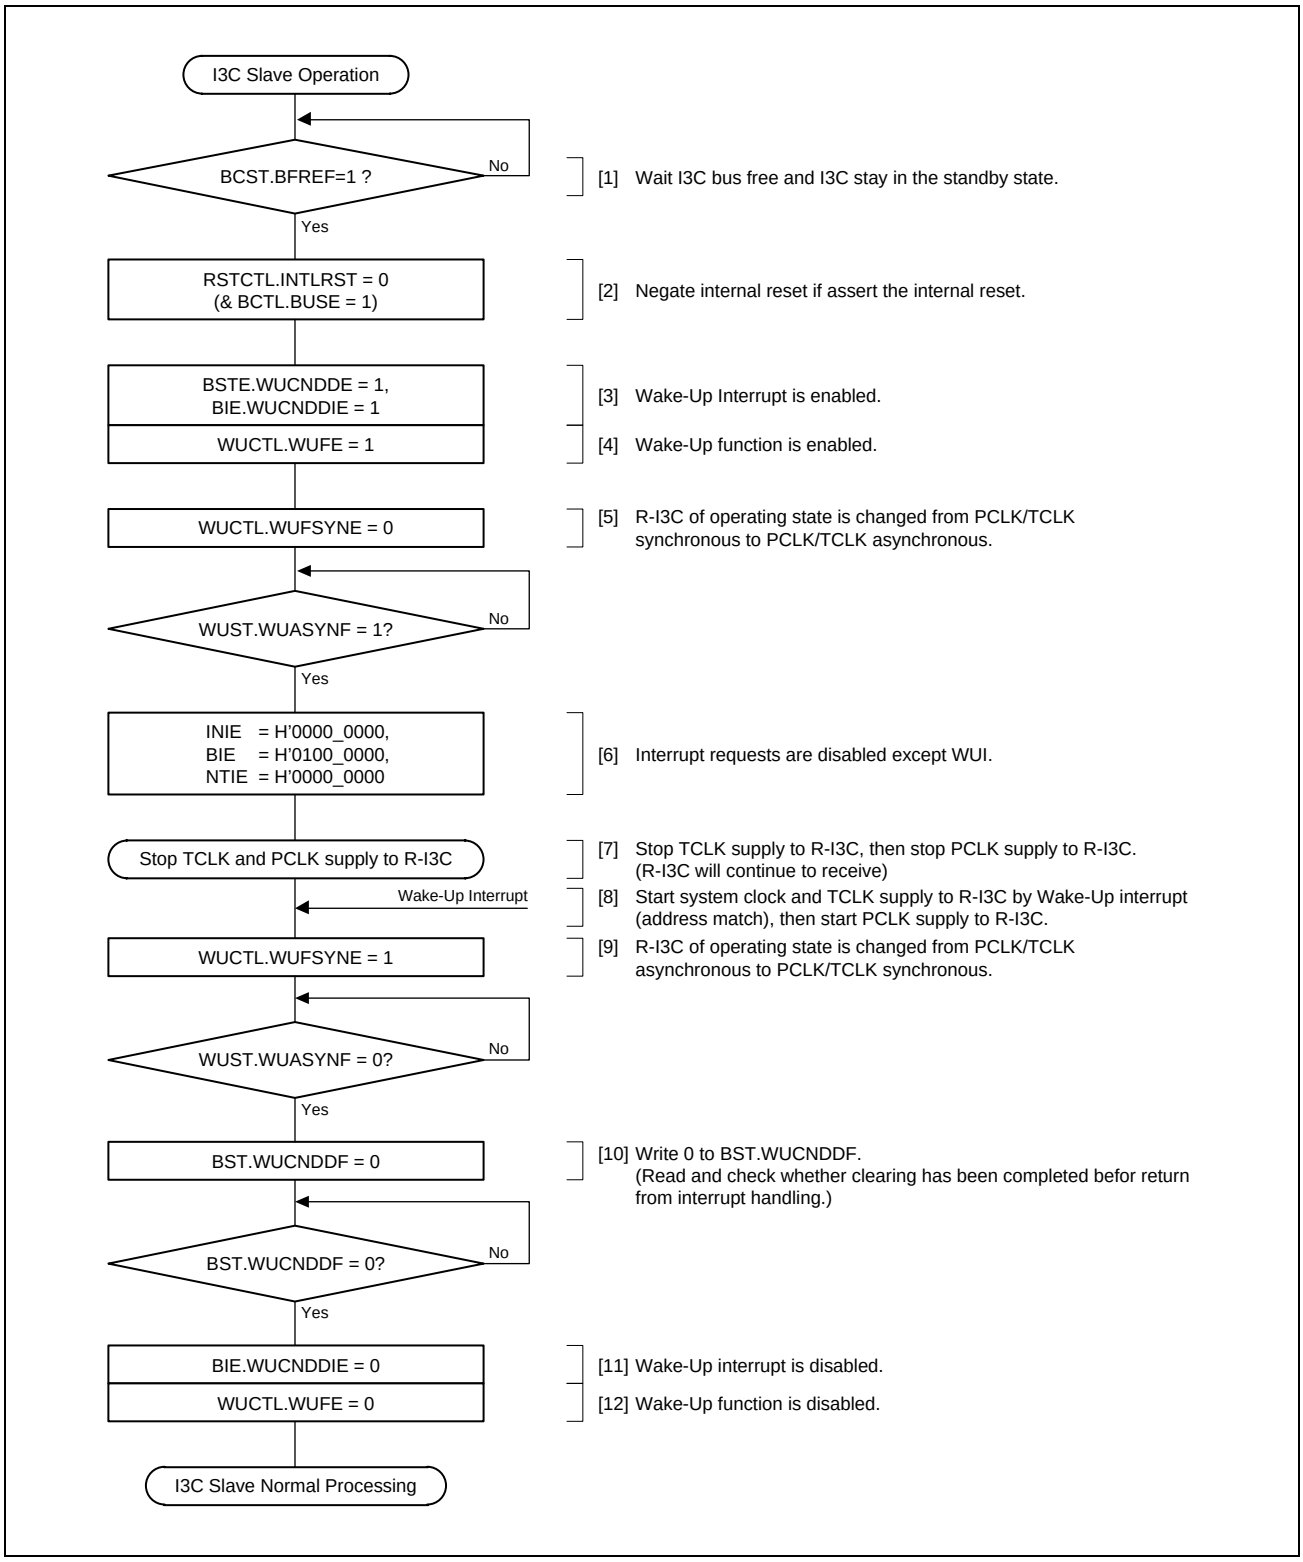

Figure 7.8-134 Use Case of I3C Slave Wake-Up
(Wake-Up Recovery by a Wake-Up Interrupt Triggered by the Match of the Slave Address)

7.8.4 Interrupt Sources

I3C can generate the following interrupt requests:

7.8.4.1 Overview

The I3C has the interrupt factors shown in **Table 7.8-17**.

The interrupt indicated by Possible in the DTC Activation column are capable of activating data transfer by the DTC.

Table 7.8-17 Interrupt Generation

Symbol	Interrupt Source	Interrupt Flag	Support			
			I^2C	I3CM	I3C2M	I3CS
INT_ri3c_resp_n	Normal response status buffer full	NTST.RSPQFF	—	✓	✓	✓

Note: ✓: Support
—: Not support

Note: I^2C: I^2C Master/Slave (Single Buffer)
I3CM: I3C Master
I3C2M: I3C Secondary Master
I3CS: I3C Slave

For I3C Protocol mode:

For details, refer to the detailed explanation of each flag bit.

- The INTCMD, INTTX0 and INTIBI (I3C Slave) interrupts are cleared under the following conditions.
  On completaion of the last write accsess by DMAC/DTC. Write 0 to this bit after 1 state is read by CPU.
- The INTRESP, INTIBI (I3C Master), INTRX0 and INTRCV interrupts are cleared under the following conditions.
  On completaion of the last read accsess by DMAC/DTC. Write 0 to this bit after 1 state is read by CPU.
- The INTCMD, INTTX0 and INTIBI (I3C Slave) interrupts are cleared when the number of empty buffers is less than the threshold corresponding to each flag.
- The INTRESP, INTIBI (I3C Master), INTRX0 and INTRCV interrupts are cleared when the number of buffer entries is less than the threshold corresponding to each flag.

7.8.6 Usage Notes

7.8.6.1 External Pull-up Resistors

The SCL and SDA pins of this LSI do not include internal pull-up resistors (Open-Drain, High-Keeper). When operating in I3C master mode, external pull-up resistors must be provided on the SCL and SDA lines.

SECTION 7 LOW-SPEED INTERFACE

7.9 CAN-FD Interface (CAN-FD)

NOTE

This LSI does not support the transmission DMA function for CAN-FD.
Related descriptions of the transmission DMA function in this section should be ignored.

7.9.1 Overview

The LSI has a 3-channel CAN-FD module (CAN-FD) that complies with ISO 11898-1 (2015) Standards. CAN-FD transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier is hereafter referred to as ID) and extended ID (29 bits). **Table 7.9-1** lists the specifications of the CAN-FD, **Figure 7.9-1** shows a block diagram of the CAN-FD, and **Table 7.9-2** lists the I/O pins.

Table 7.9-1 CAN-FD Specifications (1/2)

Parameter	Description
Number of channels	Three channels
Protocol	CAN-FD ISO 11898-1 (CD2015) compliant
Communication speed	• CAN-FD mode Nominal bit rate: Max. 1 Mbps Data bit rate: Max. 8 Mbps
Buffer	Total 288 buffers (when frame size is 76 bytes) • Individual buffers: 96 buffers (32 buffers × 3 channels) Transmit buffer: 32 buffers per channel Transmit queue: 4 queues per channel (shared with transmit buffer, up to 16 buffers allocatable) • Shared buffers: 192 buffers for all channels Receive buffers: Up to 48 RXMB Receive FIFO buffer: 8 FIFO Buffers Common FIFO buffer: Up to 9 FIFO Buffers individually configurable as RX FIFO/TX FIFO/ Gateway FIFO
Reception function	• Receives data frames and remote frames • Selects ID format (standard ID, extended ID, or both IDs) to be received • Sets interrupt enable/disable for each FIFO • Mirror function (reception of messages transmitted from the CAN node itself) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects receive message according to 384 receive rules • Sets the number of receive rules (0 to 256) for each channel • Acceptance filter processing: Sets ID and mask for each receive rule • DLC filter processing: Enables DLC filter check for each acceptance rule
Receive message transfer function	• Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer

Table 7.9-1 CAN-FD Specifications (2/2)

Parameter	Description
Transmission function	• Transmits data frames and remote frames • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer • Selects ID priority transmission or transmit buffer number priority transmission • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit message at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority
Transmit history function	Stores the history information of transmission-completed messages Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information
Gateway function	Transmits a received message automatically
Bus off recovery mode selection	Selects the method for returning from bus-off state. • ISO 11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel halt mode by program request • Transition to the error-active state by program request (forcible return from the bus-off state)
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock) • Defects error status transitions (error warning, error passive, bus-off entry, and bus-off recovery) • Reads the error counter • Monitors DLC errors
Interrupt source	11 interrupt sources • Global interrupts (2 sources) RX FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) CANm transmit interrupt (m = 0, 1, 2) – CANm transmit complete interrupt – CANm transmit abort interrupt – CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) – CANm transmit history interrupt – CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) CANm error interrupt 11 DMA requests • 8 for RX FIFO • 3 for the first common FIFO (1 source/channel)
CAN clock source	Selects the PCLKM/2 (40 MHz) or the PCLKCAN (Less than 80 MHz)
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Restricted operation mode • RAM test (read/write test) • Inter-channel communication test (CRC error test enabled)
Power down function	Module start stop function for each CAN node (Channel & Global Sleep Mode)
Bus traffic measurement	CAN bus traffic measurement of each Channel is possible

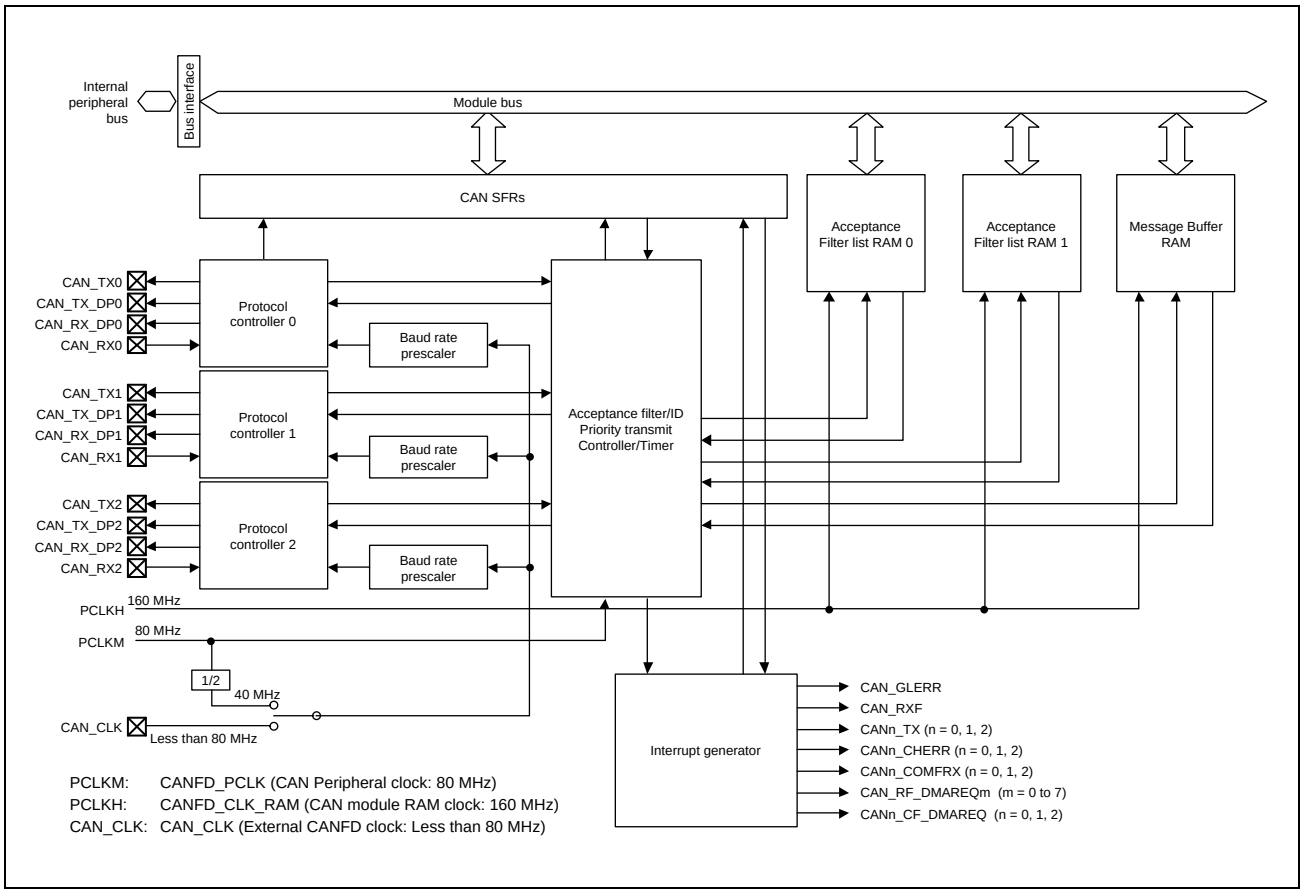

Figure 7.9-1 Block Diagram of CAN-FD

Table 7.9-2 lists the input/output pins of the CAN-FD module.

Table 7.9-2 Pin Configuration of CAN-FD

Channel	Pin Name	Signal Name in This Section	Input/Output	Functional Description
Common	CAN_CLK	PCLKCAN	Input	CAN input clock
0 to 2	CAN_RXn	CANRXn, CRX	Input	CANn receive data input
	CAN_TXn	CANTXn, CTX	Output	CANn transmit data output
	CAN_RX_DPn	CANRXnP0	Output	CANn receive data phase output
	CAN_TX_DPn	CANTXnP0	Output	CANn transmit data phase output

Note: n = 0 to 2

Table 7.9-3 CAN-FD Interrupt Sources

Name	Interrupt Sources	Cortex-A55 Request	Cortex-M33 Request	DMAC Activation
CAN_RXF	RX FIFO interrupt (INTRCANGRECC)	Possible	Possible	Not possible
CAN_GLERR	Global error interrupt (INTRCANGERR)	Possible	Possible	Not possible
CANn_TX	Channel n TX interrupt (INTRCANnTRX)	Possible	Possible	Not possible
CANn_CHERR	Channel n CAN error interrupt (INTRCANnREC)	Possible	Possible	Not possible
CANn_COMFRX	Channel n Common RX FIFO or TXQ interrupt (INTCANnERR)	Possible	Possible	Not possible
CAN_RF_DMAREQm	RX FIFO m DMA request (RXF_DMAm)	Not possible	Not possible	Possible
CANn_CF_DMAREQ	Channel n First common FIFO DMA request (COM_DMAn)	Not possible	Not possible	Possible

Note: m = 0 to 7, n = 0 to 2

7.9.2 Register Descriptions

Table 7.9-4 shows the register configuration. The CAN-FD address space is offset from the base address. The base address of CAN-FD is as follows.

CAN-FD base address: H'0_100C_0000 (Overall Address Space)
CAN-FD base address: H'400C_0000 (Cortex-M33 Address Space Secure)
CAN-FD base address: H'500C_0000 (Cortex-M33 Address Space Non-Secure)

For all repetitive registers and bits, a lowercase index is used to indicate which slice is being referenced. If an index is being used, it is defined and described below the Register Table it is being used in.

There is one global index used across all the registers and bits that need it.

Table 7.9-4 Register Configurations (1/4)

Register Name	Symbol	Value After Reset	Offset Address N/A (after)	Access Size
Channel n Nominal Bit Rate Configuration Register (n = 0, 1, 2)*2	CFDCnNCFG	H'0000_0000	H'0000 + n × H'0010	8, 16, 32

Note 1. The RAM area is initialized after HW reset, refer **7.9.4.1.6 CAN Module Configuration after Hardware Reset**.

Note 2. Access prohibited for greater than n = 3 address space.

7.9.2.1 Channel n Nominal Bit Rate Configuration Register (CFDCnNCFG) (n = 0, 1, 2)

The CFDCnNCFG register is used to configure the transmission/reception nominal bit rate parameters of the channels. Do not write this register in CH_OPERATION or CH_SLEEP mode. Set this register in CH_RESET or CH_HALT mode.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0000 + H'10 × n

9 to 0	NBRP[9:0]	All 0	R/W	Nominal Bit Rate Prescaler Nominal bit rate prescaler division ratio setting

NBRP[9:0] bits (Nominal Bit Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

NSJW[6:0] bits (Nominal Bit Rate Resynchronization Jump Width Control)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

NTSEG1[7:0] bits (Nominal Bit Rate Time Segment 1 Control)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment. Configure a Tq value only between 2 and 256, inclusive. See **7.9.4.1.2 CAN Bit Timing** for more details.

NTSEG2[6:0] bits (Nominal Bit Rate Time Segment 2 Control)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. Configure a Tq value only between 2 and 128, inclusive.

7.9.2.2 Channel n Control Register (CFDCnCTR) (n = 0, 1, 2)

The CFDCnCTR register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0004 + H'10 × n

1, 0	CHMDC[1:0]	01	R/W	Mode Select 00: Channel Communication mode 01: Channel Reset mode 10: Channel Halt mode 11: Setting prohibited

CHMDC[1:0] bits (Mode Select)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in **7.9.3.3 Channel Modes**.

Setting CHMDC[1:0] bits to 11b has no effect. When the CAN-FD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDCnCTR.BOM settings.

If CPU write access to CFDCnCTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM[1:0] = 01b, or at the end of bus-off when CFDCnCTR.BOM[1:0] = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDCnCTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDCnCTR.CHMDC[1:0] value is 00b (Operation mode).

CSLPR bit (Channel Stop Mode)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel.

When this bit is 0, a request to exit Sleep mode is generated for the related CAN-FD channel.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Forcible Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDCnSTS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDCnCTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDCnCTR.BOM[1:0] is set to 00b.

Only write to this bit when the related CAN-FD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDCnERFL.BEF bits are both 1, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDCnERFL.EWF bits are both 1, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDCnERFL.EPF are both 1.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDCnERFL.BOEF bits are both 1, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDCnERFL.BORF bits are both 1, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDCnERFL.OVLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDCnERFL.BLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDCnERFL.ALF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1 and a transmission is successfully aborted from the transmit buffer, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1 and the CFDCnFDSTS.EOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1 and the CFDCnFDSTS.SOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1 and the CFDCnFDSTS.TDCVF bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BOM[1:0] bits (Bus-Off Recovery Mode Select)

The BOM[1:0] bits control the timing of the recovery from Bus-Off mode of the CAN-FD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CAN-FD channel is in CH_RESET mode.

ERRD bit (Error Display Mode Select)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDCnERFL).

If the ERRD bit is 0 and more than one errors occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until the error flag bits [14:8] are cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CTME bit (Communication Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

CTMS[1:0] bits (Communication Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CAN-FD channel is in CH_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

CRCT bit (CRC Error Test Enable)

The CRCT bit checks the internal CRC generator logic of the protocol controller.

This bit inverts the first bit (ID bit) of the CAN message data stream that is being received, so that the internal generated CRC result does not match the received CRC value of the frame. Refer to the bit stuffing rule when using this feature for the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDCnFDCRC.CRCREG (CAN-FD frames)

Some limitations exist when using this bit:

- It is not possible to use this feature with CAN nodes connected to the device externally, only with nodes connected to the internal CAN bus communication can be used
- One CAN node can send a reference message and the receiver node can invert one bit of the incoming bit stream

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing this limitation.

The CRC Error Test mode is enabled if the CRCT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1.

Do not write to the CRCT bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode Enable)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDCnCTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.3 Channel n Status Register (CFDCnSTS) (n = 0, 1, 2)

The CFDCnSTS register shows the mode, error, and transmission/reception status of the related channel together with its reception and transmission error count values.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0008 + H'10 × n

Bit	Bit Name	Initial Value	R/W	Description
0	CRSTSTS	1	R	Channel Reset Status Flag 0: Not in Channel Reset mode 1: In Channel Reset mode

CRSTSTS bit (Channel Reset Status Flag)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

CHLTSTS bit (Channel Halt Status Flag)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

CSLPSTS bit (Channel Stop Status Flag)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CAN-FD channel enters Sleep mode, and is cleared automatically when the related CAN-FD channel exits Sleep mode.

EPSTS bit (Error Passive Status Flag)

The EPSTS bit indicates whether the related CAN-FD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of H’7F.

This bit is cleared automatically when the related CAN-FD channel exits the error passive state or enters Reset mode.

BOSTS bit (Bus-Off Status Flag)

The BOSTS bit indicates whether the related CAN-FD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds H’FF and the related CAN-FD channel is in the bus-off state (CAN Transmission Error Count Register > H’FF).

This bit is cleared automatically when the related CAN-FD channel exits bus-off state.

TRMSTS bit (Transmit Status Flag)

The TRMSTS bit indicates whether the related CAN-FD channel is transmitting a message.

This bit is set automatically when the related CAN-FD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in the bus-idle state or starts operating as a receiver node.

RECSTS bit (Receive Status Flag)

The RECSTS bit indicates whether the related CAN-FD channel is receiving a message.

This bit is set automatically when the related CAN-FD channel is operating as a receiver node.

This bit is cleared automatically when the related CAN-FD channel is in the bus-idle state or starts operating as a transmitter node.

COMSTS bit (Communication Status Flag)

The COMSTS bit indicates whether the related CAN-FD channel is ready for communication.

This bit is set automatically when the related CAN-FD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

Note: This bit is 1 during bus-off state.

ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessive for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CAN-FD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0 to it. This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CAN-FD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CAN-FD module enters GL_RESET or the CAN-FD channel is in CH_RESET mode.

TEC[7:0] bits (Transmission Error Count)

The TEC[7:0] bits increment or decrement the counter value according to error status of the CAN-FD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CAN-FD channel is in CH_HALT mode.

These bits are cleared automatically when CAN-FD module is in GL_RESET or CAN-FD channel is in CH_RESET mode.

7.9.2.4 Channel n Error Flag Register (CFDCnERFL) (n = 0, 1, 2)

The CFDCnERFL register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) for a description of error occurrence conditions.

Only write to this register when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'000C + H'10 × n

Note 1. To clear each flag of this register, software must write 0 to the corresponding bit. These flags cannot be set to 1 by software.

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds H’5F.

The setting of this bit only occurs when the TEC or REC initially exceeds H’5F. Therefore, if the TEC or REC remains > H’5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below H’60 and either TEC or REC crosses over again from a value H’5F to a value > H’5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds H’7F. Therefore, if the TEC or REC remains > H’7F and the bit is cleared by software, it is not set again until both the TEC and REC go below H’80 and either TEC or REC crosses over again from a value ≤ H’7F to a value > H’7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDCnCTR.BOM[1:0] is 00b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs
- When CFDCnCTR.BOM[1:0] is 10b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs
- When CFDCnCTR.BOM[1:0] is 11b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDCnCTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDCnCTR.BOM[1:0] is 01b
- When CFDCnCTR.BOM[1:0] is 11b and a halt request is asserted before the CAN channel reaches the end of the bus- off state.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration-lost condition.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

The bit is set automatically when an arbitration-lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SERR bit (Stuff Error Flag)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

FERR bit (Form Error Flag)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

AERR bit (Acknowledge Error Flag)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

CERR bit (CRC Error Flag)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

B1ERR bit (Recessive Bit Error Flag)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000001b.

B0ERR bit (Dominant Bit Error Flag)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

ADERR bit (Acknowledge Delimiter Error Flag)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0 to it, and can only be set by CAN-FD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 0000000b.

CRCREG[14:0] bits (CRC Calculation Data (CRC length: 15 bits))

The CRCREG[14:0] bits read the calculated CRC value when CFDCnCTR.CTME bit is 1 for the channel.

If CFDCnCTR.CTME bit is 0, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the CAN-FD channel logic when the CTME bit is enabled.

The CFDCnERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.5 Channel n Data Bit Rate Configuration Register (CFDCnDCFG) (n = 0, 1, 2)

The CFDCnDCFG register configures the transmission/reception data bit rate parameters of the channels.

Do not write to this register in CH_OPERATION or CH_SLEEP mode. Only write to this register in CH_RESET or CH_HALT mode.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1400 + H'20 × n

DBRP[7:0] bits (Data Bit Rate Prescaler Division Ratio Setting)

The DBRP[7:0] bits define the peripheral bus clock periods contained in a time quantum.

DTSEG1[4:0] bits (Data Bit Rate Time Segment 1 Control)

The DTSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 time quanta can be set.

The DTSEG1[4:0] bits are also used to set the propagation segment.

Do not write any other value to these bits. See **7.9.4.1.2 CAN Bit Timing** for more details.

DTSEG2[3:0] bits (Data Bit Rate Time Segment 2 Control)

The DTSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A value from 2 to 16 time quanta can be set.

Do not write any other value to these bits.

DSJW[3:0] bits (Data Bit Rate Resynchronization Jump Width Control)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

7.9.2.6 Channel n CAN-FD Configuration Register (CFDCnFDCFG) (n = 0, 1, 2)

The CFDCnFDCFG register configures which communication direction (transmitter/receiver) errors are counted.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1404 + H'20 × n

EOCCFG[2:0] bits (Error Occurrence Counter Configuration)

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transmitter Delay Compensation Offset Configuration)

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN- FD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

TDCE bit (Transceiver Delay Compensation Enable)

The TDCE bit enables the transceiver delay compensation for the CAN-FD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

ESIC bit (Error State Indication Configuration)

Bus controllers that are used as CAN-to-CAN gateway support that in every forwarded CAN-FD message. The ESI flag does not change to reflect the status of the gateway, bridge, or router but instead the flag is sent as it was in the original message.

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTSn.CFESI or CFDTMFDCTRn.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDCnFDCFG.TDCOC setting.

If CFDCnFDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDCnFDCFG.TDCO. See **7.9.4.1.5 Transmitter Delay Compensation** for details on how CFDCnFDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GWEN bit (CAN2.0, CAN-FD Multi-Gateway Enable)

When the GWEN bit is enabled, a multi gateway is enabled. Message received on one node can be routed to another node using the COM FIFO when they are configured as gateway FIFO (CFDCFCCn.CFM[1:0] = 10b). Furthermore, when TX Queue is set as Gateway mode, the message received on one node can be stored in TX Queue and can be sent to another node.

The FDF and BRS bits of the routed message can be changed by the configuration value of the CFDCnFDCFG.GWFDF and CFDCnFDCFG.GWBRS bits. By this, the transmitted value of these bits can be replaced.

[Example]

CFDCnFDCFG.GWEN = 1 on channel y
CFDCnFDCFG.GWFDF = 1

If a Classical CAN frame is received on channel x and routed to a gateway FIFO or TX Queue of channel y, then this CAN frame is sent on channel y as a CAN-FD frame because of the CFDCnFDCFG.GWFDF bit.

Table 7.9-5 shows how the message information is changed depending on the received and configured data.

Table 7.9-5 Modified Message Information by Received and Configured Data

Routed CAN Frame	Routed Received DLC	CAN BRS Bit	Configured CFDCnFDCFG.GWFDF Bit	Gateway Message DLC	Gateway Message BRS Bit	Gateway Message Frame Type
CAN2.0	≤ 8	N/A	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN2.0	> 8	N/A	1	= 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN-FD	≤ 8	None	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN-FD	> 8	None	1	> 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN2.0	≤ 8	N/A	0	≤ 8	N/A	CAN2.0
CAN2.0	> 8	N/A	0	> 8	N/A	CAN2.0
CAN-FD	≤ 8	None	0	≤ 8	N/A	CAN2.0
CAN-FD	> 8	None	0	= 8	N/A	CAN2.0

Note: This gateway is limited to an 8-byte data payload for different frame type. If routing and target frame type is the same, the data length code (DLC) value remains the same. If the source frame is a CAN-FD with more than 8 data bytes. Only the first 8 bytes of data perform gateway transmission.

Note: Transmission buffers other than the gateway FIFO are not affected by this feature.

Do not route remote frames through the gateway when CFDCnFDCFG.GWEN is set.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

GWFDF bit (Gateway FDF Configuration Bit)

When the GWEN bit is set to 1, the FDF bit of the transmitting gateway frame is replaced by the value of the GWFDF bit.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CAN-FD module is in CH_RESET mode.

GWBRS bit (Gateway BRS Configuration Bit)

When the GWEN bit is set to 1, the BRS bit of the transmitting gateway frame is replaced by the value of CFDCnFDCFG.GWBRS.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode.

7.9.2.7 Channel n CAN-FD Control Register (CFDCnFDCTR) (n = 0, 1, 2)

The CFDCnFDCTR register (n = 0, 1, 2) controls the error and successful occurrence counters.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1408 + H'20 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	H'00	W	Reserved These bits are read as 0. The write value should be always 0.
23 to 2	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
1	SOCCLR	0	R/W	Successful Occurrence Counter Clear 0: No successful occurrence counter clear 1: Clear successful occurrence counter
0	EOCCLR	0	R/W	Error Occurrence Counter Clear 0: No error occurrence counter clear 1: Clear error occurrence counter

EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CAN-FD logic and when the related CAN-FD channel is in CH_RESET mode.

SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CAN-FD logic and when the related CAN-FD channel is in CH_RESET mode.

7.9.2.8 Channel n CAN-FD Status Register (CFDCnFDSTS) (n = 0, 1, 2)

The CFDCnFDSTS register (n = 0, 1, 2) indicates the transceiver compensation delay result and its related FIFO message lost status.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'140C + H'20 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SOC[7:0]	H'00	R	Successful Occurrence Counter These bits show the successful occurrence counter value.
23 to 16	EOC[7:0]	H'00	R	Error Occurrence Counter These bits show the error occurrence counter value.
15	TDCVF	0	R/W	Transceiver Delay Compensation Violation Flag 0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred
14	—	0	R/W	Reserved This bit is read as 0. The write value should be always 0.
13, 12	—	00	R	Reserved These bits are read as 0.
11, 10	—	00	R/W	Reserved These bits are read as 0. The write value should be always 0.
9	SOCO	0	R/W	Successful Occurrence Counter Overflow Flag 0: Successful occurrence counter has not overflowed 1: Successful occurrence counter has overflowed
8	EOCO	0	R/W	Error Occurrence Counter Overflow Flag 0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed
7 to 0	TDCR[7:0]	H'00	R	Transceiver Delay Compensation Result

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDCnFDCFG.TDCOC configuration and the offset value in CFDCnFDCFG.TDCO. See **7.9.4.1.5 Transmitter Delay Compensation** for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between the FDF bit and the RES bit when CFDCnFDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDCnFDCFG.TDCE = 1).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

EOCO bit (Error Occurrence Counter Overflow Flag)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDCnFDSTS.EOC is H'FF and a CAN bus error is detected based on the configuration defined in CFDCnFDCFG.EOCCFG.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

SOCO bit (Successful Occurrence Counter Overflow Flag)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDCnFDSTS.SOC is H'FF and a successful message reception or successful message transmission occurs.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CAN-FD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDCnFDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDCnFDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CAN-FD module logic. These bits are cleared by writing 1 to CFDCnFDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDCnFDCFG.EOCCFG bits. When the counter reaches the value of H'FF, the update stops.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SOC[7:0] bits (Successful Occurrence Counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CAN-FD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of H’FF, the update stops. In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1 to CFDCnFDCTR.SOCCLR.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.9 Channel n CAN-FD CRC Register (CFDCnFDCRC) (n = 0, 1, 2)

The CFDCnFDCRC register (n = 0, 1, 2) holds the CRC value calculated for the CAN-FD frame.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1410 + H'20 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	SCNT[3:0]				—	—	—	CRCREG[20:16]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRCREG[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
27 to 24	SCNT[3:0]	H'0	R	Stuff Bit Count These bits shows the stuff bit count (mod 8) for the CAN-FD frame.
23 to 21	—	000	R/W	Reserved These bits are read as 0. The write value should be always 0.
20 to 0	CRCREG [20:0]	All 0	R	CRC Register Value These bits show the CRC value calculated for the CAN-FD frame.

CRCREG[20:0] bits (CRC Register Value)

The CRCREG[20:0] bits contain the CRC value calculated by the CAN-FD channel logic when the CFDCnCTR.CTME bit is enabled.

The CFDCnFDCRC.CRCREG value is updated in the first bit of the CRC field of the CAN-FD frame (reception and transmission).

When the CFDCnCTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff Bit Count)

The SCNT[3:0] bits contain the stuff count value of the CAN-FD frame. These bits indicate the number of inserted stuff bits (modulo 8, Gray-coded) for a CAN-FD frame when the CFDCnCTR.CTME bit is enabled in CFDCnFDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDCnCTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CAN-FD frame (reception and transmission).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.10 Global IP Version Register (CFDGIPV)

The CFDGIPV register shows the release version of the CAN-FD module.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0080

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	PSI[13:0]

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	00	R/W	Reserved These bits are read as 0. The write value should be always 0.
29 to 16	PSI[13:0]	10 0001 0010 0100	R	Parameter Status Information These bits show the IP configuration.
15 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
9, 8	IPT[1:0]	0*1	R	IP Type These bits show the IP type used in the product. 00: CAN IP 01: CAN-FD IP 1x: Reserved
7 to 0	IPV[7:0]	H'43	R	IP Version These bits show the main release number.

Bits	Description
[29:27]	Number of channel (100b: 4 channels*2)
[26:24]	Number of TXMB (001b: 32/channel)
[23:21]	Number of AFL entry (001b: 128/channel)
[20:17]	Number of pool buffer (0010b: 64/channel)
[16]	Same ID overwrite function of TXQ (0b: Support)

Note 1. The value depends on product package type.

Note 2. The value is not for supported channel number, but for configuration parameter.

7.9.2.11 Global Configuration Register (CFDGCFG)

The CFDGCFG register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of all CAN channels. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0084

Bit	Bit Name	Initial Value	R/W	Description
2	DRE	0	R/W	DLC Replacement Enable 0: DLC replacement disabled 1: DLC replacement enabled
1	DCE	0	R/W	DLC Check Enable 0: DLC check disabled 1: DLC check enabled
0	TPRI	0	R/W	Transmission Priority 0: ID priority 1: Message buffer number priority

TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CAN-FD stores the configured value (CFDGAFLP0n.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects the clock source for CAN communication.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

CMPOC bit (CAN-FD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCn.RFPLS, and CFDCFCCn.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CAN-FD communication is used.

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

TSBTCS[2:0] bits (Timestamp Bit Time Channel Select)

The TSBTCS[2:0] bits allow the selection of the bit time clock of a particular channel for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are H’0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

7.9.2.12 Global Control Register (CFDGCTR)

The CFDGCTR register controls the global mode of the CAN-FD module and the timestamp function. The register also enables and disables the global error interrupts.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0088

8	DEIE	0	R/W	DLC Check Interrupt Enable 0: DLC check interrupt disabled 1: DLC check interrupt enabled
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.

Bit	Bit Name	Initial Value	R/W	Description
2	GSLPR	1	R/W	Global Sleep Request 0: Global sleep request disabled 1: Global sleep request enabled
1, 0	GMDC[1:0]	01	R/W	Global Mode Control 00: Global operation mode request 01: Global reset mode request 10: Global halt mode request 11: Keep current value

GMDC[1:0] bits (Global Mode Control)

The GMDC[1:0] bits can be used to configure the modes for the CAN-FD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CAN-FD module is in Reset mode, the CAN-FD module transits to Global Sleep mode. Additionally, if CFDGCTR.GSLPR is 1 when the CAN-FD module is in Reset Mode, then the CAN-FD module transits to Global Sleep Mode.

Setting the GMDC[1:0] bits to 11b has no effect. Mode transition is described in detail in **7.9.3.2 Global Modes**.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CAN-FD module including all CAN channels. Channel sleep request is set automatically for all channels.

Only write to this bit when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

DEIE bit (DLC Check Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

MEIE bit (Message Lost Error Interrupt Enable)

When the MEIE bit is 1, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLEIE bit (TX History List Entry Lost Interrupt Enable)

When the THLEIE bit is 1, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CMPOFIE bit (CAN-FD Message Payload Overflow Flag Interrupt Enable)

When the CMPOFIE bit is 1, an interrupt is generated when a CAN-FD message payload overflow condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

QOWEIE bit (TXQ Message Overwrite Error Interrupt Enable)

When the QOWEIE bit is 1, an interrupt is generated when a TXQ message overwrite condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

QMEIE bit (TXQ Message Lost Error Interrupt Enable)

When the QMEIE bit is 1, an interrupt is generated when a TXQ message lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

MOWEIE bit (GW FIFO Message Overwrite Error Interrupt Enable)

When the MOWEIE bit is 1, an interrupt is generated in GW mode and a GW FIFO message overwrite condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

TSRST bit (Timestamp Reset)

When the TSRST bit is 1, the Global Timestamp Register is reset to H’0000.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the CAN-FD logic.

7.9.2.13 Global Status Register (CFDGSTS)

The CFDGSTS register indicates the global status of the CAN-FD module.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'008C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	GHLTSTS	0	R	Global Halt Status 0: Not in Halt mode 1: In Halt mode
0	GRSTSTS	1	R	Global Reset Status 0: Not in Reset mode 1: In Reset mode

GRSTSTS bit (Global Reset Status)

The GRSTSTS bit indicates the status of Global CAN-FD module Reset mode.

This bit is set automatically when the CAN-FD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CAN-FD module exits the GL_RESET mode.

GHLTSTS bit (Global Halt Status)

The GHLTSTS bit indicates the status of Global CAN-FD module Halt mode.

This bit is set automatically when the CAN-FD module enters GL_HALT mode.

This bit is cleared automatically when the CAN-FD module exits the GL_HALT mode.

GSLPSTS bit (Global Sleep Status)

The GSLPSTS bit indicates the status of Global CAN-FD module Sleep mode.

This bit is set automatically when the CAN-FD module enters GL_SLEEP mode.

This bit is cleared automatically when the CAN-FD module exits the GL_SLEEP mode.

GRAMINIT bit (Global RAM Initialization)

The GRAMINIT bit indicates the status of Global CAN-FD module RAM initialization.

This bit is set automatically when the CAN-FD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CAN-FD module completes RAM initialization.

7.9.2.14 Global Error Flag Register (CFDGERFL)

The CFDGERFL register indicates the detection of global errors.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0090

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	MES	0	R	Message Lost Error Status 0: Message lost error not detected 1: Message lost error detected

Bit	Bit Name	Initial Value	R/W	Description
0	DEF	0	R/W	DLC Error Flag 0: DLC error not detected 1: DLC error detected

DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when a DLC error is detected in a received frame.

The bit is cleared by writing 0 to it.

This bit is cleared automatically in GL_RESET mode.

MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CAN-FD module is in GL_RESET mode.

THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CAN-FD module is in GL_RESET mode.

CMPOF bit (CAN-FD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CAN-FD message payload overflow is detected on at least one channel.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0 to it. Writing 1 to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared automatically in GL_RESET mode.

QOWES bit (TXQ Message Overwrite Error Status)

The QOWES bit is set automatically when a TXQ message overwrite error is detected.

This bit is cleared automatically when all TXQ message overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

QMES bit (TXQ Message Lost Error Status)

The QMES bit is set automatically when a TXQ message lost error is detected.

This bit is cleared automatically when all TXQ message lost flags are cleared.

This bit is cleared automatically in GL_RESET mode.

MOWES bit (Message Overwrite Error Status)

The MOWES bit is set automatically when GW mode and COMFIFO message overwrite error is detected.

This bit is cleared automatically when all COMFIFO Message Overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

EEF0 bit (ECC Error Flag for Channel 0)

The EEF0 bit specifies whether an ECC error has occurred on Channel 0.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

EEF1 bit (ECC Error Flag for Channel 1)

The EEF1 bit specifies whether an ECC error has occurred on Channel 1.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

7.9.2.15 Global TX Interrupt Status Register 0 (CFDGTINTSTS0)

The CFDGTINTSTS0 indicates the detection of transmit specific interrupts.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1300

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	TSIF0	0	R	TX Successful Interrupt Flag Channel 0 0: Channel 0 TX Successful Interrupt flag not set 1: Channel 0 TX Successful Interrupt flag set

TSIFn bit (TX Successful Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.TSIFn bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAIFn bit (TX Abort Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.TAIFn bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIFn bit (TX Queue Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.TQIFn bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFTIFn bit (COM FIFO in TX/GW Mode Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.CFTIFn bit is set to 1 when the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIFn bit (TX History List Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.THIFn bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQOFIFn bit (TX Queue One Frame Transmission Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.TQOFIFn bit is set to 1 when the TX Queue One Frame Transmission Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue One Frame Transmission Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFOTIFn bit (COM FIFO One Frame Transmission Interrupt Flag Channel n (n = 0, 1, 2))

The CFDGTINTSTS0.CFOTIFn bit is set to 1 when the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is set (when the Interrupt is enabled).

This bit is cleared automatically:

- When the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

7.9.2.16 Global Timestamp Counter Register (CFDGTSC)

The CFDGTSC register stores the timestamp based on the selected configuration.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0094

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
15 to 0	TS[15:0]	All 0	R	Timestamp value

TS[15:0] bits (Timestamp value)

The proper incrementing of the Time Stamp counter cannot be guaranteed when moving to Halt state.

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS, and TSP.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

7.9.2.17 Global Acceptance Filter List Entry Control Register (CFDGAFLECTR)

The CFDGAFLECTR register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0098

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
8	AFLDAE	0	R/W	Acceptance Filter List Data Access Enable 0: Acceptance Filter List data access disabled 1: Acceptance Filter List data access enabled
7	—	0	R/W	Reserved This bit is read as 0. The write value should be always 0.
6 to 0	AFLPN[6:0]	All 0	R/W	Acceptance Filter List Page Number Select an Acceptance Filter List page

AFLPN[6:0] bits (Acceptance Filter List Page Number)

The AFLPN[6:0] bits select the page number to access the desired RAM area of the Acceptance Filter List. One Acceptance Filter List page consists of 16 Acceptance Filter List entries.

Read/write accesses to the Acceptance Filter List can only be performed through a fixed window.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode. Enter only the values between H'00 and H'0F, inclusive.

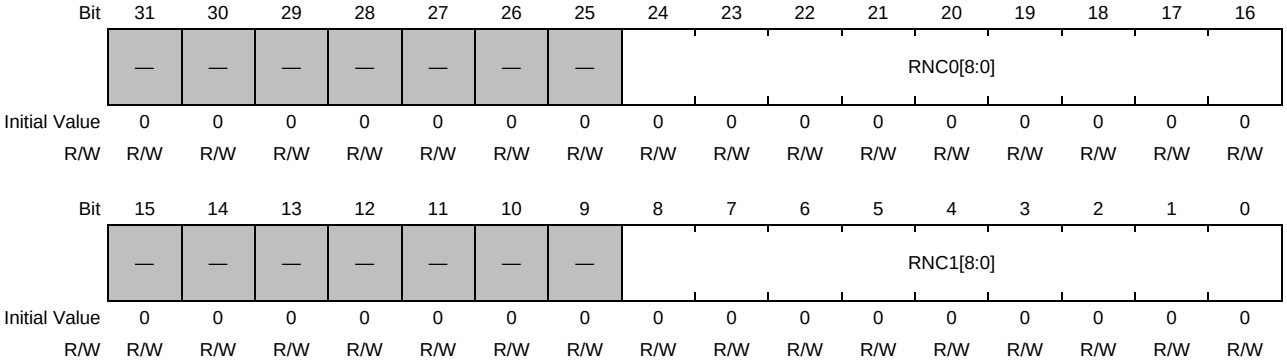
AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

Data can be read from the Acceptance Filter List independent of the status of this bit.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Set this bit to enable write access for the Acceptance Filter List.

7.9.2.18 Global Acceptance Filter List Configuration Register 0 (CFDGAFLCFG0)



The CFDGAFLCFG0 register is used to define the number of rules for entries in the Acceptance Filter List, applicable for channels 0 to 1.

The total number of available entries in the Acceptance Filter List is 256 for 2 CAN channels. However, the filters can be allocated flexibly to the different channels depending on requirements as long as both of the following conditions are satisfied:

- The maximum number of acceptance filter per channel is 256
- The total number of rules defined for all channels is not exceeding the number of available entries in the Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'009C

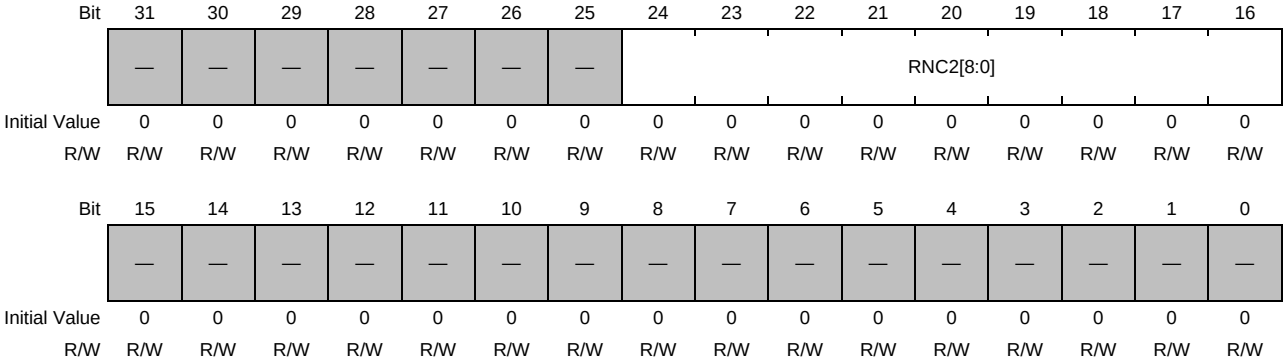
Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
24 to 16	RNC0[8:0]	All 0	R/W	Rule Number for Channel 0 Number of rules dedicated to channel 0
15 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
8 to 0	RNC1[8:0]	All 0	R/W	Rule Number for Channel 1 Number of rules dedicated to channel 1

RNCn[8:0] bits (Rule Number for Channel n (n = 0, 1))

The RNCn[8:0] bits define the number of rules in the Acceptance Filter List for channel n.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

7.9.2.19 Global Acceptance Filter List Configuration Register 1 (CFDGAFLCFG1)



The CFDGAFLCFG1 register is used to define the number of rules for entries in the Acceptance Filter List, applicable for channels 2.

The total number of available entries in the Acceptance Filter List is 256 for 1 CAN channels. However, the filters can be allocated flexibly to the different channels depending on requirements as long as both of the following conditions are satisfied:

- The maximum number of acceptance filter per channel is 256
- The total number of rules defined for all channels are not exceeding the number of available entries in the Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'00A0

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
24 to 16	RNC2[8:0]	All 0	R/W	Rule Number for Channel 2 Number of rules dedicated to channel 2
15 to 0	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.

RNCn[8:0] bits (Rule Number for Channel n (n = 2)

The RNC2[8:0] bits define the number of rules in the Acceptance Filter List for channel n.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

7.9.2.20 Global Acceptance Filter List ID Registers n (CFDGAFLIDn) (n = 1 to 16)

The CFDGAFLIDn register (n = 1 to 16) is used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1800 + H'10 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

29	GAFLLB	0	R/W	Global Acceptance Filter List Entry Loopback Configuration 0: Global Acceptance Filter List entry ID for acceptance filtering with attribute RX 1: Global Acceptance Filter List entry ID for acceptance filtering with attribute TX
28 to 0	GAFLID[28:0]	All 0	R/W	Global Acceptance Filter List Entry ID Field ID part of the Global Acceptance Filter List entry

GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

The acceptance filter process compares this field against the ID of a received CAN message. For alignment of these bits in standard and extended frame formats, see **7.9.2.90 Identifier Bits Alignment.**

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See **7.9.5.5 Loopback Modes** for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

7.9.2.21 Global Acceptance Filter List Mask Registers n (CFDGAFLMn) (n = 1 to 16)

The CFDGAFLMn register (n = 1 to 16) is used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1804 + H'10 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDEM	0	R/W	Global Acceptance Filter List IDE Mask 0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching
30	GAFLRTRM	0	R/W	Global Acceptance Filter List Entry RTR Mask 0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching
29	GAFLIFL1	0	R/W	Global Acceptance Filter List Information Label 1 Global Acceptance Filter List information label bit 1
28 to 0	GAFLIDM [28:0]	All 0	R/W	Global Acceptance Filter List ID Mask Field Global Acceptance Filter List Mask field bits for ID field

GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0: Corresponding STD-ID/EXT-ID bit is not used for ID matching
1: Corresponding STD-ID/EXT-ID bit is used for ID matching

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.
Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTS.RMIFL[1], CFDRFFDSTS.RFIFL[1], CFDCFFDCSTSn.CFIFL[1]) of the storage location of an incoming message.

Note: This bit is stored in CFDTHLACC1n.TIFL[1] when CFDTHLCCn.THLDGE = 1 is set up using Gateway function.

GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

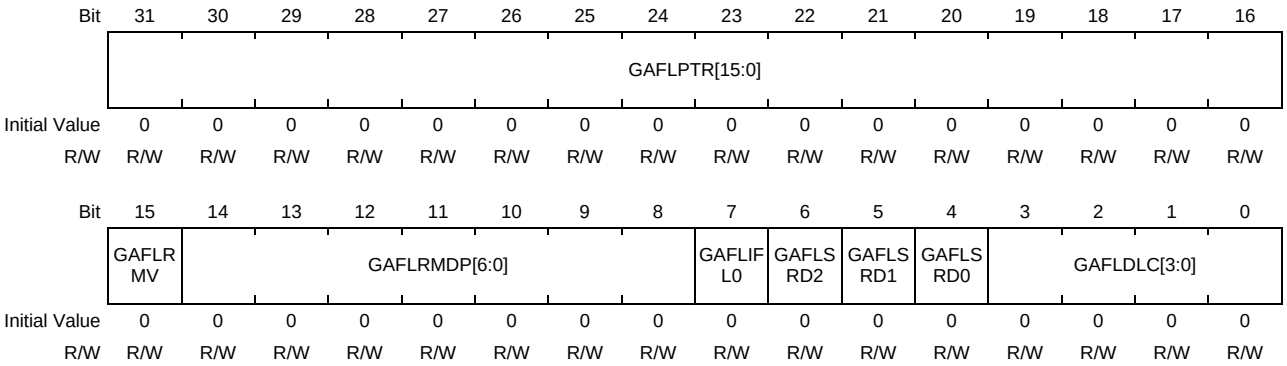
The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0, the STD-ID comparison takes place.

If the received IDE bit is 1, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.



Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

7.9.2.22 Global Acceptance Filter List Pointer 0 Registers n (CFDGAFLP0n) (n = 1 to 16)

The CFDGAFLP0n register (n = 1 to 16) is used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1808 + H'10 × n

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	GAFLPTR [15:0]	All 0	R/W	Global Acceptance Filter List Pointer
15	GAFLRMV	0	R/W	Global Acceptance Filter List RX Message Buffer Valid 0: Single message buffer direction pointer is invalid 1: Single message buffer direction pointer is valid
14 to 8	GAFLRMDP [6:0]	All 0	R/W	Global Acceptance Filter List RX Message Buffer Direction Pointer RX message buffer number for storage of received messages
7	GAFLIFL0	0	R/W	Global Acceptance Filter List Information Label 0
6	GAFLSRD2	0	R/W	Global Acceptance Filter List Select Routing Destination 2 0: Routing target is CFIFO2 1: Routing target is TX Queue 2 instead of CFIFO2
5	GAFLSRD1	0	R/W	Global Acceptance Filter List Select Routing Destination 1 0: Routing target is CFIFO1 1: Routing target is TX Queue 1 instead of CFIFO1
4	GAFLSRD0	0	R/W	Global Acceptance Filter List Select Routing Destination 0 0: Routing target is CFIFO0 1: Routing target is TX Queue 0 instead of CFIFO0
3 to 0	GAFLDLC [3:0]	H'0	R/W	Global Acceptance Filter List DLC Field Minimum number of data bytes in a data frame required for acceptance

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0.

Table 7.9-6 shows DLC value that can be configured.

Table 7.9-6 Configuration of DLC Value

DLC[3:0]	Description
0000b	DLC of received message = 0 or more (DLC filter check is disabled)
0001b	DLC of received message = 1 or more
0010b	DLC of received message = 2 or more
0011b	DLC of received message = 3 or more
0100b	DLC of received message = 4 or more
0101b	DLC of received message = 5 or more
0110b	DLC of received message = 6 or more
0111b	DLC of received message = 7 or more
1000b	DLC of received message = 8 or more
1001b	DLC of received message = 12 or more
1010b	DLC of received message = 16 or more
1011b	DLC of received message = 20 or more
1100b	DLC of received message = 24 or more
1101b	DLC of received message = 32 or more
1110b	DLC of received message = 48 or more
1111b	DLC of received message = 64

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD0 bit (Global Acceptance Filter List Select Routing Destination 0)

The GAFLSRD0 bit changes a copy destination to CFIFO0 or TXQ0 by routing.

If this bit is set as 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ0.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO0.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD1 bit (Global Acceptance Filter List Select Routing Destination 1)

The GAFLSRD1 bit changes a copy destination to CFIFO1 or TXQ1 by routing.

If this bit is set to 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ1.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO1.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD2 bit (Global Acceptance Filter List Select Routing Destination 2)

The GAFLSRD2 bit changes a copy destination to CFIFO2 or TXQ2 by routing.

If this bit is set to 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ2.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO2.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the CAN-FD module is in CH_RESET or CH_HALT mode.

GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTS.RMIFL[0], CFDRFFDSTS.RFIFL[0], CFDCFFDCSTSn.CFIFL[0]) of the storage location of an incoming message.

This bit is stored in CFDTHLACC1n.TIFL[0] when CFDTHLCCn.THLDGE = 1 is set up using the gateway function.

GAFLRMDP[6:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[6:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[7:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0n.GAFLRMDP[6:0] bits should only be between H’00 and CFDRMNB.NRXMB[7:0] to 1 less.

If CFDRMNB.NRXMB[7:0] = H’00, the GAFLRMV bit should be configured as 0.

GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

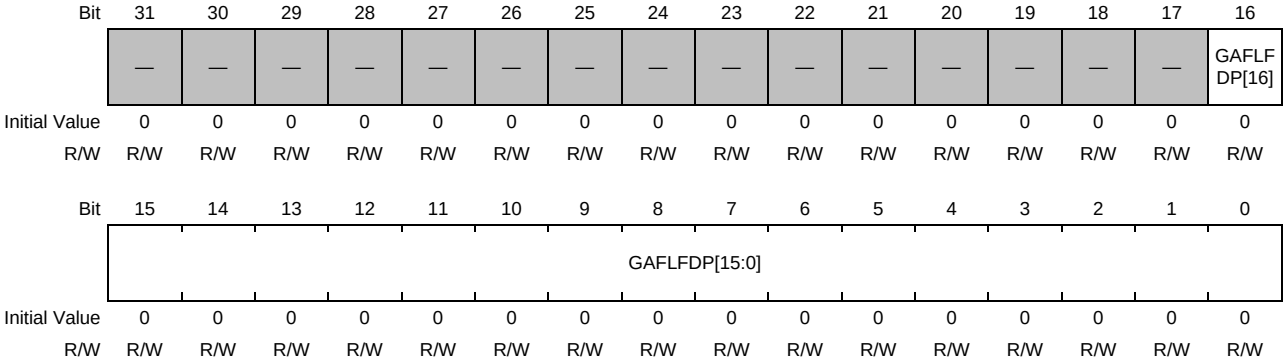
Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.



Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

7.9.2.23 Global Acceptance Filter List Pointer 1 Registers n (CFDGAFLP1n) (n = 1 to 16)

The CFDGAFLP1n register (n = 1 to 16) is used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'180C + H'10 × n

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
16 to 0	GAFLFDP [16:0]	All 0	R/W	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage

GAFLFDP[16:0] bits (Global Acceptance Filter List FIFO Direction Pointer)

The GAFLFDP[16:0] bits allow the configuration of FIFO buffers as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. Each bit of the CFDGAFLP1n.GAFLFDP[16:0] is configured as dedicated FIFO.

Table 7.9-7 Global Acceptance Filter List entry (1/2)

Bit	Value (binary)	Function
0	0	Disable RX FIFO 0 as target for reception
	1	Enable RX FIFO 0 as target for reception
1	0	Disable RX FIFO 1 as target for reception
	1	Enable RX FIFO 1 as target for reception
2	0	Disable RX FIFO 2 as target for reception
	1	Enable RX FIFO 2 as target for reception
3	0	Disable RX FIFO 3 as target for reception
	1	Enable RX FIFO 3 as target for reception
4	0	Disable RX FIFO 4 as target for reception
	1	Enable RX FIFO 4 as target for reception
5	0	Disable RX FIFO 5 as target for reception
	1	Enable RX FIFO 5 as target for reception
6	0	Disable RX FIFO 6 as target for reception
	1	Enable RX FIFO 6 as target for reception

Table 7.9-7 Global Acceptance Filter List entry (2/2)

Bit	Value (binary)	Function
7	0	Disable RX FIFO 7 as target for reception
	1	Enable RX FIFO 7 as target for reception
8	0	Disable Common FIFO 0 and Channel 0 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0: Enable Common FIFO 0 as target for reception GAFLSRD0 = 1: Enable Channel 0 TX Queue 0 as target for reception
9	0	Disable Common FIFO 1 and Channel 0 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0: Enable Common FIFO 1 as target for reception GAFLSRD1 = 1: Enable Channel 0 TX Queue 1 as target for reception
10	0	Disable Common FIFO 2 and Channel 0 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0: Enable Common FIFO 2 as target for reception GAFLSRD2 = 1: Enable Channel 0 TX Queue 2 as target for reception
11	0	Disable Common FIFO 3 and Channel 1 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0: Enable Common FIFO 3 as target for reception GAFLSRD0 = 1: Enable Channel 1 TX Queue 0 as target for reception
12	0	Disable Common FIFO 4 and Channel 1 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0: Enable Common FIFO 4 as target for reception GAFLSRD1 = 1: Enable Channel 1 TX Queue 1 as target for reception
13	0	Disable Common FIFO 5 and Channel 1 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0: Enable Common FIFO 5 as target for reception GAFLSRD2 = 1: Enable Channel 1 TX Queue 2 as target for reception
14	0	GAFLSRD0 = 0: Enable Common FIFO 6 as target for reception GAFLSRD0 = 1: Enable Channel 2 TX Queue 0 as target for reception
	1	Disable Common FIFO 6 and Channel 1 TX Queue 1 as target for reception
15	0	GAFLSRD1 = 0: Enable Common FIFO 7 as target for reception GAFLSRD1 = 1: Enable Channel 2 TX Queue 1 as target for reception
	1	Disable Common FIFO 7 and Channel 1 TX Queue 2 as target for reception
16	0	GAFLSRD2 = 0: Enable Common FIFO 8 as target for reception GAFLSRD2 = 1: Enable Channel 2 TX Queue 2 as target for reception
	1	Disable Common FIFO 8 and Channel 1 TX Queue 2 as target for reception

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0. Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

For storage in TX queue, TX queue buffers of a target that is in GW mode is possible.

Only one of the following configurations is valid:

- Up to 8 destination FIFO buffers
- 7 destination FIFO buffers plus one RX message buffer
- 8 destination TX queue buffers
- 7 destination TX queue buffers plus one RX message buffer
- A maximum of 8 destinations in all at FIFO buffer and TX queue buffer.

7.9.2.24 RX Message Buffer Number Register (CFDRMNB)

The CFDRMNB register is used to configure the total number of RX message buffers allocated to all channels.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'00AC

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	NRXMB[7:0]	H'00	R/W	Number of RX Message Buffers

NRXMB[7:0] bits (Number of RX Message Buffers)

The NRXMB[7:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Enter only values between 0 and 32 inclusive, with H'00 indicating that no RX message buffer is allocated.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

The RMPLS[2:0] bits are used to configure the message buffer payload data size.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

7.9.2.25 RX Message Buffer New Data Register n (CFDRMNDn) (n = 0, 1)

The CFDRMND0 specifies the new data storage status of the RX message buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'00B0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15 to 0	RMNS[47:32]	All 0	R/W	RX Message Buffer New Data Status for RX MB47-32 0: New data not stored in corresponding RX message buffer 1: New data stored in corresponding RX message buffer

RMNS[47:0] bits (RX Message Buffer New Data Status)

The RMNS[47:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

no_of_channels = 3
no_of_CFDRMBCPs_per_channel = (number of RX message buffer components per channel) = 16
no_of_CFDRMBCPs = no_of_channels × no_of_CFDRMBCPs_per_channel = 3 × 16 = 48
no_of_bits_per_register = 32
no_of_CFDRMNDs (number of CFDRMND Registers) = roundup (no_of_CFDRMBCPs/no_of_bits_per_register) = roundup (48/32) = 2
t = [0 ... no_of_CFDRMNDs − 1]
u = [t × 32 ... (no_of_CFDRMBCPs − ((no_of_CFDRMNDs − 1 − t) × 32) − 1)]

The parameter t can be calculated from the target of the New Data Status flag (u) using the formula t = floor (u/32)

Bit position can be calculated using the formula (u − (t × 32))

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.

Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKM cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKM cycles + 1 for each 4 bytes (maximum of 20 PCLKM cycles for 64 bytes).

7.9.2.26 RX FIFO Configuration/Control Register n (CFDRFCCn) (n = 0 to 7)

The CFDRFCCn registers (n = 0 to 7) are used to configure and control the eight RX FIFOs.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'00C0 + H'04 × n

0	RFE	0	R/W	RX FIFO Enable 0: FIFO disabled 1: FIFO enabled

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 000b (CFDRFCCn.RFDC[2:0] > 000b).

Set the RFE bit with a separate write access to the CFDRFCCn register, after all the other bits in the CFDRFCCn register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFFIE bit (RX FIFO Full Interrupt Enable)

The RFFIE bit enables generation of the RX FIFO full interrupt. Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

- Interruption output in number of arbitrary stages (CFDRFCCn.RFIGCV)
- Interruption output in FIFO full state.

Note: Management of the receiving data of FIFO can be performed by these notices of interruption.

7.9.2.27 RX FIFO Status Register n (CFDRFSTSn) (n = 0 to 7)

The CFDRFSTSn register (n = 0 to 7) shows the status of messages stored in the corresponding FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'00E0 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	RFFLL	0	R	RX FIFO Full 0: FIFO not full 1: FIFO full
0	RFEMP	1	R	RX FIFO Empty 0: FIFO not empty 1: FIFO empty

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0
- The CAN-FD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0
- The CAN-FD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CAN-FD module is in GL_RESET mode.

RFMC[7:0] bits (RX FIFO Message Count)

The RFMC[7:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CAN-FD module is in GL_RESET mode.

RFFIF bit (RX FIFO Full Interrupt Flag)

The RFFIF bit is not cleared automatically when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the FIFO full interrupt condition is satisfied. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared by writing 0 to it.

The bit is also cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.28 RX FIFO Pointer Control Register n (CFDRFPCTRn) (n = 0 to 7)

The CFDRFPCTRn register (n = 0 to 7) can be used to increment the read pointer of the corresponding RX FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0100 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	RFPC[7:0]	H'00	W	RX FIFO Pointer Control Increments read pointer of the corresponding RX FIFO buffers

RFPC[7:0] bits (RX FIFO Pointer Control)

When the value H'FF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write H'FF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always H'00.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

7.9.2.29 Common FIFO Configuration/Control Register n (CFDCFCCn) (n = 0 to 8)

The CFDCFCCn register (n = 0 to 8) is used to configure the Common FIFOs.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0120 + H'04 × n

CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode or GW mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.

This bit can only be set if the configured FIFO depth is greater than 0 (CFDC bit > 0).

Set the CFE bit with a separate write access to the CFDCFCCn register, after all the other bits in this register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see **7.9.6 FIFO Buffers and Normal Message Buffer Configuration**.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFM[1:0] bits (Common FIFO Mode)

The CFM[1:0] bits select the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode. Do not configure these bits to 11b.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CAN-FD communication is used.*[1]

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFTML[4:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[4:0] bits select the normal transmit message buffer position where the TX or GW FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX or GW mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = H’0000, set the CFITT[7:0] bits to H’00.

7.9.2.30 Common FIFO Configuration/Control Enhancement Register n (CFDCFCCEn) (n = 0 to 8)

The CFDCFCCEn register (n = 0 to 8) is used to configure the Common FIFOs.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0180 + H'04 × n

2	CFOFTXIE	0	R/W	Common FIFO One Frame Transmission Interrupt Enable 0: One Frame TX interrupt generation disabled 1: One Frame TX interrupt generation enabled
1	CFOFRXIE	0	R/W	Common FIFO One Frame Reception Interrupt Enable 0: One Frame RX interrupt generation disabled 1: One Frame RX interrupt generation enabled
0	CFFIE	0	R/W	Common FIFO Full Interrupt Enable 0: FIFO Interrupt generation disabled 1: FIFO Interrupt generation enabled

CFFIE bit (Common FIFO Full Interrupt Enable)

The CFFIE bit enables generation of the FIFO full interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

1. Interruption output in number of arbitrary stages (CFDCFCCn.CFIGCV).
2. Interruption output in FIFO full state.

Management of the receiving data of FIFO can be performed by these notices of interruption.

CFOFRXIE bit (Common FIFO One Frame Reception Interrupt Enable)

The CFOFRXIE bit enables generation of the one frame reception interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFOFTXIE bit (Common FIFO One Frame Transmission Interrupt Enable)

The CFOFTXIE bit enables generation of the one frame transmission interrupt when the interrupt flag is set after transmission of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFMOWM bit (Common FIFO Message Overwrite Mode)

When the CFMOWM bit is 0, a receiving message is discarded and FIFO is full. When the CFMOWM bit is 1, a receiving message is overwritten and FIFO is full.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write 1 to this bit when the common FIFO is in GW mode.

Do not write 1 to this bit when the CFE bit is 1.

CFBME bit (Common FIFO Buffering Mode Enable)

When the CFBME bit is 0, messages are transmitted from FIFO. When the CFBME bit is 1, messages are not transmitted from FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Additionally, do not write 1 to this bit when the CFE bit is 1.

7.9.2.31 Common FIFO Status Register n (CFDCFSTSn) (n = 0 to 8)

The CFDCFSTSn register (n = 0 to 8) shows the status of messages stored in the corresponding FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'01E0 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

2	CFMLT	0	R/W	Common FIFO Message Lost 0: FIFO message not lost 1: FIFO message lost

Bit	Bit Name	Initial Value	R/W	Description
1	CFFLL	0	R	Common FIFO Full 0: FIFO not full 1: FIFO full
0	CFEMP	1	R	Common FIFO Empty 0: FIFO not empty 1: FIFO empty

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX or GW mode
- The FIFO is disabled by setting the CFE bit to 0
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET when FIFO configured in TX or GW mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX or GW mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode when FIFO buffer is configured in TX or GW mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX or GW mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in GW mode or RX mode.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in GW mode.

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in GW or TX mode.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFMC[7:0] bits (Common FIFO Message Count)

The CFMC[7:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CAN-FD to be read by the CPU
- Number of CAN messages stored by the CAN-FD in the GW FIFO pending for transmission.

The CFMC[7:0] bits are cleared automatically when:

- The FIFO is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFFIF bit (Common FIFO Full Interrupt Flag)

The CFFIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the FIFO Full Interrupt condition is satisfied for Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFFIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFOFRXIF bit (Common FIFO One Frame Reception Interrupt Flag)

The CFOFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for the FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the One Frame Reception Interrupt condition is satisfied for the Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFOFRXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.
- This bit is not influenced by the value of **CFDCFCCn.CFIM**.

CFOFTXIF bit (Common FIFO One Frame Transmission Interrupt Flag)

The CFOFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the One Frame Transmission Interrupt condition is satisfied for Common FIFO buffers configured in GW mode or TX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.
- This bit is not influenced by the value of **CFDCFCCn.CFIM**

CFMOW bit (Common FIFO Message Overwrite)

The CFMOW bit is set automatically whenever a message is an overwrite storage of a new message when CFDCFCCEn.CFMOWM = 1 and FIFO is already full in GW mode.

If the set from the CAN channel occurs simultaneously with the clear by a write access, the bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMOW bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

7.9.2.32 Common FIFO Pointer Control Register n (CFDCFPCTRn) (n = 0 to 8)

The CFDCFPCTRn register (n = 0 to 8) can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0240 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
7 to 0	CFPC[7:0]	H'00	W	Common FIFO Pointer Control Increments read or write pointer of the corresponding Common FIFO buffers depending on the mode configuration.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value H'FF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always H'00.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Only write H'FF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode
- The Common FIFO buffer is enabled and is not configured in GW mode.

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

7.9.2.33 FIFO Empty Status Register (CFDFESTS)

The CFDFESTS register shows status of the empty bits of the FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02A0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXEMP[8]

7 to 0	RFXEMP[7:0]	All 1	R	RX FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty

RFXEMP[7:0] bits (RX FIFO Empty Status)

Bit [7] (RFXEMP[7]) is associated with FIFO index 7 and bit [0] (RFXEMP[0]) is associated with FIFO index 0.

The RFXEMP[7:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXEMP[8:0] bits (Common FIFO Empty Status)

Bit [16] (CFXEMP[8]) is associated with common FIFO index 8 and bit [8] (CFXEMP[0]) is associated with common FIFO index 0.

The CFXEMP[8:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.34 FIFO Full Status Register (CFDFFSTS)

The CFDFFSTS register shows status of the full bits of the FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02A4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXFLL[8]

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are read as 0.
16 to 8	CFXFLL[8:0]	All 0	R	Common FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full
7:0	RFXFLL[7:0]	All 0	R	RX FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full

RFXFLL[7:0] bits (RX FIFO Full Status)

Bit [7] (RFXFLL[7]) is associated with FIFO index 7 and bit [0] (RFXFLL[0]) is associated with FIFO index 0.

The RFXFLL[7:0] bits are cleared when CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXFLL[8:0] bits (Common FIFO Full Status)

Bit [16] (CFXFLL[8]) is associated with common FIFO index 8 and bit [8] (CFXFLL[0]) is associated with common FIFO index 0.

The CFXFLL[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.35 FIFO Message Lost Status Register (CFDFMSTS)

The CFDFMSTS register shows status of the message lost bits of the FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02A8

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXMLT[8]
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	CFXMLT[7:0]								RFXMLT[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are read as 0.
16 to 8	CFXMLT[8:0]	All 0	R	Common FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set
7 to 0	RFXMLT[7:0]	All 0	R	RX FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set

RFXMLT[7:0] bits (RX FIFO Message Lost Status)

Bit [7] (RFXML[7]) is associated with FIFO index 7 and bit [0] (RFXML[0]) is associated with FIFO index 0.

The RFXMLT[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXMLT[8:0] bits (Common FIFO Message Lost Status)

Bit [16] (CFXMLT[8]) is associated with common FIFO index 8 and bit [8] (CFXMLT[0]) is associated with common FIFO index 0.

The CFXMLT[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.36 RX FIFO Interrupt Flag Status Register (CFDRFISTS)

The CFDRFISTS register shows status of the interrupt flag bits of the RX FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02AC

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	RFXFFLL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RFXIF[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
23 to 16	RFXFFLL[7:0]	All 0	R	RX FIFO[x] Interrupt Full Flag Status 0: Corresponding RX FIFO Interrupt Full flag not set 1: Corresponding RX FIFO Interrupt Full flag set
15 to 8	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
7 to 0	RFXIF[7:0]	All 0	R	RX FIFO[x] Interrupt Flag Status 0: Corresponding RX FIFO Interrupt flag not set 1: Corresponding RX FIFO Interrupt flag set

RFXIF[7:0] bits (RX FIFO Interrupt Flag Status)

Bit [7] (RFXIF[7]) is associated with FIFO index 7 and bit [0] (RFXIF[0]) is associated with FIFO index 0.

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

RFXFFLL[7:0] bits (RX FIFO Interrupt Full Flag Status)

Bit [23] (RFXFFLL[7]) is associated with FIFO index 7 and bit [16] (RFXFFLL[0]) is associated with FIFO index 0.

Each bit is set automatically when the corresponding interrupt full flag bit is set in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt full flag bit is cleared in the RX FIFO Status Registers.

7.9.2.37 Common FIFO RX Interrupt Flag Status Register (CFDCFRISTS)

The CFDCFRISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02B0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CFXRXIF[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
8 to 0	CFXRXIF[8:0]	All 0	R	Common FIFO RX Interrupt Flag Status 0: Corresponding Common FIFO RX Interrupt flag not set 1: Corresponding Common FIFO RX Interrupt flag set

CFXRXIF[8:0] bits (Common FIFO RX Interrupt Flag Status)

Bit [8] (CFXRXIF[8]) is associated with FIFO index 8 and bit [0] (CFXRXIF[0]) is associated with FIFO index 0.

Each bit is set automatically when the corresponding RX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXRXIF[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding RX interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.38 Common FIFO TX Interrupt Flag Status Register (CFDCFTISTS)

The CFDCFTISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02B4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
8 to 0	CFXTXIF[8:0]	All 0	R	Common FIFO TX Interrupt Flag Status 0: Corresponding Common FIFO TX Interrupt flag not set 1: Corresponding Common FIFO TX Interrupt flag set

CFXTXIF[8:0] bits (Common FIFO TX Interrupt Flag Status)

Bit [8] (CFXTXIF[8]) is associated with FIFO index 8 and bit [0] (CFXTXIF[0]) is associated with FIFO index 0.

Each bit is set automatically when the corresponding TX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXTXIF[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding TX interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.39 FIFO FDC Full Status Register (CFDFFFSTS)

The CFDFFFSTS register shows status of the full interrupt flag bits of the FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02C4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXFFLL[8]

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are read as 0.
16 to 8	CFXFFLL[8:0]	All 0	R	COMMON FIFO FDC Level Full Status 0: Corresponding FIFO full interrupt not set 1: Corresponding FIFO full interrupt set
7 to 0	RFXFFLL[7:0]	All 0	R	RX FIFO FDC Level Full Status 0: Corresponding FIFO full interrupt not set 1: Corresponding FIFO full interrupt set

RFXFFLL[7:0] bits (RX FIFO FDC Level Full Status)

Bit [7] (RFXFFLL[7]) is associated with FIFO index 7 and bit [0] (RFXFFLL[0]) is associated with FIFO index 0.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

CFXFFLL[8:0] bits (COMMON FIFO FDC Level Full Status)

Bit [16] (CFXFFLL[8]) is associated with common FIFO index 8 and bit [8] (CFXFFLL[0]) is associated with common FIFO index 0.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

The CFXFFLL[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.40 Common FIFO Message Overwrite Status Register (CFDCFMOWSTS)

The CFDCFMOWSTS register shows the status of the Interrupt Flag bits of the Common FIFO Buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02C0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
8 to 0	CFXMOW [8:0]	All 0	R	Common FIFO Massage Overwrite Status 0: Corresponding FIFO Overwrite flag not set 1: Corresponding FIFO Overwrite flag set

CFXMOW[8:0] bits (Common FIFO Massage Overwrite Status)

Bit [8] (CFXMOW[8]) is associated with common FIFO index 8 and bit [0] (CFXFMOW[0]) is associated with common FIFO index 0.

The CFXMOW[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode. This register is only valid in GW mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.41 Common FIFO One Frame RX Interrupt Flag Status Register (CFDCFOFRISTS)

The CFDCFOFRISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02B8

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are read as 0.
8 to 0	CFXOFRXIF[8:0]	All 0	R	Common FIFO One Frame RX Interrupt Flag Status 0: Corresponding Common FIFO One Frame RX Interrupt flag not set 1: Corresponding Common FIFO One Frame RX Interrupt flag set

CFXOFRXIF[8:0] bits (Common FIFO One Frame RX Interrupt Flag Status)

Bit [8] (CFXFRXIF[8]) is associated with common FIFO index 8 and bit [0] (CFXFRXIF[0]) is associated with common FIFO index 0.

Each bit is set automatically when the corresponding One Frame RX Interrupt flag bit is set in the Common FIFO Status Registers.

The CFXOFRXIF[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame RX Interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.42 Common FIFO One Frame TX Interrupt Flag Status Register (CFDCFOFTISTS)

The CFDCFOFTISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02BC

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are read as 0.
8 to 0	CFXOFTXIF [8:0]	All 0	R	Common FIFO One Frame TX Interrupt Flag Status 0: Corresponding Common FIFO One Frame TX Interrupt flag not set 1: Corresponding Common FIFO One Frame TX Interrupt flag set

CFXOFTXIF[8:0] bits (Common FIFO One Frame TX Interrupt Flag Status)

Bit [8] (CFXOFTXIF [8]) is associated with common FIFO index 8 and bit [0] (CFXOFTXIF[0]) is associated with common FIFO index 0.

Each bit is set automatically when the corresponding One Frame TX Interrupt flag bit is set in the Common FIFO Status Registers.

The CFXOFTXIF[8:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame TX Interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.43 DMA Transfer Control Register (CFDCDTCT)

The CFDCDTCT register controls the start and stop of DMA transfer operation.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1330

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

1	RFDMAE1	0	R/W	DMA Transfer Enable for RX FIFO 1 0: DMA transfer request disabled 1: DMA transfer request enabled

Bit	Bit Name	Initial Value	R/W	Description
0	RFDMAE0	0	R/W	DMA Transfer Enable for RX FIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled

RFDMAEn (n = 0 to 7) bit (DMA Transfer Enable for RX FIFOn)

Number of RX FIFOs = 8

The RFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0, 1, 2) bit (DMA Transfer Enable for Common FIFO 0 of Channel 0, 1, 2)

The CFDMAEn bit enables or disables DMA transfer request for common FIFO 0 of channel 0, 1 or 2. Only Common FIFO 0 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel.

To link Common FIFO 2, see bit CFDCDTTCT.CFDMAEn in **7.9.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**.

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX or GW FIFO.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.44 DMA Transfer Status Register (CFDCDTSTS)

The CFDCDTSTS register shows the status of the DMA transfer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1334

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	RFDMASTS1	0	R	DMA Transfer Status for RX FIFO 1 0: DMA transfer stopped 1: DMA transfer on going

Bit	Bit Name	Initial Value	R/W	Description
0	RFDMASTS0	0	R	DMA Transfer Status for RX FIFO 0 0: DMA transfer stopped 1: DMA transfer on going

RFDMASTSn (n = 0 to 7) bit (DMA Transfer Status for RX FIFO n)

Number of RX FIFOs = 8

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEn (see CFDCDTCT.RFDMAEn bit in **7.9.2.43 DMA Transfer Control Register (CFDCDTCT)**) is set to 0 while DMA transfer for the corresponding FIFO is ongoing, the RFDMASTSn bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMASTSn (n = 0, 1, 2) bit (DMA Transfer Status only for Common FIFO 0 of Channel 0, 1, 2)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAEn (see CFDCDTCT.CFDMAEn bit in **7.9.2.43 DMA Transfer Control Register (CFDCDTCT)**) is set to 0 while DMA transfer for the corresponding FIFO is ongoing, the CFDMASTSn bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.45 DMA TX Transfer Control Register (CFDCDTTCT)

The CFDCDTTCT register controls the start and stop of DMA transfer operation.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1340

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	TQ0DMAE0	0	R/W	DMA TX Transfer Enable for TXQ 0 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled

TQ0DMAEn (n = 0, 1, 2) bit (DMA TX Transfer Enable for TXQ 0 of Channel n)

The TQ0DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

TQ3DMAEn (n = 0, 1, 2) bit (DMA TX Transfer Enable for TXQ 3 of Channel n)

The TQ3DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0, 1, 2) bit (DMA TX Transfer Enable for Common FIFO 2 of Channel n)

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Only common FIFO 2 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel. To link Common FIFO 0, see CFDCDTCT.CFDMAEn bit in **7.9.2.43 DMA Transfer Control Register (CFDCDTCT)**.

Do not enable a DMA transfer for a Common FIFO that is configured as RX or GW FIFO.

The CFDMAEn bit is cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.46 DMA TX Transfer Status Register (CFDCDTTSTS)

The CFDCDTTSTS register shows the status of the DMA TX transfer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1344

0	TQ0DMASTS0	0	R	DMA TX Transfer Status for TXQ0 of Channel 0 0: DMA TX transfer stopped 1: DMA TX transfer enabled

TQ0DMASTSn (n = 0, 1, 2) bit (DMA TX Transfer Status for TXQ 0 of Channel n)

The TQ0DMASTSn bit is set when the CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is set (see **7.9.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**).

This bit is cleared when:

- The CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

TQ3DMASTSn (n = 0, 1, 2) bit (DMA TX Transfer Status for TXQ 3 of Channel n)

The TQ3DMASTSn bit is set when the CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is set (see **7.9.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**).

This bit is cleared when:

- The CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

CFDMASTSn (n = 0 ,1, 2) bit (DMA TX Transfer Status only for Common FIFO 2 of Channel n)

The CFDMASTSn bit is set when the CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is set (see **7.9.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**).

This bit is cleared when:

- The CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

7.9.2.47 Global RX Interrupt Status Register n (CFDGRINTSTSn) (n = 0, 1, 2)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1350 + H'04 × n

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	QFIF[2:0]	000	R	TXQ Full Interrupt Flag Channel n (n = 0, 1, 2) 0: Corresponding TXQ Full Interrupt flag is not set 1: Corresponding TXQ Full Interrupt flag is set

QFIF[2:0] bits (TXQ Full Interrupt Flag Channel n (n = 0, 1, 2))

The QFIF[2:0] bits are set automatically when the TXQ Full Interrupt flag of the related channel is set when the interrupt is enabled.

The QFIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

BQFIF[1:0] bits (Borrowed TXQ Full Interrupt Flag Channel n (n = 0, 1, 2))

The BQFIF[1:0] bits are set when a flexible transmission buffer assignment function is used and the borrowed TXQ is in full status. Operation is the same as CFDGRINTSTSn.QFIF.

The bit of the channel that lends TXMB is a reserved bit.

QOFRIF[2:0] bits (TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1, 2))

The QOFRIF[2:0] bits are set automatically when the TXQ One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The QOFRIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET or CH_RESET mode.

BQOFRIF[1:0] bits (Borrowed TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1, 2))

The BQOFRIF[1:0] bits are set when a flexible transmission buffer assignment function is used and the borrowed TXQ receives one frame. Operation is the same as CFDGRINTSTSn.QOFRIF.

The bit of the channel that lends TXMB is a reserved bit.

CFRIF[2:0] bits (Common FIFO RX Interrupt Flag Channel n (n = 0, 1, 2))

The CFRIF[2:0] bits are set automatically when the Common FIFO RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET or CH_RESET mode.

CFRFIF[2:0] bits (Common FIFO FDC Level Full Interrupt Flag Channel n (n = 0, 1, 2))

The CFRFIF[2:0] bits are set automatically when the Common FIFO Full Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRFIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

CFOFRIF[2:0] bits (Common FIFO One Frame RX Interrupt Flag Channel n (n = 0, 1, 2))

The CFOFRIF[2:0] bits are set automatically when the Common FIFO One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFOFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.48 TX Message Buffer Control Register n (CFDTMCn) (n = 0 to 191)

The CFDTMCn register (n = 0 to 191) configures the TX message buffer functions.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'02D0 + H'01 × n

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	TMOM	0	R/W	TX Message Buffer One-shot Mode 0: TX message buffer not configured in one-shot mode 1: TX message buffer configured in one-shot mode
1	TMTAR	0	R/W	TX Message Buffer Transmission Abort Request 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested
0	TMTR	0	R/W	TX Message Buffer Transmission Request 0: TX Message buffer transmission not requested 1: TX message buffer transmission requested

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CAN-FD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CAN-FD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX or GW mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the CFDTMSTSn register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CAN-FD module logic at the end of a successful transmission
- CAN-FD module logic at the end of a transmission abort, requested by the corresponding CFDTMCn.TMTAR bit
- CAN-FD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCn.TMOM bit is set for the message buffer
- CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CAN-FD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CAN-FD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CAN-FD module logic at the end of a successful transmission
- The CAN-FD module logic at the end of a transmission abort
- The CAN-FD module logic when there is detection of a CAN bus error or arbitration loss
- The CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CAN-FD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSn.TMTRF[1:0] bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

7.9.2.49 TX Message Buffer Status Register n (CFDTMSTSn) (n = 0 to 191)

The CFDTMSTSn register (n = 0 to 191) shows status of the transmission and transmission abort for the corresponding message buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'07D0 + H'01 × n

Bit	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	000	R/W	Reserved These bits are read as 0. The write value should be always 0.
4	TMTARM	0	R	TX Message Buffer Transmission Abort Request Mirrored 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested
3	TMTRM	0	R	TX Message Buffer Transmission Request Mirrored 0: TX message buffer transmission not requested 1: TX message buffer transmission requested
2, 1	TMTRF[1:0]	00	R/W	TX Message Buffer Transmission Result Flag 00: No result 01: Transmission aborted from the TX message buffer 10: Transmission successful from the TX message buffer and transmission abort was not requested 11: Transmission successful from the TX message buffer and transmission abort was requested
0	TMTSTS	0	R	TX Message Buffer Transmission Status 0: No on-going transmission 1: On-going transmission

TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00b: Transmission in progress or has not been requested
- 01b: Transmission has been aborted from the corresponding TX message buffer
- 10b: Transmission was successful from the corresponding TX message buffer and the CFDTMCn.TMTAR bit was not set for this TX message buffer

- 11b: Transmission was successful from the corresponding TX message buffer, but the CFDTMCn.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is cleared.

TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

The TMTARM bit is set when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is cleared.

7.9.2.50 TX Message Buffer Transmission Request Status Register n (CFDTMTRSTSn) (n = 0 to 5)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0CD0 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TMTRSTS[15:0] bits (TX Message Buffer Transmission Request Status)

The TMTRSTS[15:0] bits show status of the CFDTMCn.TMTR bits of the TX Message Buffer Control Registers.

Alignment of the TMTRSTS[15:0] bits is shown in **Table 7.9-8**.

Table 7.9-8 Alignment of TMTRSTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 − fmin × 32	n × 64 + 31
n × 64 + 32 − fmax × 32	n × 64 + 32
n × 64 + 33 − fmax × 32	n × 64 + 33
⋮	⋮
n ×64 + 62 − fmax × 32	n × 64 + 62
n × 64 + 63 − fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCn), and only when the message buffer does not belong to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.51 TX Message Buffer Transmission Abort Request Status Register n (CFDTMTARSTSn) (n = 0 to 5)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0D70 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0.
15 to 0	TMTARSTS [15:0]	All 0	R	TX Message Buffer Transmission Abort Request Status 0: Transmission abort not requested for corresponding TX message buffer 1: Transmission abort requested for corresponding TX message buffer

TMTARSTS[15:0] bits (TX Message Buffer Transmission Abort Request Status)

The TMTARSTS[15:0] bits show status of the CFDTMCn.TMTAR bits of the TX Message Buffer Control Registers. Alignment of the TMTARSTS[15:0] bits is shown in **Table 7.9-9**.

Table 7.9-9 Alignment of TMTARSTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 − fmin × 32	n × 64 + 31
n × 64 + 32 − fmax × 32	n × 64 + 32
n × 64 + 33 − fmax × 32	n × 64 + 33
⋮	⋮
n × 64 + 62 − fmax × 32	n × 64 + 62
n × 64 + 63 − fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.52 TX Message Buffer Transmission Completion Status Register n (CFDTMTCSTSn) (n = 0 to 5)

Base address: H'0_100C_0000

Offset address: H'0E10 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMTCSTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0.
15 to 0	TMTCSTS [15:0]	All 0	R	TX Message Buffer Transmission Completion Status 0: Transmission not completed for corresponding TX message buffer 1: Transmission completed for corresponding TX message buffer

TMTCSTS[15:0] bits (TX Message Buffer Transmission Completion Status)

The TMTCSTS[15:0] bits show status of successful completion of the TX Message Buffer Status Registers.

Alignment of the TMTCSTS[15:0] bits is shown in **Table 7.9-10**.

Table 7.9-10 Alignment of TMTCSTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 − fmin × 32	n × 64 + 31
n × 64 + 32 − fmax × 32	n × 64 + 32
n × 64 + 33 − fmax × 32	n × 64 + 33
⋮	⋮
n × 64 + 62 − fmax × 32	n × 64 + 62
n × 64 + 63 − fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1,fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CAN-FD module is in GL_RESET mode

- The related CAN-FD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

7.9.2.53 TX Message Buffer Transmission Abort Status Register n (CFDTMTASTSn) (n = 0 to 5)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0EB0 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

n × 64 + 63 − fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the CFDTMSTSn.TMTRF[1:0] bits are set to 01b in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when:

- The CFDTMSTSn.TMTRF[1:0] bits are cleared in the corresponding TX Message Buffer Status Register

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.54 TX Message Buffer Transmission Interrupt Enable Register n (CFDTMIECn) (n = 0 to 5)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'0F50 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMIE[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
15 to 0	TMIE[15:0]	All 0	R/W	TX Message Buffer Interrupt Enable 0: TX message buffer interrupt disabled for corresponding TX message buffer 1: TX message buffer interrupt enabled for corresponding TX message buffer

TMIE[15:0] bits (TX Message Buffer Interrupt Enable)

If the TMIE[15:0] bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See **7.9.7 Interrupt and DMA** for TX Message Buffer Interrupt specification.

Alignment of the TMIE[15:0] bits is shown in **Table 7.9-12**.

Table 7.9-12 Alignment of TMIE[15:0] bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 31 − fmin × 32	n × 64 + 31
n × 64 + 32 − fmax × 32	n × 64 + 32
n × 64 + 33 − fmax × 32	n × 64 + 33
⋮	⋮
n × 64 + 62 − fmax × 32	n × 64 + 62
n × 64 + 63 − fmax × 32	n × 64 + 63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Do not write to the TMIE[15:0] bits when:

- The CAN-FD module is in GL_SLEEP mode

- The related CAN-FD channel is in CH_SLEEP mode
- The corresponding TX message buffer is part of a TX Queue
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCCn.CFTML[4:0] bits.

7.9.2.55 TX Queue Configuration/Control Register 0n (CFDTXQCC0n) (n = 0, 1, 2)

The CFDTXQCC0n register (n = 0, 1, 2) is used to configure the TX Queue transmission.

TXQ0 is composed of TXMB0 to TXMB31 (at the maximum) when TXQE is enabled.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1000 + H'04 × n

4, 3	—	00	R/W	Reserved These bits are read as 0. The write value should be always 0.

Bit	Bit Name	Initial Value	R/W	Description
2	TXQOWE	0	R/W	TX Queue Overwrite Mode Enable 0: TX Queue OW mode disabled 1: TX Queue OW mode enabled
1	TXQGWE	0	R/W	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled
0	TXQE	0	R/W	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is H'00 (CFDTXQCC0n.TXQDC[4:0] = H'00).

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue GW mode.

When this bit is set, CPU must not access the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC0n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[31] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 32 or less.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQFIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit in Gateway mode (CFDTXQCC0n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFRXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit in GW mode (CFDTXQCC0n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFTXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.56 TX Queue Configuration/Control Register 1n (CFDTXQCC1n) (n = 0, 1, 2)

The CFDTXQCC1n register (n = 0, 1, 2) is used to configure the TX Queue transmission.

TXQ1 is composed of TXMB31 to TXMB0 (at the maximum) when TXQE is enabled.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1060 + H'04 × n

1	TXQGWE	0	R/W	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled
0	TXQE	0	R/W	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is H'00 (CFDTXQCC1n.TXQDC[4:0] = H'00).

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode.

When this bit is set, CPU must not access the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC1n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC1n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[31] down to MB[0] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 32 or less.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQFIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFRXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFTXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.57 TX Queue Configuration/Control Register 2n (CFDTXQCC2n) (n = 0, 1, 2)

The CFDTXQCC2n register (n = 0, 1, 2) is used to configure the TX Queue transmission.

TXQ2 is composed of TXMB32 to TXMB63 (at the maximum) when TXQE is enabled.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'10C0 + H'04 × n

1	TXQGWE	0	R/W	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled
0	TXQE	0	R/W	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is H'00 (CFDTXQCC2n.TXQDC[4:0] = H'00).

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode. When this bit is set, CPU must not access the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC2n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC2n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[32] up to MB[63] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 32 or less.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQFIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFRXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFTXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.58 TX Queue Configuration/Control Register 3n (CFDTXQCC3n) (n = 0, 1, 2)

The CFDTXQCC3n register (n = 0, 1, 2) is used to configure the TX Queue transmission.

TXQ3 is composed of TXMB63 to TXMB32 (at the maximum) when TXQE is enabled.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1120 + H'04 × n

1	—	0	R/W	Reserved This bit is read as 0. The write value should be always 0.

Bit	Bit Name	Initial Value	R/W	Description
0	TXQE	0	R/W	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is H'00 (CFDTXQCC3n.TXQDC[4:0] = H'00).

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC3n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC3n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[63] down to MB[32] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 32 or less.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS3n.TXQOFTXIF bit.

Cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.59 TX Queue Status Register 0n (CFDTXQSTS0n) (n = 0, 1, 2)

The CFDTXQSTS0n register (n = 0, 1, 2) shows the status of the TX Queue of corresponding CAN Channel.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1020 + H'04 × n

1	TXQFLL	0	R	TX Queue Full 0: TX Queue not full 1: TX Queue full

Bit	Bit Name	Initial Value	R/W	Description
0	TXQEMP	1	R	TX Queue Empty 0: TX Queue not empty 1: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC0n.TXQGWE = 1) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC0n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.60 TX Queue Status Register 1n (CFDTXQSTS1n) (n = 0, 1, 2)

The CFDTXQSTS1n register (n = 0, 1, 2) shows the status of the TX Queue of corresponding CAN Channel.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1080 + H'04 × n

1	TXQFLL	0	R	TX Queue Full 0: TX Queue not full 1: TX Queue full
0	TXQEMP	1	R	TX Queue Empty 0: TX Queue not empty 1: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC1n.TXQGWE = 1) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC1n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.61 TX Queue Status Register 2n (CFDTXQSTS2n) (n = 0, 1, 2)

The CFDTXQSTS2n register (n = 0, 1, 2) shows the status of the TX Queue of corresponding CAN Channel.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'10E0 + H'04 × n

1	TXQFLL	0	R	TX Queue Full 0: TX Queue not full 1: TX Queue full
0	TXQEMP	1	R	TX Queue Empty 0: TX Queue not empty 1: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC2n.TXQGWE = 1) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC2n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.62 TX Queue Status Register 3n (CFDTXQSTS3n) (n = 0, 1, 2)

The CFDTXQSTS3n register (n = 0, 1, 2) shows the status of the TX Queue of corresponding CAN Channel.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1140 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	000	R/W	Reserved These bits are read as 0. The write value should be always 0.
28	—	0	R	Reserved These bits are read as 0.
27 to 21	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
20	TXQMOW	0	R/W	TXQ Message Overwrite 0: No message overwrite in TXQ 1: Message overwrite in TXQ
19	—	0	R/W	Reserved This bit is read as 0. The write value should be always 0.
18	TXQOFTXIF	0	R/W	TXQ One Frame Transmission Interrupt Flag When one frame transmits from TXQ, an interrupt is set.
17 to 14	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
13 to 8	TXQMC[5:0]	All 0	R	TX Queue Message Count Number of messages in the TX Queue.
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	TXQTXIF	0	R/W	TX Queue TX Interrupt Flag 0: TX Queue interrupt condition not satisfied after a frame TX 1: TX Queue interrupt condition satisfied after a frame TX
1	TXQFLL	0	R	TX Queue Full 0: TX Queue not full 1: TX Queue full
0	TXQEMP	1	R	TX Queue Empty 0: TX Queue not empty 1: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC3n.TXQOWE = 1 and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

Cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.63 TX Queue Pointer Control Register 0n (CFDTXQPCTR0n) (n = 0, 1, 2)

The CFDTXQPCTR0n register (n = 0, 1, 2) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1040 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	TXQPC[7:0]	H'00	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value H'FF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always H'00. Do not write to the FIFO control registers when DMA is enabled.

Cannot write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write H'FF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

7.9.2.64 TX Queue Pointer Control Register 1n (CFDTXQPCTR1n) (n = 0, 1, 2)

The CFDTXQPCTR1n register (n = 0, 1, 2) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'10A0 + H'04 × n

7 to 0	TXQPC[7:0]	H'00	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value H'FF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always H'00. Cannot write to the FIFO control registers when DMA is enabled.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write H'FF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

7.9.2.65 TX Queue Pointer Control Register 2n (CFDTXQPCTR2n) (n = 0, 1, 2)

The CFDTXQPCTR2n register (n = 0, 1, 2) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1100 + H'04 × n

7 to 0	TXQPC[7:0]	H'00	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value H'FF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always H'00. Cannot write to the FIFO control registers when DMA is enabled.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write H'FF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

7.9.2.66 TX Queue Pointer Control Register 3n (CFDTXQPCTR3n) (n = 0, 1, 2)

The CFDTXQPCTR3n register (n = 0, 1, 2) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1160 + H'04 × n

3 to 0	TXQ0OW[3:0]	H'0	R	TXQ Message Overwrite Status Flag for Channel 0 0: TXQ message overwrite flag not set 1: TXQ message overwrite flag set

TXQnOW[3:0] (n = 0 ,1, 2) bits (TXQ Message Overwrite Status Flag)

Each bit is set automatically when the corresponding bit is set in the TX Queue Message Overwrite Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Queue Message Overwrite Status Register.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

Bit Position	Corresponding TX Queue
0	Channel 0 TX Queue 0
1	Channel 0 TX Queue 1
2	Channel 0 TX Queue 2
3	Channel 0 TX Queue 3
4	Channel 1 TX Queue 0
5	Channel 1 TX Queue 1
6	Channel 1 TX Queue 2
7	Channel 1 TX Queue 3
8	Channel 2 TX Queue 0
9	Channel 2 TX Queue 1
10	Channel 2 TX Queue 2

Bit Position	Corresponding TX Queue
11	Channel 2 TX Queue 3
31:12	Reserved

7.9.2.71 TX Queue Interrupt Status Register (CFDTXQISTS)

The CFDTXQISTS register shows the status of the interrupt flag of the TXQ buffers.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1190

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8	THLIE	0	R/W	TX History List Interrupt Enable 0: TX History List Interrupt disabled 1: TX History List Interrupt enabled
7 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
0	THLE	0	R/W	TX History List Enable 0: TX History List disabled 1: TX History List enabled

THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDGE bit (TX History List Dedicated Gateway Enable)

The THLDGE bit selects the condition for storing an entry in the TX History List after successful transmission.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

7.9.2.76 TX History List Status Register n (CFDTHLSTSn) (n = 0, 1, 2)

The CFDTHLSTSn register (n = 0, 1, 2) shows the status of data stored in the TX History List buffer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1220 + H'04 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
13 to 8	THLMC[5:0]	All 0	R	TX History List Message Count Number of messages stored in TX History List
7 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
3	THLIF	0	R/W	TX History List Interrupt Flag 0: TX History List interrupt condition not satisfied 1: TX History List interrupt condition satisfied
2	THLELT	0	R/W	TX History List Entry Lost 0: No entry lost in TX History List 1: TX History List entry Lost
1	THLFLL	0	R	TX History List Full 0: TX History List not full 1: TX History List full
0	THLEMP	1	R	TX History List Empty 0: TX History List not empty 1: TX History List empty

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 32 entries (each channel has a dedicated TX History List).

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

THLMC[5:0] bits (TX History List Message Count)

The THLMC[5:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.77 Channel n TX History List Access Register 0 (CFDTHLACC0n) (n = 0, 1, 2)

The CFDTHLACC0n register (n = 0, 1, 2) provides access to the entry in the TX History List based on the read timestamp value.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'8000 + H'08 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TMTS[15:0]	All 0	R	Transmit Timestamp Transmit timestamp value for software drivers.
15	TGW	0	R	Transmit Gateway Buffer Indication 0: No transmission from gateway 1: Transmission from gateway
14 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
9 to 3	BN[6:0]	All 0	R	Buffer Number Number of the message buffer
2 to 0	BT[2:0]	000	R	Buffer Type 001: Flat TX message buffer 010: TX FIFO message buffer number and gateway FIFO message number 100: TX Queue message buffer number Others: Setting prohibited

BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

BN[6:0] bits (Buffer Number)

The BN[6:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

TGW bit (Transmit Gateway Buffer Indication)

The TGW bit is automatically set to 1 when transmission is completed in GW mode.

TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

In the case of can_race_ts_en=1, the information as which CFDTHLACC0n.TMTS is inputted from can_race_ts is reflected.

See **7.9.8.1.3 Timestamp** for the timestamp in detail.

7.9.2.78 Channel n TX History List Access Register 1 (CFDTHLACC1n) (n = 0, 1, 2)

The CFDTHLACC1n register (n = 0, 1, 2) provides access to entry in the TX History List based on the read pointer value.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'8004 + H'08 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be aways 0.
17, 16	TIFL[1:0]	00	R	Transmit Information Label These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers.
15 to 0	TID[15:0]	All 0	R	Transmit ID These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers.

TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRn.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTSn.CFPTR) is for use by software drivers.

When transmission in Gateway mode, these bits indicate the AFL pointer field (CFDGAFLP0n.GAFLPTR) instead of the message buffer reference ID (CFDTMFDCTRn.TMPTR).

TIFL[1:0] bits (Transmit Information Label)

The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRn.TMIFL) or the TX FIFO information label (CFDCFFDCSTSn.CFIFL) is for use by software drivers.

When transmission in Gateway mode, these bits indicate the AFL pointer field (CFDGAFLMn.GAFLIFL1 and CFDGAFLP0n.GAFLIFL0) instead of the MB information label (CFDTMFDCTRn.TMIFL).

7.9.2.79 TX History List Pointer Control Register n (CFDTHLPCTRn) (n = 0, 1, 2)

The CFDTHLPCTRn register (n = 0, 1, 2) is used to increment the read pointer of the TX History List.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1240 + H'04 × n

31 to 8	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
7 to 0	THLPC[7:0]	H'00	W	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel

THLPC[7:0] bits (TX History List Pointer Control)

When H'FF is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.

The read value from these bits is always H'00. Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Only write H'FF to these registers when the corresponding TX History List is enabled and not empty.

7.9.2.80 Global Reset Control Register (CFDGRSTC)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1380

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
15 to 8	KEY[7:0]	H'00	W	Key Code These bits control the validity of rewriting of the SRST bit.
7 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
0	SRST	0	R/W	Software Reset 0: Normal state 1: Software reset state

SRST bit (Software Reset)

When the SRST bit is set, the CAN-FD module is in the same state as hardware reset. When a reset is required, write 1 then write 0 to this bit.

This bit is cleared when the CAN-FD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

KEY[7:0] bits (Key Code)

When H'C4 is written in the KEY[7:0] bits, a write to the SRST bit is valid.

The read value from these bits is always H'00.

Write a SRST bit and the KEY bits simultaneously.

7.9.2.81 Global Flexible CAN Mode Configuration Register (CFDGFCMC)

Flexible CAN mode configured in the CFDGFCMC register and Flexible transmission buffer assignment configured in the CFDGFTBAC register should not be used simultaneously.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1384

0	FLXC0	0	R/W	Flexible CAN Mode between Channel 0 and Channel 1 0: Normal mode 1: Flexible CAN mode

FLXC0 bit (Flexible CAN Mode between Channel 0 and Channel 1)

When the FLXC0 bit is set, Channel 0 and Channel 1 of a CAN-FD module are in Flexible CAN mode.

Channel 1 uses TX/RX terminal of Channel 0. The TX/RX terminal of Channel 1 cannot be used.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

7.9.2.82 Global Flexible Transmission Buffer Assignment Configuration Register (CFDGFTBAC)

Flexible transmission buffer assignment configured in the CFDGFTBAC register and Flexible CAN mode configured in the CFDGFCMC register should not be used simultaneously.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'138C

FLXMB0[3:0] bits (Flexible Transmission Buffer Assignment between Channel 0 and Channel 1)

Channel 0 can use the number TXMB of channel 1 from 0 to 32 by the configuration of these bits.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

7.9.2.83 Global Test Configuration Register (CFDGTSTCFG)

The CFDGTSTCFG register is used to configure the CAN channels joining the internal CAN bus communication test mode and the RAM test mode page.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1308

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
25 to 16	RTMPS[9:0]	All 0	R/W	RAM Test Mode Page Select Select a RAM test mode page
15 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	C2ICBCE	0	R/W	Channel 2 Internal CAN Bus Communication Test Mode Enable 0: Channel 2 internal CAN bus communication disabled 1: Channel 2 internal CAN bus communication enabled
1	C1ICBCE	0	R/W	Channel 1 Internal CAN Bus Communication Test Mode Enable 0: Channel 1 internal CAN bus communication disabled 1: Channel 1 internal CAN bus communication enabled
0	C0ICBCE	0	R/W	Channel 0 Internal CAN Bus Communication Test Mode Enable 0: Channel 0 internal CAN bus communication disabled 1: Channel 0 internal CAN bus communication enabled

CnICBCE (n = 0, 1, 2) bits (Channel n Internal CAN Bus Communication Test Mode Enable)

When the C0ICBCE and C1ICBCE bits are set and CAN-FD module is configured in the internal CAN bus communication test mode, then CAN channel n joins the internal CAN bus communication test mode operation.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

RTMPS[9:0] bits (RAM Test Mode Page Select)

The RTMPS[9:0] bits select the RAM page mode for CPU read/write access when the CAN-FD module is configured in RAM test mode.

See **7.9.9.2.1 RAM Test Mode** for the RAM test mode specification.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 15 (H’00F) for the AFL RAM and 16 to 76 (H’04C) for the message buffer RAM.

The setting range of these bits depends on the combination of parameters.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in GL_RESET mode.

7.9.2.84 Global Test Control Register (CFDGTSTCTR)

The CFDGTSTCTR register is used to control the global test modes of the CAN-FD module.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'130C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	RTME	0	R/W	RAM Test Mode Enable 0: RAM test mode disabled 1: RAM test mode enabled
1	—	0	R/W	Reserved This bit is read as 0. The write value should be always 0.
0	ICBCTME	0	R/W	Internal CAN Bus Communication Test Mode Enable 0: Internal CAN Bus Communication test mode disabled 1: Internal CAN Bus Communication test mode enabled

ICBCTME bit (Internal CAN Bus Communication Test Mode Enable)

When the ICBCTME bit is set, internal CAN bus communication is enabled for the CAN channels that are configured for internal CAN bus communication participation. See **7.9.9.2.2 Internal CAN Bus Communication Mode** for the specification of internal CAN bus communication test mode.

Only write to this bit when the CAN-FD module is in GL_HALT mode.

Clear this bit when the CAN-FD module is in GL_HALT mode.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RTME bit (RAM Test Mode Enable)

When the RTME bit is set, the CAN-FD module is configured in RAM test mode. See **7.9.9.2.1 RAM Test Mode** for RAM test mode specification.

Only write to this bit when the CAN-FD module is in GL_HALT mode.

Clear this bit when the CAN-FD module is in GL_HALT mode.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

7.9.2.85 Global FD Configuration Register (CFDGFDCFG)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1314

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
9, 8	TSCCFG[1:0]	00	R/W	Timestamp Capture Configuration 00: Timestamp capture at the sample point of SOF (start of frame) 01: Timestamp capture at frame valid indication 10: Timestamp capture at the sample point of RES bit 11: Reserved
7 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
0	RPED	0	R/W	RES Bit Protocol Exception Disable 0: Protocol exception event detection enabled 1: Protocol exception event detection disabled

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CAN-FD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDGFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CAN-FD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Set 01b to these bits when can_race_ts_en is 1.

See **7.9.8.1.3 Timestamp** for the timestamp in detail.

7.9.2.86 Global Lock Key Register (CFDGLOCKK)

The CFDGLOCKK register is a write-only register that is used to unlock the protection for special test bits. See **7.9.9.2 Global Test Modes** for Lock key specification.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'131C

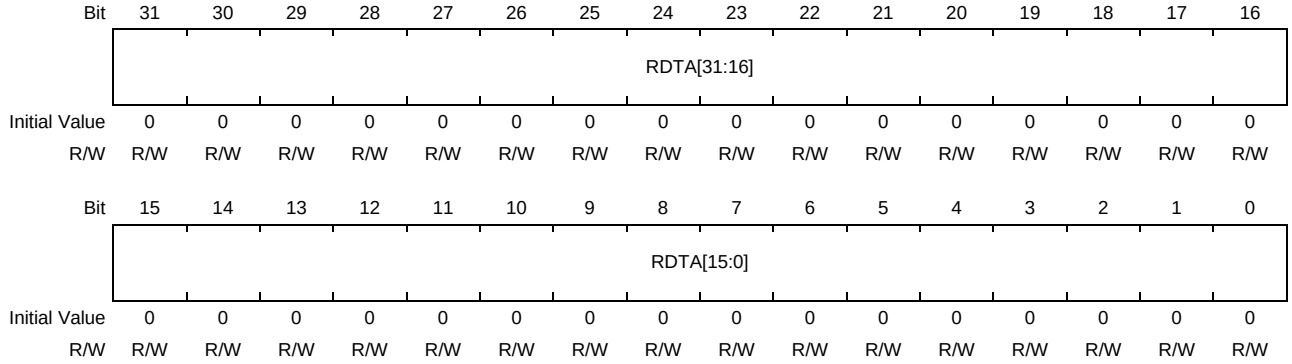
15 to 0	LOCK[15:0]	H'0000	W	Lock Key Key bits for unlocking the protection of test modes

LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CAN-FD module in RAM test modes.

The read value from these bits is always H'0000.



Cannot write to these bits when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CAN-FD module is in GL_OPERATION mode.

7.9.2.87 RAM Test Page Access Register n (CFDRPGACCn) (n = 0 to 63)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'8400 + H'04 × n

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDTA[31:0]	All 0	R/W	RAM Data Test Access RAM data bytes

RDTA[31:0] bits (RAM Data Test Access)

Data can be read from or written into the RDTA[31:0] bits when the CAN-FD module is configured in RAM test mode.

Only write to this bit when the CAN-FD module is in GL_HALT mode and RAM test mode is enabled.

If data is read when RAM test mode is not enabled, then it is always read as H'0000_0000.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

7.9.2.88 Channel n Bus Load Control Register (CFDCnBLCT) (n = 0, 1, 2)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1418 + H'20 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
8	BLCLD	0	W	Bus Load Counter Load When CFDCnBLCT.BLCLD is set, it is reset after a bus load counter value is loaded.
7 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
0	BLCE	0	R/W	Bus Load Counter Enable 0: Bus load counter disabled 1: Bus load counter enabled

BLCE bit (Bus Load Counter Enable)

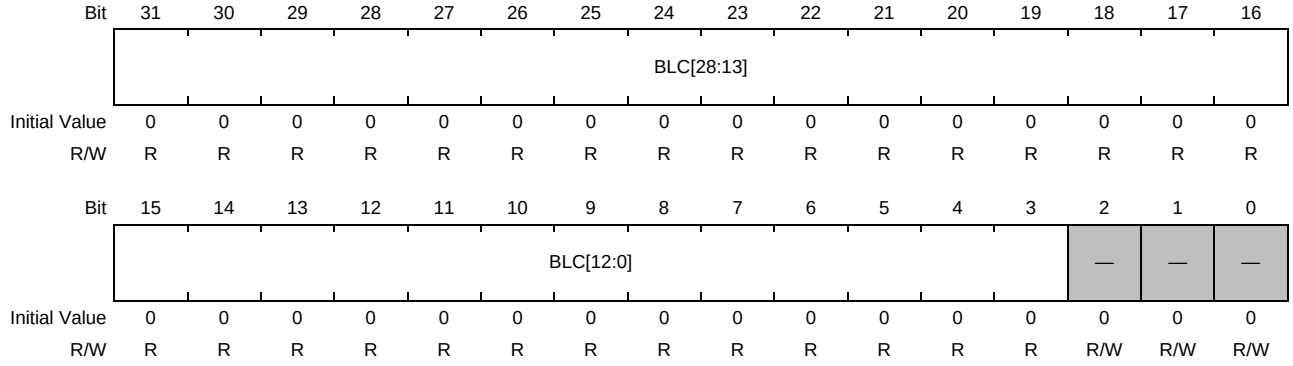
The BLCE bit indicates the enabling signal of a bus load counter. Write to this bit after setting up the CFDCnNCFG register.

When this bit is 0, the bus load counter stops but the counter is not clear.

The bit is cleared when the related CAN-FD channel is in CH_RESET mode.

Do not write to this bit in CH_SLEEP mode.

BLCLD bit (Bus Load Counter Load)



When the BLCLD bit is set, the bus load counter value is loaded into CFDCnBLSTS.BLC and the bus load counter is reset.

The read value is always 0.

7.9.2.89 Channel n Bus Load Status Register (CFDCnBLSTS) (n = 0, 1, 2)

Base address: CAN-FD = H'0_100C_0000

Offset address: H'141C + H'20 × n

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	BLC[28:0]	All 0	R	Bus Load Counter Status These bits indicate the bus load counter value.
2 to 0	—	000	R/W	Reserved These bits are read as 0. The write value should be always 0.

BLC[28:0] bits (Bus Load Counter Status)

The bus load counter increases by PCLKM/2 period while CAN bus is in an idle state.

When the CFDCnBLCT.BLCLD bit is set, the bus load counter value is loaded to BLC[28:0] bits and the bus load counter is reset.

These bits are set only by the CAN-FD module. Writing any value has no effect.

7.9.2.90 Identifier Bits Alignment

Standard Identifier (11 bits) format: ID28 to ID18 is aligned to b10 to b0, b11 to b28 should be 0.

Extended Identifier (29 bits) format: ID28 to ID0 is aligned to b28 to b0

For Standard Identifier format bits 11 to 28 (b11 to b28) should be all 0.

Table 7.9-13 Standard Identifier (11-Bit Format)

7.9.2.91 Message Buffer Component Structure

7.9.2.91.1 Start Addresses

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components and the number of channels.

Table 7.9-15 Channel Components Features

number_of_channels	i	2
number_of_RMBCPs_per_channel	b	16
number_of_RFMBCPs	b	8
number_of_CFMBCPs_per_channel	b	3
number_of_TMBCPs_per_channel	b	64

The start addresses for each register in the Message Buffer component are depicted in **Table 7.9-16**.

Table 7.9-16 Message Buffer Component Register Start Addresses

b = Message Buffer Component Index	MBCP	Register	p	Start Address n = 0, 1, 2
0 to number_of_RMBCPs_per_channel - 1	RMBCPb[i]	RMID	—	H’2000 + b × H’0080 + n × H’800
		RMPTR	—	H’2004 + b × H’0080 + n × H’800
		RMFDSTS	—	H’2008 + b × H’0080 + n × H’800
		RMDFp	0 to 15	H’200C + p ×H’0004 + b ×H’0080 + n ×H’800
0 to number_of_RFMBCPs - 1	RFMBCPb[i]	RFID	—	H’6000 + b × H’0080
		RFPTR	—	H’6004 + b × H’0080
		RFFDSTS	—	H’6008 + b × H’0080
		RFDFp	0 to 15	H’600C + p × H’0004 + b × H’0080
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb[i]	CFID	—	H’6400 + b × H’0080 + n × H’180
		CFPTR	—	H’6404 + b × H’0080 + n × H’180
		CFFDCSTS	—	H’6408 + b × H’0080 + n × H’180
		CFDFp	0 to 15	H’640C + p × H’0004 + b × H’0080 + n × H’180
0 to number_of_TMBCPs_per_channel - 1	TMBCPb[i]	TMID	—	H’1_0000 + b × H’0080 + n × H’2000
		TMPTR	—	H’1_0004 + b × H’0080 + n × H’2000
		TMFDCTR	—	H’1_0008 + b × H’0080 + n × H’2000
		TMDFp	0 to 15	H’1_000C + p × H’0004 + b × H’0080 + n × H’2000

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[i])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[i])
- Common FIFO Access Message Buffer Component (CFDCFMBCPb[i])
- TX Message Buffer Component (CFDTMBCPb[i]).

Where b = the Message Buffer component index having a range that varies based on the type of Message Buffer component and i = channel index that has a range from 0 to n.

For a summary of this configuration, see **Figure 7.9-28 Message Buffer Configuration**. For a detailed description of the number of and the different types of message buffers, see **7.9.6 FIFO Buffers and Normal Message Buffer Configuration**.

As described in **7.9.2 Register Descriptions**, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

p is the Data Field register index having a range that varies based on the type of Message Buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index having a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains ‘-’ means reserved and has the same behavior as reserved bits for registers in **7.9.2 Register Descriptions**.

7.9.2.91.2 RX Message Buffer Component b (CFDRMBCPb[i])

Base address: CAN-FD = H'0_100C_0000

Offset address: RMID: H'2000 + H'0080 × b + H'800 × n
RMPTR: H'2004 + H'0080 × b + H'800 × n
RMFDSTS: H'2008 + H'0080 × b + H'800 × n
RMDFp: H'200C + H'0004 × p + H'080 × b + H'800 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Rc[31:16]

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Rc	All 0	R	RX Message Buffer Component c Refer to **Table 7.9-17**, **Table 7.9-18** and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.

(no_of_channels = 4)

(i = 0 .. no_of_channels – 1)

(b = RX Message Buffer Component index = [0…no_of_CFDRMBCPs_per_channel-1])

(no_of_CFDRMBCPs_per_channel = No. of RX Message Buffer Components per Channel = 16)

Where the total number of CFDRMBCPs = no_of_CFDRMBCPs_per_channel × no_of_channels = 16 × 4 = 64 as shown in **Figure 7.9-28 Message Buffer Configuration**.

(c = RX Message Buffer Component Register index = [0…no_of_REGs_per_CFDRMBCP-1])

no_of_REGs_per_CFDRMBCP = No. of Registers per RX Message Buffer Component = 19

Rc bit (RX Message Buffer Component c)

The RX Message Buffer Component is made up of the following registers: **CFDRMID**, **CFDRMPTR**, **CFDRMFDSTS**, and **CFDRMDFp**. Refer to **Table 7.9-18, RX Message Buffer Component Detailed** for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 7.9-17 RX Message Buffer Component Summary

RX Message Buffer Component (RMBCP)	
Rc	Description
R0	RX Message Buffer ID Registers CHn
R1	RX Message Buffer Pointer Register CHn

7.9.2.91.3 RX Message Buffer ID Register n (CFDRMIDn) (n = 0 to 47)

The CFDRMIDn register (n = 0 to 47) stores the ID field, IDE bit, and RTR bit of the received message.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'2000 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	RMIDE	0	R	RX Message Buffer IDE Bit 0: STD-ID is stored 1: EXT-ID is stored
30	RMRTR	0	R	RX Message Buffer RTR Bit 0: Data frame 1: Remote frame
29	—	0	R/W	Reserved This bit is read as 0. The write value should be always 0.
28 to 0	RMID[28:0]	All 0	R	RX Message Buffer ID Field STD-ID/EXT-ID fields

RMID[28:0] bits (RX Message Buffer ID Field)

The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.90 Identifier Bits Alignment**.

See **7.9.2.91.1 Start Addresses** for details on how to interpret the structure of this buffer component.

RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).

RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

7.9.2.91.4 RX Message Buffer Pointer Register n (CFDRMPTRn) (n = 0 to 47)

The CFDRMPTRn register (n = 0 to 47) stores the DLC and Timestamp fields for the received message.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'2004 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	RMDLC[3:0]	H'0	R	RX Message Buffer DLC Field Number of data bytes received in a CAN frame.
27 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
15 to 0	RMTS[15:0]	H'0000	R	RX Message Buffer Timestamp Field Timestamp value stored for the message in the RX message buffer

RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFDCFG.TSCCFG of the received message.

In the case of can_race_ts_en=1, the information as which CFDRMPTR.RMTS is inputted from can_race_ts is reflected. See **7.9.8.1.3 Timestamp** for the timestamp in detail.

RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See *Table 5 in ISO 11898-1 (2015) Specification* for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS.

7.9.2.91.5 RX Message Buffer CAN-FD Status Register n (CFDRMFDSTSn) (n = 0 to 47)

The CFDRMFDSTSn register (n = 0 to 47) shows the status of the FDF, BRS, and ESI bits, and pointer of the received CAN-FD frame.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'2008 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMPTR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RMIFL[1:0]		—	—	—	—	—	RMFDF	RMBRS	RMESI
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	RMPTR[15:0]	H'0000	R	RX Message Buffer Pointer Field
15 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
9, 8	RMIFL[1:0]	00	R	RX Message Buffer Information Label Field
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	RMFDF	0	R	CAN-FD Format bit 0: Non CAN-FD frame received 1: CAN-FD frame received
1	RMBRS	0	R	Bit Rate Switch bit 0: CAN-FD frame received with no bit rate switch 1: CAN-FD frame received with bit rate switch
0	RMESI	0	R	Error State Indicator bit 0: CAN-FD frame received from error active node 1: CAN-FD frame received from error passive node

RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

RMFDF bit (CAN-FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CAN-FD frame.

RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

RMPTR[15:0] bits (RX Message Buffer Pointer Field)

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

7.9.2.91.6 RX Message Buffer Data Field p Register n (CFDRMDFp_n) (p = 0 to 15, n = 0 to 47)

The CFDRMDFp_n register (p = 0 to 15, n = 0 to 47) stores the data bytes (4 × p) to data bytes (4 × p + 3) of the received message.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'200C + H'004 × p + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDB_HH[7:0]								RMDB_HL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMDB_LH[7:0]								RMDB_LL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RMDB_HH [7:0]	H'00	R	RX Message Buffer Data Byte (4 × p + 3)
23 to 16	RMDB_HL [7:0]	H'00	R	RX Message Buffer Data Byte (4 × p + 2)
15 to 8	RMDB_LH [7:0]	H'00	R	RX Message Buffer Data Byte (4 × p + 1)
7 to 0	RMDB_LL [7:0]	H'00	R	RX Message Buffer Data Byte (4 × p)

RMDB_LL[7:0] bits (RX Message Buffer Data Byte (4 × p))

The RMDB_LL[7:0] bits store data bytes (4 × p) of the message in the RX message buffer. Unused data bytes are filled with H'00.

RMDB_LH[7:0] bits (RX Message Buffer Data Byte (4 × p + 1))

The RMDB_LH[7:0] bits store data bytes (4 × p + 1) of the message in the RX message buffer. Unused Data Bytes are filled with H'00.

RMDB_HL[7:0] bits (RX Message Buffer Data Byte (4 × p + 2))

The RMDB_HL[7:0] bits store data bytes (4 × p + 2) of the message in the RX message buffer. Unused data bytes are filled with H'00.

RMDB_HH[7:0] bits (RX Message Buffer Data Byte (4 × p + 3))

The RMDB_HH[7:0] bits store data bytes (4 × p + 3) of the message in the RX message buffer. Unused data bytes are filled with H'00.

7.9.2.91.7 RX FIFO Access Message Buffer Component b (CFDRFMBCPb[i])

Base address: CAN-FD = H'0_100C_0000

Offset address: RFID: H'6000 + H'0080 × b
RFPTR: H'6004 + H'0080 × b
RFFDSTS: H'6008 + H'0080 × b
RFDFp: H'600C + H'0004 × p + H'080 × b

7.9.2.91.8 RX FIFO Access ID Register n (CFDRFIDn) (n = 0 to 7)

The CFDRFIDn register (n = 0 to 7) stores the ID field, IDE bit, and RTR bit of the message.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'6000 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28 to 0	RFID[28:0]	All 0	R	RX FIFO Buffer ID Field STD-ID/EXT-ID fields

RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.90 Identifier Bits Alignment**.

RFRTR bit (RX FIFO Buffer RTR bit)

The RFRTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

7.9.2.91.9 RX FIFO Access Pointer Register n (CFDRFPTRn) (n = 0 to 7)

The CFDRFPTRn register (n = 0 to 7) stores the DLC and Timestamp fields for the received message.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'6004 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—

27 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
15 to 0	RFTS[15:0]	H'0000	R	RX FIFO Timestamp Value Timestamp value of the received CAN frame

RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message.

In the case of can_race_ts_en=1, the information as which CFDRFPTR.RFTS is inputted from can_race_ts is reflected.

See **7.9.8.1.3 Timestamp** for the timestamp in detail.

RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See *Table 5 in ISO 11898-1 (2015) Specification* for details in defining the number of data bytes that were received.

7.9.2.91.10 RX FIFO Access CAN-FD Status Register n (CFDRFFDSTSn) (n = 0 to 7)

The CFDRFFDSTSn register (n = 0 to 7) shows the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'6008 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	RFESI	0	R	Error State Indicator bit 0: CAN-FD frame received from error active node 1: CAN-FD frame received from error passive node

RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

RFFDF bit (CAN-FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CAN-FD frame.

RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

7.9.2.91.11 RX FIFO Access Data Field p Register n (CFDRFDFp_n) (p = 0 to 15, n = 0 to 7)

The CFDRFDFpn register (p = 0 to 15, n = 0 to 7) stores data bytes (4 × p) to data bytes (4 × p + 3) of the received message.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'600C + H'004 × p + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RFDB_HH [7:0]	H'00	R	RX FIFO Buffer Data Byte (4 × p + 3)
23 to 16	RFDB_HL [7:0]	H'00	R	RX FIFO Buffer Data Byte (4 × p + 2)
15 to 8	RFDB_LH [7:0]	H'00	R	RX FIFO Buffer Data Byte (4 × p + 1)
7 to 0	RFDB_LL[7:0]	H'00	R	RX FIFO Buffer Data Byte (4 × p)

RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte (4 × p))

The RFDB_LL[7:0] bits store data bytes (4 × p) of the message present in the FIFO buffer. Unused data bytes are filled with H'00 according to the configured data payload size CFDRFCCn.RFPLS.

RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 1))

The RFDB_LH[7:0] bits store data bytes (4 × p + 1) of the message present in the FIFO buffer. Unused data bytes are filled with H'00.

RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 2))

The RFDB_HL[7:0] bits store data bytes (4 × p + 2) of the message present in the FIFO buffer. Unused data bytes are filled with H'00.

RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 3))

The RFDB_HH[7:0] bits store data bytes (4 × p + 3) of the message present in the FIFO buffer. Unused data bytes are filled with H'00.

7.9.2.91.12 Common FIFO Access Message Buffer Component b (CFDCFMBCPb[i])

Base address: CAN-FD = H'0_100C_0000

Offset address: CFID: H'6400 + H'0080 × b + H'180 × n
CFPTR: H'6404 + H'0080 × b + H'180 × n
CFFDSTS: H'6408 + H'0080 × b + H'180 × n
CFDFp: H'640C + H'0004 × p + H'080 × b + H'180 × n

no_of_REGs_per_CFDCFMBCP = No. of Registers per Common FIFO Access Message Buffer Component = 19

Rc bit (Common FIFO Access Message Buffer Component c)

The Common FIFO Access Message Buffer Component is made up of the following registers: **CFDCFID**, **CFDCFPTR, CFDCFFDCSTS**, and **CFDCFDFp**. Refer to **Table 7.9-22 Common FIFO Access Message Buffer Component Detailed** for details of how to interpret the structure of this buffer component and how to access the respective registers.

7.9.2.91.13 Common FIFO Access ID Register n (CFDCFIDn) (n = 0 to 8)

The CFDCFIDn register (n = 0 to 8) stores the ID field, IDE bit, and RTR bit of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'6400 + H'080 × n

29	THLEN	0	R/W	THL Entry Enable TX FIFO mode: 0: Entry is not to be stored in THL after successful TX 1: Entry is to be stored in THL after successful TX RX FIFO mode: Reserved, this bit is read as 0.
28 to 0	CFID[28:0]	All 0	R/W	Common FIFO Buffer ID Field STD-ID/EXT-ID fields

CFID[28:0] bits (Common FIFO Buffer ID Field)

The CFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.90 Identifier Bits Alignment**.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

THLEN bit (THL Entry Enable)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR bit)

The CFRTR bit selects whether a data frame or a remote frame is to be transmitted from or was received in the FIFO buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame is received (RX mode), the register reflects the state of the received value (RRS bit in FD frame format). When CAN-FD transmission (TX or GW mode CFDCFID.CFFDF = 1), the bit is always transmitted dominant (data frame).

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE bit)

The CFIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from or was received in the FIFO buffer.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

7.9.2.91.14 Common FIFO Access Pointer Register n (CFDCFPTRn) (n = 0 to 8)

The CFDCFPTRn register (n = 0 to 8) stores the DLC and Timestamp fields.

In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'6404 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	CFDLC[3:0]	H'0	R/W	Common FIFO Buffer DLC Field Number of data bytes received in a CAN frame, or transmitted in a CAN frame.
27 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
15 to 0	CFTS[15:0]	H'0000	R/W	Common FIFO Timestamp Value Timestamp value of the received CAN frame (FIFO in RX mode).

CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In the case of can_race_ts_en=1, the information as which CFDCFPTR.CFTS is inputted from can_race_ts

is reflected. See **7.9.8.1.3 Timestamp** for the timestamp in detail.

CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See *Table 5 in ISO 11898-1 (2015) Specification* for details in defining the number of data bytes.

In TX mode, you can read and write data from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

7.9.2.91.15 Common FIFO Access CAN-FD Control/Status Register n (CFDCFFDCSTSn) (n = 0 to 8)

The CFDCFFDCSTSn register (n = 0 to 8) shows the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame or the CAN-FD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'6408 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	CFPTR[15:0]	H'0000	R/W	Common FIFO Buffer Pointer Field
15 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
9, 8	CFIFL[1:0]	00	R/W	COMMON FIFO Buffer Information Label Field
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	CFFDF	0	R/W	CAN-FD Format bit 0: Non CAN-FD frame received or to transmit 1: CAN-FD frame received or to transmit
1	CFBRS	0	R/W	Bit Rate Switch bit 0: CAN-FD frame received or to transmit with no bit rate switch 1: CAN-FD frame received or to transmit with bit rate switch
0	CFESI	0	R/W	Error State Indicator bit 0: CAN-FD frame received or to transmit by error active node 1: CAN-FD frame received or to transmit by error passive node

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, when the CAN-FD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, the CFESI bit is updated with the ESI bit value of the CAN-FD frame when it has been received, indicating the error state of the transmitting node. In RX or GW mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, the CAN-FD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, the CFBRS bit is updated with the BRS bit value of the CAN-FD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CAN-FD frame.

In RX or GW mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

CFFDF bit (CAN-FD Format bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, the CAN-FD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CAN-FD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CAN-FD frame (1).

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

7.9.2.91.16 Common FIFO Access Data Field p Register n (CFDCFDFp_n) (p = 0 to 15, n = 0 to 8)

The CFDCFDFpn register (p = 0 to 15, n = 0 to 8) stores data bytes (4 × p) to data bytes (4 × p + 3) of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'640C + H'004 × p + H'080 × n

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CFDB_HH [7:0]	H'00	R/W	Common FIFO Buffer Data Byte (4 × p + 3)
23 to 16	CFDB_HL [7:0]	H'00	R/W	Common FIFO Buffer Data Byte (4 × p + 2)
15 to 8	CFDB_LH [7:0]	H'00	R/W	Common FIFO Buffer Data Byte (4 × p + 1)
7 to 0	CFDB_LL[7:0]	H'00	R/W	Common FIFO Buffer Data Byte (4 × p)

CFDB_LL[7:0] bits (Common FIFO Buffer Data Byte (4 × p))

The CFDB_LL[7:0] bits store data bytes (4 × p) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with H'00, according to their configured data payload size CFDCFCCn.CFPLS.

CFDB_LH[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 1))

The CFDB_LH[7:0] bits store data bytes (4 × p + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with H'00, according to their configured data payload size CFDCFCCn.CFPLS.

CFDB_HL[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 2))

The CFDB_HL[7:0] bits store data bytes (4 × p + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with H’00, according to their configured data payload size CFDCFCCn.CFPLS.

CFDB_HH[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 3))

The CFDB_HH[7:0] bits store data bytes (4 × p + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, Cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with H’00, according to their configured data payload size CFDCFCCn.CFPLS.

7.9.2.91.17 TX Message Buffer Component b (CFDTMBCPb[i])

Base address: CAN-FD = H'0_100C_0000

Offset address: TMID: H'1_0000 + H'0080 × b + H'2000 × n
TMPTR: H'1_0004 + H'0080 × b + H'2000 × n

7.9.2.91.18 TX Message Buffer ID Register n (CFDTMIDn) (n = 0 to 191)

The CFDTMIDn register (n = 0 to 191) stores the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1_0000 + H'080 × n

28:0	TMID[28:0]	All 0	R/W	TX Message Buffer ID Field STD-ID/EXT-ID fields

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.90 Identifier Bits Alignment**.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CAN-FD format. For a CAN-FD transmission (CFDTMFDCTR.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.91.19 TX Message Buffer Pointer Register n (CFDTMPTRn) (n = 0 to 191)

The CFDTMPTRn register (n = 0 to 191) stores the DLC fields of the message to transmit from the associated buffer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1_0004 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	TMDLC[3:0]	H'0	R/W	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.
27 to 0	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

See *Table 5 in ISO 11898-1 (2015) Specification* for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.91.20 TX Message Buffer CAN-FD Control Register n (CFDTMFDCTRn) (n = 0 to 191)

The CFDTMFDCTRn register (n = 0 to 191) shows the status of the FDF, BRS, and ESI bits, including the pointer fields of the CAN-FD frame to be transmitted.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1_0008 + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMPTR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TMIFL[1:0]		—	—	—	—	—	TMFDF	TMBRS	TMESI
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TMPTR[15:0]	H'0000	R/W	TX Message Buffer Pointer Field
15 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
9, 8	TMIFL[1:0]	00	R/W	TX Message Buffer Information Label Field
7 to 3	—	All 0	R/W	Reserved These bits are read as 0. The write value should be always 0.
2	TMFDF	0	R/W	CAN-FD Format bit 0: Non CAN-FD frame to transmit 1: CAN-FD frame to transmit
1	TMBRS	0	R/W	Bit Rate Switch bit 0: CAN-FD frame to transmit with no bit rate switch 1: CAN-FD frame to transmit with bit rate switch
0	TMESI	0	R/W	Error State Indicator bit 0: CAN-FD frame to transmit by error active node 1: CAN-FD frame to transmit by error passive node

TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CAN-FD channel is in CH_SLEEP mode.

TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CAN-FD channel is in CH_SLEEP mode.

TMFDF bit (CAN-FD Format bit)

Do not write to the TMFDF bit when the related CAN-FD channel is in CH_SLEEP mode.

TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMPTR[15:0] bits (TX Message Buffer Pointer Field)

The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.91.21 TX Message Buffer Data Field p Register n (CFDTMDFp_n) (p = 0 to 15, n = 0 to 191)

The CFDTMDFp_n register (p = 0 to 15, n = 0 to 191) stores data bytes (4 × p) to data bytes (4 × p + 3) of the message to transmit from the associated buffer.

Base address: CAN-FD = H'0_100C_0000

Offset address: H'1_000C + H'004 × p + H'080 × n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMDB_HH[7:0]								TMDB_HL[7:0]

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TMDB_HH [7:0]	H'00	R/W	TX Message Buffer Data Byte (4 × p + 3)
23 to 16	TMDB_HL [7:0]	H'00	R/W	TX Message Buffer Data Byte (4 × p + 2)
15 to 8	TMDB_LH [7:0]	H'00	R/W	TX Message Buffer Data Byte (4 × p + 1)
7 to 0	TMDB_LL [7:0]	H'00	R/W	TX Message Buffer Data Byte (4 × p)

TMDB_LL[7:0] bits (TX Message Buffer Data Byte (4 × p))

Data bytes (4 × p)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte (4 × p + 1))

Data bytes (4 × p + 1)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte (4 × p + 2))

Data bytes (4 × p + 2)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte (4 × p + 3))

Data bytes (4 × p + 3)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

7.9.3 Operation

7.9.3.1 Overview

The modes of the CAN-FD module can be classified into 2 groups:

- Global modes
- Channel modes

7.9.3.2 Global Modes

Global modes are applicable for the complete CAN-FD module. The global modes of the CAN-FD module are:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation

Figure 7.9-2 shows the possible transitions between the Global modes.

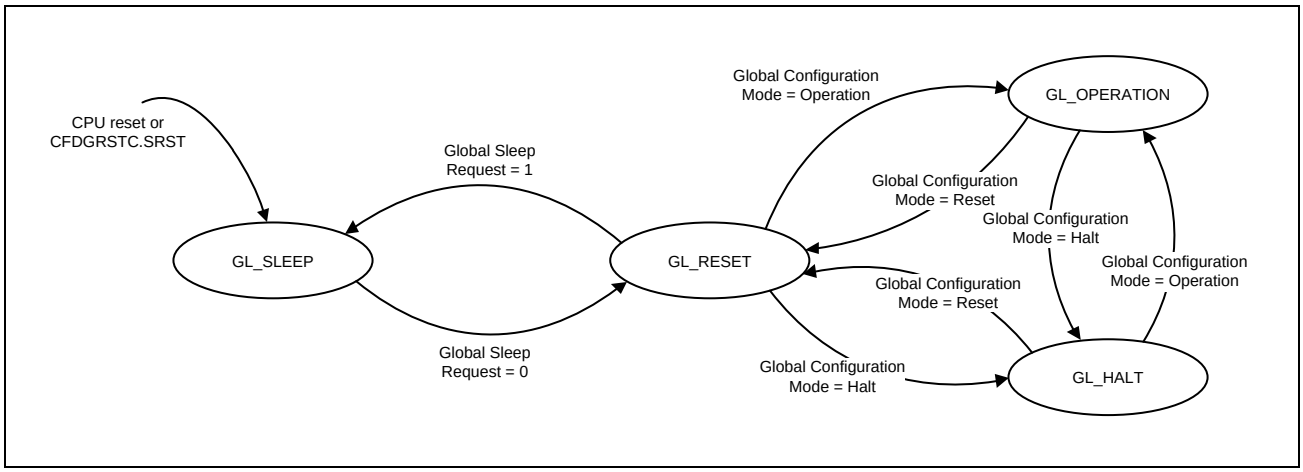

Figure 7.9-2 Transition between CAN-FD Global Modes

Changes in the Global mode can affect the Channel mode. **Table 7.9-25** shows the effect of a Global mode transition on a Channel mode.

Table 7.9-25 Possible CAN-FD Channel Modes and Global Modes

	Target Global Mode			
Current Global Mode	Sleep	Reset	Halt	Operation
Sleep	—	Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A	—	—
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	—

7.9.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, the CAN-FD module automatically enters Global Sleep mode.

The CAN-FD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets all Channel Sleep Request bits and forces all channels into the Channel Sleep mode. Sleep mode is used for power saving purpose. When CAN-FD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CAN-FD module are suspended.

Read access from all registers is still possible and all register values are preserved.

In Global Sleep mode, RAM access is prohibited because the logic which generates a RAM address does not operate.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

Figure 7.9-3 shows the procedure for entering Global Sleep mode and **Figure 7.9-4** shows the procedure for exiting Global Sleep mode.

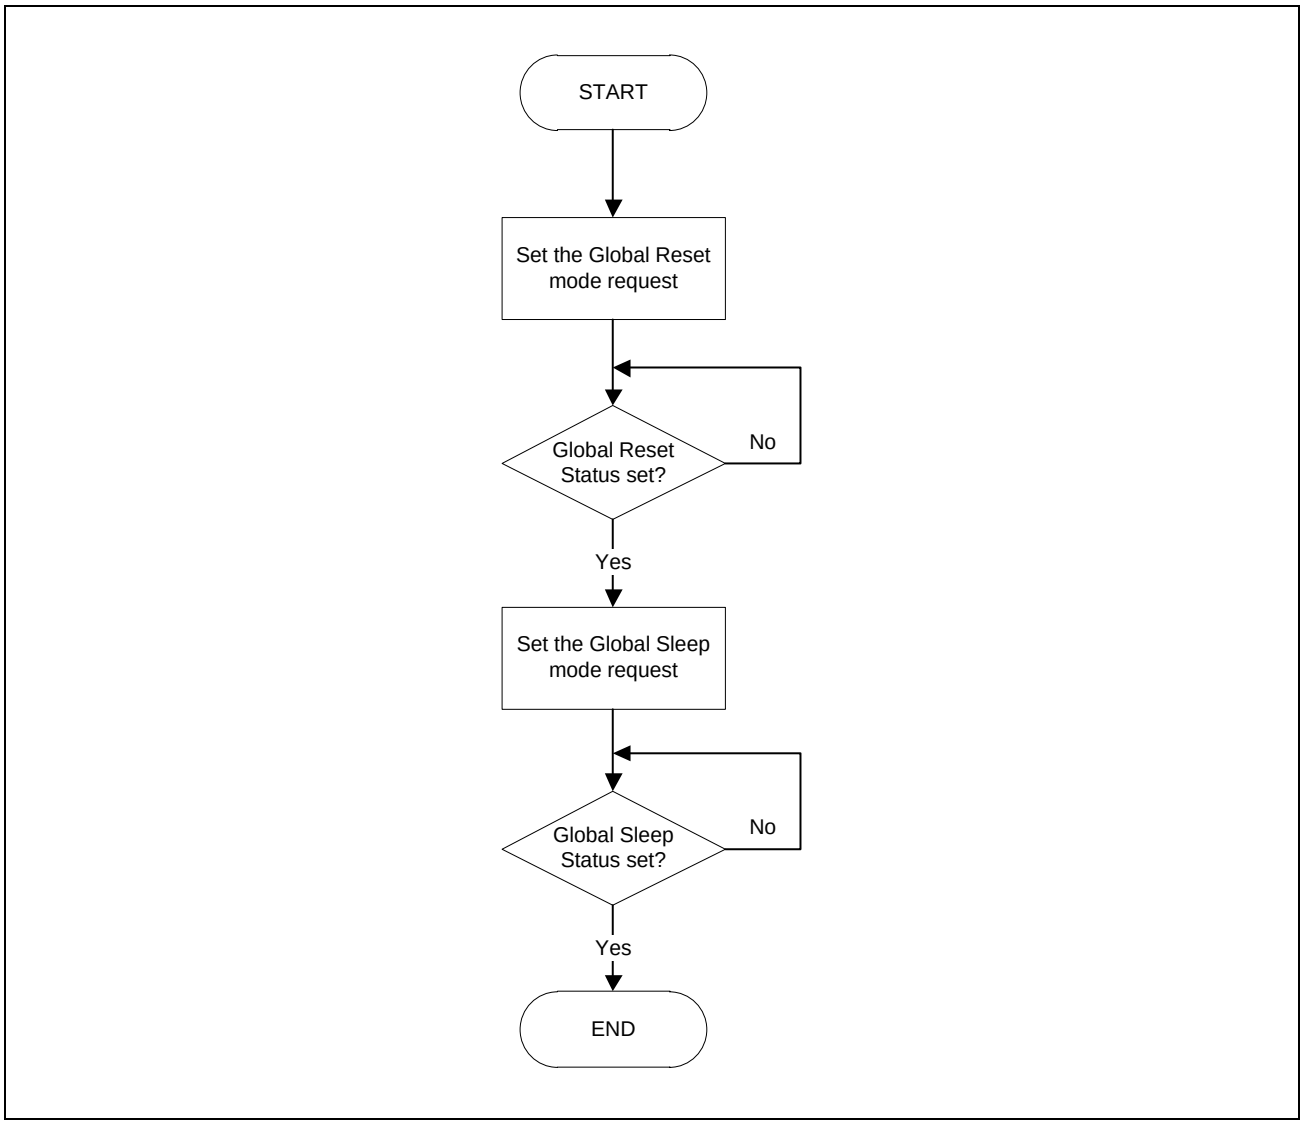

Figure 7.9-3 Procedure for Entering Global Sleep Mode

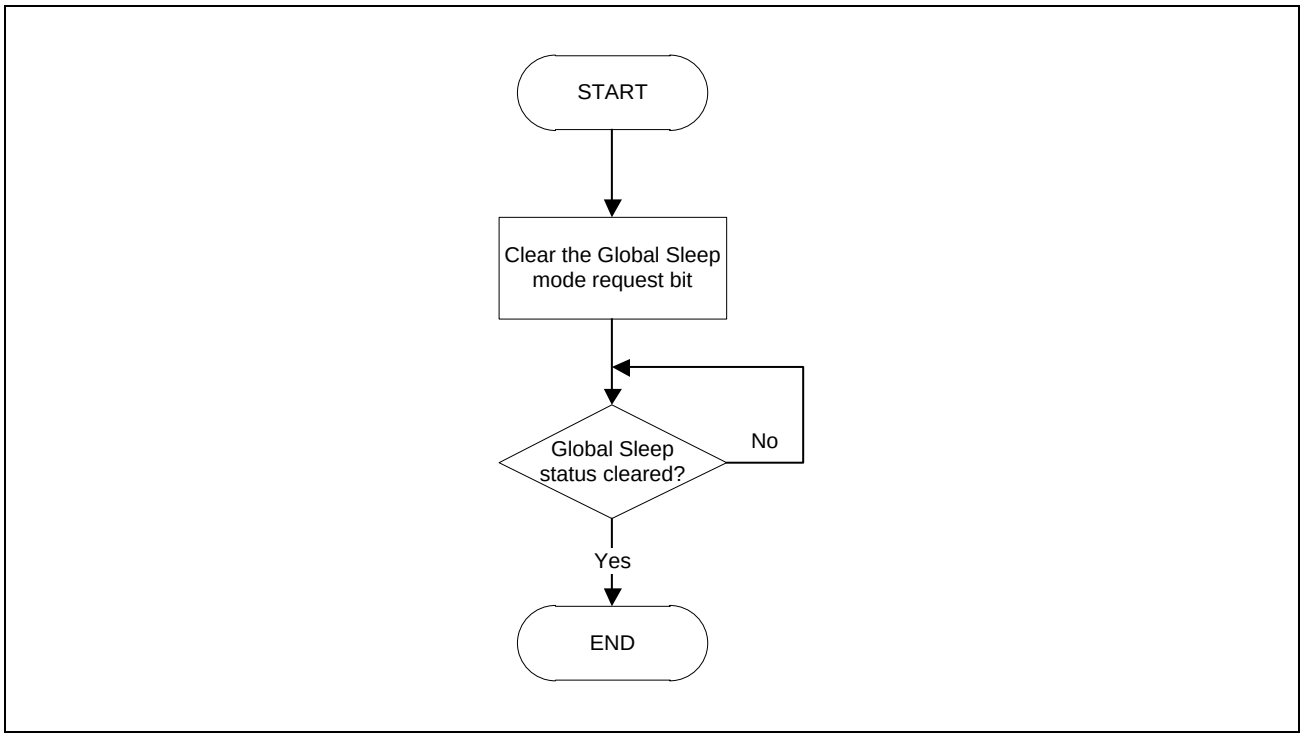

Figure 7.9-4 Procedure for Exiting Global Sleep Mode

7.9.3.2.2 Global Reset Mode

The CAN-FD module enters the Global Reset mode in the following ways:

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Reset mode while the CAN-FD module is in Global Halt or Global Operation mode.
- Global Sleep Mode Request bit is cleared while CAN-FD module is in Global Sleep mode.

In Global Reset mode, all CAN-FD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and all channel TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their device reset values and the CAN-FD module can be configured.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Global Reset mode.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register to 01b sets all Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers to 01b and forces all channels into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDCnCTR.CHMDC[1:0] of related channel already set to 01b).

After setting Global Mode Control bits CFDGCTR.GMDC[1:0] to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

Figure 7.9-5 shows the procedure for entering Global Reset mode and **Figure 7.9-6** shows the procedure for exiting Global Reset mode.

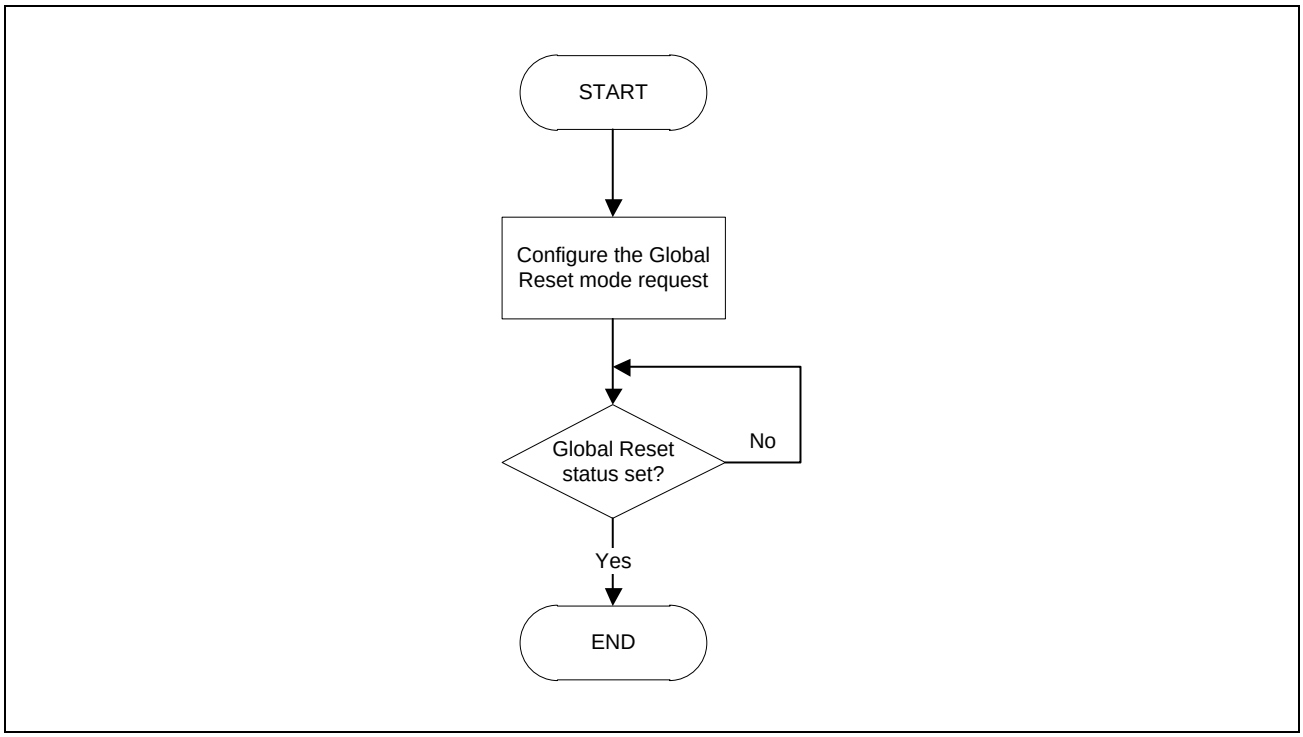

Figure 7.9-5 Procedure for Entering Global Reset Mode

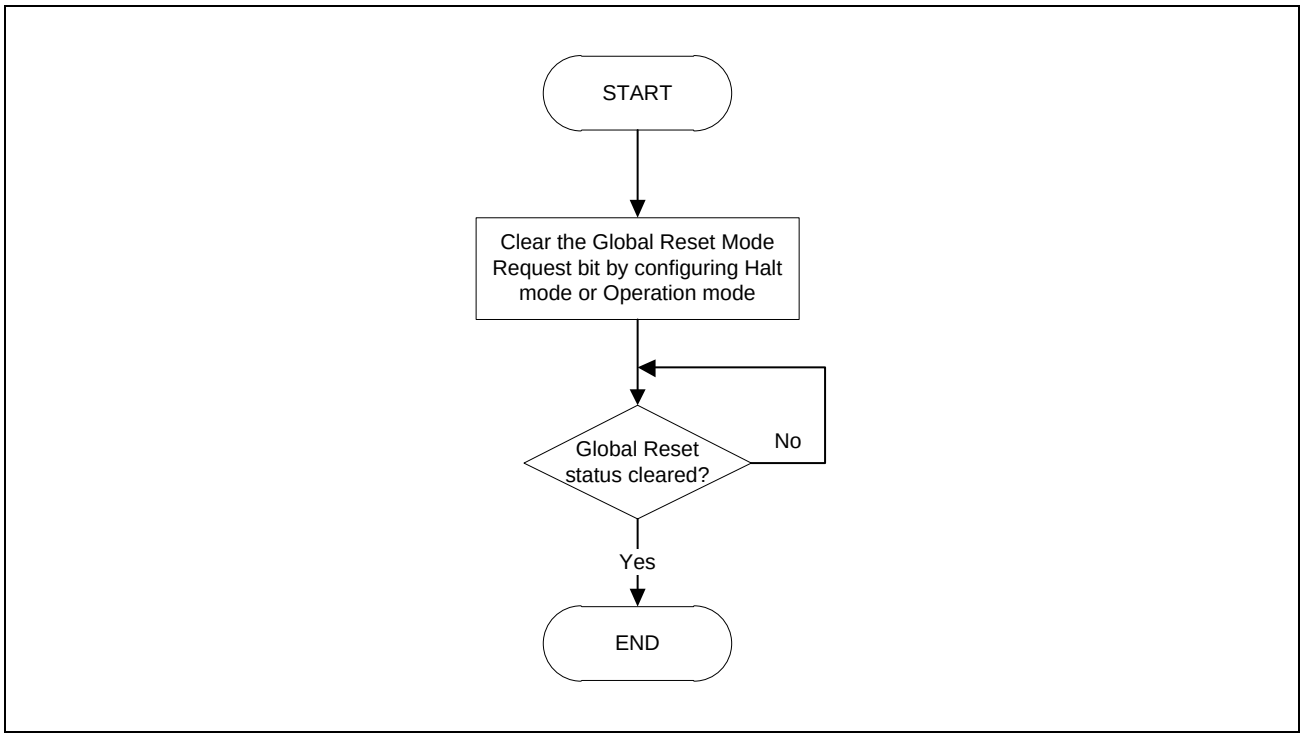

Figure 7.9-6 Procedure for Exiting Global Reset Mode

7.9.3.2.3 Global Halt Mode

The CAN-FD module enters the Global Halt mode in the following ways:

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Halt mode while the CAN-FD module is in Global Reset mode:
  - The channel is in either Channel Reset or Channel Sleep mode and remains in this mode.
- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Halt mode while the CAN-FD module is in Global Operation mode:
  - All channels in Channel Reset, Channel Halt, or Channel Sleep mode remain in this mode
  - All channels in Channel Operation mode transit to Channel Halt mode
  - Global Halt Mode Status bit is set when all channels have left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off state, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CAN-FD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off state that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt mode by setting the Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register to 10b sets all Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers to 10b for the channels that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For channels that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CAN-FD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bits CFDGCTR.GMDC[1:0] to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

Figure 7.9-7 shows the procedure for entering Global Halt mode and **Figure 7.9-8** shows the procedure for exiting Global Halt mode.

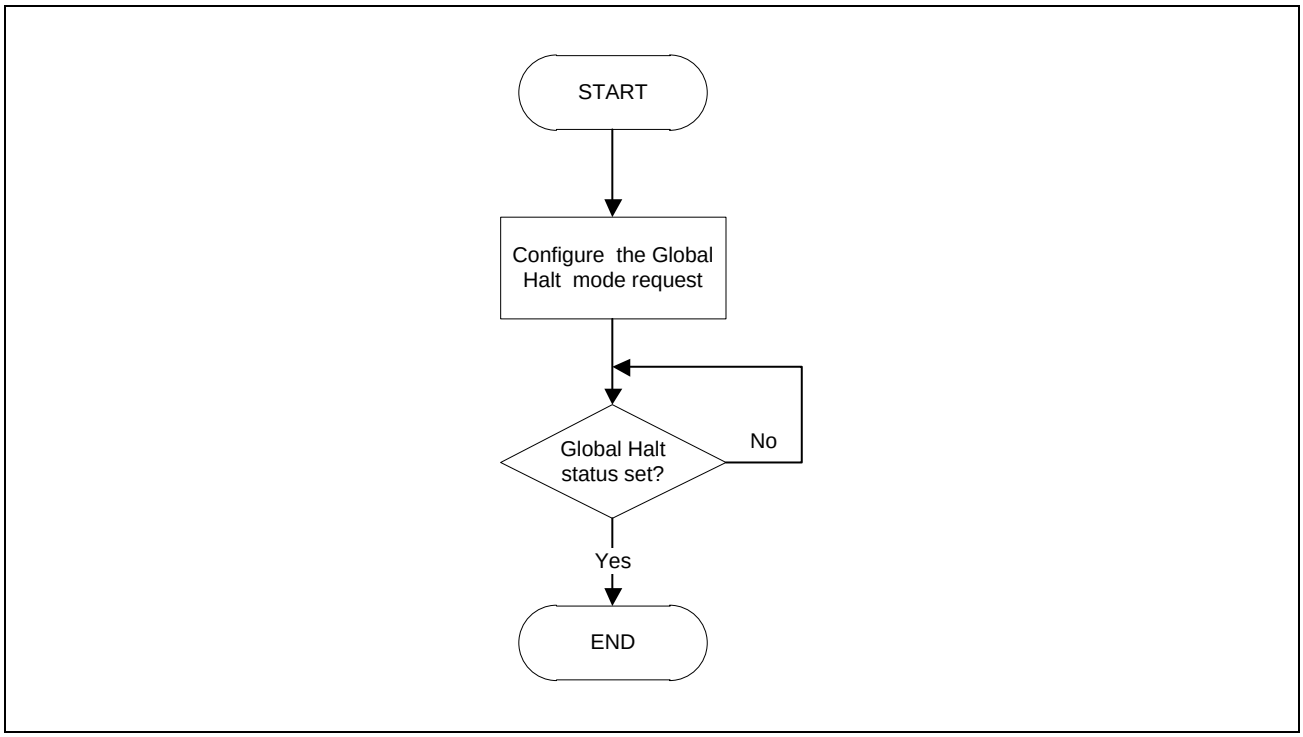

Figure 7.9-7 Procedure for Entering Global Halt Mode

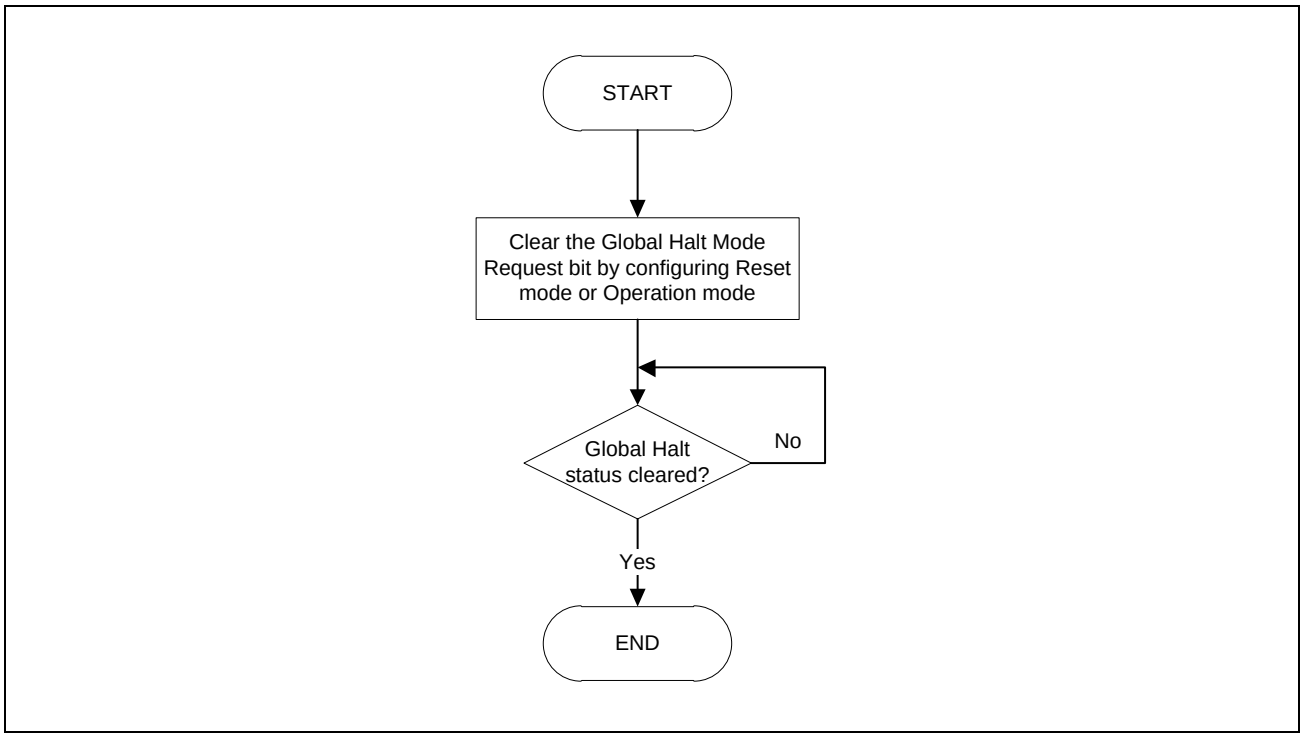

Figure 7.9-8 Procedure for Exiting Global Halt Mode

7.9.3.2.4 Global Operation Mode

The CAN-FD module enters the Global Operation mode when the Global Mode Configuration bits are set to Global Operation mode.

The CAN-FD channels can only be set to Channel Operation mode and start CAN communication when CAN-FD is in Global Operation mode.

After setting the Global Mode Control bits CFDGCTR.GMDC[1:0] to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

Figure 7.9-9 shows the procedure for entering Global Operation mode and **Figure 7.9-10** shows the procedure for exiting Global Operation mode.

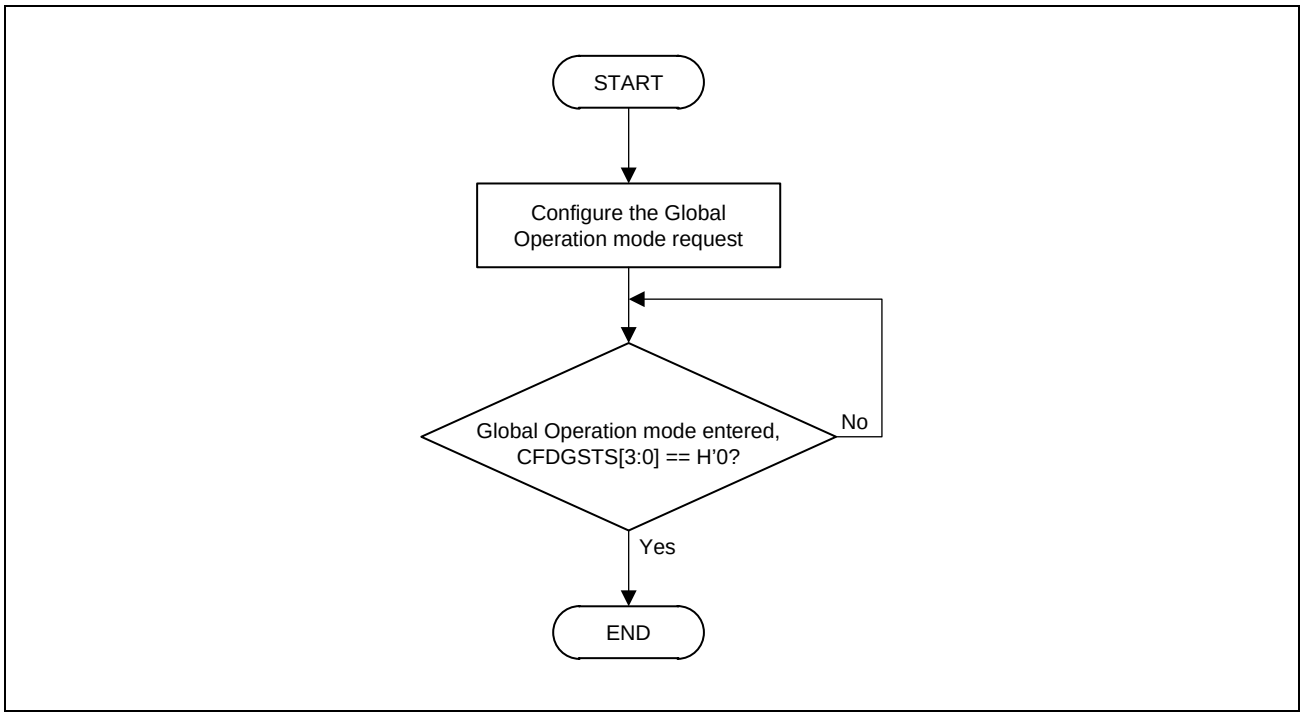

Figure 7.9-9 Procedure for Entering Global Operation Mode

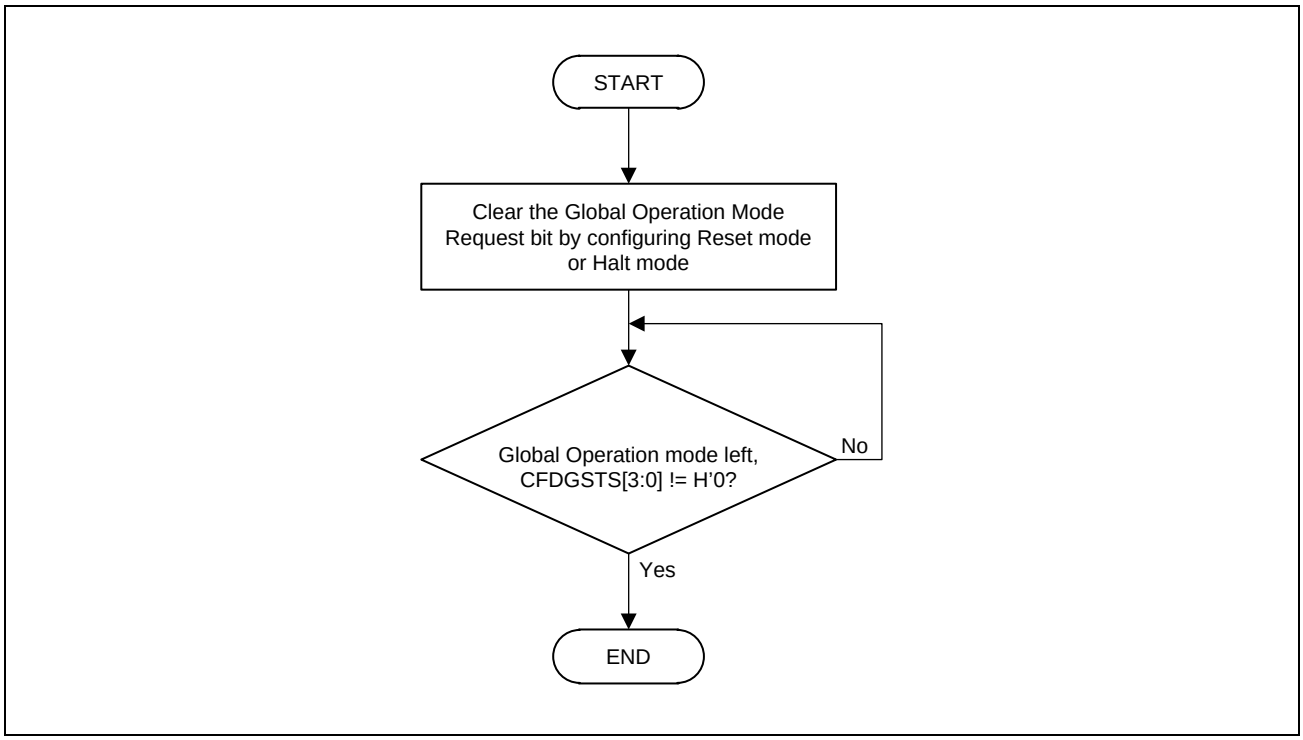

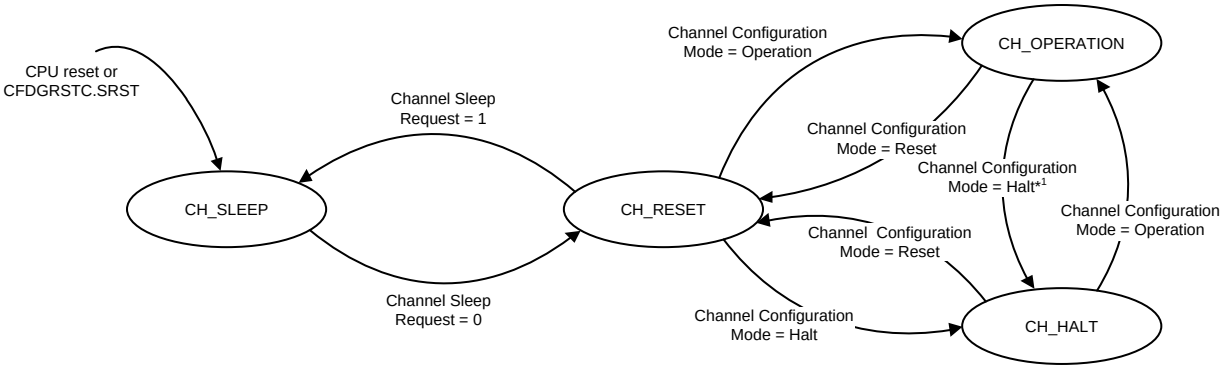

Figure 7.9-10 Procedure for Exiting Global Operation Mode

7.9.3.3 Channel Modes

Each CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep

Figure 7.9-11 shows possible transitions between the channel modes.

Note 1. The transition timing depends on BOM[1:0] setting in the Channel Control Register (CFDCnCTR):
When BOM[1:0] = 01b, the state transition timing is immediate after entering bus-off state
When BOM[1:0] = 10b, the state transition timing is at the end of bus-off state
When BOM[1:0] = 11b, the state transition timing is matching with the setting of CHMDC to HALT mode

Figure 7.9-11 Transition between CAN Channel Modes

7.9.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, each CAN channel of the CAN- FD module automatically enters Channel Sleep mode.

Each CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

7.9.3.3.2 CAN Channel Reset Mode

A CAN-FD CAN channel enters the CAN Channel Reset mode in the following ways:

- Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bits CFDGCTR.GMDC[1:0] is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally all channel-related transmission control bits are cleared and the channel-related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDCnSTS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDCnCTR.CHMDC[1:0] bits can be modified again.

See **Table 7.9-26** for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.

Table 7.9-26 Transition Behavior in CAN Reset Mode and Halt Mode

	State		
Mode	Receiver	Transmitter	Bus-Off
CAN Channel Reset mode (CFDCnCTR.CHMDC[1:0] = 01b)	The CAN channel transits to Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt Mode (CFDCnCTR.CHMDC[1:0] = 10b)	The CAN channel transits to Channel Halt mode at the end of the ongoing reception or error.*2	The CAN channel transits to Channel Halt mode after completion of the ongoing transmission.	When CFDCnCTR.BOM[1:0] is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDCnCTR.BOM[1:0] is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM[1:0] is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM[1:0] is set to 11b, the CAN channel transits to Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at a dominant level after an error flag, software can detect this situation by monitoring the channel related Bus Lock flag and resolve the lock condition by setting the CAN channel to Channel Reset mode.

7.9.3.3.3 CAN Channel Halt Mode

A CAN-FD CAN channel enters the CAN Channel Halt mode in the following ways:

- Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers are configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bits CFDGCTR.GMDC[1:0] are set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for the channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure Channel Test modes.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDCnSTS.CHLTSTS in the related Channel Status Register is updated to indicate a successful transition to Channel Halt mode before the related CFDCnCTR.CHMDC[1:0] bits can be modified again.

See **Table 7.9-26** for the behavior of transitioning to Channel Halt mode while CAN communication is ongoing.

7.9.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDCnCTR.CHMDC[1:0] bits to 00b. If 11 consecutive recessive bits are detected after entering CAN Channel Operation mode, the CFDCnSTS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see **Figure 7.9-12**):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self-Test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDCnSTS.CRSTSTS and the Channel Halt Mode Status bit CFDCnSTS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDCnCTR.CHMDC[1:0] bits can be changed again.

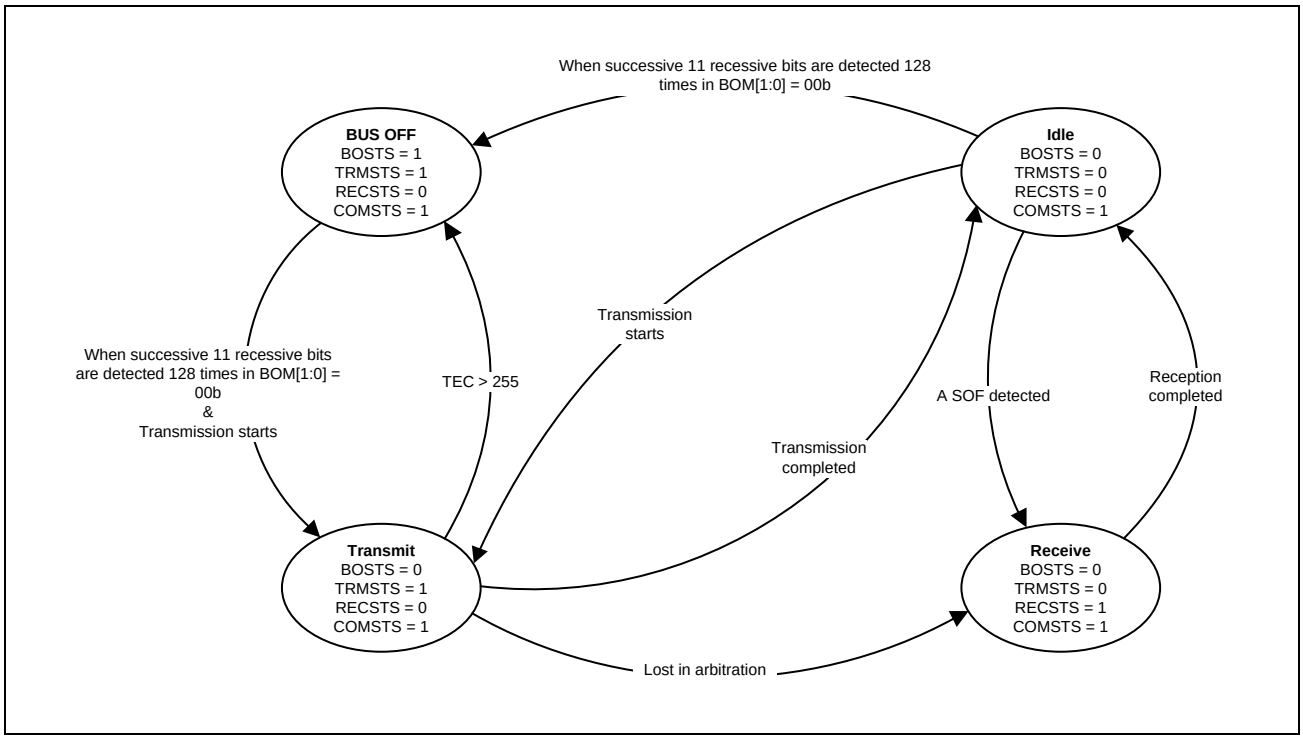

Figure 7.9-12 Sub-Modes of CAN Channel Operation Mode (Only when BOM[1:0] = 00b)

7.9.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDCnCTR.BOM[1:0] = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM[1:0] = 01b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC[1:0] bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set in this case.
- CFDCnCTR.BOM[1:0] = 10b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC[1:0] bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM[1:0] = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set. Without setting CFDCnCTR.CHMDC[1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDCnCTR.BOM[1:0] = 00b.

Note: If the recovery from bus-off occurs normally in Channel Halt mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDCnERFL.BORF is set.

When software writes to the CFDCnCTR.CHMDC[1:0] bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM[1:0] = 01b, or at the end of bus-off when CFDCnCTR.BOM[1:0] = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDCnCTR.CHMDC[1:0] bits to Channel Halt mode request is performed when the CFDCnCTR.CHMDC[1:0] bits value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDCnCTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDCnCTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX or GW mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSn.TMTRF[1:0]). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTSn.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTSn.CFEMP).

The CFDCnCTR.RTBO bit should be used for bus-off recovery only when CFDCnCTR.BOM[1:0] is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 7.9-27 shows the settings for the Bus-Off Entry flag CFDCnERFL.BOEF and the Bus-Off Recovery flag CFDCnERFL.BORF for the different configurations of CFDCnCTR.BOM[1:0].

Table 7.9-27 Behavior of Bus-off Entry and Recovery Flags

BOM[1:0]	BOEF Bit Setting	BORF Bit Setting
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDCnCTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDCnCTR.RTBO to 1
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in **Figure 7.9-13**.

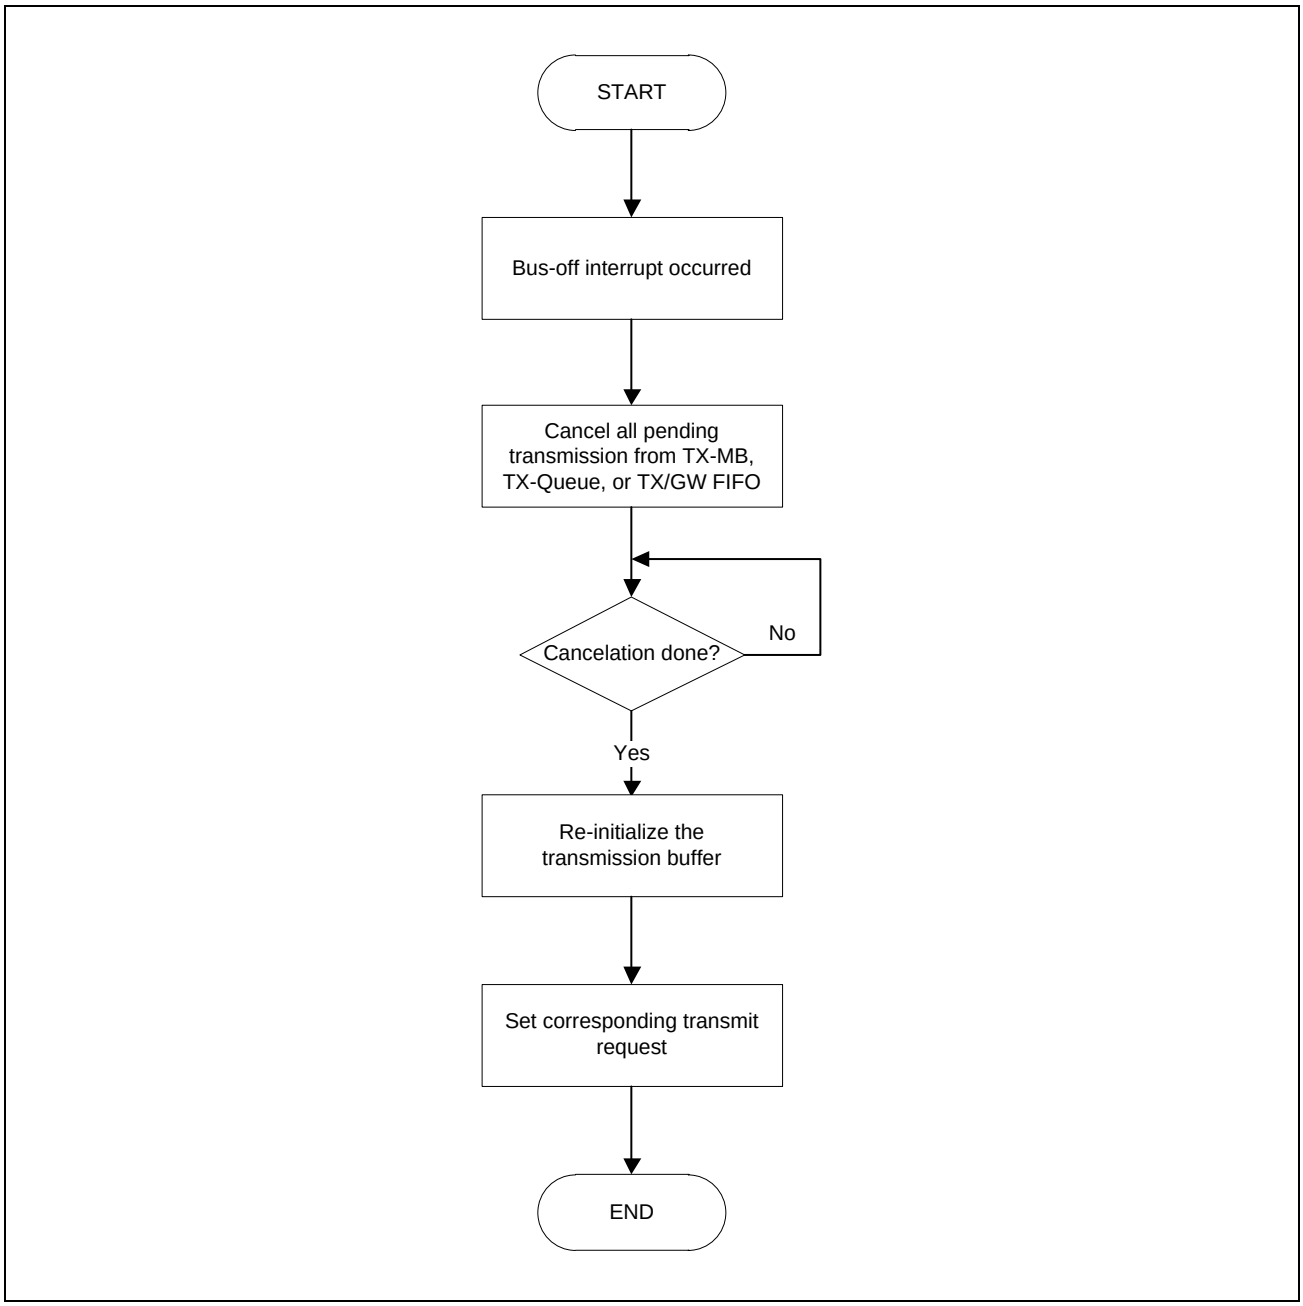

Figure 7.9-13 Transmission Re-Initialization during Bus-Off State

7.9.3.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers does not affect the Global Mode Control bits CFDGCTR.GMDC[1:0].
- Changing the Global Mode Control bits CFDGCTR.GMDC[1:0] affects the channel mode control as described in **Table 7.9-28**.

Table 7.9-28 Instruction between Global and Channel Mode Transition

Global Mode Change	Channel Mode	Channel Mode Transition Action
Sleep → Reset	Sleep	Channel remains in Sleep mode
Sleep → Halt	— (Global mode change not possible)	
Sleep → Operation	— (Global mode change not possible)	
Reset → Sleep	Sleep	Channel remains in Sleep mode
	Reset	Channel Sleep request bit is set automatically, channel transits to Sleep mode
Reset → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Reset → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Halt → Sleep	— (Global mode change not possible)	
Halt → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel transits to Reset mode
Halt → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
Operation → Sleep	— (Global mode change not possible)	
Operation → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel transits to Reset mode
	Operation	Channel mode control is set to Reset mode, channel transits to Reset mode
Operation → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
	Operation	Channel mode control is set to Halt mode, channel transits to Halt mode after communication finished

7.9.3.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

From	To	Maximum Transition Time
GL_SLEEP	GL_RESET	3 peripheral clock cycles*2
GL_RESET	GL_SLEEP	3 peripheral clock cycles
GL_RESET	GL_HALT	10 peripheral clock cycles
GL_RESET	GL_OPERATION	10 peripheral clock cycles
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1,*3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.

Note 3. TQ, CAN frame, and CAN bits are related to the individual channels. For maximum transition time, the channel with the lowest baud rate must be used.

7.9.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

From	To	Maximum transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*2
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1,*3

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDCnCTR.BOM[1:0] bits.

Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 3. In general, if the baud rate prescaler value CFDCnNCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

7.9.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud rate setting (nominal and data rate)
- CAN-FD setting
- Acceptance filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

7.9.4.1 Initialization of CAN Clock, Bit Timing and Baud Rate

7.9.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the limitations that apply to the segment setting.

1. Each segment setting SS = Fixed to 1 TQ
   TSEG1 = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   TSEG2 = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   SJW = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   SS + TSEG1 + TSEG2 = 5 to 49 TQs for data bit rate and 8 to 385 for nominal bit rate

2. Limitations on TSEG1, TSEG2 and SJW
   TSEG1 (N) > TSEG2 (N) ≥ SJW (N)
   TSEG1 (D) ≥ TSEG2 (D) ≥ SJW (D)
   Table 7.9-29 shows an example of how to set the bit timing to achieve the required Sample Point settings.

Table 7.9-29 Transition Behavior in CAN Reset Mode and Halt Mode

	Set Value (TQ)				
1 Bit	SS	TSEG1	TSEG2	SJW	Sample Point*1 (%)
5 TQ	1	2	2	1	60.00
8 TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10 TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12 TQ	1	8	3	1	75.00
	1	9	2	1	83.33
15 TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16 TQ	1	10	5	1	68.75
	1	11	4	1	75.00
20 TQ	1	12	7	1	65.00
	1	13	6	1	70.00
24 TQ	1	15	8	1	66.66
	1	16	7	1	70.83
50 TQ	1	39	10	4	80.00

Note 1. Sample Point (in Case of 75%)

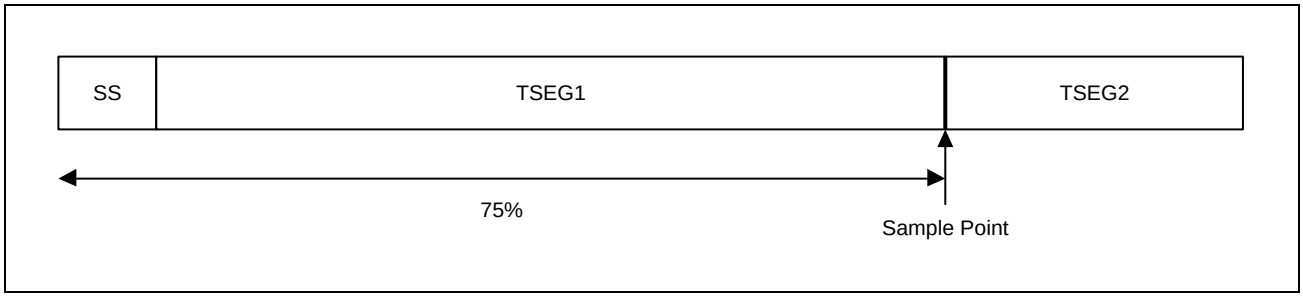

Figure 7.9-14 Sample Point (in Case of 75%)

7.9.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for each channel using the related CFDCnNCFG and CFDCnDCFG registers.

Figure 7.9-15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

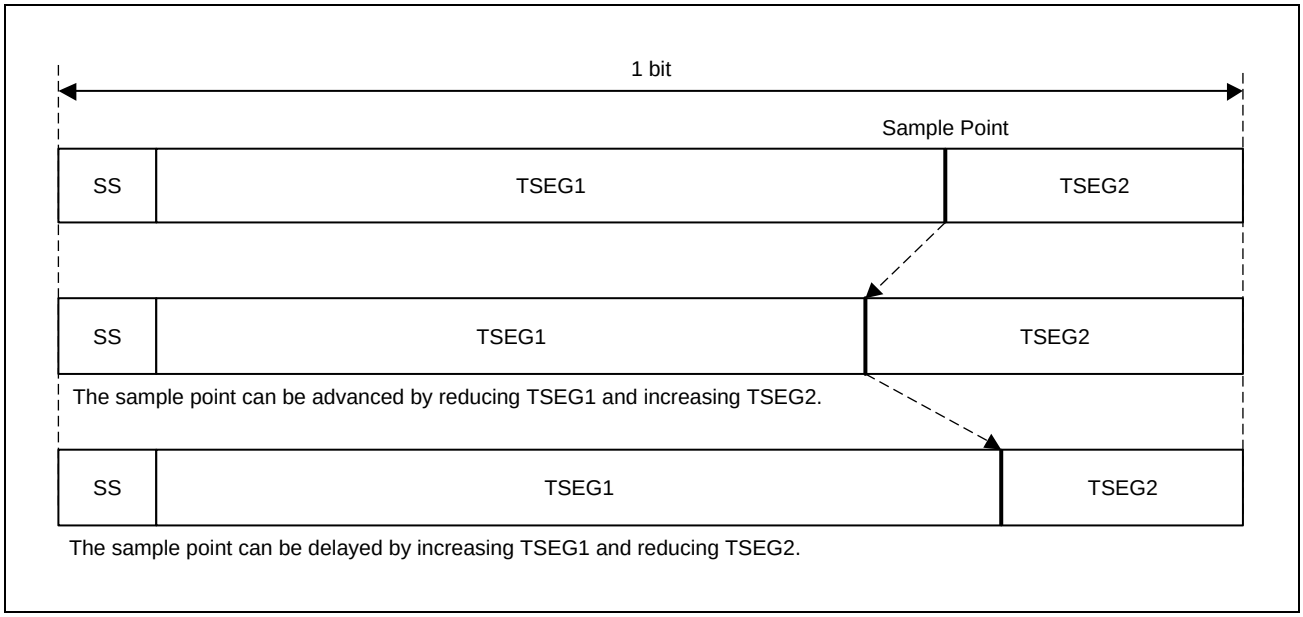

Figure 7.9-15 Segment Composition of a Bit and the Sample Point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 7.9-15 shows only one symbolic sample point.

7.9.4.1.3 Baud Rate

Either PCLKM or PCLKCAN can be selected globally for all CAN channels as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{Baud rate} = \frac{\text{DLL_Clock}}{(\text{number_of_time_quanta_per_bit}) \times (\text{BRP} + 1)}$$

Figure 7.9-16 shows a block diagram of the circuit that generates the CAN channel system clock, **Table 7.9-30** and **Table 7.9-31** show baud rate examples.

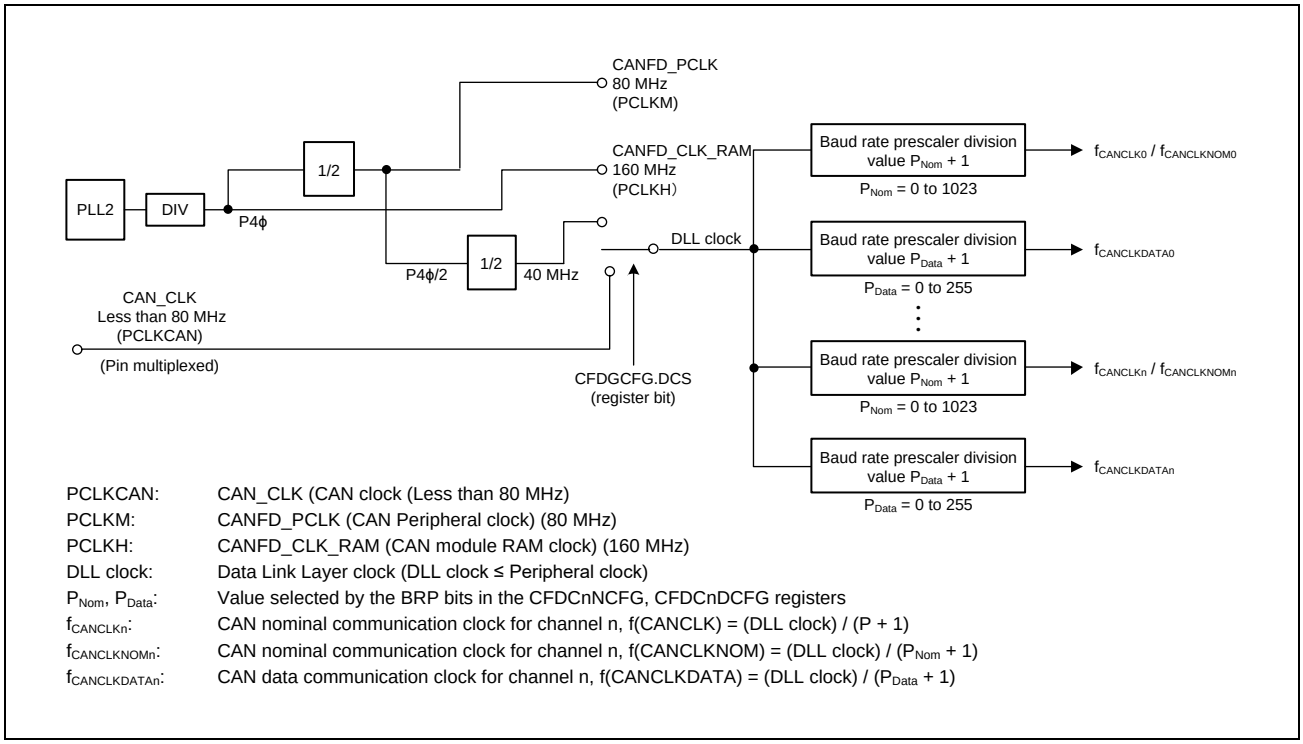

Figure 7.9-16 Block Diagram of the Circuit that Generates the CAN Channel Communication Clock

Table 7.9-30 Nominal Baud Rate Calculation Formula and Example CAN Communication Configurations

Baud rate calculation Formula	(DLL Clock) (Baud Rate Prescaler Divide-By-N Value*1) × (Number of TQs in One Bit)

Note: Shown in ( ) are the baud rate prescaler divided-by-N values.

Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 to 1023), P: value selected by the BRP bits in the Channel Configuration Registers.

Note 2. Minimum Frequency to achieve maximum. Nominal Baud Rate of 1Mbps.

Table 7.9-31 Baud Rate Calculation Example for Nominal and Data Bit Rate CAN Communication Configurations

Baud rate calculation formula	(DLL Clock) (Baud Rate Prescaler Divide-By-N Value*1) × (Number of TQs in One Bit)		
	80 MHz	40 MHz	20 MHz
Normal 1 Mbps Data 8 Mbps	80 TQ (1)	40 TQ (1)	20 TQ (1)
	10 TQ (1)	5 TQ (1)	Not possible
Normal 1 Mbps Data 5 Mbps	80 TQ (1)	40 TQ (1)	20 TQ (1)
	16 TQ (1)	8 TQ (1)	Not possible
Normal 500 Kbps Data 2 Mbps	160 TQ (1)	80 TQ (1)	40 TQ (1)
	40 TQ (1)	20 TQ (1)	10 TQ (1)

Note: Shown in ( ) are the baud rate prescaler divided-by-N values.

Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 to 1023), P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDCnDCFG.DBRP[7:0] bits to be greater than 1, as 1 means divide by 2.

7.9.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 7.9-17 shows the procedure for setting the CAN clock and the baud rate for each channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

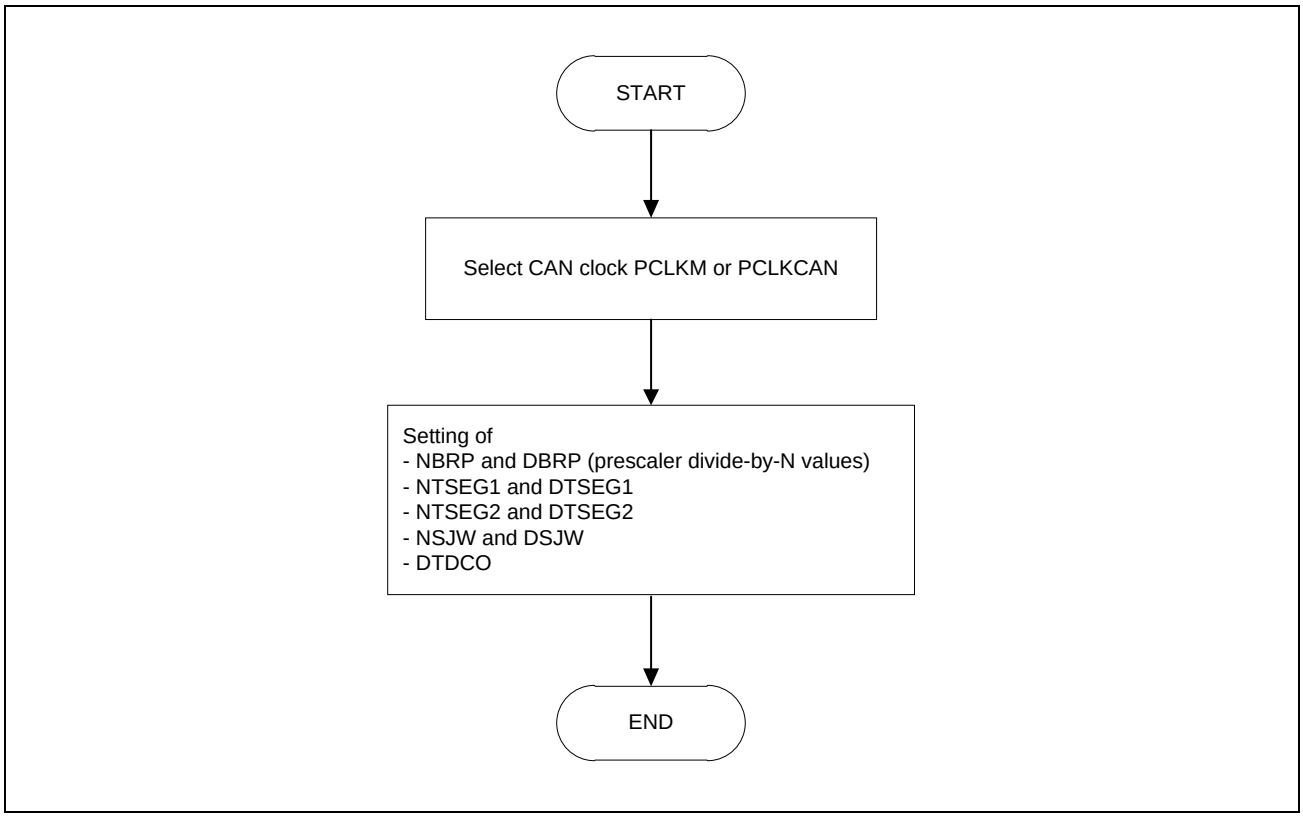

Figure 7.9-17 Procedure for Setting the CAN Bit Timing and Baud Rate

7.9.4.1.5 Transmitter Delay Compensation

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CAN-FD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CAN-FD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDCnFDSTS.TDCR) as shown in **Figure 7.9-18**.

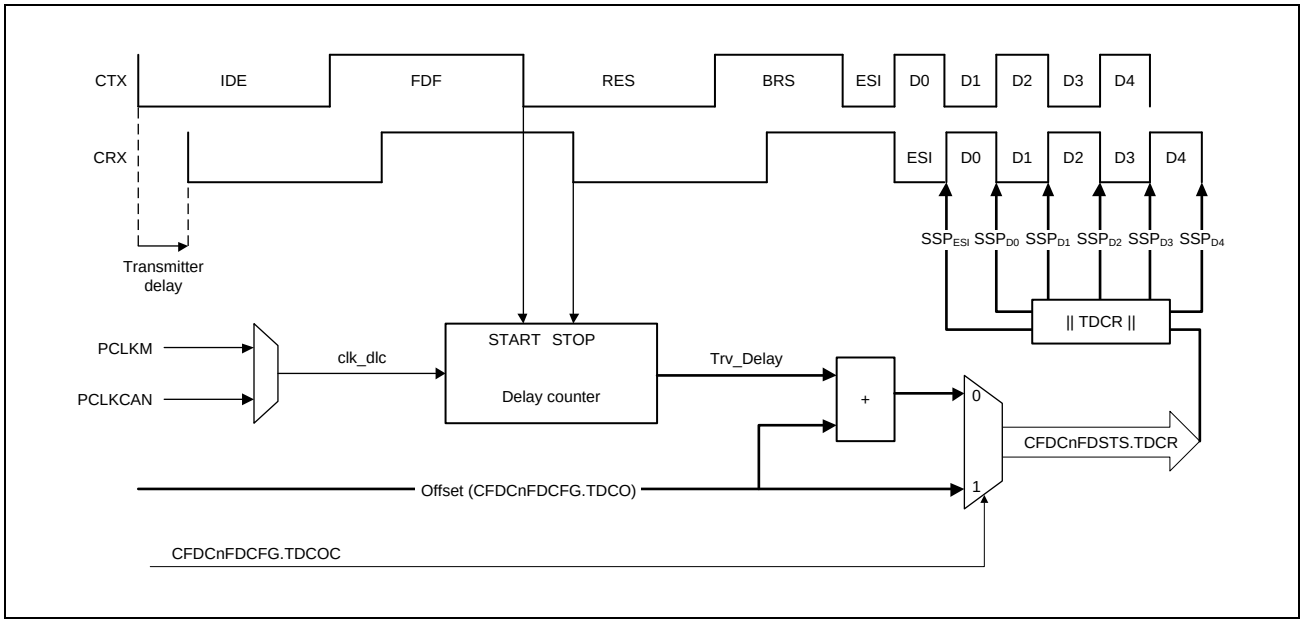

Figure 7.9-18 Transmitter Delay Compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles. The delay is counted up by 1 for each started clock until the dominant value is seen on CAN_RX. **Figure 7.9-19** shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

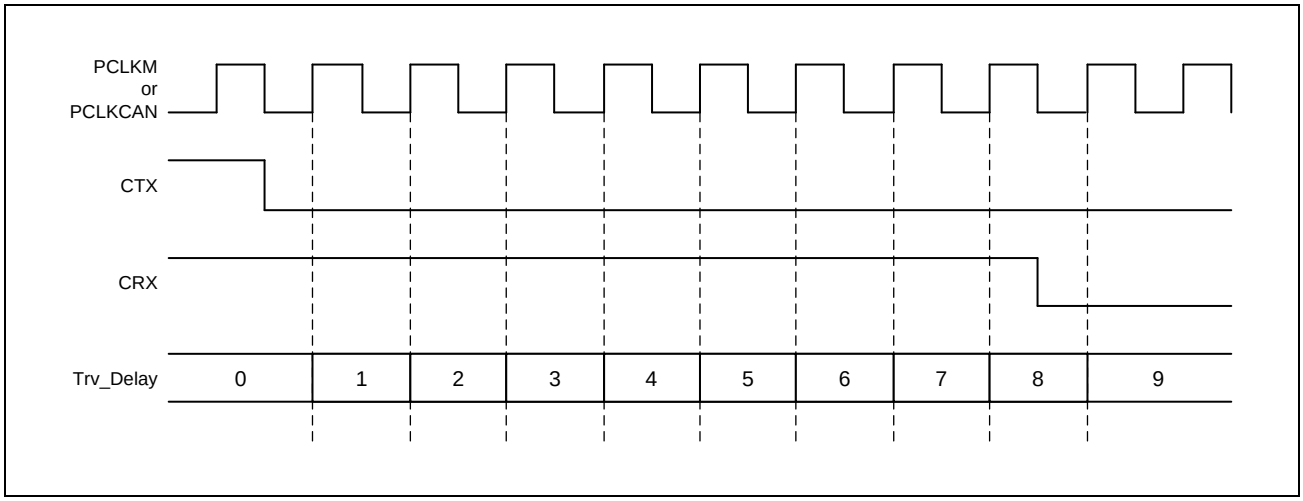

Figure 7.9-19 Trv_Delay Measurement Example

The SSP is calculated by taking the result from CFDCnFDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 7.9-20 shows the positioning of the secondary sample point. When CFDCnFDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (Sync Segment data + TSEG1 data) to position the SSP to a theoretical location of the sample point.

If the CFDCnFDCFG.TDCOC is equal to 1, the SSP is defined by CFDCnFDCFG.TDCO. If CFDCnDCFG.DBRP[7:0] is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

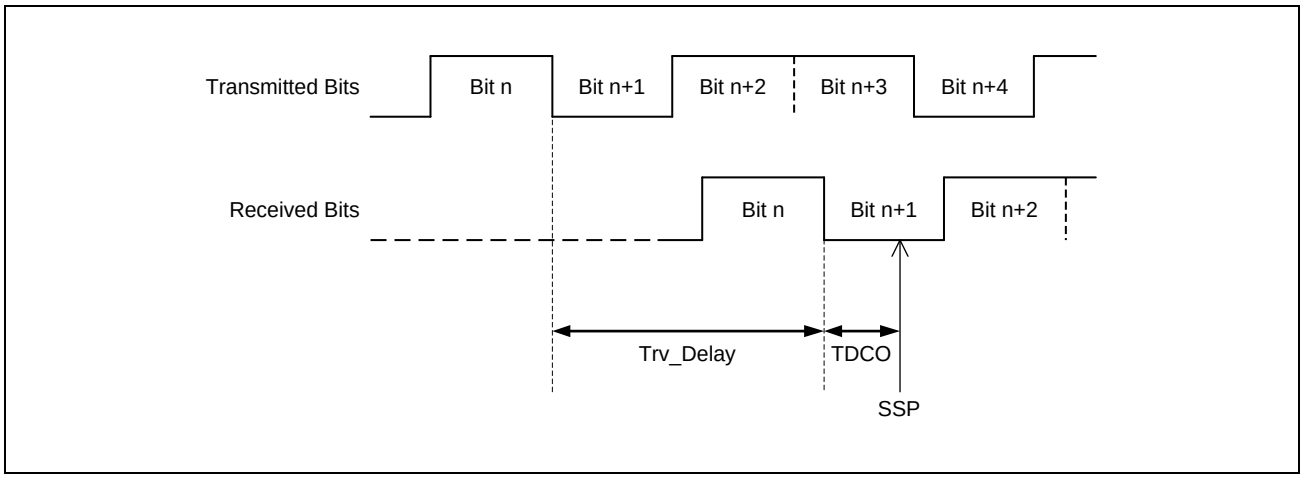

Figure 7.9-20 Position of the Secondary Sample Point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CAN-FD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDCnNCFG.NBRP and CFDCnDCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in **Figure 7.9-21**.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

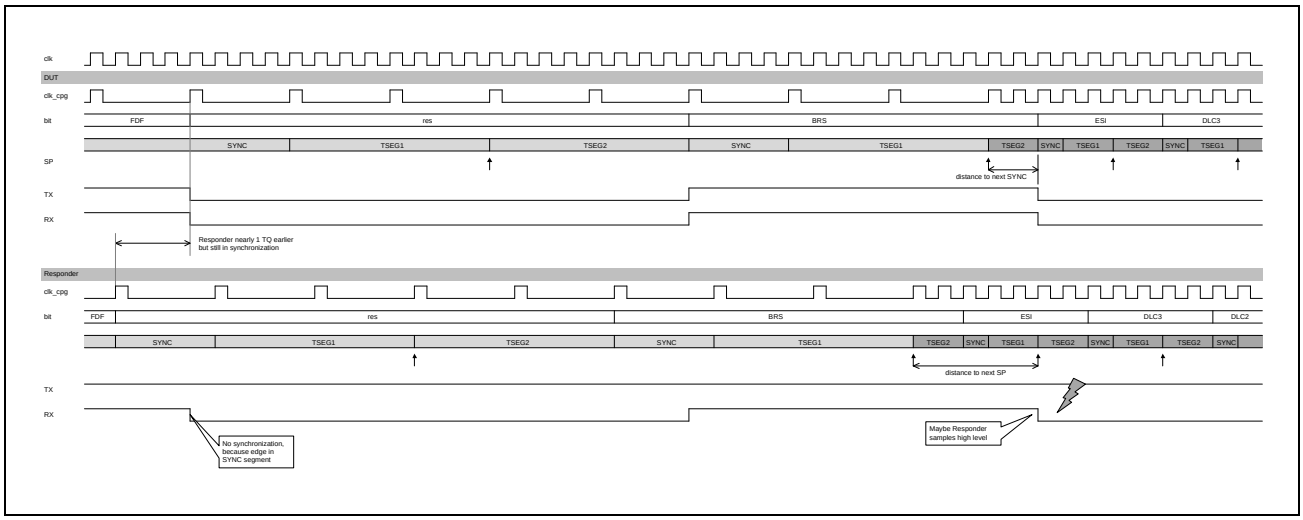

Figure 7.9-21 Loss of Synchronization between 2 CAN Nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDCnFDCFG.TDCE = 1, CFDCnFDCFG.TDCOC = 0).

Figure 7.9-22 shows the read flow to get the measured transmitter delay compensation result.

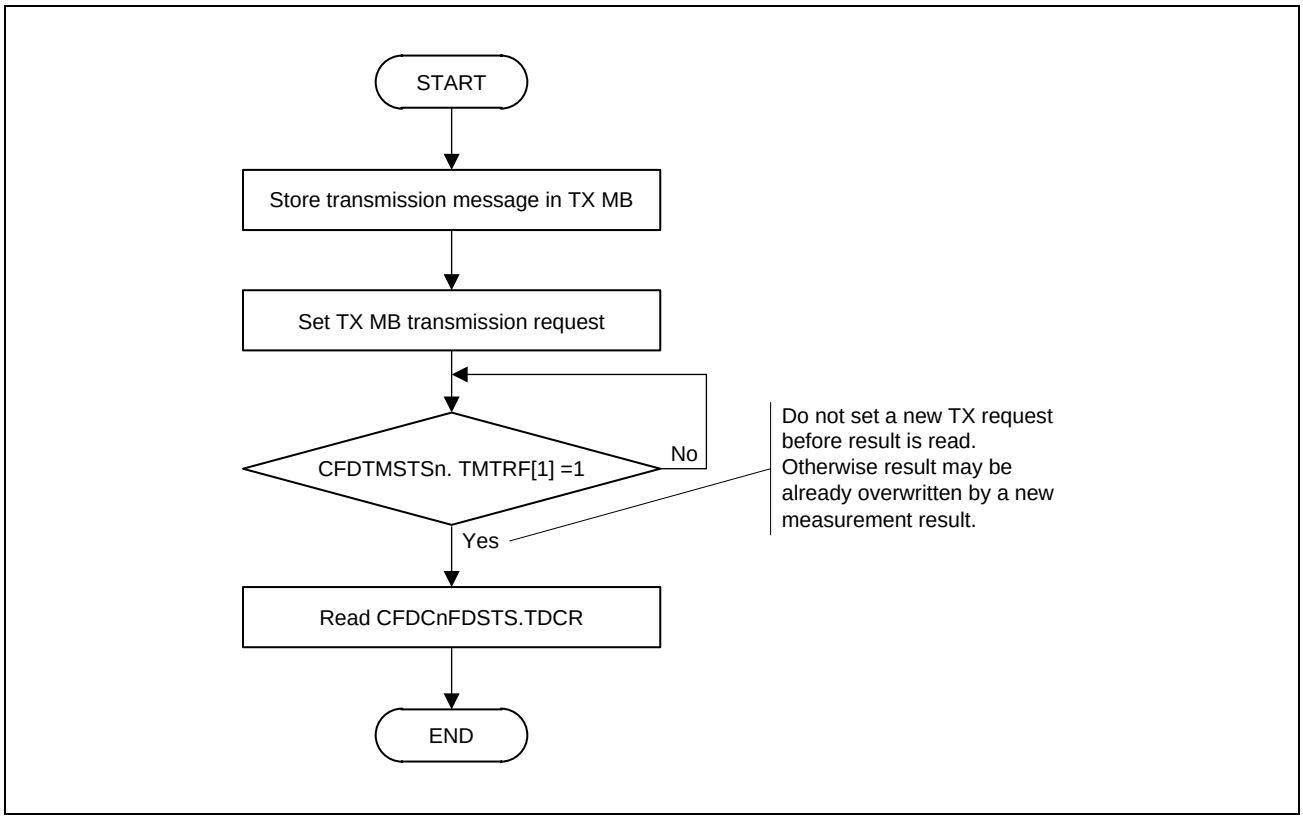

Figure 7.9-22 TDC Result Read Flow

7.9.4.1.6 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing the CFDGRSTC.SRST bit, the CAN-FD module enters Global Sleep mode automatically.

To enable configuration of the CAN-FD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CAN-FD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after hardware resets the random data presented in the RAM.

Do not access registers of the CAN-FD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, each required CAN channel must be configured such as CAN bit timing. For this configuration, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

For this, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 7.9-23 shows the configuration procedure. For details about each step, see **7.9.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)**, **7.9.6 FIFO Buffers and Normal Message Buffer Configuration**, **7.9.7 Interrupt and DMA**, and **7.9.4.1.3 Baud Rate**.

The CAN-FD module does not perform RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

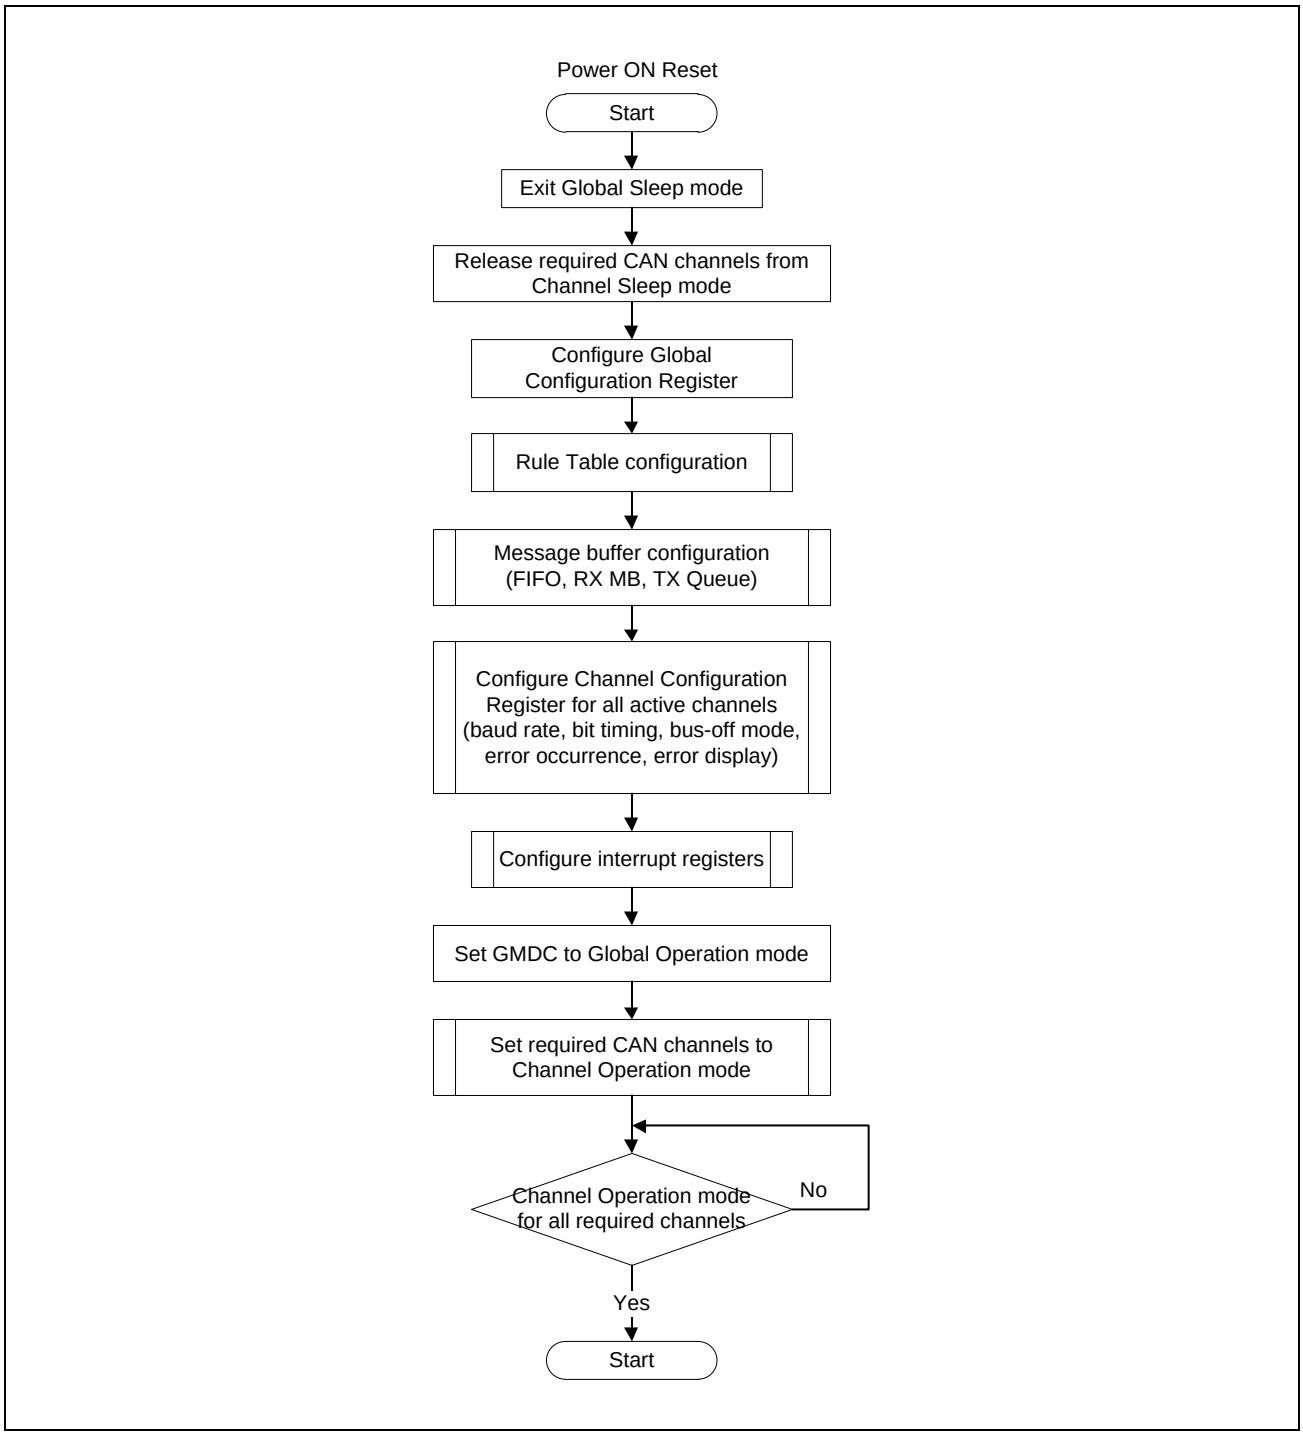

Figure 7.9-23 Configuration Procedure after a Hardware Reset

7.9.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

7.9.5.1 Overview

The CAN-FD module can handle message acceptance filtering for all channels with a global Acceptance Filter List (AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

The 3-channel CAN-FD module allows a maximum of 384 AFL entries across all channels with a maximum of 256 AFL entries per channel.

During the acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

The AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than H’0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as H’00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is H’0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception or gateway function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 8 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than eight target destinations is not allowed. When more destinations are programmed then internal timing, a race condition can occur and received message may not be stored to the message RAM. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]), the corresponding CFDFMSTS.RFXMLT[7:0] or CFDFMSTS.CFXMLT[5:0] bits are not set to 1, respectively.

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]), the corresponding CFDFMSTS.RFXMLT[7:0] or CFDFMSTS.CFXMLT[5:0] bits are set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF.

7.9.5.2 Allocation of AFL Entries to Each CAN Channel

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see **Figure 7.9-24**).

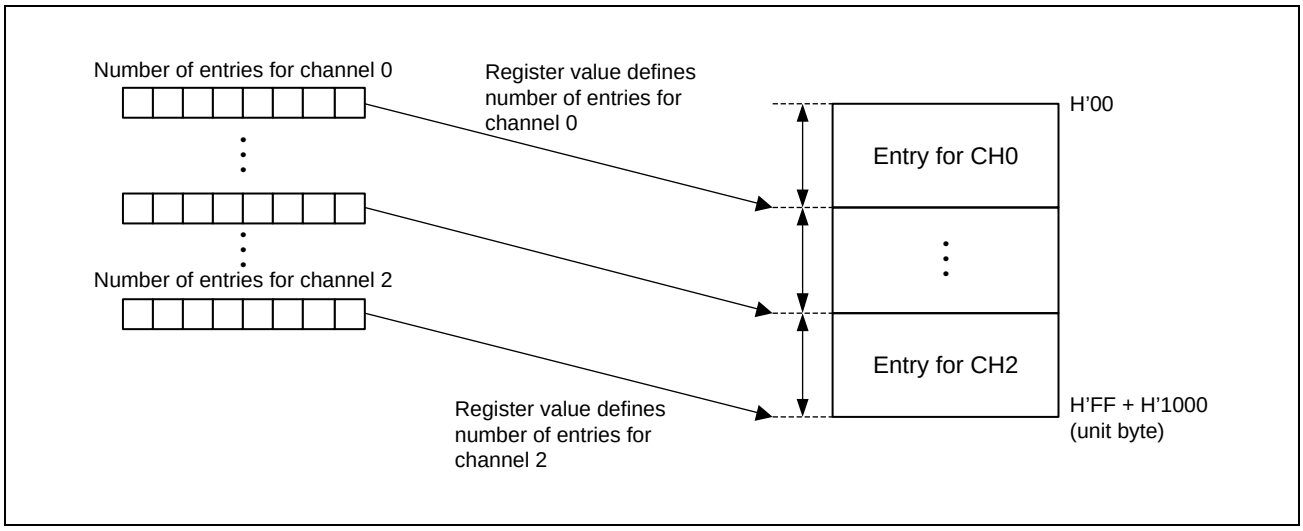

Figure 7.9-24 Configuration of AFL for Each Channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries for one channel is 256. The total number of entries for all channels should not exceed the maximum limit of (n + 1) × 128.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CAN-FD module does not flag errors related to the configuration of the AFL.

7.9.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):
  Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see **Figure 7.9-25**.
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.
- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.
- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed. If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

Note: A message received on channel A can be routed to Common FIFO buffer of another channel. If this Common FIFO buffer is configured in Gateway mode, then the message stored in this Common FIFO Buffer is transmitted on that channel because Common FIFO buffer is associated with channel.

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

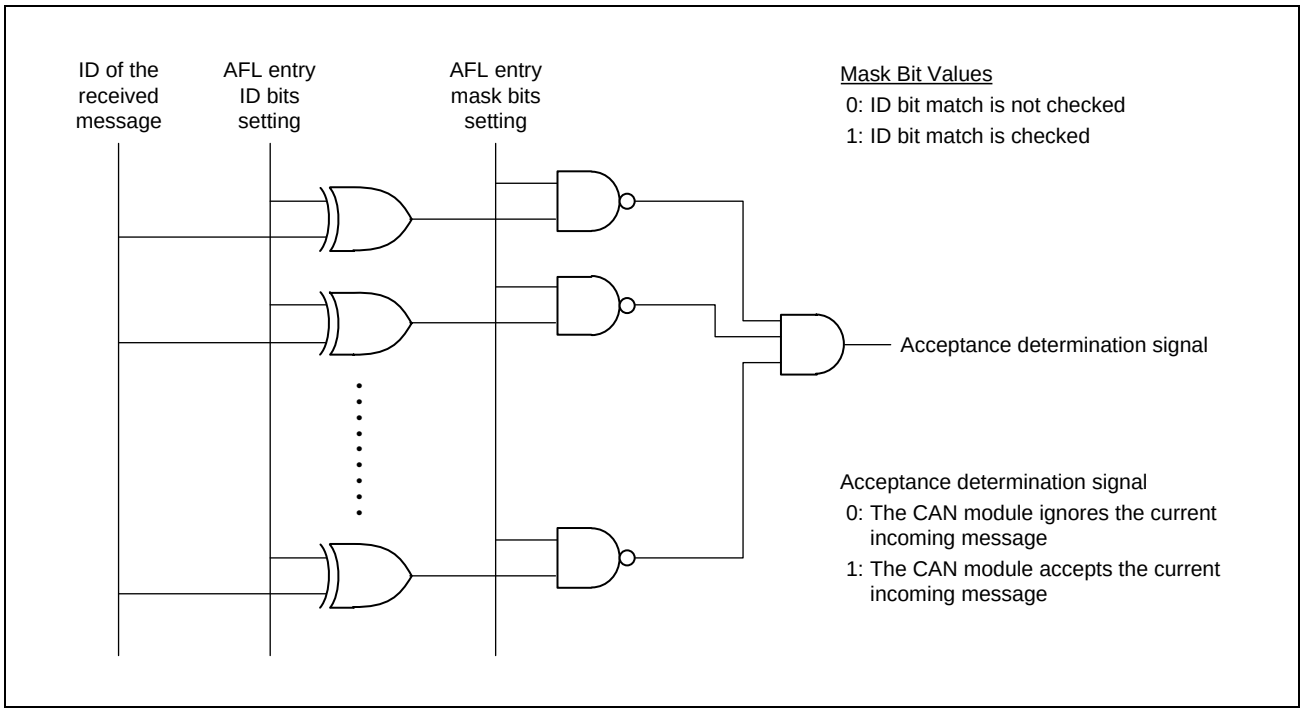

Figure 7.9-25 Acceptance Function

7.9.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CAN-FD module, 3-channel version, 16 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Table 7.9-32 Mapping between Pages and AFL Entries

Page 0	Entry 0 - 15
Page 1	Entry 16 - 31
Page 2	Entry 32 - 47
Page 3	Entry 48 - 63
Page 4	Entry 64 - 79
Page 5	Entry 78 - 95
Page 6	Entry 96 - 111
Page 7	Entry 112 - 127
Page 8	Entry 128 - 143
Page 9	Entry 144 - 159
Page 10	Entry 160 - 175
Page 11	Entry 176 - 191
Page 12	Entry 192 - 207
Page 13	Entry 208 - 223
Page 14	Entry 224 - 239
Page 15	Entry 240 - 255

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (see **Figure 7.9-26**). This register has the following fields:

- 4 bits to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL

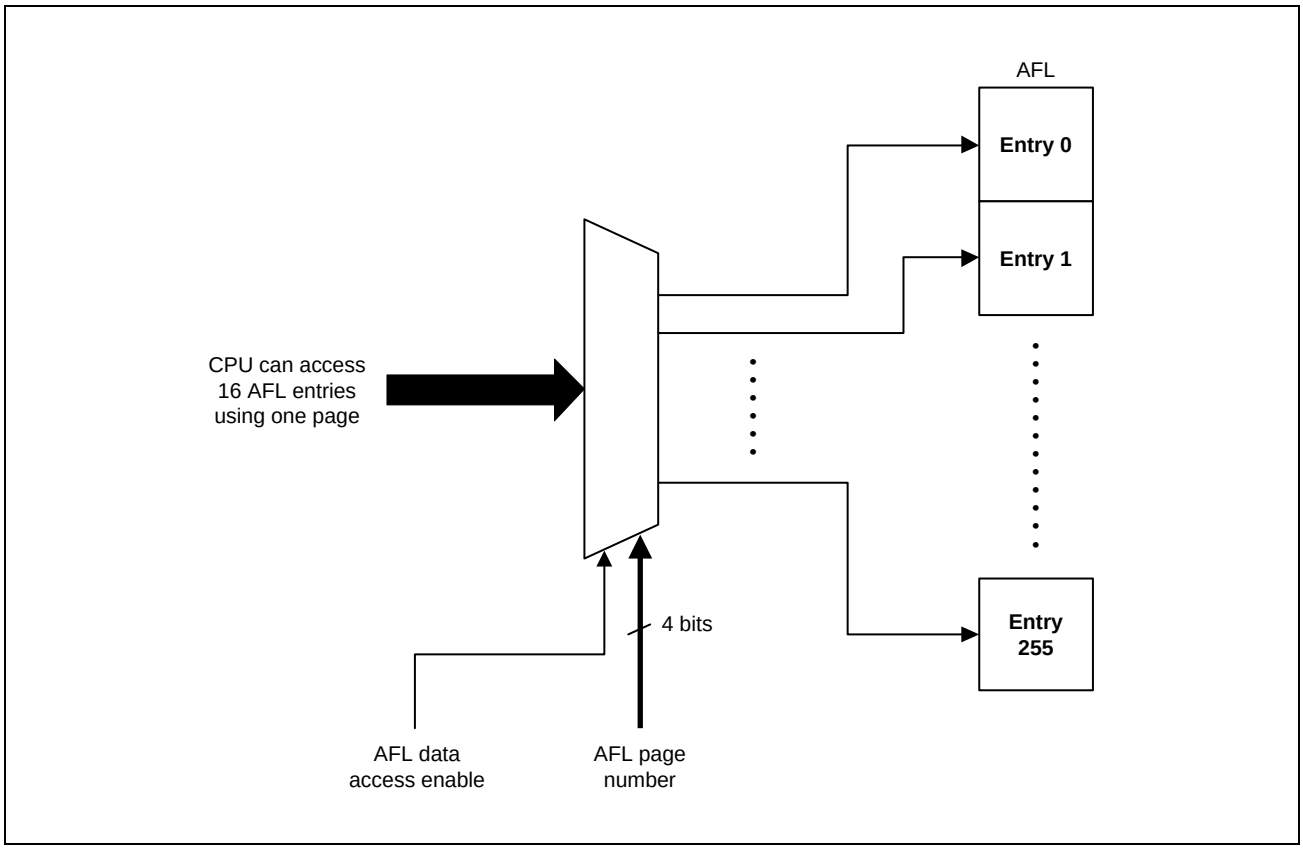

Figure 7.9-26 AFL Page Access

Application software should not write numbers higher than H’F for the AFL page number.

Follow the configuration shown in **Figure 7.9-27** to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

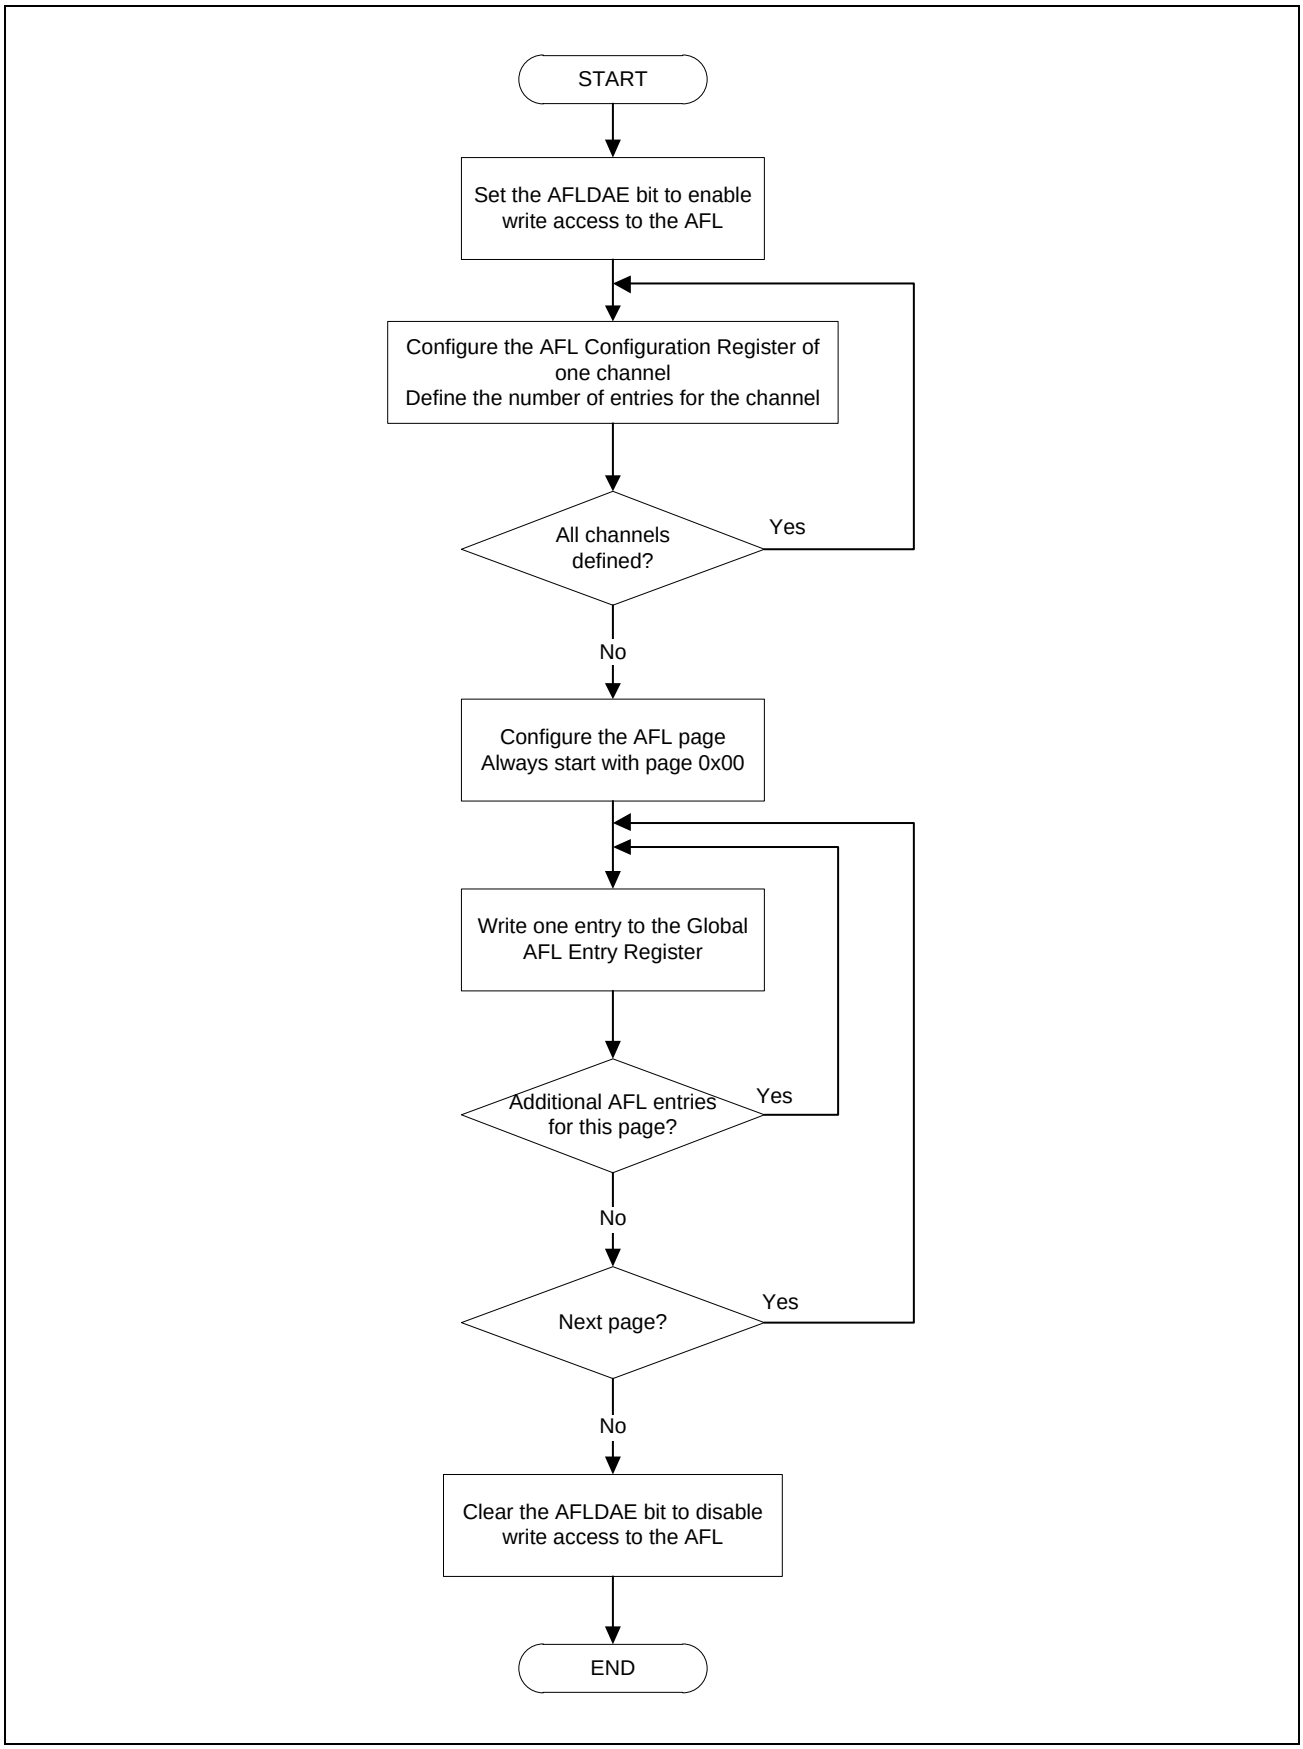

Figure 7.9-27 AFL Configuration Flow

7.9.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If mirror mode and loopback test mode are configured at the same time, the loopback test mode behavior applies.

Table 7.9-33 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 7.9-33 Behavior of Acceptance Filter Based on the Loopback Configuration Setting in AFL Entry

Mirror Mode Enable (MME Configuration Bit)	Loopback in Test Mode (Self-test mode 0 or Self-test mode 1)	Channel Mode	Loopback Configuration Bit in AFL Entry	AFL Entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

7.9.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

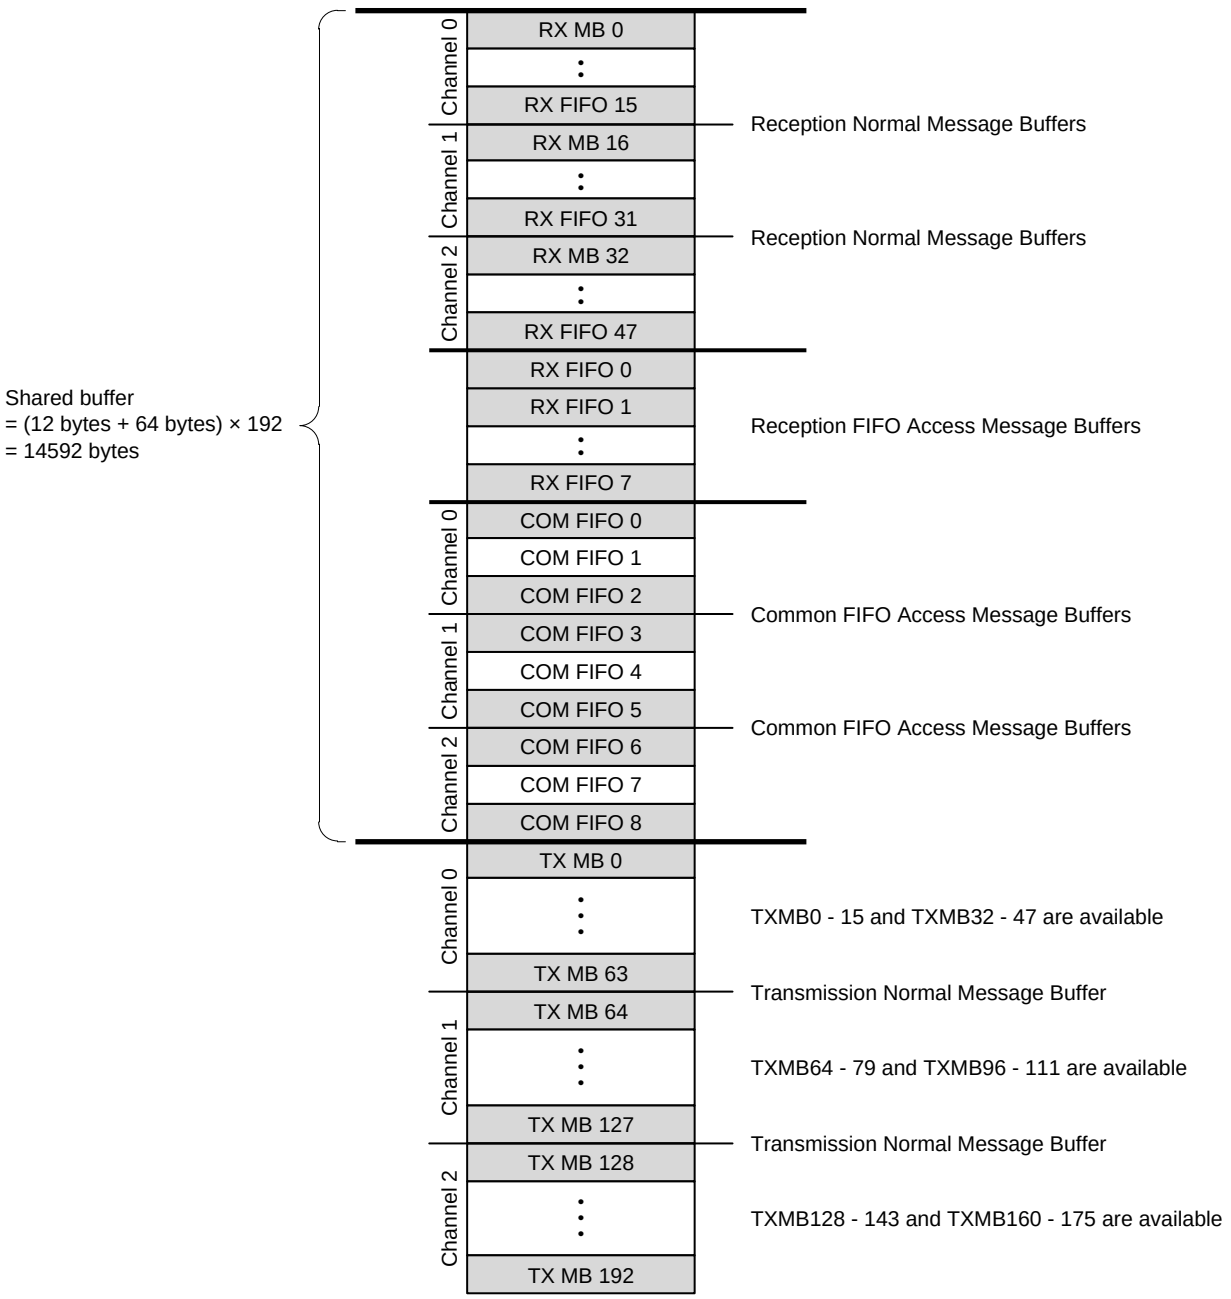
Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = H’C055_3A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = H’220/ID[28:0] = H’055_3A20
  - CFDGAFLMn = H’0000_FFFF → IDEM = 0, RTRM = 0, IDM[10:0] = H’7FF/IDM[28:0] = H’0000_FFFF
- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = H’220 is received, this is considered as a match
  - If a frame with IDE = 0 and ID = H’320 is received, this is not a match
  - If a frame with IDE = 1 and ID = H’1FFF_3A20 is received, this is considered as a match
  - If a frame with IDE = 1 and ID = H’0880_3220 is received, this is not a match.

7.9.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CAN-FD module. The message buffers are mapped as shown in **Figure 7.9-28**.

The RX message buffers can be accessed with the RX Message Buffer Registers.



The RX FIFO buffers and the common FIFO buffers configured in RX mode, TX mode, or GW mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in GW mode or RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

Note: The total number of bytes in RXMB_cfg, RXFIFO_cfg, and CFIFO_cfg are less than or equal to 14,592 bytes.
RXMB_cfg = (12 bytes + CFDRMNB.RMPLS) × CFDRMNB.NRXMB
RXFIFO_cfg = SUM ((12 bytes + CFDRFCCn.RFPLS) × CFDRFCCn.RFDC)
CFIFO_cfg = SUM ((12 bytes + CFDCFCCn.CFPLS) × CFDCFCCn.CFDC)

Figure 7.9-28 Message Buffer Configuration

7.9.6.1 Normal RX Message Buffers

In CAN-FD module, the frames received by various channels can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

7.9.6.1.1 Normal RX Message Buffer Configuration

In CAN-FD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = H’00 (no normal RX MB)
- Maximum value = (16 × number of CAN channels) = 16 × 3 = 48 = H’30 (48 flat RX MBs for 3 channels)

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CAN-FD module against incorrect configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS[2:0] bits. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

7.9.6.2 FIFO Buffer

The CAN-FD module provides a fixed number of FIFO buffers to support storage of frames for reception, transmission, and gateway functions for various CAN channels.

The number of reception-only FIFO buffers is fixed to 8. However, 3 common FIFO buffers per channel can be configured to store messages for transmission, reception, or gateway function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO or GW FIFO

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

7.9.6.2.1 FIFO Buffers Configuration

In CAN-FD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 8 RX FIFO buffers + 6 common FIFO buffers = 14 FIFO buffers for 3 channels and message overwrite mechanism.

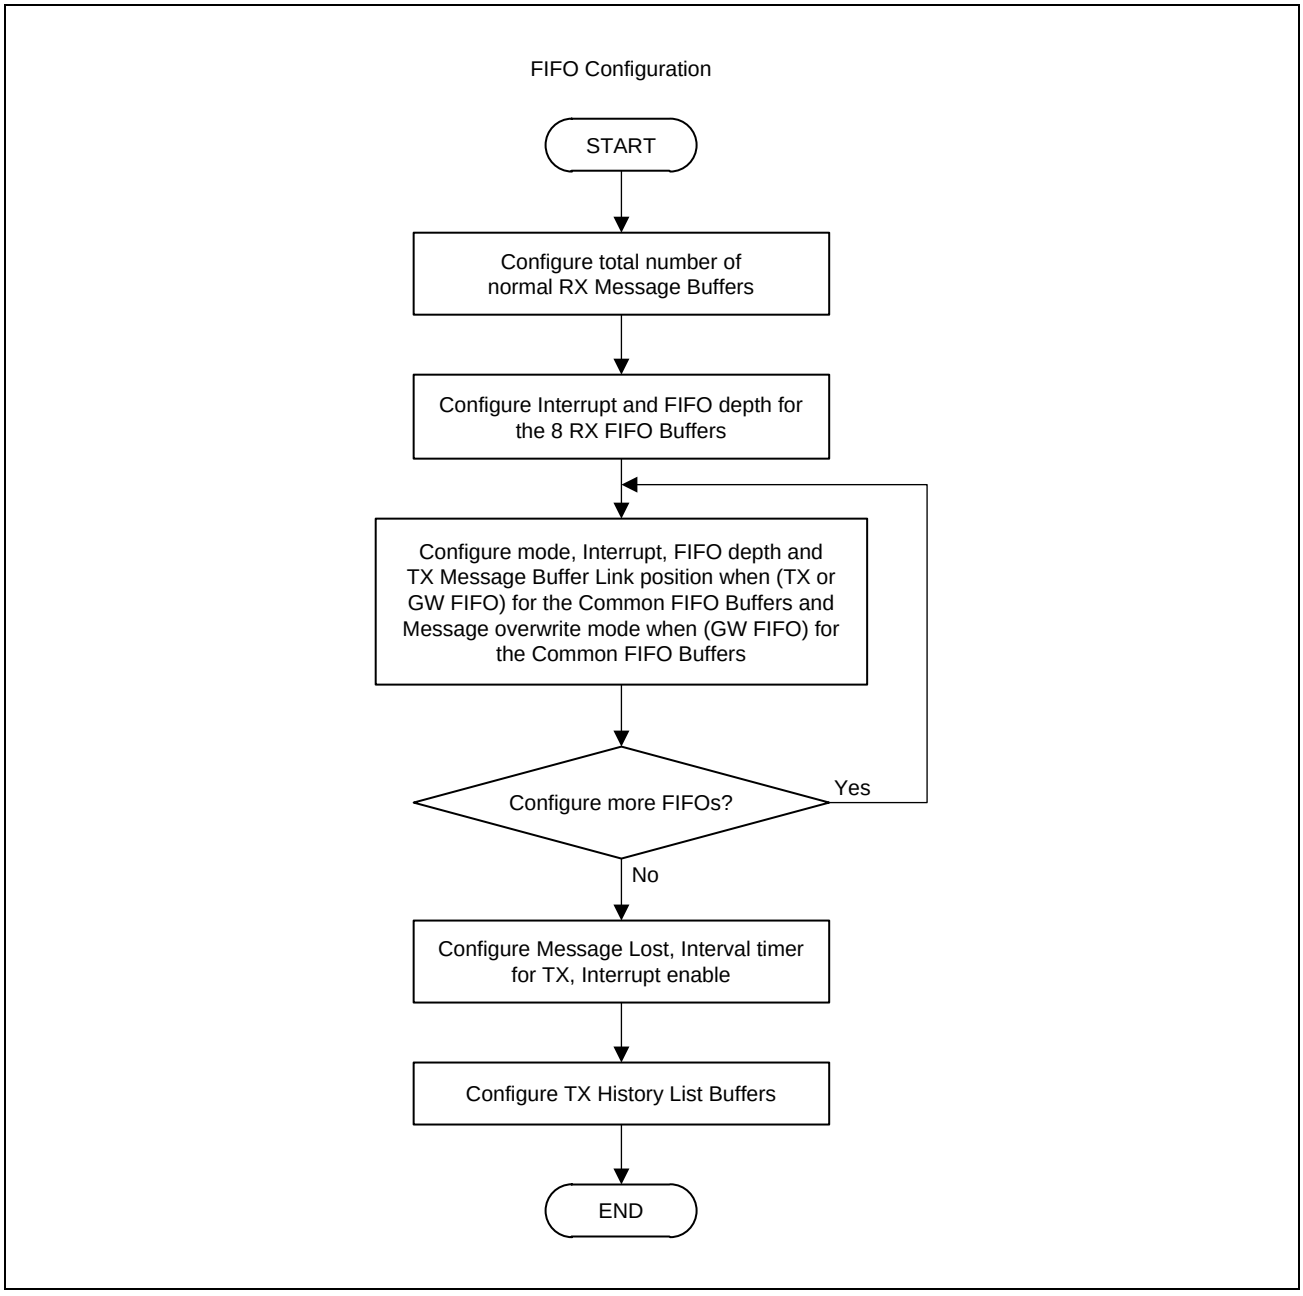


Figure 7.9-29 FIFO Buffer Configuration Flow in CAN-FD Module

As shown in **Figure 7.9-29**, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 8 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth

- FIFO payload data size

For the common FIFO buffers, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position

(1) FIFO Mode Configuration of Common FIFO Buffers

The mode of the common FIFO buffers can be configured by writing to the CFDCFCCn.CFM[1:0] bits in the Common FIFO Configuration/Control Registers. The possible modes of configuration for Common FIFO buffers are:

- 00b: RX mode (default mode after hardware reset)
- 01b: TX mode
- 10b: GW mode
- 11b: Reserved (do not write this value to the register bits)

Messages can only be read from the RX FIFO buffers and the Common FIFO buffers configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffers configured in TX mode. These messages are transmitted on the appropriate CAN channel.

Messages can only be read from the Common FIFO buffers configured in GW mode. However, the CPU read access has no impact on the read or write pointers. The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CAN-FD module.

After a hardware reset, all the Common FIFO buffers are configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffers in the required modes.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting the CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded, and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message. The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message. The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point is then moves to the next message automatically. Do not write to this bit when the CFDCFCCn.CFE bit is 1.

(2) FIFO TX Message Buffer Link Configuration

When the common FIFO is configured as TX or GW FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan of a CAN channel.

The link to a normal TX message buffer must be unique, for example the same TX message buffer cannot be shared between 2 or more common FIFO buffers.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- H’00: TX Message Buffer 32
- H’01: TX Message Buffer 33
  ⋮
- H’1F: TX Message Buffer 63

(3) FIFO Depth Configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCn.RFDC[2:0] bits and CFDCFCCn.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The 8 available options for depth configuration are:

- 000b: 0 Messages (FIFO buffer cannot be enabled)
- 001b: 4 Messages
- 010b: 8 Messages
- 011b: 16 Messages
- 100b: 32 Messages
- 101b: 48 Messages
- 110b: 64 Messages
- 111b: 128 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to (n + 1) × 256 messages. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CAN-FD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCCn.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

Note: If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO Payload Size Configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCn.RFPLS[2:0] bits and CFDCFCCn.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes

- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

(5) FIFO Interrupt Configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCn.RFIM bit and the CFDCFCCn.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCn.RFIGCV/ CFDCFCCn.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
  - GW FIFO mode
    Frame RX: Interrupt generated when message counter increments and reaches the interrupt threshold value
    Frame TX: Interrupt generated when the last message is transmitted successfully from FIFO
- 1:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message
  - GW FIFO mode
    Frame RX: Interrupt generated when message is stored in the FIFO
    Frame TX: Interrupt generated when message is successfully transmitted from the FIFO

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCn.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCCn.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCn.RFIGCV[2:0] and CFDCFCCn.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see **Table 7.9-34**.

Table 7.9-34 FIFO Interrupt Generation Counter and FIFO Depth Configuration

RFDC[2:0] (FDC[2:0])	RFIGCV[2:0] (CFGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							
101b	Allowed							
110b	Allowed							
111b	Allowed							

Common FIFO buffer can set an interrupt output at the completion time of transmitting one frame, or the completion of reception. In addition, Common FIFO and RX FIFO can set an interrupt output, when stored to the setup number (CFDC/ RFDC) of FIFO stages.

7.9.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCn.RFIE
- CFDRFCCn.RFFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Registers:

- CFDCFCCn.CFRXIE
- CFDCFCCn.CFTXIE
- CFDCFCCEn.CFFIE
- CFDCFCCEn.CFOFRXIE
- CFDCFCCEn.CFOFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCn.RFE and CFDCFCCn.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers to allow transmission and reception of messages.

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in the Common FIFO, and transmission is stopped. Transmission starts when CFDCFCCEn.CFBME = 0.

Do not write 1 from 0 for this bit when the CFDCFCCn.CFE bit is 1.

7.9.7 Interrupt and DMA

7.9.7.1 Interrupts

The CAN-FD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional Status Flag register. These status bits are only set when the corresponding interrupt enables are set.

The Status Flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CAN-FD module can be classified into 2 groups, global interrupts and channel interrupts:

- Global interrupts

The CAN-FD module can generate 2 global interrupts:

1. One Global interrupt for successful reception into the 8 RX FIFO buffers
2. One Global error interrupt

- Channel interrupts:

Each channel of the CAN-FD module can generate 3 channel interrupts:

1. Channel transmission
   Transmission completed from channel
   Transmission abort from channel
   Transmission from TX Queue for a channel
   Channel THL Interrupt
   Successful transmission from a Common FIFO in TX or GW mode for a channel
2. Channel error interrupt
3. Successful reception in a Common FIFO in RX or GW mode for a channel or successful routing in a TXQ

The interrupts are cleared when the corresponding flag bits are cleared or interrupt enable bits are cleared.

Table 7.9-35 provides an overview of interrupt.

Table 7.9-35 Overview of Interrupt Source

Parameter	Interrupt	Interrupt Source	Interrupt Clearing
Global Interrupts	Successful reception into at least one RX FIFO	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	FIFO full into at least one RX FIFO	FIFO Full Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the FIFO Full Interrupt flags of corresponding RX FIFO buffer for which interrupt is enabled
	Global error	Any of the following: • DLC Error flag • Message Lost Status bit • Message Overwrite Status bit • TXQ Message Lost Status bit • TXQ Message Overwrite Status bit • TX History Entry Lost Status bit • CAN-FD Message Payload overflow flag	Clear all of: • DLC Error flag • Message Lost flags in all of the FIFO Status Registers • Message Overwrite flags in all of the Common FIFO Status Registers • Message Lost flags in all of the TXQ Status Registers • Message Overwrite Flags in all of the TXQ Status Registers • TX History List Entry Lost flag • CAN-FD Message Payload Overflow flag
Channel Transmission Interrupts	Channel n successful transmission	Any channel related TX MB Successful flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled
	Channel n abort	Any channel related TX MB Abort flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled globally
	Channel n transmission from TX Queue	Related channel TX Queue Interrupt flag	Clear related channel TX Queue Interrupt flag
	Channel n THL Interrupt	Channel n THL Interrupt Status flag	Clear the relevant THL Interrupt Status flag
	Channel n COM FIFO TX Interrupt	Interrupt flag for Common FIFOs in TX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in TX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame TX Interrupt	One Frame Transmission Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of Common FIFOs belonging to the related channel
	Channel n TXQ One Frame TX Interrupt	One Frame Transmission Interrupt flag for TXQs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of TXQs belonging to the related channel
Channel COM RX FIFO Interrupt	Channel n COM FIFO RX Interrupt	Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame RX Interrupt	One Frame Reception Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Reception Interrupt flags of Common FIFOs belonging to the related channel
	Channel n COM FIFO Full Interrupt	FIFO Full Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n TXQ One Frame Routing Interrupt	One Frame Routing Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the One Frame Routing Interrupt flags of TXQs in GW mode belonging to the related channel
	Channel n TXQ Full Interrupt	TXQ Full Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of TXQs in GW mode belonging to the related channel
Channel Error Interrupt	Channel n Error	Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register

Note 1. These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a common FIFO.

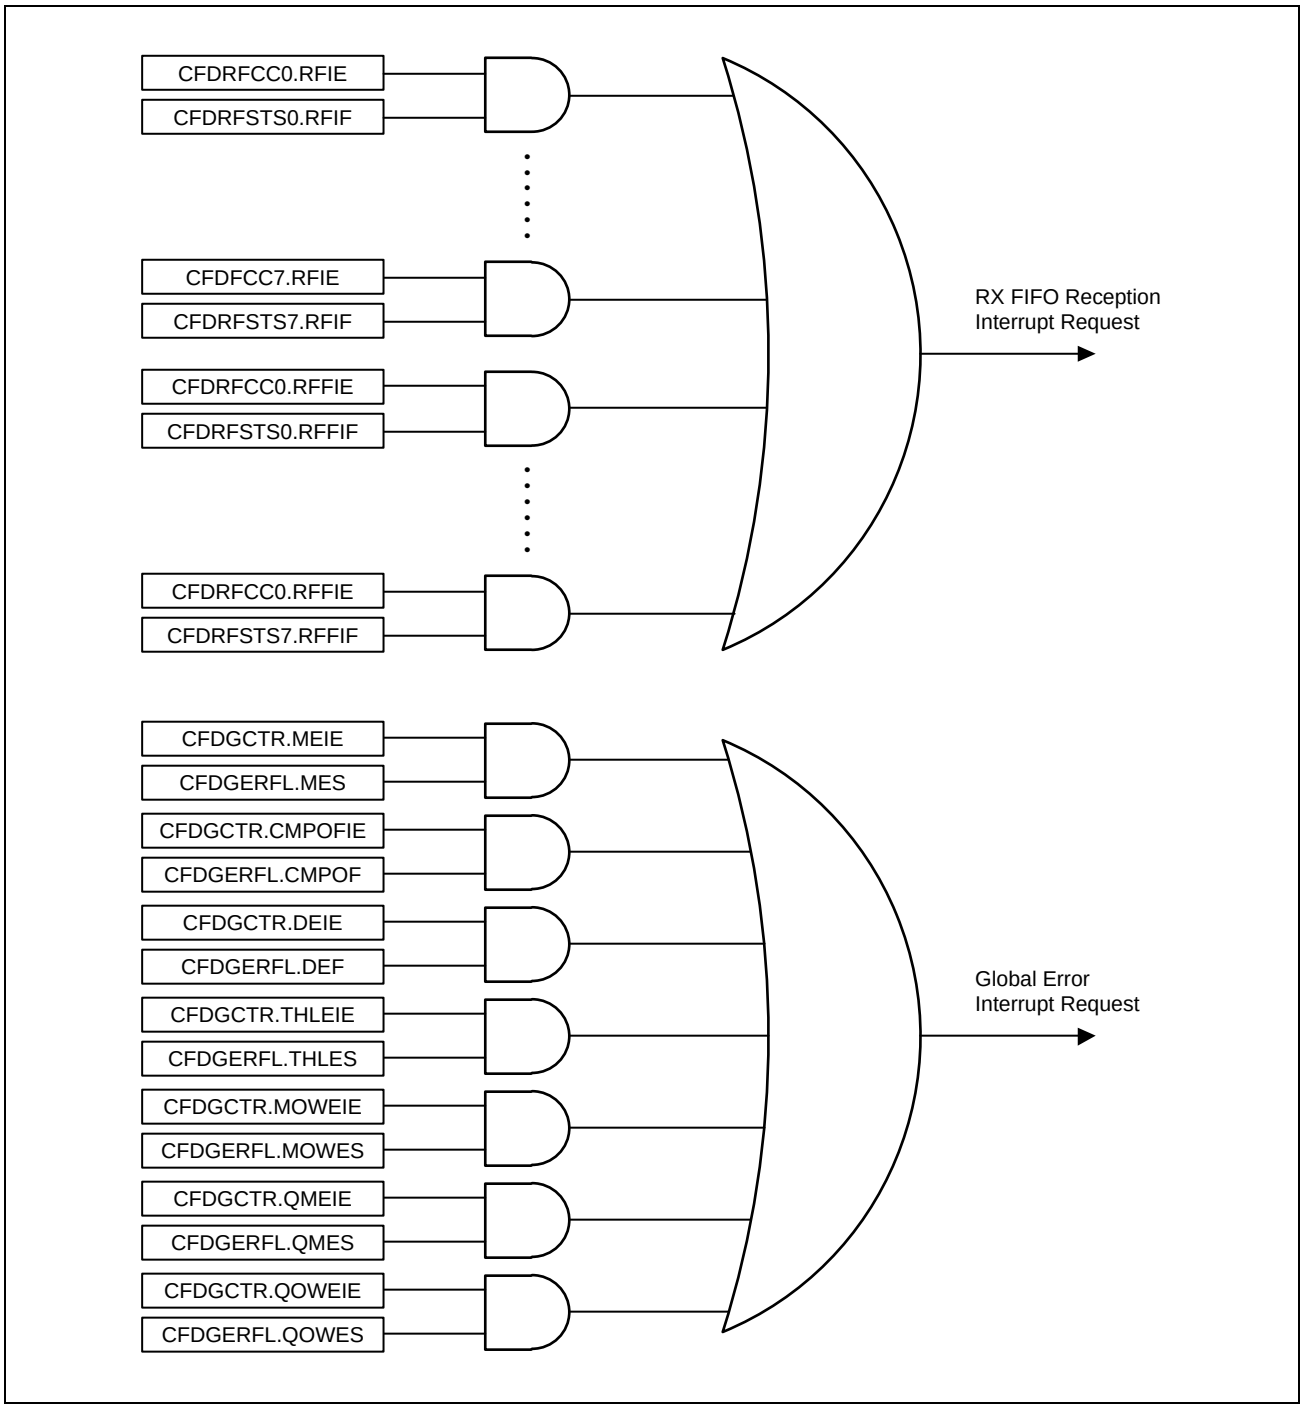

Figure 7.9-30 Block Diagram of Global Interrupt

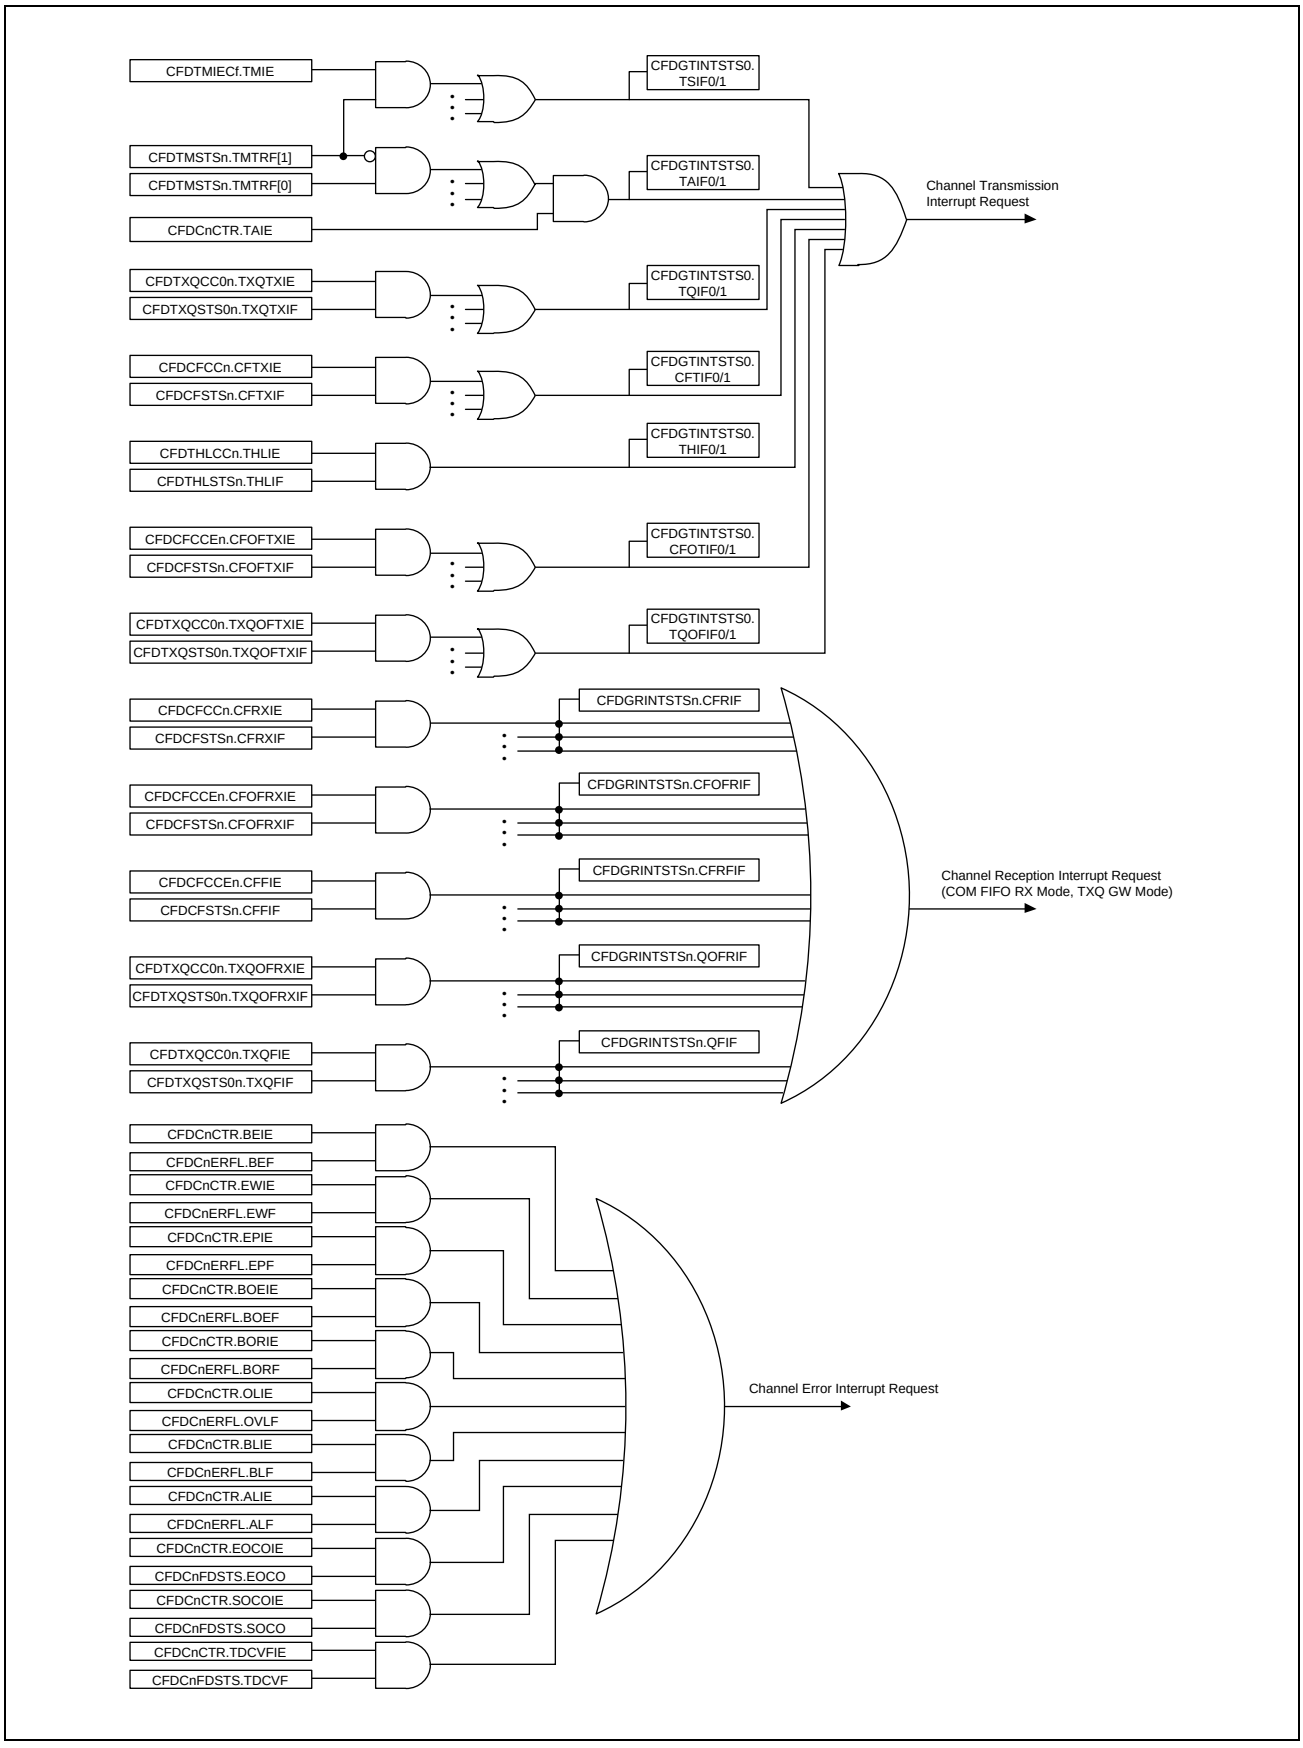

Figure 7.9-31 Block Diagram of Channel Interrupt

7.9.7.2 DMA Transfer

The CAN-FD module has some message buffer which can be associated with a DMA channel:

- Reception DMA
  - 8 RX FIFO Message Buffers
  - 3 Common FIFO Message Buffers
- Transmission DMA
  - 16 TXQ Message Buffers (TXQ0, TXQ3)
  - 3 Common FIFO Message Buffer

Figure 7.9-32 shows the potential DMA channels.

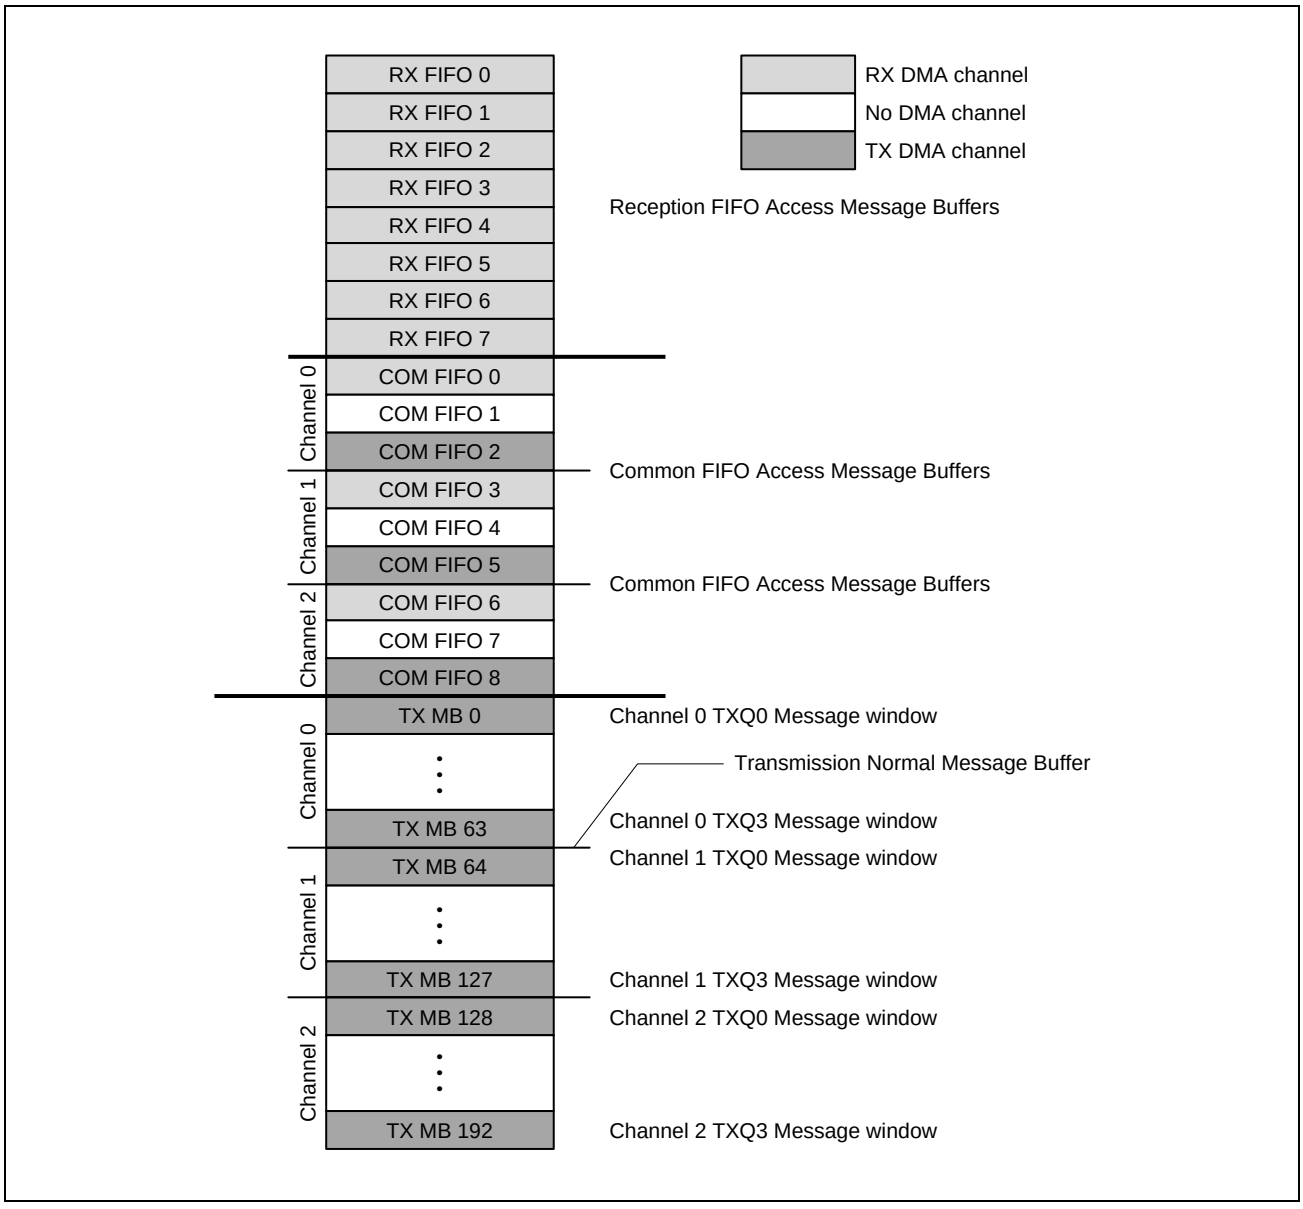

Figure 7.9-32 Message Buffer Connectable to DMA Channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO interrupt should be disabled for this particular FIFO (CFDRFCCn.RFIE or CFDCFCCn.CFRXIE).

Use the regular start address for the DMA access window address and add H’8000 to the regular start address for the debugger access window. See **Table 7.9-36**.

Table 7.9-36 DMA Channel Access Window Address

b = Message Buffer Component Index	MBCP	Register	p	Start Address n = 0, 1, 2
0 to number_of_RFMBCPs - 1	RFMBCPb	RFID	x	H’6000 + b × H’0080
		RFPTR	x	H’6004 + b × H’0080
		RFFDSTS	x	H’6008 + b × H’0080
		RFDFp	0 to 15	H’600C + p × H’0004 + b × H’0080
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb	CFID	x	H’6400 + b × H’0080 + n × H’0180
		CFPTR	x	H’6404 + b × H’0080 + n × H’0180
		CFFDCSTS	x	H’6408 + b × H’0080 + n × H’0180
		CFDFp	0 to 15	H’640C + p × H’0004 + b × H’0080 + n × H’0180

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

The software debugger must access outside of the regular SFR address range from H’E000 to H’EFFF.

Do not write to the FIFO and TXQ control registers when DMA is enabled.

The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time, the procedure in this section is a configuration flow for an initial setup.

When CFDCDTTCT.TQ0DMAE or CFDCDTTCT.TQ3DMAE or CFDCDTTCT.CFDMAE is set, the messages of the corresponding TXQ or Common FIFO can be handled by DMA controller.

Use the following procedure when the TXQ or the Common FIFO can be handled by DMA controller.

1. CPU checks the TXQ or the Common FIFO is not full.
2. When transmit data can be used, CPU sets this data to Common FIFO or TXQ.
   When using Common FIFO, transmit data is write in CFDCFIDn, CFDCFPTRn, CFDCFFDCSTSn, and CFDTMBCPb[i] registers.
   When using TXQ, transmit data is write in CFDTMIDn, CFDTMPTRn, CFDTMFDCTRn, and CFDTMDFp_n registers.
3. For Common FIFO, the common FIFO pointer is incremented automatically when DMA controller writes the last data payload byte configured by CFDCFCCn.CFPLS.
   For TXQ, if the data of 64 data payload is written, a TXQ pointer increases automatically. When payload data is less than 64 bytes, dummy data must be written in and 64 data payload size must be done.

Note: Only 32-bit write-access can be possible on the DMA message handling.

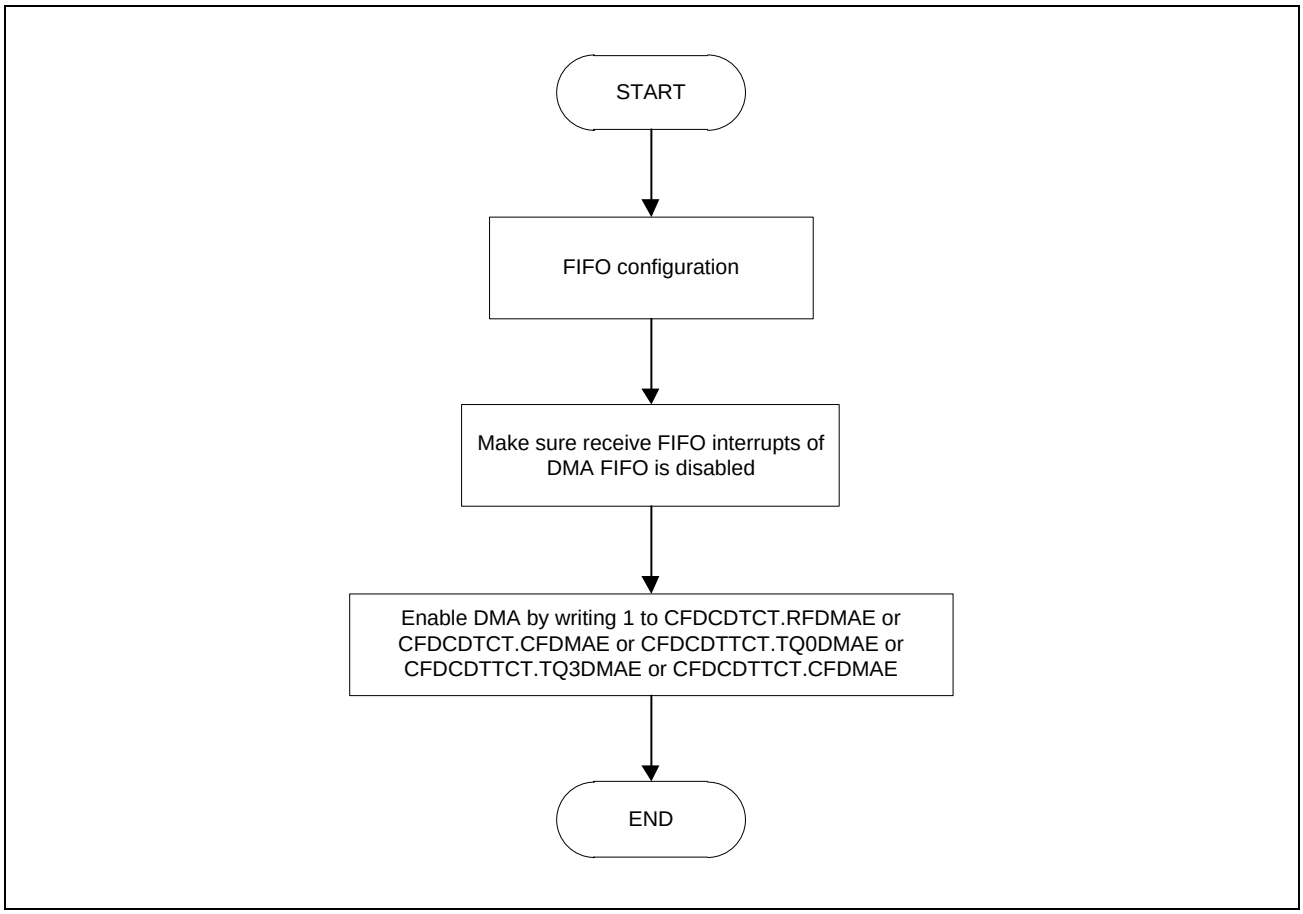

Figure 7.9-33 DMA Enable Flow

To disable a DMA transfer requested, disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then this must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS. For reference, see the flow in **Figure 7.9-34**. When the DMA is disabled, then consider what to do with the remaining or new incoming messages to this particular FIFO reception.

When the FIFO is not disabled, reception to the FIFO continues.

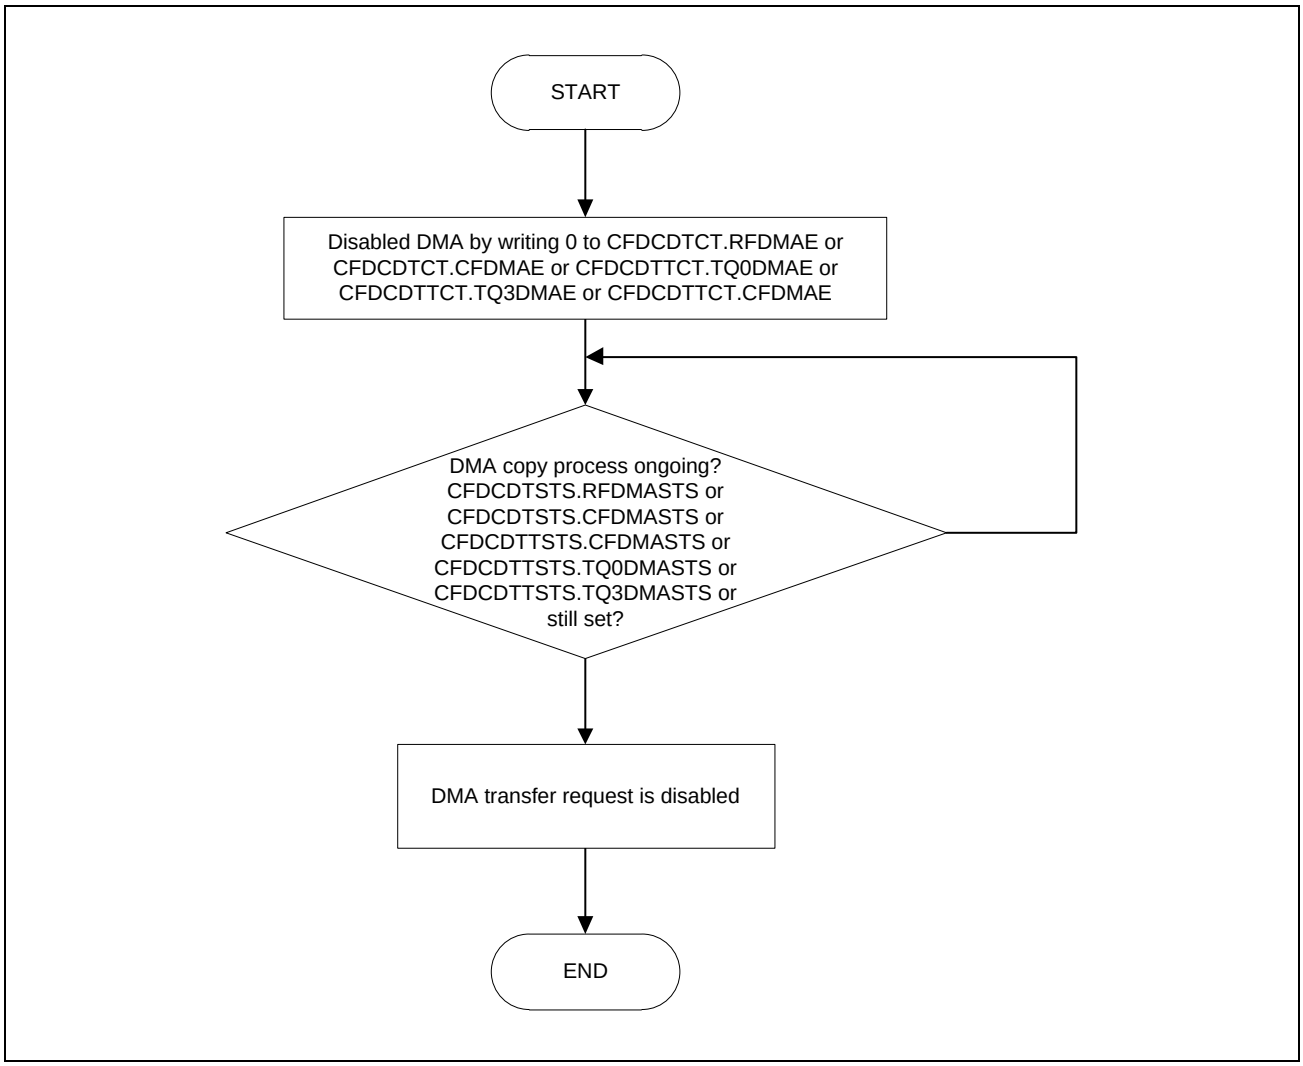

Figure 7.9-34 DMA Disable Flow

7.9.8 Reception and Transmission

7.9.8.1 Reception

FIFO buffers or Common FIFO buffers configured in RX mode or GW mode depending on the Acceptance Filter List entries are as follows:

- Up to 32 RX Message Buffers can be configured
- 8 RX FIFO buffers available
- Up to 9 Common FIFO buffers can be configured in RX mode or GW mode
- Up to 4 TX Queues can be configured in GW mode

7.9.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX Message Buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX Message Buffer.

If a new message is stored into a RX Message Buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX Message Buffer. If such a loss of messages is not acceptable, then RX FIFO should be used to store related messages.

Note: Interrupts are not provided for the RX Message Buffers in the CAN-FD module and so the RX Message Buffer New Data Register should be accessed periodically to check if a new message has been stored in the RX Message Buffers.

Note: Unused data bytes are filled with H'00 depending on the DLC value.

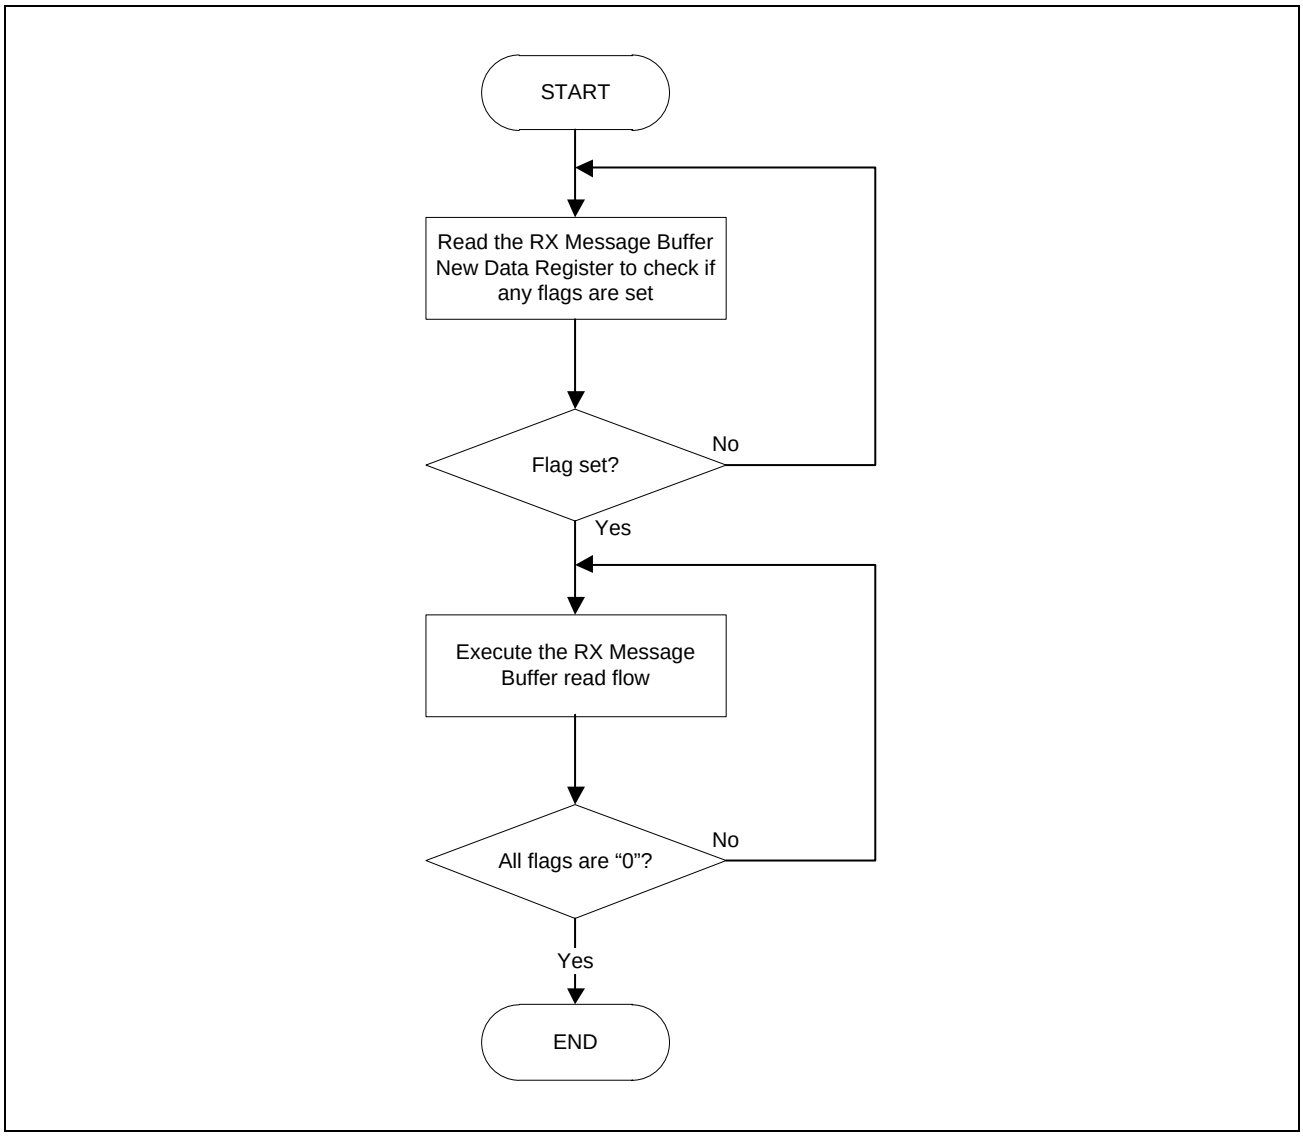

Figure 7.9-35 RX Message Buffer Message Access Flow

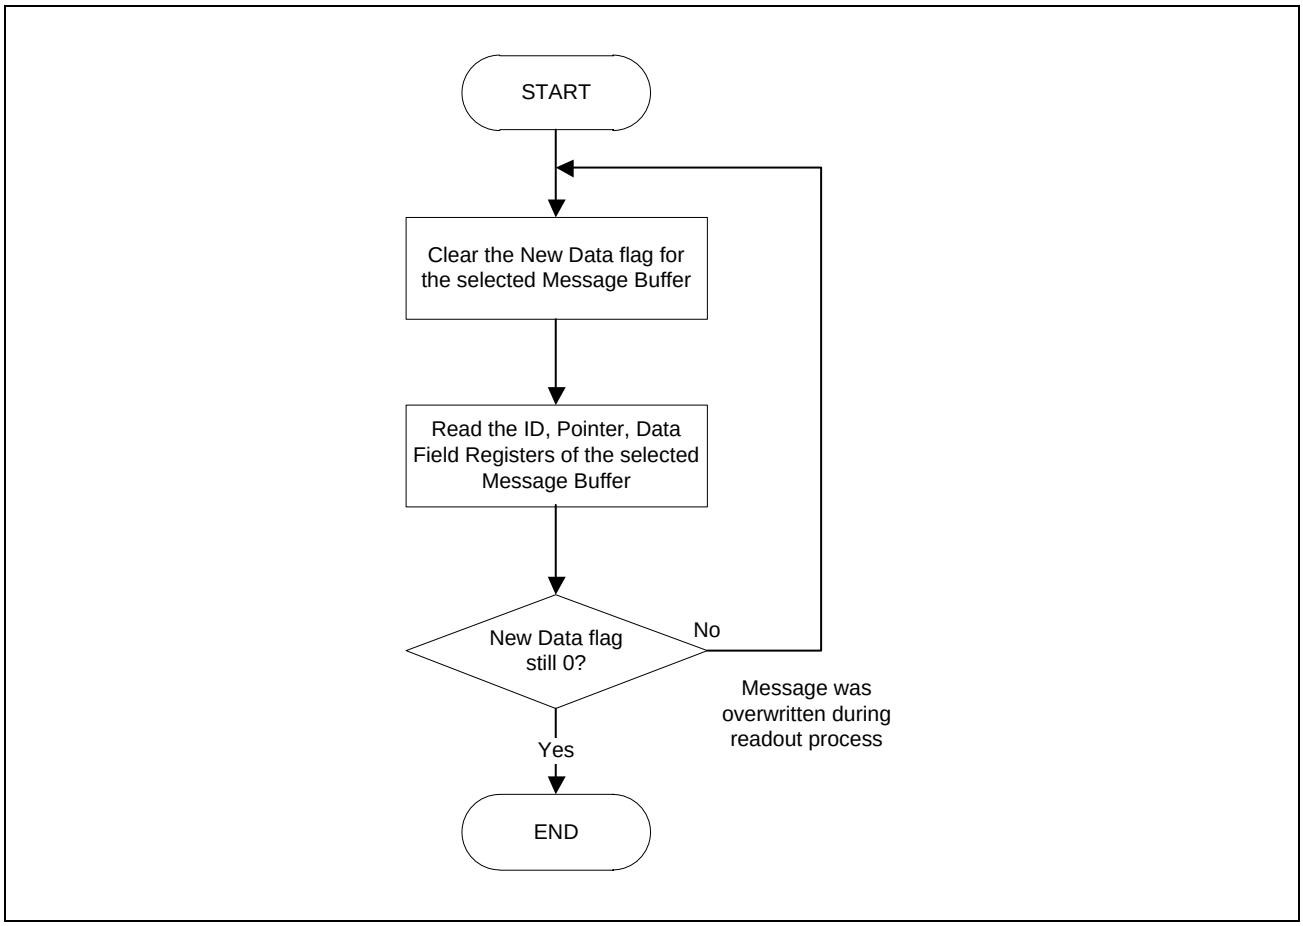

Figure 7.9-36 RX Message Buffer Read Flow

7.9.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffers configured in RX or GW mode should be configured based on system requirements.

The CFDGAFLP1n.GAFLFDP[31:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffers configured in RX mode or GW mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Registers.

Depending on the configuration of the FIFO buffers, an interrupt may also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value H'FF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write H'FF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to overrun condition.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, if a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission of the message is not performed. The read point moves to the next message automatically.

Do not write change for this bit when the CFDCFCCn.CFE bit is 1. Common FIFO can set interrupt when:

- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

Note: The message lost can be set only in RX or GW mode by CAN, the flag is not set when the CPU is overloading the FIFO buffers.

Note: When CFDGAFLP0n.GAFLSRDi (i = 0 to 2) is set and CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1, 2) is also set, a receiving frame is stored in the target TXQ as send data by routing.

The RX FIFO Buffers and the Common FIFO Buffers configured in RX or GW mode can be disabled at any time by clearing the CFDRFCCn.RFE or CFDCFCCn.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCn.RFE or CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO Buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO Buffers or Common FIFO Buffers configured in RX mode are assigned as DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write H’FF to the FIFO Pointer Control Register (CFDCFPCTRn.CFPC or CFDRFPCTRn.RFPC), because this could lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO Buffer and then the FIFO is disabled, the interrupt flag is not automatically cleared. The interrupt flag should be cleared before disabling the FIFO.

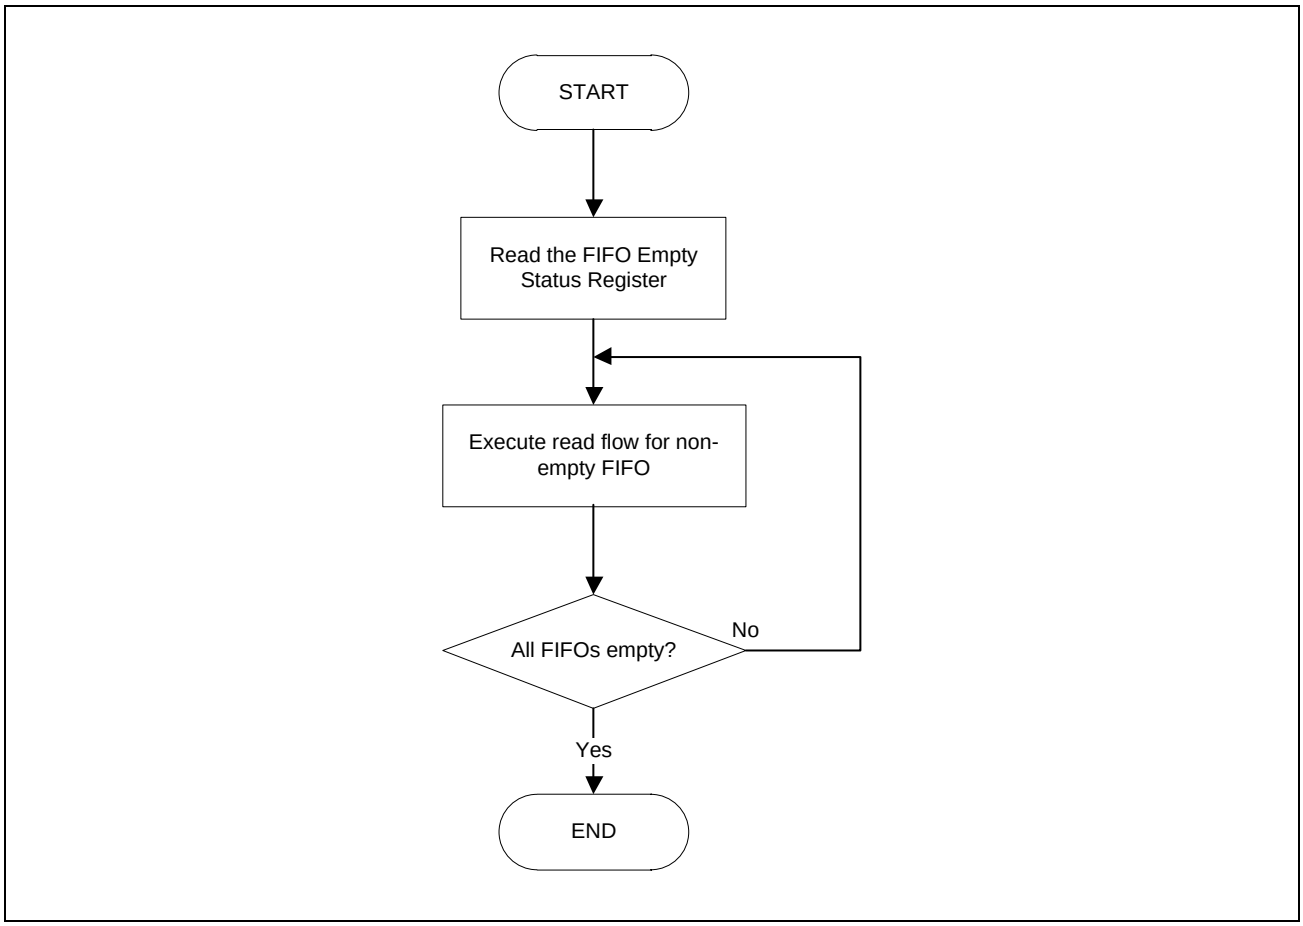

Figure 7.9-37 FIFO Buffer Message Access Flow (Example for Polling Case)

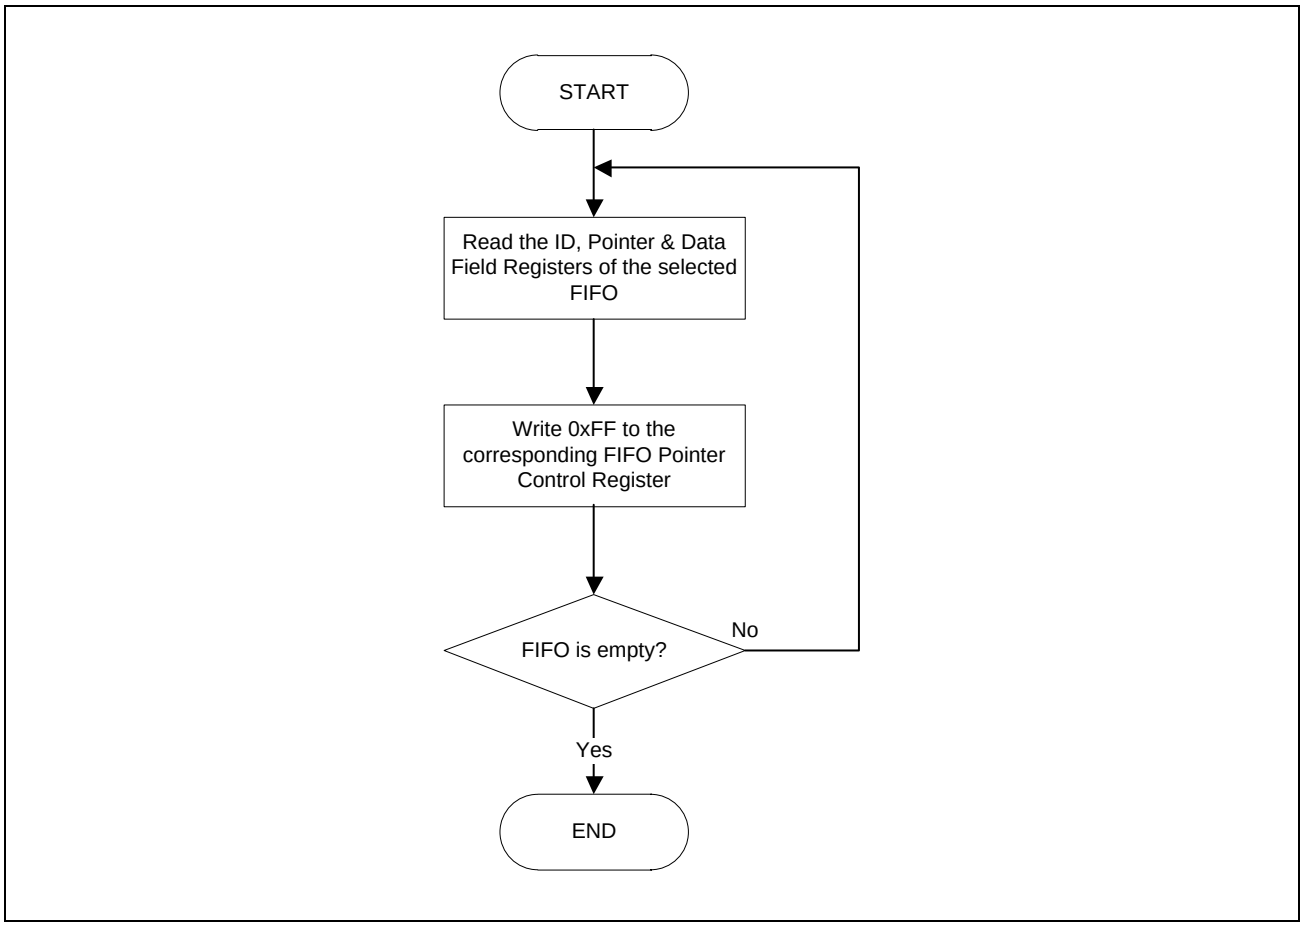

Figure 7.9-38 RX FIFO Buffer Read Flow (Example for Polling Case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even if it clears an interruption flag after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the deadline, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

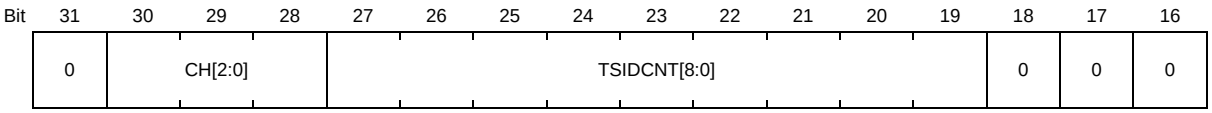
7.9.8.1.3 Timestamp

The Timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CAN-FD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and Data into the target RX Message Buffer or RX/GW FIFO.

For transmit message, the Timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If it is 0, the peripheral clock is used. If it is 1, the selected CAN channel bit time clock is used.

The channel selection is done with the CFDGCFG.TSBTCS bit of the Global Configuration Register.



Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset mode for this channel, the Timestamp counter is stopped. Therefore, for other CAN channels, the Timestamp counter value is also not updated.

If peripheral clock is selected as the Timestamp counter clock source, Channel modes do not influence the Timestamp counter function.

The source clock for the Timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (Timestamp Prescaler) in the Global Configuration Register.

The Timestamp counter can be reset to H’0000 with the CFDGCTR.TSRST bit (Timestamp Reset).

The Timestamp counter filed format is described below.

7.9.8.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- TX Queue transmission
  A fixed number of transmission message buffers (64 TX message buffers) are dedicated for each channel. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue and/or Common FIFO in TX or GW mode can be configured in the following way (see **Figure 7.9-39**):
  - TX Queue: Up to 32 transmission message buffers for one channel can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ1 or TXQ3. Lower transmission message buffers are used to form the TXQ0 or TXQ2.
    Transmission control and status registers of these transmission message buffers should not be used. One channel has four TX Queues. Each TXQ has an access window:
    - TXQ0 is transmission Message Buffer 0 of each channel
    - TXQ1 is transmission Message Buffer 31 of each channel
    - TXQ2 is transmission Message Buffer 32 of each channel
    - TXQ3 is transmission Message Buffer 63 of each channel

    When using TXQ1 and TXQ0 simultaneously, the sum of the depths of TXQ1 and TXQ0 should not exceed 32.
    When using TXQ3 and TXQ2 simultaneously, the sum of the depths of TXQ3 and TXQ2 should not exceed 32.
- Common FIFO (TX/GW mode): Each Common FIFO in TX or GW mode is linked to a dedicated channel.
  Each channel has a fixed number of three Common FIFOs assigned to it. Within the channel, a Common FIFO configured in TX or GW mode, can be freely linked (assigned) between 32 and 39 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission control and status registers of these transmission message buffers should not be used.

See **Figure 7.9-28** for information on Common FIFO buffer assignment to related channels.

Note: Common FIFO buffers should not be linked to TX message buffers that are already part of a TX Queue.

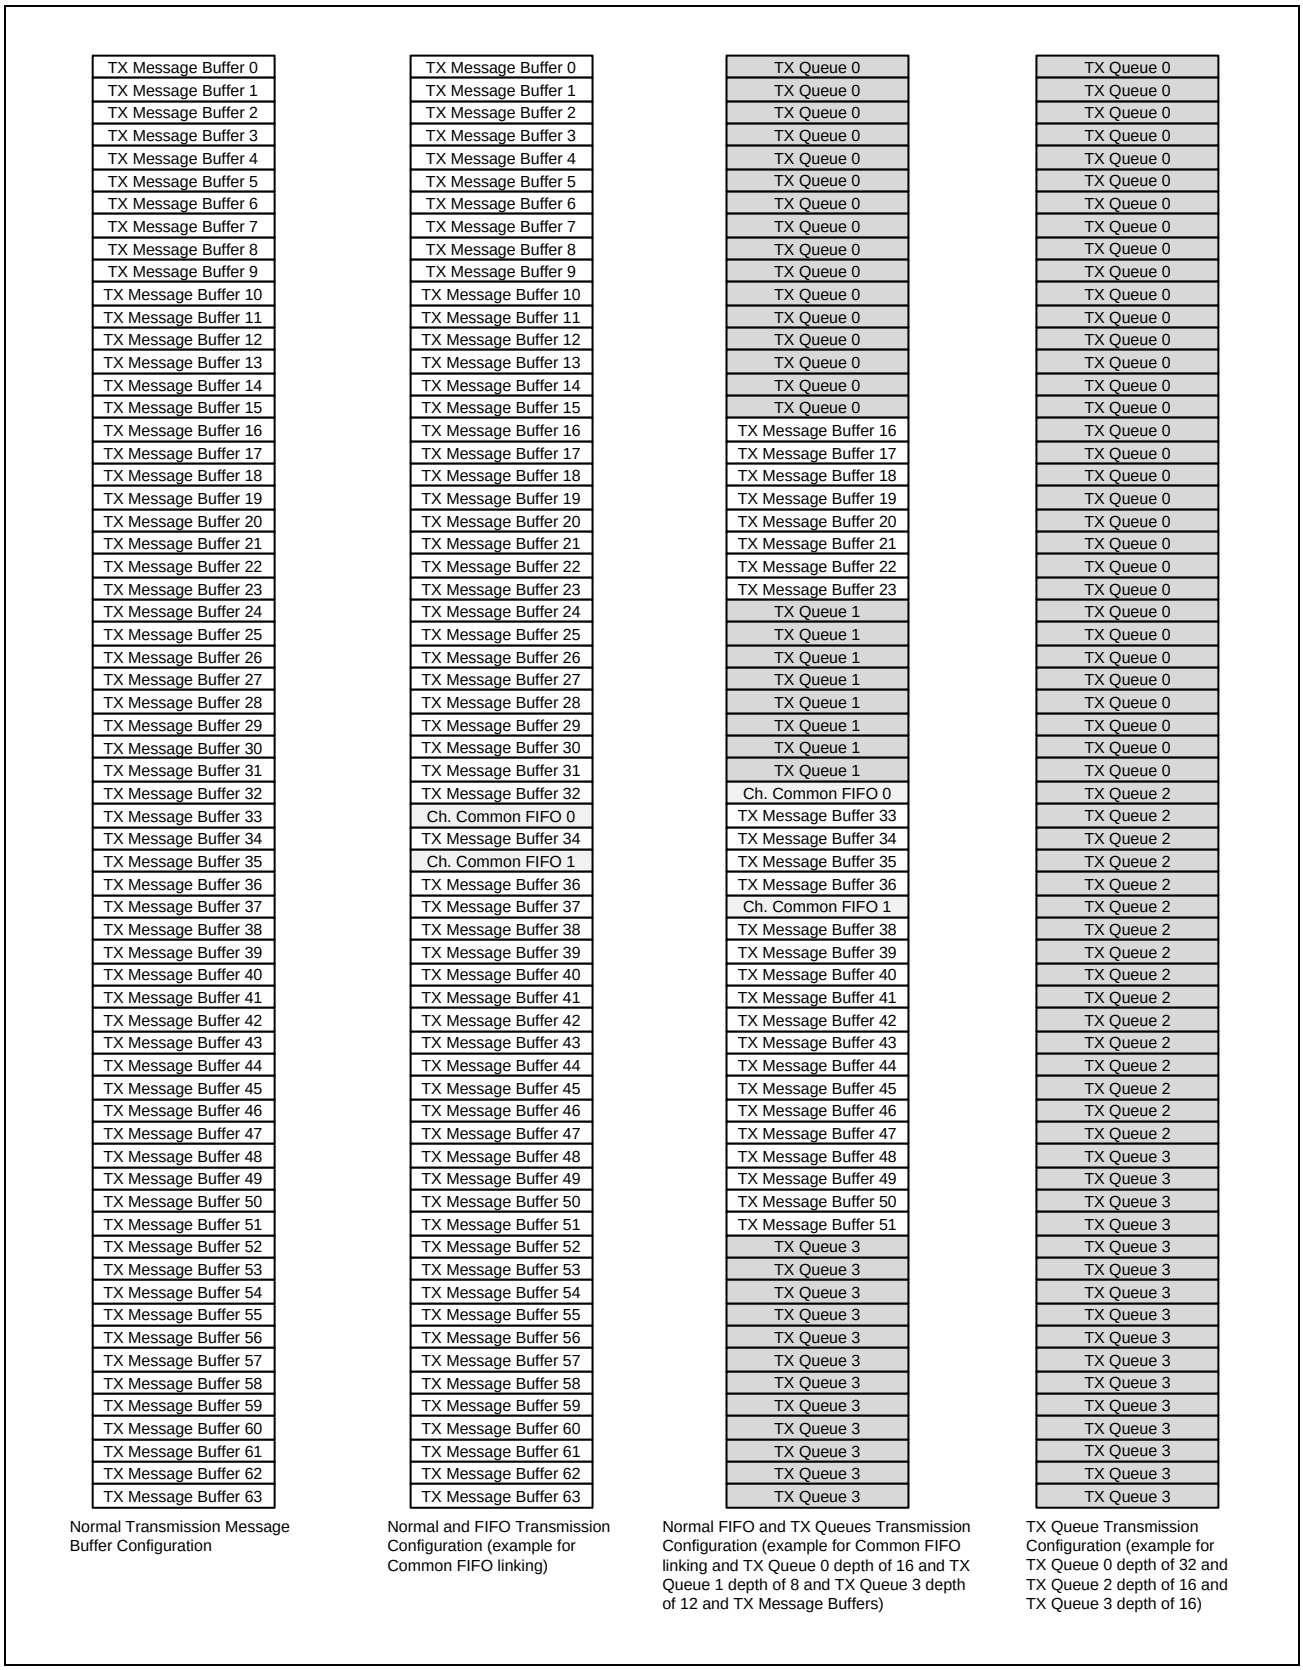


Figure 7.9-39 Channel Transmission Message Buffer Configuration

7.9.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, the transmission priority in the CAN-FD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority

The transmission priority mode is common for all message buffers and all CAN channels. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffers configured in TX mode or GW mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.
If the message is being transmitted from the FIFO, the next pending message within the same FIFO will be considered in the transmission arbitration.
In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 7.9-40 shows the transmission configuration flow.

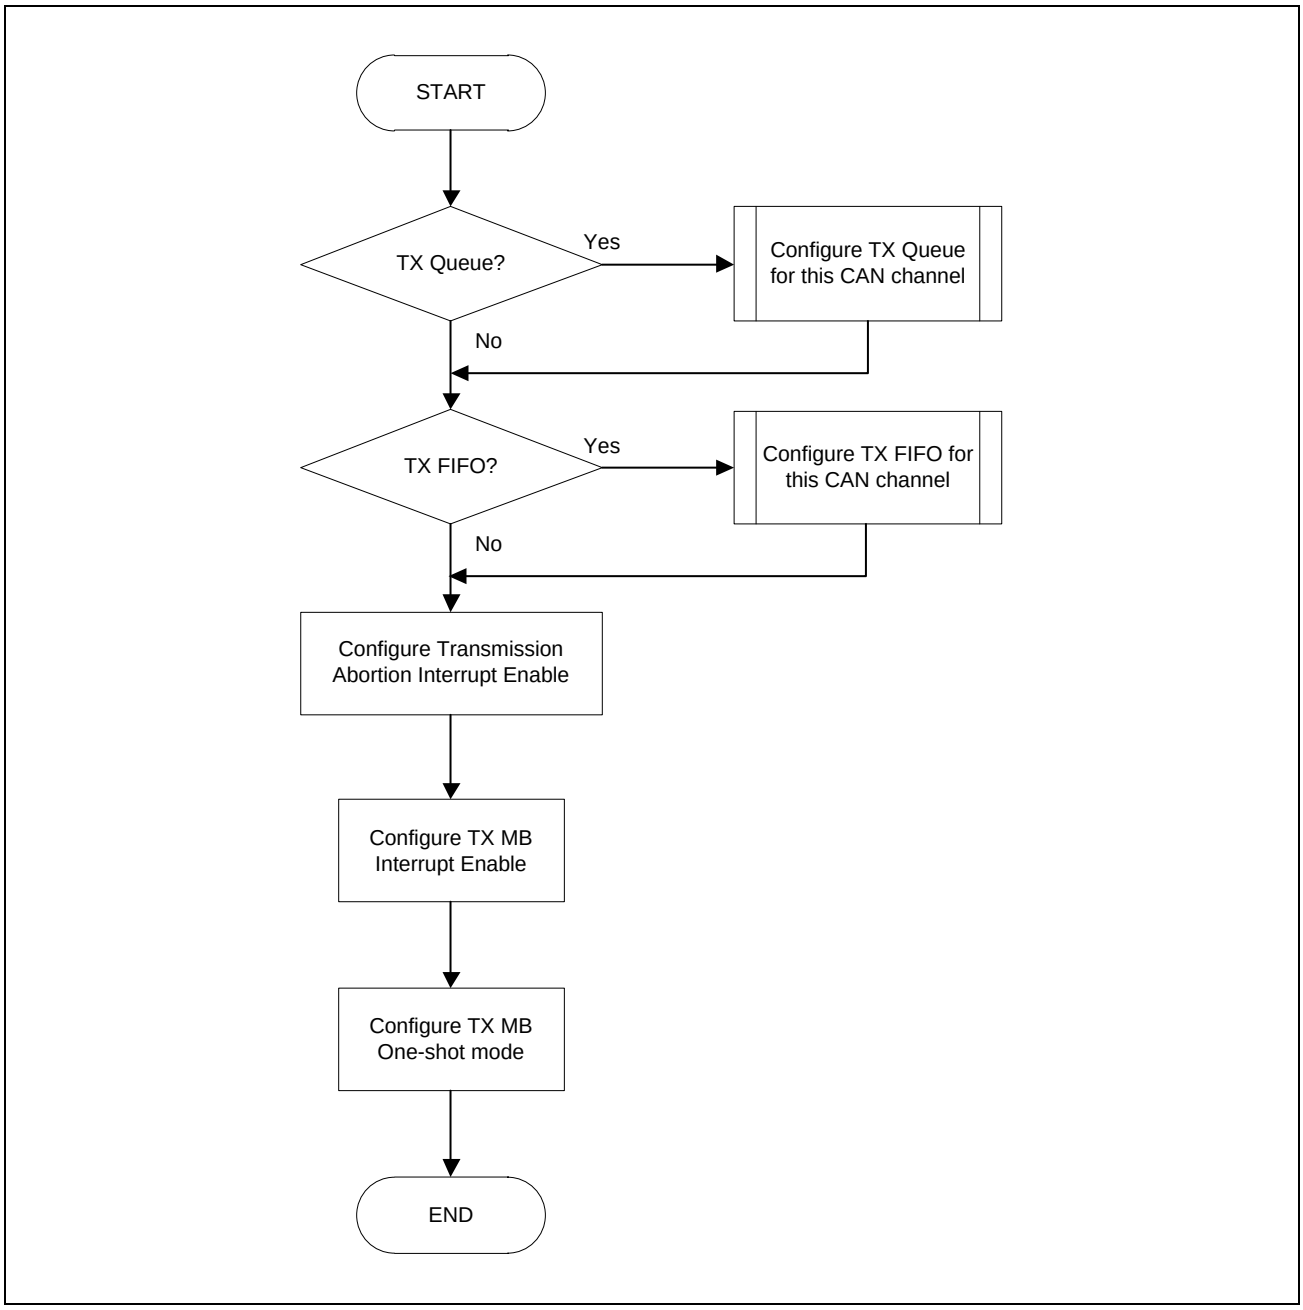

Figure 7.9-40 Transmission Configuration Flow

7.9.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

- Regular transmission mode
  If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
  Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.
  When arbitration is lost or an error occurs, message transmission will be attempted further if no transmission abort request is set for this transmission message buffer.
  New internal transmission arbitration for this channel is performed for all message buffers with transmission request.
- One-shot transmission mode
  When the CFDTMCn.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, then the message buffer is placed in one-shot transmission mode and attempts to transmit a message only once.
  Completion of one-shot transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. The CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b when the one-shot transmission is successful.
  The CFDTMSTSn.TMTRF[1:0] bits are set to 01b when arbitration is lost or an error occurs during the transmission of the related message buffer.
  Additional message transmission will not be attempted in this case.

The regular transmission request procedure after a configuration is shown in **Figure 7.9-41**.

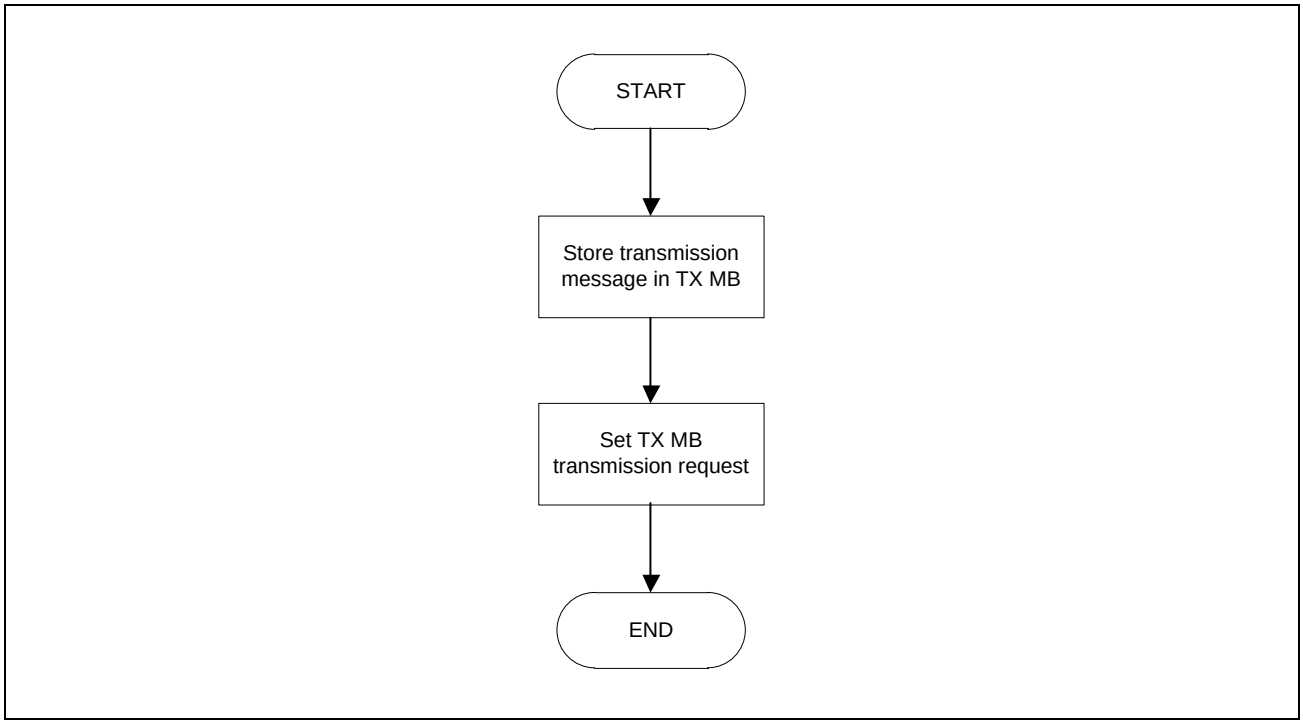

Figure 7.9-41 Transmission Request Procedure Using Normal TX Message Buffer Mode

(1) TX Message Buffer Control Register Setting

Table 7.9-37 shows configuration of the normal CAN transmission mode.

Table 7.9-37 Configuration of CAN Transmission Mode

Transmission Request CFDTMCn.TMTR	Transmission Abortion Request CFDTMCn.TMTAR	One Shot Enable CFDTMCn.TMOM	Communication Activity
0	0	0	Message buffer is disabled
0	0	1	Message buffer is disabled
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abortion is requested
1	1	1	One shot transmission abortion is requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 7.9-42 shows timings for successful transmission for two message buffers of one channel.

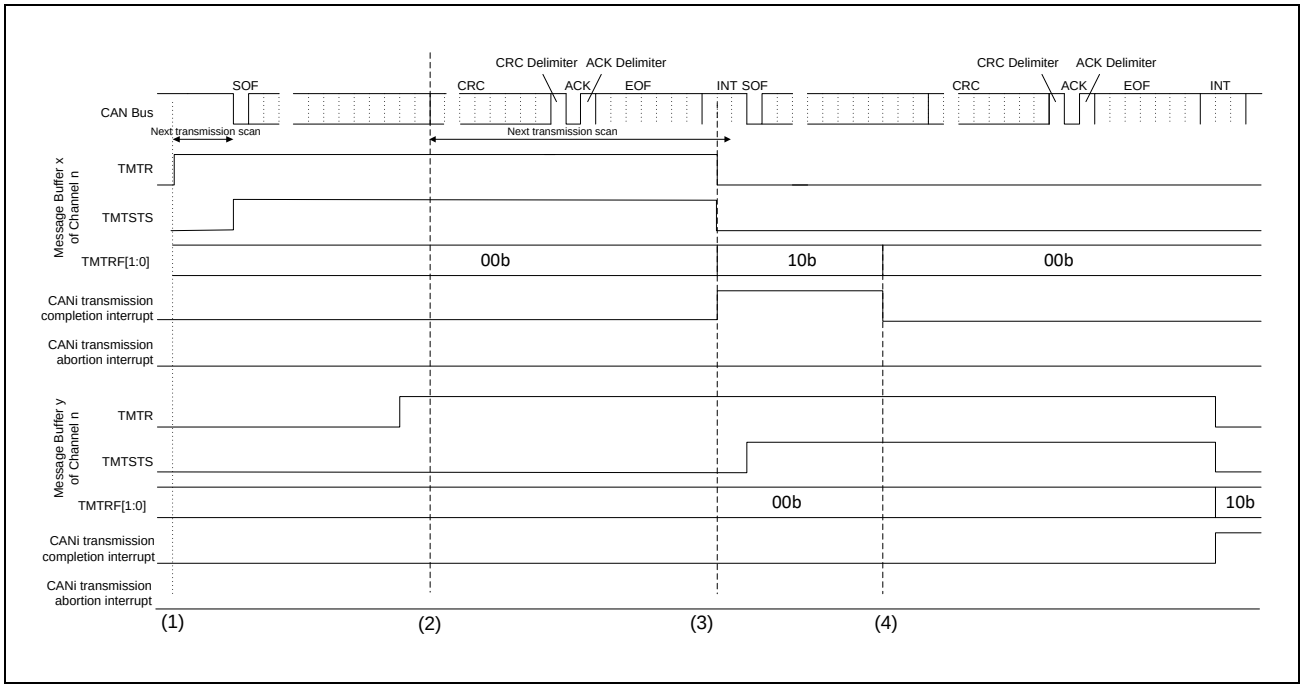

Figure 7.9-42 Timing of Request and Flag Bits for Successful Transmission

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the related TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission*[1].
2. On the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.

The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.

3. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared. When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line the CFDTMSTSn.TMTRF flag bits must be cleared.
4. Before starting the next transmission, clear the CFDTMSTSn.TMTRF[1:0] bits. Load the next message in the transmission message buffer and set the CFDTMCn.TMTR bit again. CFDTMCn.TMTR bit cannot be set again before CFDTMSTSn.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during the transmission or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSn.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 7.9-43 shows timings for transmission abort for two message buffers of one channel.

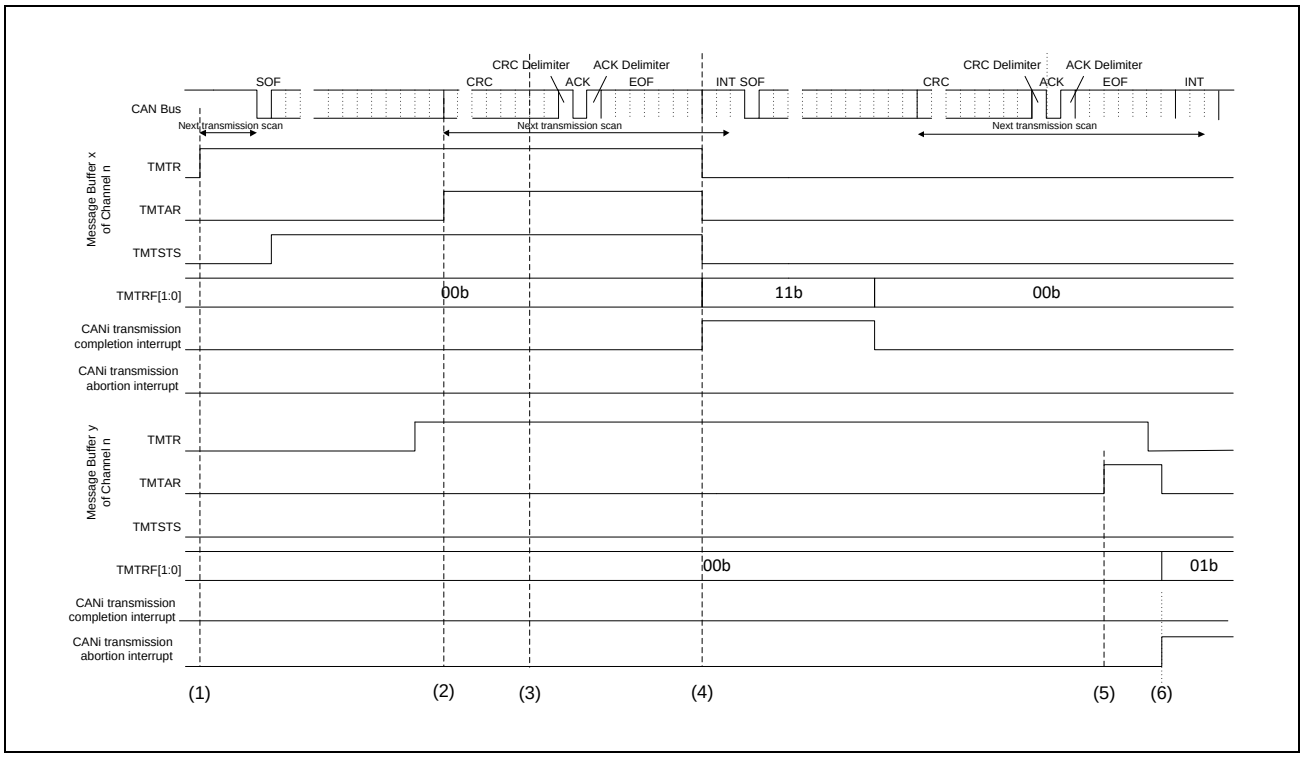

Figure 7.9-43 Timing of Request and Flag Bits for Transmission Abort

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission*[1].
2. If the CFDTMCn.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. On the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example timing diagram, message buffer y is not selected as the next transmission message buffer.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.
4. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared.
   When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSn.TMTSTS not set). If the CFDTMCn.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSn.TMTRF[1:0] bits are set to 01b.
   If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCn.TMTR, and CFDTMCn.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set, an interrupt is generated for successful transmission abort.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS is cleared. The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit. If an error occurs, either during the transmission, or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer.

7.9.8.2.3 TX FIFO or GW FIFO Transmission

Three common FIFO buffers are assigned to each channel. The three FIFO buffers can be linked to any normal TX Message Buffer position for this channel by the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Register if configured in TX or GW mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX Message Buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX Message Buffer linked to a FIFO buffer configured in TX or GW mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value H'FF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers.

If the message count matches the FIFO Depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, an interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCCn.CFIM bit is 1, an interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

Common FIFO can set interrupt when CAN frame transmitted is completed.

The Common FIFO buffers configured in TX mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Registers. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCCn.CFE bit only when the Empty flag is set for the corresponding Common FIFO Buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCCn.CFE is set again, ensure that CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the TX FIFO.

When the CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in **Figure 7.9-44**.

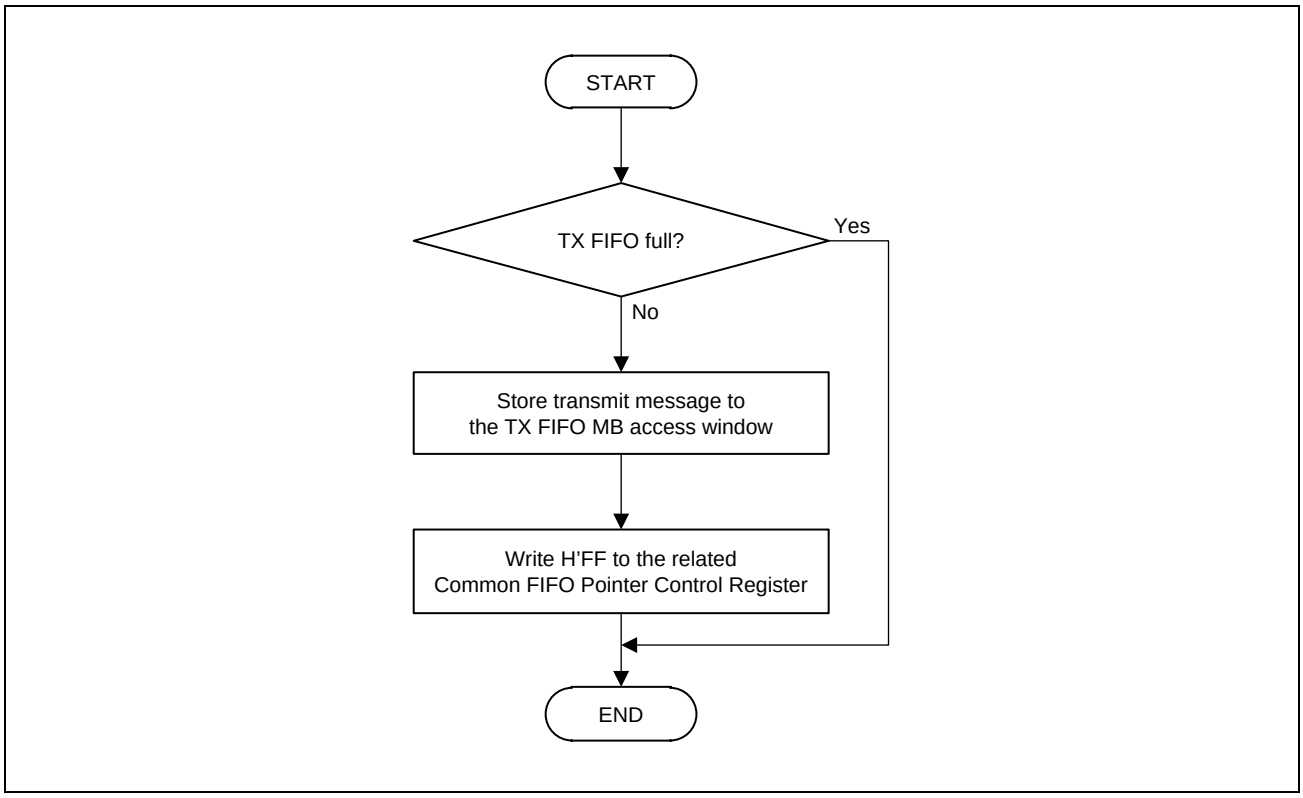

Figure 7.9-44 TX FIFO Transmission Request Procedure

(2) GW FIFO Operation

The AFL entries for routing the received messages to GW FIFO buffers should be configured based on the requirements of the system. The matching AFL entry selects the GW FIFO buffer for storage of a received message on any of the CAN channels.

When a message is successfully received and stored in a GW FIFO buffer, the FIFO message count in the corresponding FIFO Status Register is incremented by 1.

If the message count matches the FIFO depth, then the FIFO Full flag is set.

The oldest message in the GW FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the GW FIFO, the message count value is decremented by 1. When all the messages from the GW FIFO are transmitted, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1.
- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive. FIFO buffer is full of

data, the oldest data in the buffer is overwritten with the received message.
The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message is overwritten with the received message.
In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point moves to the next message automatically.

The interrupt generation conditions for the GW FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, then RX interrupt flag is set when FIFO counter increments and reaches value configured by CFDCFCCn.CFIGCV and the TX interrupt flag is set when FIFO transmits the last message successfully.

If CFDCFCCn.CFIM bit is 1, then RX interrupt flag is set at the end of storage of every received message and TX interrupt flag is set if a message is successfully transmitted from the FIFO.

Common FIFO can set interrupt when:

- CAN frame transmitted is completed
- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in Common FIFO, and transmission is stopped. Transmission will be started if it is set as CFDCFCCEn.CFBME = 0.

The Common FIFO buffers configured in GW mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared, the GW FIFO becomes empty as follows:

- Immediately if the message from the GW FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the GW FIFO is already scheduled for transmission or already in transmission

Other possible messages pending from the GW FIFO are lost.

Before CFDCFCCn.CFE is set again, ensure that the CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the GW FIFO.

When the CFDCFCCn.CFE bit is cleared and the CFDCFSTSn.CFEMP bit is set, the message read and write pointers of the GW FIFO are cleared and are no longer active. Therefore, all messages in the GW FIFO buffers are lost and no further message can be stored into the GW FIFO.

In applications intended to be used as CAN-to-CAN gateways, it is useful if the Error State Indication (ESI) information of the routing messages is not replaced by the sending node Error State Indication. For this, each channel has the control function register CFDCnFDCFG.ESIC to replace their own ESI information by the routing ESI information.

Note: If the sending node is error passive, the ESI bit is sent anyway as error passive (ESI = 1).

(3) Interval Timer for FIFO Transmission

For each Common FIFO in TX or GW mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCCn.CFE bit is set.

When the Common FIFO in TX or GW mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCCn.CFE bit
- CAN channel is in CH_RESET mode

The interval time is specified by the CFDCFCCn.CFITT value in the Common FIFO Configuration/Control Register and can be specified from 0 to 255 timer units.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, a value of 0 should be selected.

The timer source can be selected by the configuration bit CFITSS in the Common FIFO Configuration/Control Register. For the timer source the CAN bit timing clock of the FIFO related channel or a global reference clock can be selected.

If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT or CH_RESET or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See **Table 7.9-38** for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency/period.

Table 7.9-38 Configuration Example for the FIFO Interval Timer Reference Clock

	Reference Clock		
Peripheral Clock (PCLKM)	1 µs	100 µs	500 µs
80 MHz / 12.5 ns	80	8000	40000
100 MHz / 10 ns	100	10000	50000

Additionally, the reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCCn.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (×1 or ×10).

The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX/GW FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time.

Figure 7.9-45 shows an example timing of the internal processing.

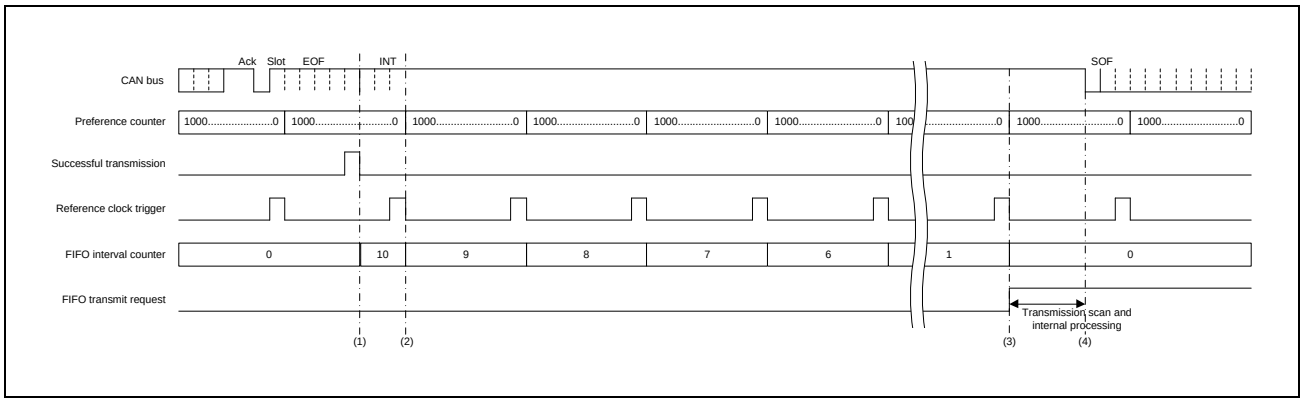

Figure 7.9-45 Example for Interval Processing Time

The configuration for the above timing is as follows:

- Peripheral clock frequency = 100 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 1000 times
- Reference clock due to the above settings = 10 µs
- Common FIFO interval timer source selection (CFDCFCCn.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCCn.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCCn.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to one reference clock interval.
2. With the next reference clock trigger, the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0 the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing this usually takes less than 3 CAN bit time, between internal FIFO transmit request set 3 and actual transmission.

In the worst case when multi events such as reception scan, internal message routing, transmit scan on all channels occur, then it can take up to 432 peripheral clock cycles.

As shown in **Figure 7.9-45**, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCCn.CFITT to the required minimum value + 1.

If additional TX message buffers or TX/GW FIFOs are configured for transmission for the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time due to higher priority message transmission from these TX message buffers or TX/GW FIFOs.

Figure 7.9-46 shows a block diagram of the FIFO interval time generation circuit.

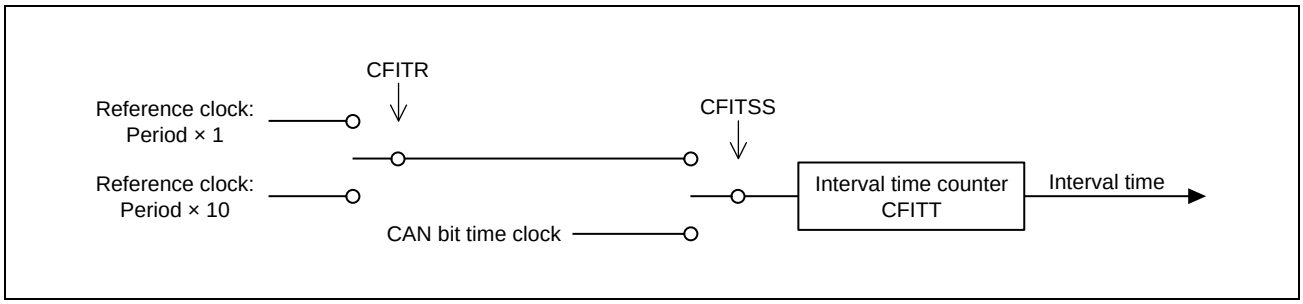

Figure 7.9-46 Block Diagram of FIFO Interval Timer

7.9.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 32 TX message buffers, which are accessed by one access window. One channel has 4 TX Queues. One TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 0 as access window (referred to as TXQ0). The second TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 31 as access window (referred to as TXQ1). The third TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 32 as access window (referred to as TXQ2). The fourth TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 63 as access window (referred to as TXQ3).

All TXQ0, TXQ1, TXQ2, and TXQ3 messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ0 are CFDTXQCC0n, CFDTXQSTS0n, and CFDTXQPCTR0n.
The registers for TXQ1 are CFDTXQCC1n, CFDTXQSTS1n, and CFDTXQPCTR1n.
The registers for TXQ2 are CFDTXQCC2n, CFDTXQSTS2n, and CFDTXQPCTR2n.
The registers for TXQ3 are CFDTXQCC3n, CFDTXQSTS3n, and CFDTXQPCTR3n.

When access window TX Message Buffer No.63 (TXQ3) or TX Message Buffer No.32 (TXQ2) or TX Message Buffer No.31 (TXQ1) or TX Message Buffer No.0 (TXQ0) is used, refer to the related access registers TX Message Buffer ID Registers (CFDTMIDn), TX Message Buffer Pointer Registers (CFDTMPTRn), TX Message Buffer Data Field 0 Registers (CFDTMDF0_n), and TX Message Buffer Data Field 1 Registers (CFDTMDF1_n).

The depth of each TXQ0 buffer can be configured by writing to the CFDTXQCC0n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ0 can set from TXMB0 to TXMB31 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- H’00: TX Queue disabled
- H’01: Reserved
- H’02: 3 messages
  ⋮
- H’1D: 30 messages
- H’1E: 31 messages
- H’1F: 32 messages

The depth of each TXQ1 buffer can be configured by writing to the CFDTXQCC1n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ1 can set from TXMB31 to TXMB0 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- H’00: TX Queue disabled
- H’01: Reserved
- H’02: 3 messages
  ⋮
- H’1D: 30 messages
- H’1E: 31 messages
- H’1F: 32 messages

The depth of each TXQ2 buffer can be configured by writing to the CFDTXQCC2n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ2 can set from TXMB32 to TXMB63 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- H’00: TX Queue disabled
- H’01: Reserved
- H’02: 3 messages
  ⋮
- H’1D: 30 messages
- H’1E: 31 messages
- H’1F: 32 messages

The depth of each TXQ3 buffer can be configured by writing to the CFDTXQCC3n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ3 can set from TXMB63 to TXMB32 as a queue buffer at the maximum.

The 31 available options for depth configuration are:

- H’00: TX Queue disabled
- H’01: Reserved
- H’02: 3 messages
  ⋮
- H’1D: 30 messages
- H’1E: 31 messages
- H’1F: 32 messages

When using TXQ1 and TXQ0 simultaneously, the depth of TXQ is 32 or less in total.

When using TXQ3 and TXQ2 simultaneously, the depth of TXQ is 32 or less in total.

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 63, TX Message Buffer No. 32, TX Message Buffer No. 31 and TX Message Buffer No. 0, which acts as TX Queue access window).

When CFDGAFLP0n.GAFLSRD i (i = 0 to 2) is set and the CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1, 2) is also set, a receiving frame is stored in the target TXQ as send data by routing.

When CFDTXQCCn.TXQOWE bit is 1, the TX Queue is in TX Queue overwrite mode. If the message of the same ID is stored in TX Queue when a frame is received and it is stored in TX Queue, an old message is overwritten by a new message. Therefore, an old message is not transmitted. When the old message of the same ID is transmitting and a CAN bus error and an arbitration-lost occur, the message of old ID is not resent.

When using the function in GW mode and TX Queue overwrite mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3. If it accesses by routing in gateway mode when a TXQ buffer is full, CFDTXQSTS.TXQMLT is set and send data is thrown away.

The function is valid for the standard ID frame and is invalid for the extended ID frame.

Explanation of operation of the TX Queue with same ID over-writing function in GW mode is shown in **Figure 7.9-47**.

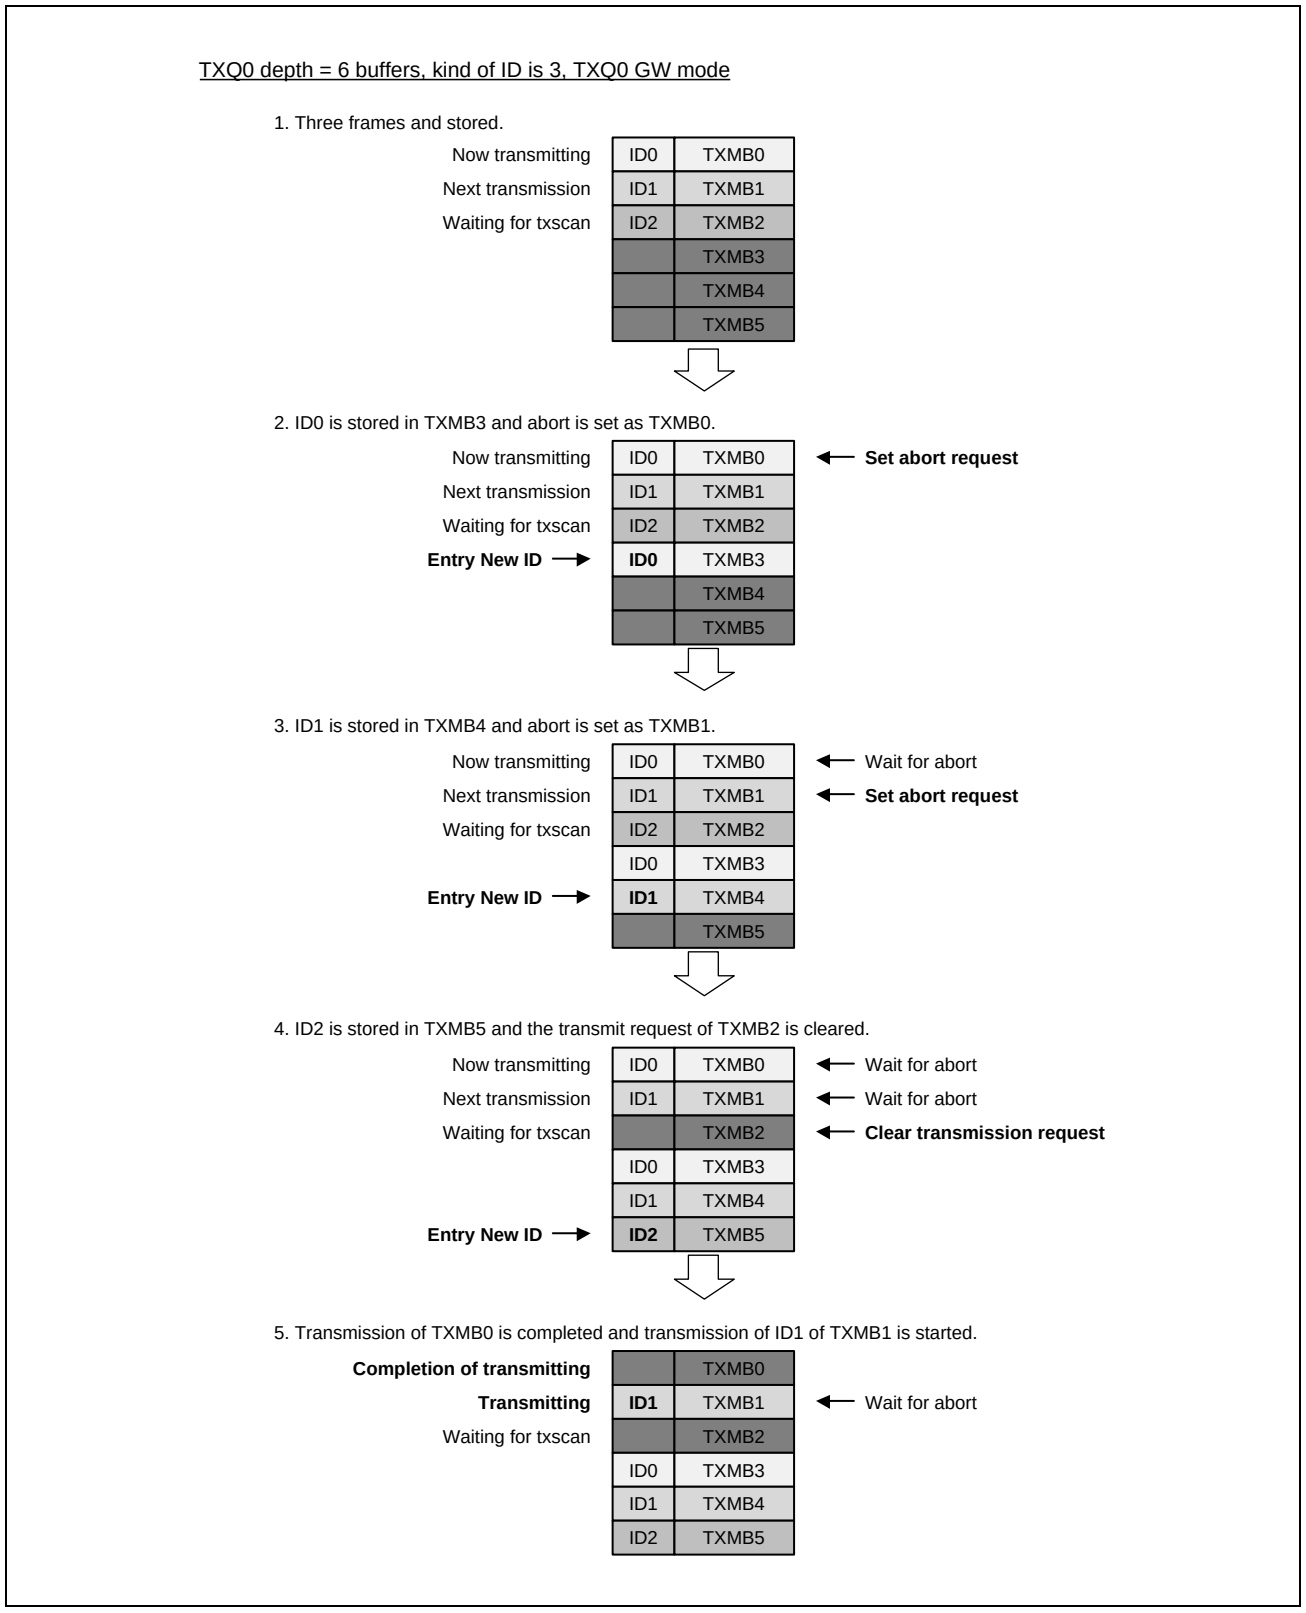

Figure 7.9-47 Operation of TXQ0 in Gateway Mode

When a system writes in TXQ, a system should write in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full then no further access should be done to the queue, until it is no longer full. If it accesses by software writing in when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTSn.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored into the TX Queue.

When a message has been stored to the TX Queue, H’FF must be written into the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same identifier are stored in the TX Queue, then the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same identifier is stored in the TX Queue. Or if TX queue overwrite mode is used, the frame of the same ID is rewritten on a new frame.

For the TX Queue a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCCn.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in **Figure 7.9-48**.

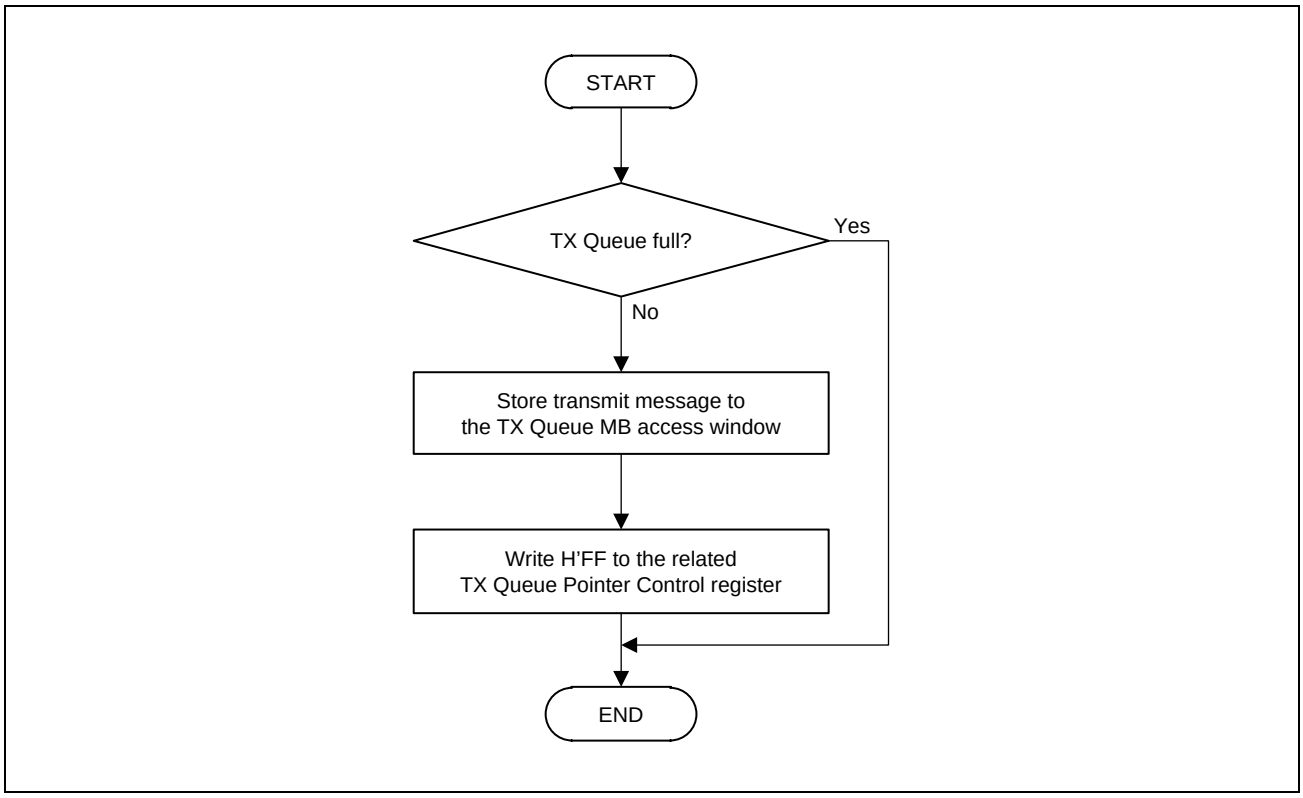

Figure 7.9-48 TX Queue Transmission Request

Table 7.9-39 TX Queue Access Point Selection

TXQ Name	Access Window	Range Width	Direction	Hardware Routing Access Point	CPU Access Point	DMA Access Point	Note
TXQ0	TXMB0	0, 3 - 32	TXMB0 → TXMB31	Yes	Yes	Yes	When using both TXQ0/1, the total number of stages is 32 or less
TXQ1	TXMB31	0, 3 - 32	TXMB31 → TXMB0	Yes	Yes	No	
TXQ2	TXMB32	0, 3 - 32	TXMB32 → TXMB63	Yes	Yes	No	When using both TXQ2/3, the total number of stages is 32 or less
TXQ3	TXMB63	0, 3 - 32	TXMB63 → TXMB32	No	Yes	Yes	

TXQ0 can use hardware routing, CPU access, and DMA access.

Hardware routing access, CPU access, and DMA access should not be used simultaneously. Choose one access method.

7.9.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List buffers for each CAN channel. Two TX History List buffers are provided for each CAN channel and each TX History List buffer can store up to 16 TX History List entries for a CAN channel.

The CFDTHLCCn.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFOs/TX Queue is stored or if all transmit message information from TX Queue, TX FIFO or normal TX message buffers should be stored in the TX History List for a CAN channel.

When a CFDTHLCCn.THLDGE bit is set up, the information on all the frames transmitted in GW mode is stored in TX History List.

Each transmit message can be individually configured for acceptance to the TX History List by the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted on that CAN channel.

Storing to the List is not synchronized with the status of CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the List can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF bit is set to 1 when the THLIE is configured to 1 or when the TX History List counter CFDTHLSTSn.THLMC[5:0] is increased.

The delay time is dependent on the number of channels due to internal processing.

- Maximum delay time from setting the CFDTMSTSn.TMTRF to storing the TX History List data is 224 peripheral bus clock cycles.

The History list records the following information of the transmitted message:

- Buffer type:
  - 001b: TX Message Buffer
  - 010b: TX FIFO
  - 100b: TX Queue
- Buffer number:
  TX Message Buffer, TX Queue Message Buffer, or TX Message Buffer Link for the Common FIFO Buffer from which the transmission occurred. The number depends on the buffer type, see **Table 7.9-40**.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at the capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.
- Transmit gateway buffer indication:
  For data transmitted from the gateway, CFDTHLACC0n.TGW bit is set to 1.

Table 7.9-40 TX History List Buffer Number Entry

CFDTHLACC0n.BT[2:0] Buffer Type		
001b	101b	100b
TX Message Buffer	TX FIFO	TX Queue
TXMB0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO Configuration	Number shown corresponds to the message buffer belonging to the TX Queue for which the frame was transmitted.
TXMB1		
TXMB2		
TXMB3		
⋮		
TXMB30		
TXMB31		
TXMB32		
TXMB33		
TXMB34		
⋮		
TXMB61		
TXMB62		
TXMB63		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTSn.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, the identification number is then stored together with the other message related information to the TX History List and can be read with the Transmission ID (TID) of the TX History List Access Register.

Also for normal TX message buffers, the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List. Information label is the same.

Figure 7.9-49 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, H’FF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 7.9-50 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCCn.THLIM bit of the corresponding TX History List Configuration/Control Registers and enabled with the CFDTHLCCn.THLIE bit of the same registers, either to generate an interrupt when the history list reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTSn.THLELT bit in the TX History List Status Register.

Status of this bit is also shown by the THLES bit in the Global Error Flag Register.

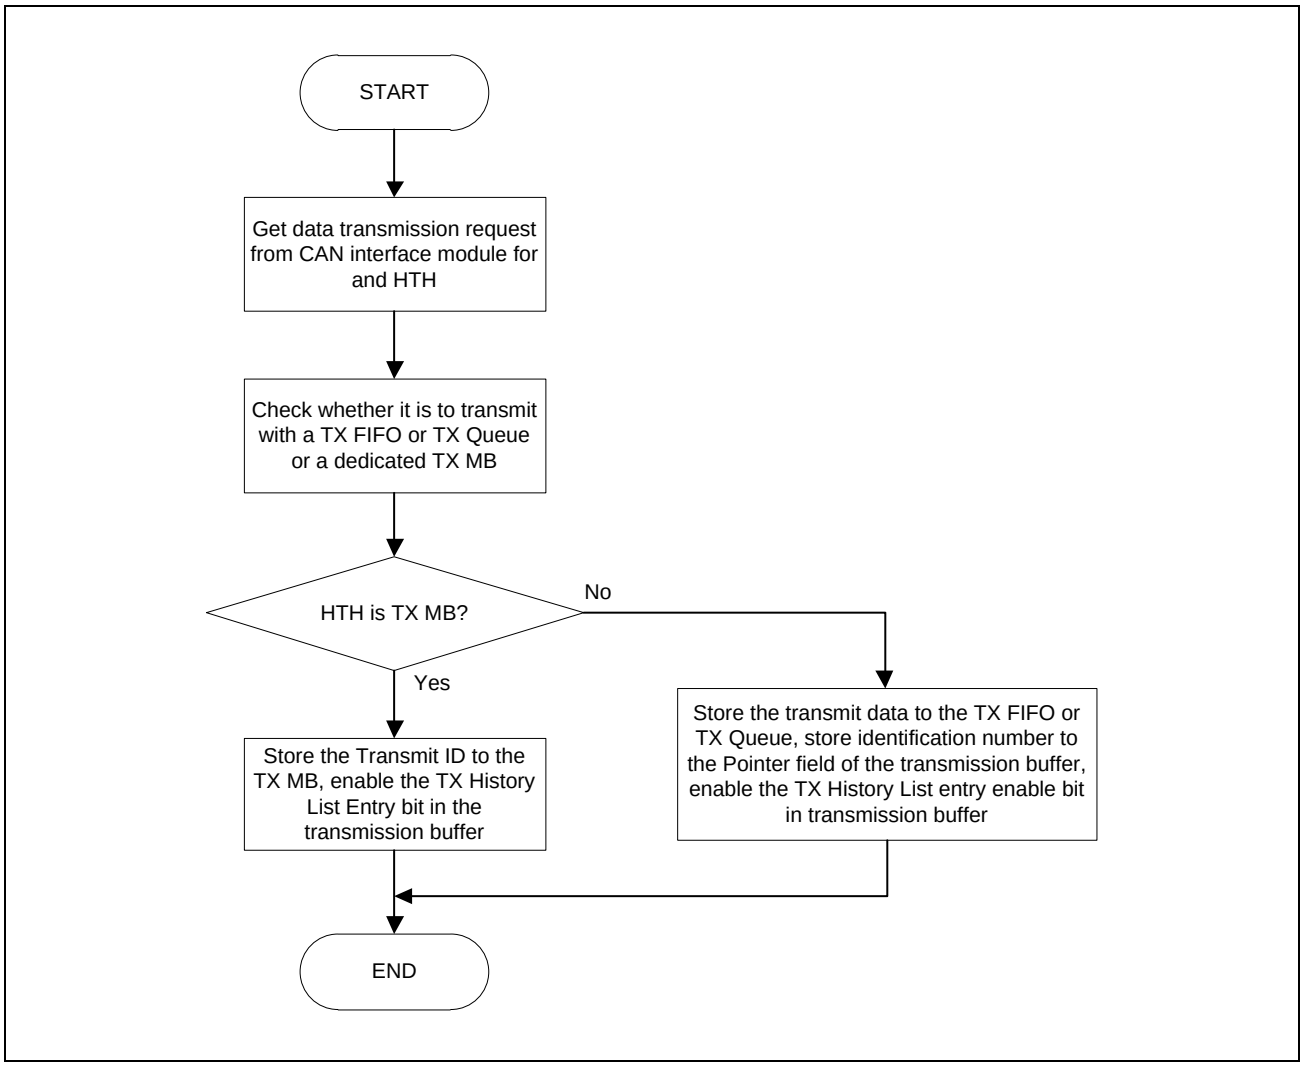

Figure 7.9-49 Transmission Preparation Flow when TX History List is Used

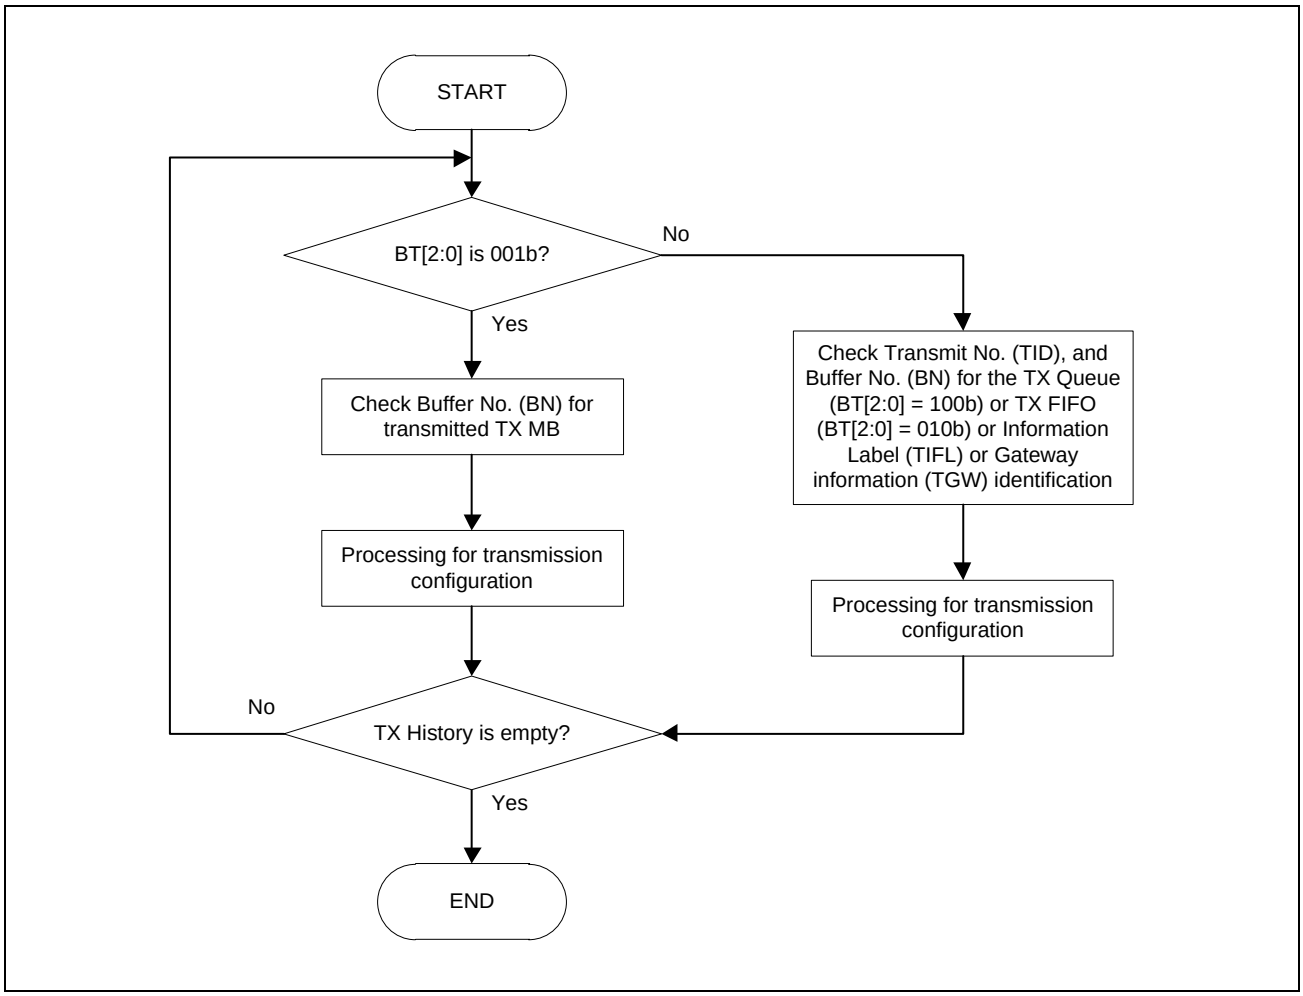

Figure 7.9-50 Example Flow for Processing TX History List Information

7.9.8.2.6 TX Data Padding

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, then the data bytes beyond the restricted range are replaced by bytes with the value of CC HEX.

This can happen for Common FIFOs configured as (TX or GW) when the transmit message DLC is higher than CFDCFCCn.CFPLS.

7.9.9 Test Mode

The CAN-FD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CAN-FD module in test modes.

All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes

7.9.9.1 Channel Specific Test Modes

Each CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External Loop Back mode)
- Self-test mode 1 (Internal Loop Back mode)
- Restricted operation mode

7.9.9.1.1 Basic Test Mode

The Basic test mode should be used when a particular test setting must be enabled other than when in Listen-Only and Self- test modes.

7.9.9.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional Bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, Overload flag, Active Error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX Message Buffer or TX-/GW-FIFO of this channel.

Note: If a message is stored in GW FIFO or Routing TXQ, ensure that the transmitting channel is not in Listen-only mode so that transmission is not requested for this channel from the GW FIFO or Routing TXQ.

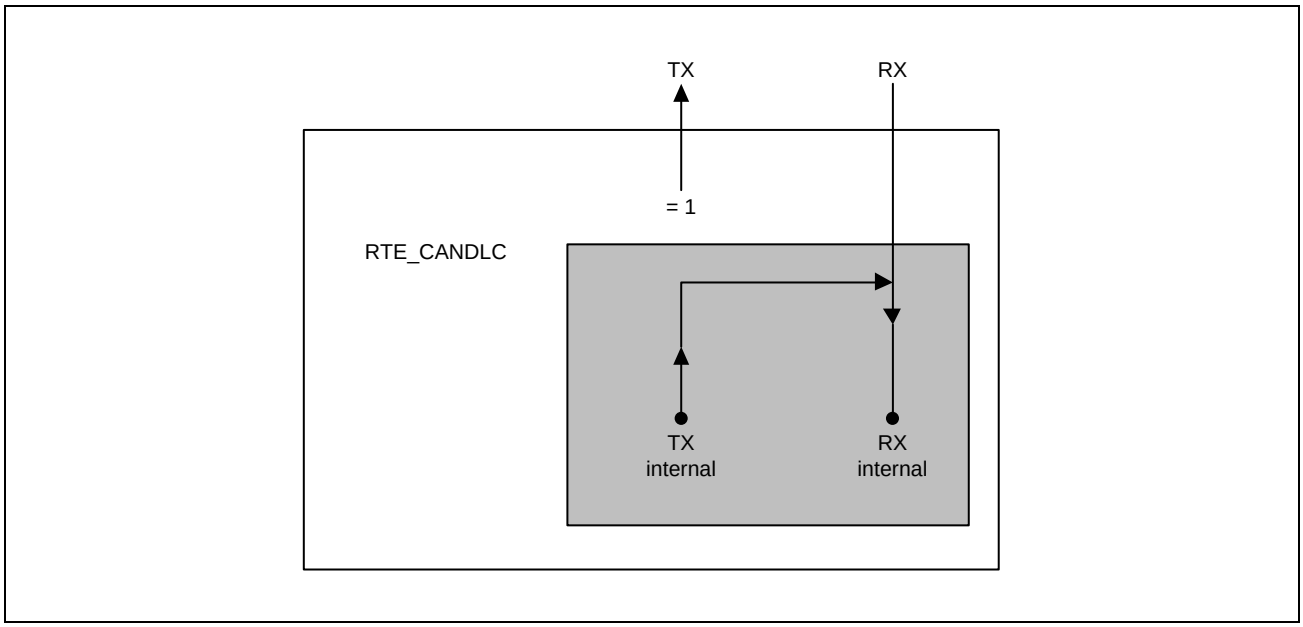

Figure 7.9-51 Listen-Only Mode

7.9.9.1.3 Self-Test Mode 0 (External Loop Back Mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and can store them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests.

The RX/TX pins should be connected to the transceiver.

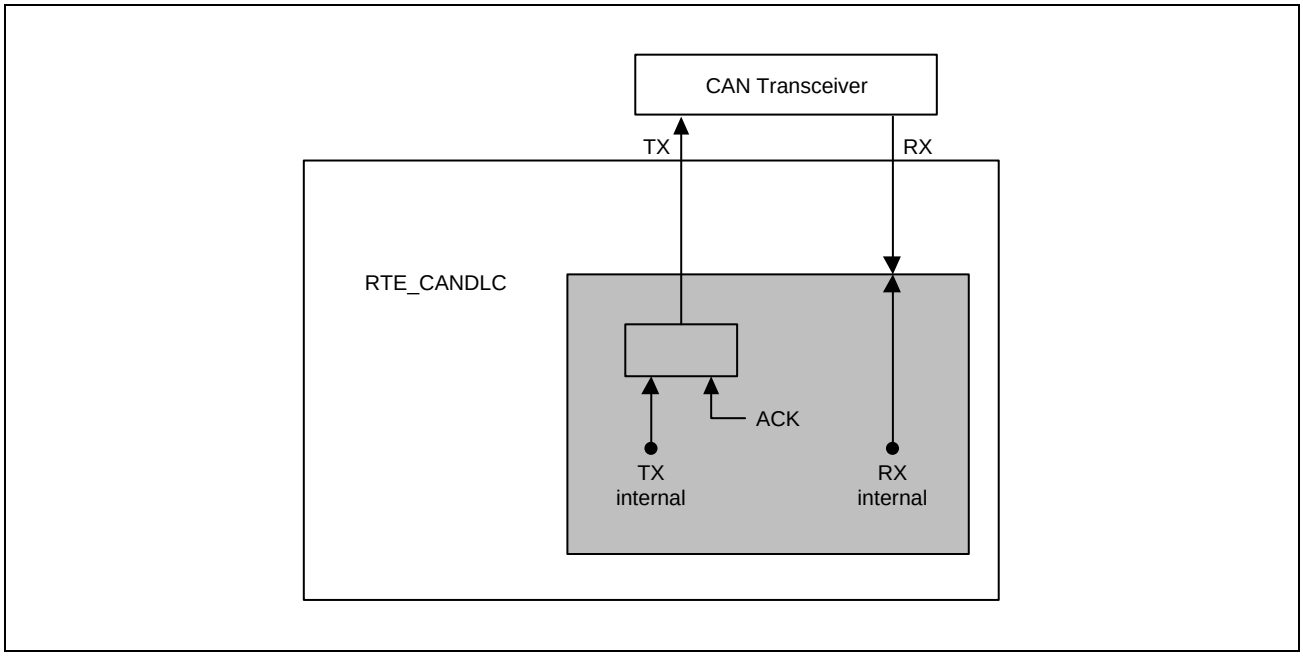

Figure 7.9-52 Self-Test Mode 0 (External Loop Back Mode)

7.9.9.1.4 Self-Test Mode 1 (Internal Loop Back Mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits.

The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.

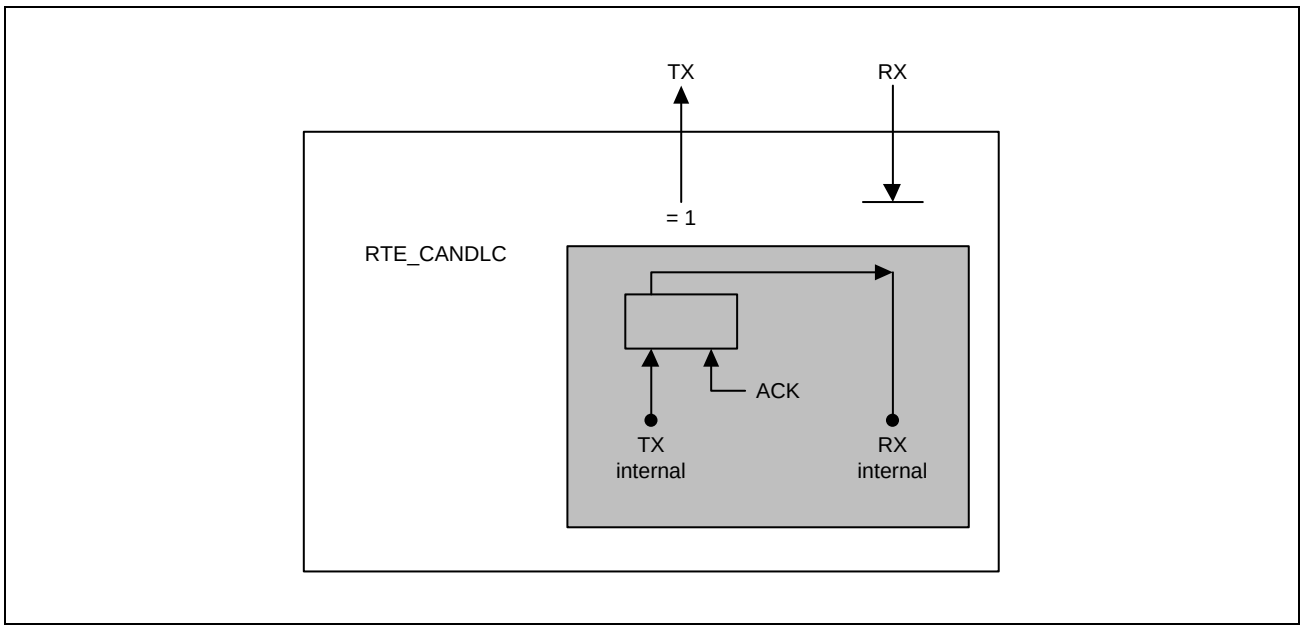

Figure 7.9-53 Self-Test Mode 1 (Internal Loop Back Mode)

7.9.9.1.5 Restricted Operation Mode

In Restricted operation mode, the CAN node is able to receive valid data and remote frames that generates the Acknowledge bit.

Active error and overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors.

The mode is specified as in ISO 11898-1. However, it is permitted to set any requested transmit.

7.9.9.2 Global Test Modes

The CAN-FD module can be configured into the following test modes:

- RAM test mode
- Internal CAN bus communication mode
- CRC error test

These test modes are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key, the related unlock key can be seen in the following table.

Test Mode	Unlock Key 1	Unlock Key 2
RAM test mode	H’7575	H’8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word accesses) is interrupted by any other write access to the SFR or if incorrect data is written to the Global Unlock Key Register, then the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding Test Mode Enable bit. If this is not followed, the unlock mechanism resets and the Test Mode Enable bit cannot be set. At this time, the unlock sequence must be restarted.

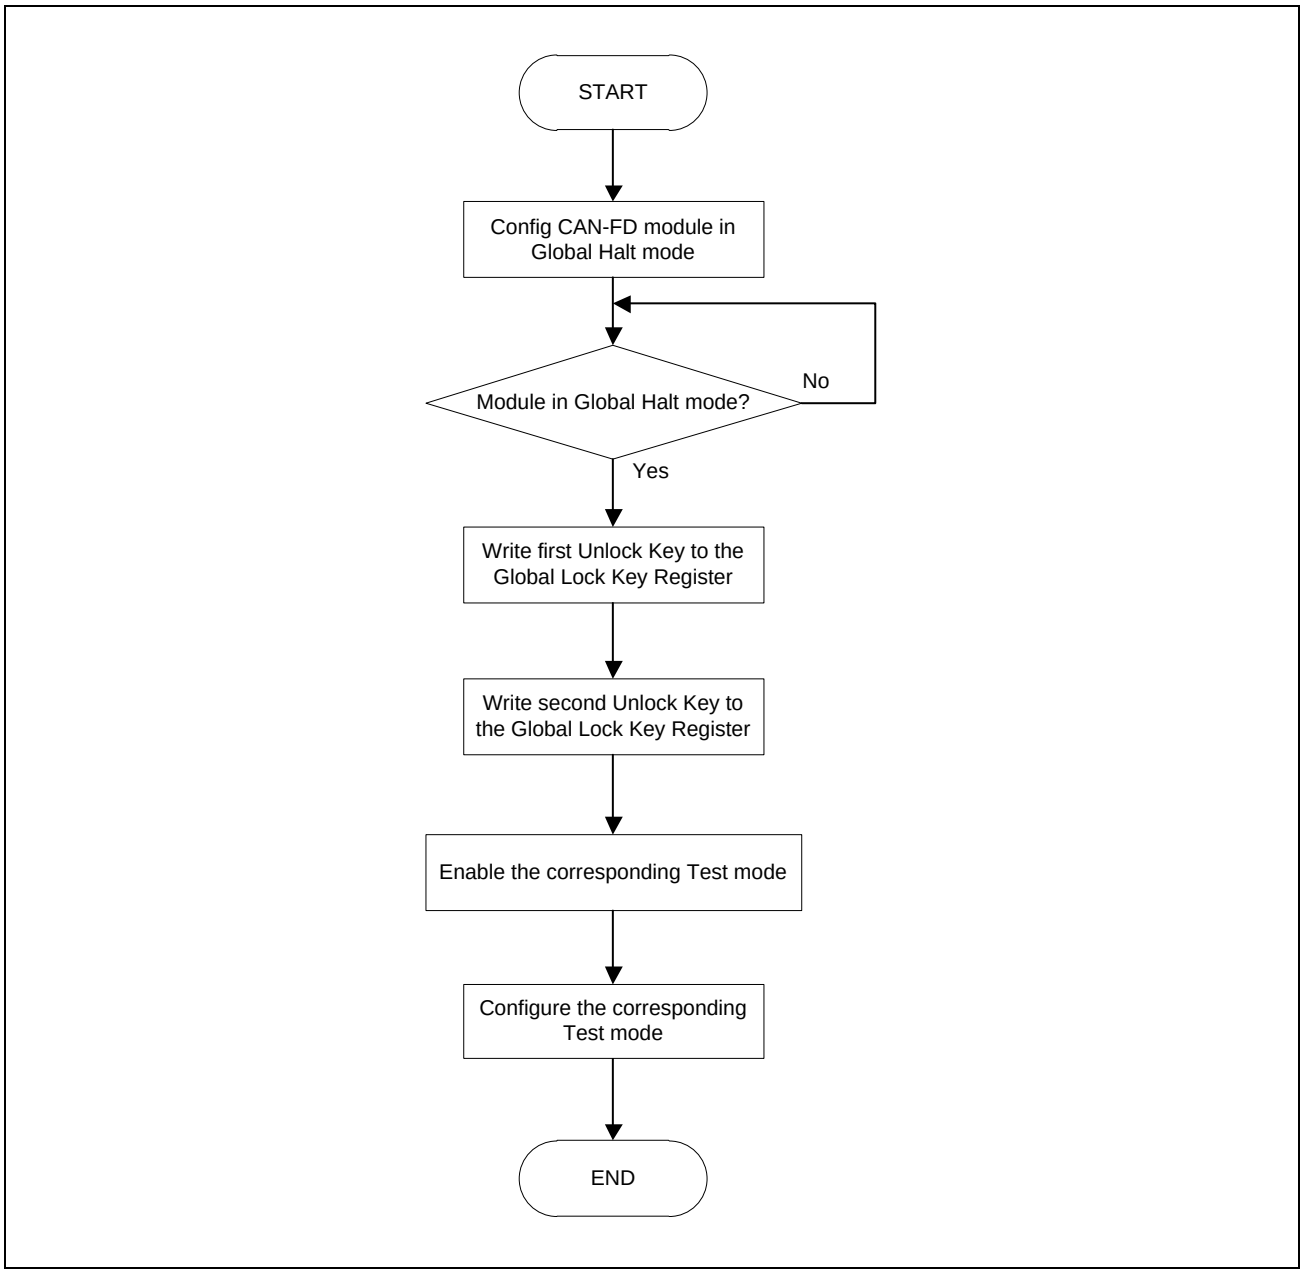

Figure 7.9-54 Unlock Software Protection Routine

7.9.9.2.1 RAM Test Mode

The CAN-FD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which the complete RAM area can be accessed.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes each. Which can be accessed with the CFDRPGACCn register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[9:0] bits in the Global Test Control Register. Data can then be read from or written into the RAM Test Page Access Registers.

Figure 7.9-55 shows the structure of the pages in the RAM when performing a RAM test mode.

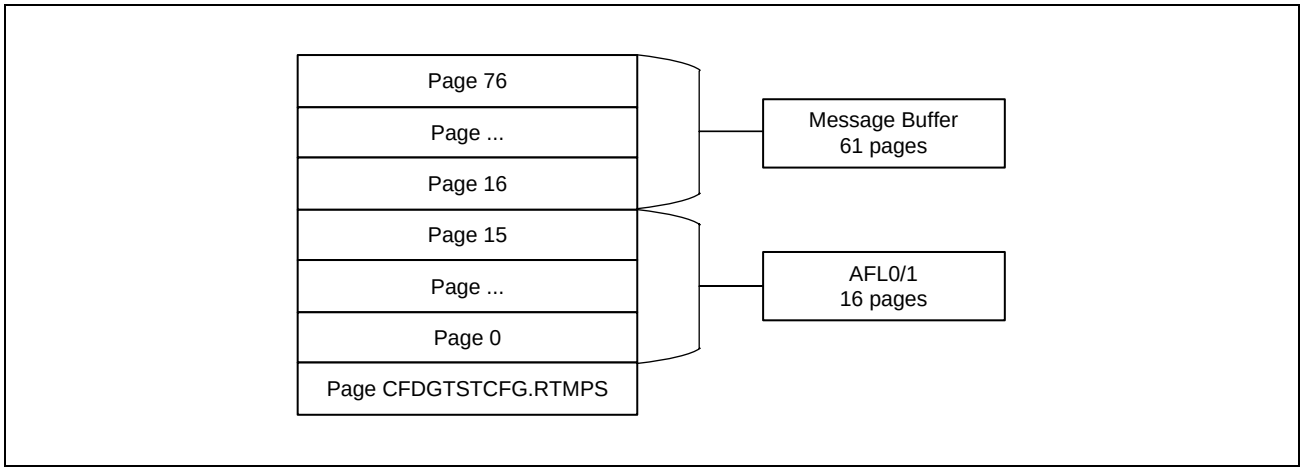

Figure 7.9-55 RAM Page Structure

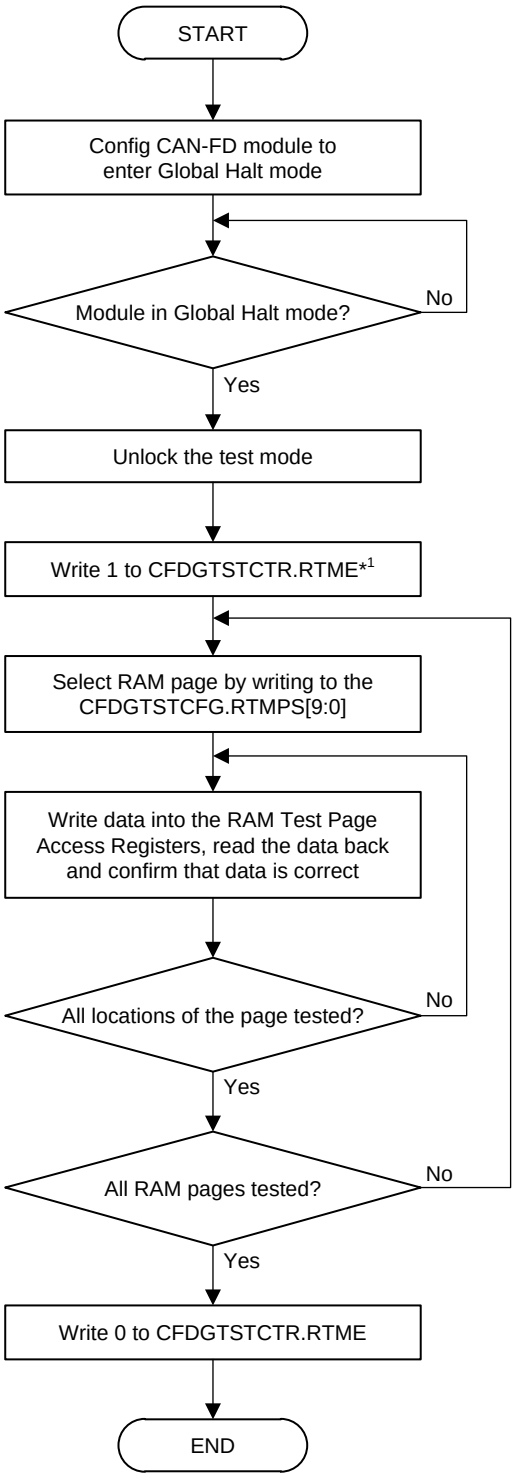
The total available RAM size for a 2-CAN channel version is 4096 bytes for the AFL RAM and 15488 bytes for the Message Buffer RAM.

AFL RAM0/1 can treat RAM test mode as one RAM.



The number of pages (pn) and CFDGTSTCFG.RTMPS[9:0] values for the AFL and MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes/number of bytes per page)

- AFL RAM:
  pn = ceil (4096/256) = 16 pages
  CFDGTSTCFG.RTMPS[9:0] = 0 to 15 (H’00F) inclusive
- MB RAM:
  pn = ceil (15488/256) = 61 pages
  CFDGTSTCFG.RTMPS[9:0] = 16 to 76 (H’04C) inclusive

Do not access more than 128 bytes of RAM on the last page (RTMPS[9:0] = H’04C).

Figure 7.9-56 shows the software flow for RAM test mode.

Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request of transmission
- Disable of all the FIFO and TXQ
- Clear of the receiving flag of a receiving buffer

Figure 7.9-56 Software Flow of RAM Test Mode

To exit this test mode, clear the CFDGTSTCTR.RTME bit. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CAN-FD module enters Global Reset mode from the test mode.

7.9.9.2.2 Internal CAN Bus Communication Mode

The CAN-FD module can be configured in Internal CAN bus communication test mode by setting the CFDGTSTCTR.ICBCTME bit in the Global Test Control Register. This is a special test mode, in which the CAN channels can be connected together internally to generate a CAN cluster within the CAN-FD module.

Only use the following sequence to enter Internal CAN bus communication test mode:

1. Configure all channels in Halt mode and check that all channels have entered Global Halt mode.
2. Write data into the Global Test Configuration Register to select the channels participating in the Internal CAN bus communication test.
3. Set the CFDGTSTCTR.ICBCTME bit of the Global Test Control Register.
4. Check that CFDGTSTCTR.ICBCTME bit is set in the Global Test Control Register.

In this mode, the TXD outputs of the channels participating (configured) in Internal CAN bus communication mode are connected together using AND gate. The output of the AND gate is connected to the RXD inputs of all participating channels to create a CAN cluster within the CAN-FD module. The channels are isolated from the external CAN bus while the CAN-FD module is in this test mode.

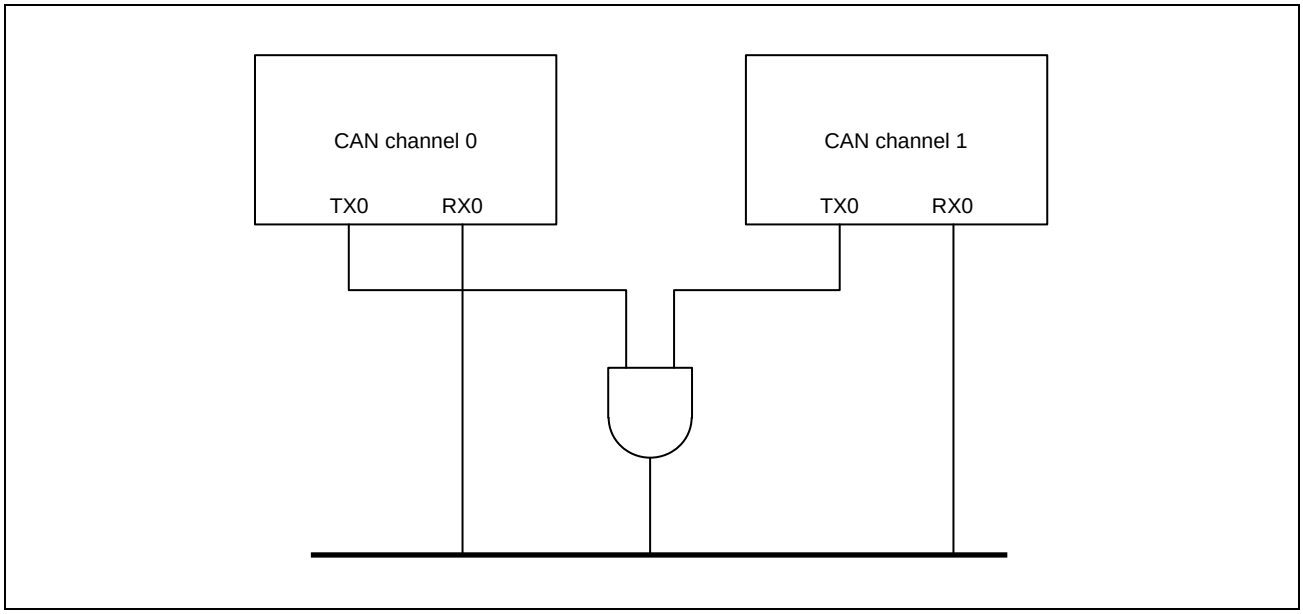


Figure 7.9-57 Internal CAN Bus Connections

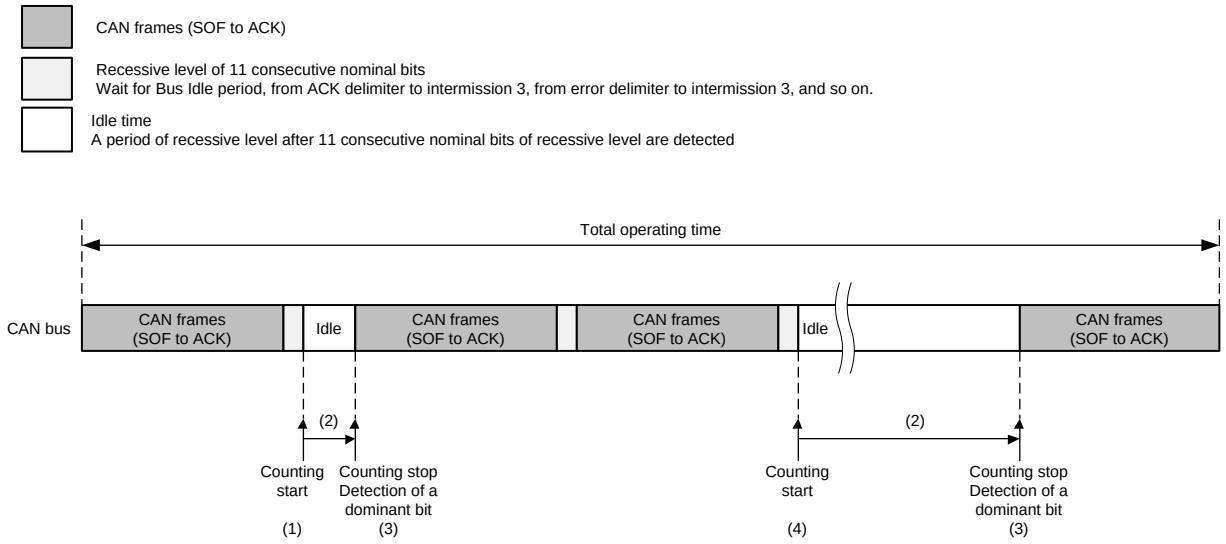
The AFL, Flat RX message buffers, FIFO buffers, Flat TX message buffers, and various registers can now be configured as normal to start communication between channels.

The channels not participating in Internal CAN bus should only be configured in Halt mode.

7.9.9.2.3 CRC Error Test

After the CAN-FD module has been configured in Internal CAN bus communication test mode, use the following sequence to perform CRC error testing. In the following sequence, channel x is the reference transmitter CAN-FD module and channel y is the receiver CAN-FD module where (x, y = [0, …, n] and x ≠ y):

1. Configure channel x node to transmit one reference message.
2. Set the CFDCyCTR.CRCT bit to 1, in order to invert the first bit of the incoming bit stream from channel x.
3. Set the CFDTMCx.TMTR.
4. Read either CFDCyERFL.CRCREG or CFDCyFDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from channel x.
5. Check that CFDCyERFL.CERR is 1.



As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC error test.

7.9.10 Bus Traffic Measurement

The idle time of the CAN bus can be measured using PCLKM or PCLKCAN. Bus traffic can be calculated based on the measurement results.

7.9.10.1 How to Count the CAN Bus Idle Time

Figure 7.9-58 shows the concept of measuring the idle time of the CAN bus.

(1) With the PCLKM clock, counting of the idle time starts after a recessive level input of 11 consecutive nominal bits are detected.
(2) The counting continues until a dominant level is detected on the CAN bus.
(3) The counting stops after a dominant level is detected on the CAN bus.
(4) After that, the counting restarts when 11 consecutive nominal bits are detected.

Figure 7.9-58 How to Measure Idle Time of the CAN Bus

7.9.10.2 Operations and Measurement Procedure

The following procedure is for measuring the idle time of the CAN bus.

1. The channel to be measured transits to operation mode.
2. Write 1 to CFDCnBLCT.BLCE bit to set the measuring counter to operating mode.
3. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register.
4. Detect a recessive level input of 11 consecutive nominal bits.
5. Start counting the bus idle time.
6. Detect a dominant level.
7. The counting stops.
8. Detect a recessive level input of 11 consecutive nominal bits.
9. The counting starts.

10. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the counter value to CFDCnBLSTS.
11. Read the value of CFDCnBLSTS.

To stop the measurement counter, write 0 to CFDCnBLCT.BLCE bit.

To initialize the counter, write 1 to CFDCnBLCT.BLCLD bit.

This measurement is enabled when the channel to be measured is in Operation mode.

When the relevant channels are in reset mode, the counter does not operate.

Also, accurate measurements are not available in test mode.

Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the value of the counter to CFDCnBLSTS.

The lower 3 bits of CFDCnBLSTS are fixed to 0.

Based on the values of the counter, software can calculate the CAN bus traffic according to the following formulas:

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{\text{Bus operating time}}{\text{Total operating time}} = \text{Bus usage ratio}$$

- Total idle time: a value read from CFDCnBLSTS × a clock cycle of PCLKM
- Total operating time: a setting interval of CFDCnBLCT.BLCLD bit

Example: Below is a calculation example under the following conditions:

- Conditions: nominal bit rate = 1 Mbps
- PCLKCAN clock = 40 MHz (= 25 ns)
- A setting interval of CFDCnBLCT.BLCLD bit = cycle of 1 ms
- A read value of CFDCnBLSTS register = H’4E20

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{(1000000\ \text{ns} - 20000 \times 25\ \text{ns})}{1000000\ \text{ns}} = 50\%$$

SECTION 7 LOW-SPEED INTERFACE

7.10 A/D Converter (ADC0)

7.10.1 Features

This LSI has a successive approximation A/D converter with 12-bit accuracy. Up to eight analog input channels can be selected.

■ Resolution

12 bits

■ Eight input channels

■ Input voltage range

0 V to 1.8 V

■ Minimum conversion time

1.0 µs per channel (when A/D conversion clock ADC0_ADCLK is 100 MHz)

■ Twelve data registers

The A/D conversion result is stored in a 32-bit data register corresponding to each channel.

■ Sample-and-hold function

■ Trigger mode

- Software trigger mode and hardware trigger mode are available.
- Software trigger mode to start A/D conversion by software
- Hardware trigger mode to start A/D conversion by an asynchronous trigger or synchronous trigger
  - Asynchronous trigger using an external pin (ADC_TRG) as the activation source
  - Synchronous trigger using the multi-function timer pulse unit 3 (MTU3a) or general-purpose
  - PWM timer (GPT) as the activation source

■ Operating mode

- Select mode and scan mode are available.
- Select mode to convert the specified single analog input channel
  - 1-buffer mode or 4-buffer mode can be specified for storing the A/D conversion result.
  - In 4-buffer mode, A/D conversion proceeds four times for the selected analog input and the A/D conversion results are stored in four registers.
- Scan mode to convert the analog inputs of arbitrarily selected channels in ascending order of channel number
  - 1-buffer mode can be specified for storing the A/D conversion result.

■ Conversion mode

- Single mode and repeat mode are available.
- Single mode to proceed A/D conversion only once
- Repeat mode to repeatedly proceed A/D conversion

■ A single interrupt source

- An A/D conversion end interrupt (INTAD) can be generated on completion of A/D conversion.
  - In the select mode with 1-buffer mode selected, an A/D conversion end interrupt is generated on completion of a single conversion.
  - In the select mode with 4-buffer mode selected, an A/D conversion end interrupt is generated on completion of four rounds of conversion.
  - In scan mode, an A/D conversion end interrupt is generated on completion of scanning of all the selected channels.

Table 7.10-1 shows the outline of the functions of the A/D converter.

Table 7.10-1 Functions of A/D Converter (1/2)

Note 1. To set ADC_TRG as the trigger for starting A/D conversion, set the general-purpose I/O function. For details, see **4.2 Pin Function Controller (PFC)**.

Table 7.10-2 lists the I/O pins used in the A/D converter.

Table 7.10-2 I/O Pins of A/D Converter

Pin Name	Input/Output	Functional Description
ADC_CH0 to ADC_CH7	Input	Analog input pins
ADC_TRG	Input	External trigger input pin for starting A/D conversion
VAA18_ADC	Input	A/D converter power supply pin
AVSS_ADC	Input	A/D converter ground pin

7.10.2 List of Registers

Table 7.10-3 shows the register list of this module.

The base address is as follows.

Base address: H'0_1005_8000 (Cortex-A55 Address Space)
Base address: H'4005_8000 (Cortex-M33 Address Space Secure)
Base address: H'5005_8000 (Cortex-M33 Address Space Non-Secure)

Table 7.10-3 List of Registers of A/D Converter

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
A/D converter mode register 0	ADM0	R/W	H'0000	H'0	32
A/D converter mode register 1	ADM1	R/W	H'0000	H'4	32
A/D converter mode register 2	ADM2	R/W	H'0000	H'8	32
A/D converter mode register 3	ADM3	R/W	H'0000	H'C	32
Reserved	—	R/W	H'0000	H'10	32

A/D conversion result register 4	ADCR4	R	H'0000	H'40	32
A/D conversion result register 5	ADCR5	R	H'0000	H'44	32
A/D conversion result register 6	ADCR6	R	H'0000	H'48	32
A/D conversion result register 7	ADCR7	R	H'0000	H'4C	32
Reserved	—	R	H'0000	H'50 – 6C	32
Renesas reserved area*1	—	R/W	Undefined	H'70 – 7F	32

Note: When writing successively to the same register, the notes in **7.10.5.2 Timing Restrictions**, need to be observed.

Note 1. Writing to a Renesas reserved area is prohibited.

7.10.3 Register Descriptions

7.10.3.1 A/D Converter Mode Register 0 (ADM0)

The ADM0 is a 32-bit register that controls A/D conversion and the power-saving mode of the A/D converter, and also executes a software reset. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRESB	—	—	—	—	—	—	—	—	—	—	—	—	PWDWNB	ADBSY	ADCE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
15	SRESB	0	R/W	Issues a software reset to the A/D converter. Circuits (e.g. registers) other than those of the A/D converter will not be reset. To release the A/D converter from the reset state, write 1 to this bit. 0: A/D converter is reset. 1: A/D converter is released from the reset state. The A/D converter enters the power-saving mode when this bit is used to execute a reset.
14 to 3	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
2	PWDWNB	0	R/W	Specifies the A/D converter to enter or exit the power-saving mode. 0: Power-saving mode 1: Normal mode
1	ADBSY	0	R	Indicates the status of the A/D converter. This bit is read-only. Writing to this bit is ignored. 0: A/D converter is stopped. 1: A/D converter is busy. For operation of the ADBSY bit, see **Figure 7.10-1**.
0	ADCE	0	R/W	Stops or enables the A/D converter. 0: A/D converter is stopped. 1: A/D converter is enabled. When 0 is written to the ADCE bit, the A/D converter stops operating. For operation of the ADCE bit at reading, see **Figure 7.10-1**.

Note: Notes regarding the ADM0 register are given on the next page.

NOTES

1. To enable A/D conversion operation using the ADCE bit, first switch from PWDWNB = 0 (power-saving mode) to PWDWNB = 1 (normal mode) and then wait for a period equal to or longer than the stabilization wait time before setting the ADCE bit to 1. The stabilization wait time is 1 µs.
2. To make a transition to the power-saving mode using the PWDWNB bit, first stop operation of the A/D converter (ADCE = 0) and then confirm that A/D conversion is completed (ADBSY = 0) before setting the PWDWNB bit to 0.

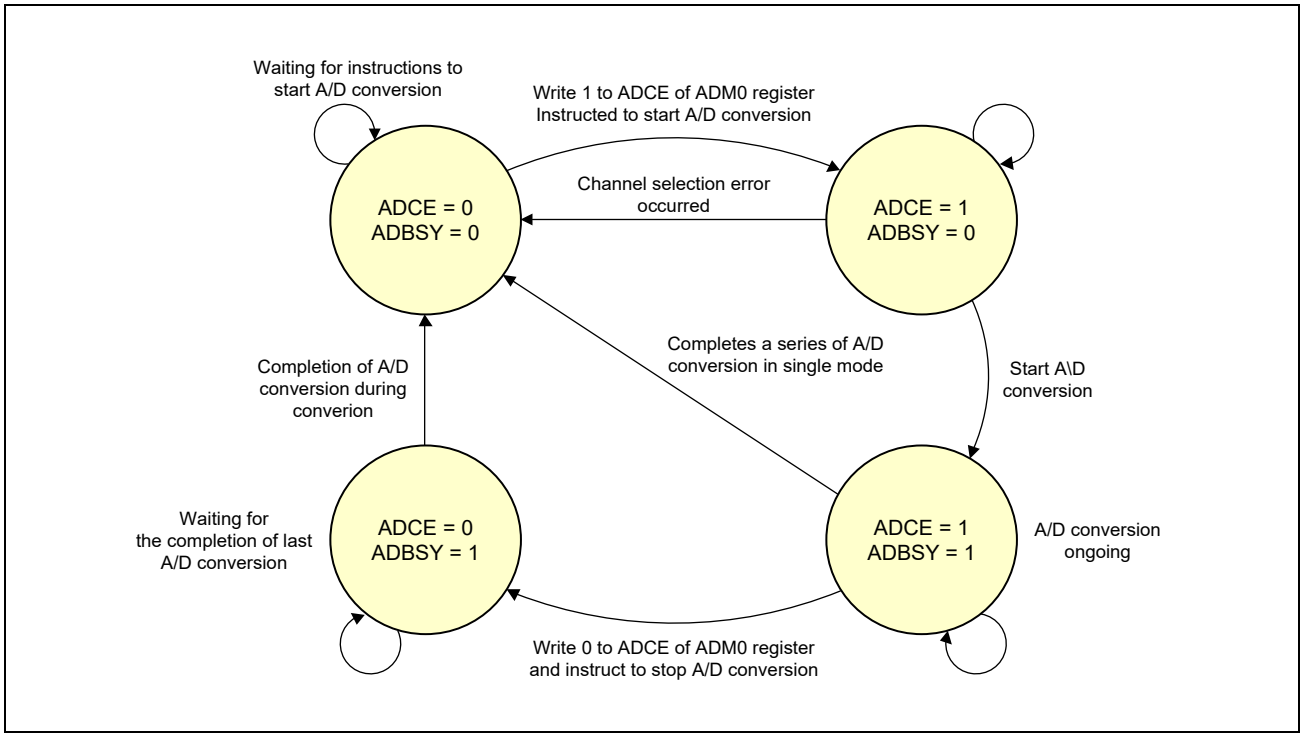

Figure 7.10-1 State Transitions of ADCE Bit and ADBSY Bit

7.10.3.2 A/D Converter Mode Register 1 (ADM1)

The ADM1 is a 32-bit register that controls A/D conversion and sets the mode for a hardware trigger. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TRGEN5	TRGEN4	TRGEN3	TRGEN2	TRGEN1	TRGEN0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	EGA1	EGA0	—	—	—	—	—	—	—	BS	RPS	MS	TRGIN	TRG
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
21 to 16	TRGEN[5:0]	All 0	R/W	These bits select the hardware trigger pin. For details, see **Table 7.10-4**.
15, 14	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
13, 12	EGA[1:0]	00	R/W	These bits select the valid edge of the trigger pin.

EGA1	EGA0	Valid Edge
0	0	Hardware trigger is invalid
0	1	Falling edge
1	0	Rising edge
1	1	Both edges

Note: When the EGA[1:0] bits are set to 00 in hardware trigger mode, a trigger from the trigger pin will be ignored. When a trigger pin of the MTU3a or GPT is used, the falling edge is always valid and the setting of the EGA[1:0] bits (01b, 10b, or 11b) will be ignored. When the external trigger pin (ADC_TRG) is used, the valid edge is set by the EGA[1:0] bits.
For details, see **Table 7.10-4**.

Bit	Bit Name	Initial Value	R/W	Description
11 to 5	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
4	BS	0	R/W	Selects the buffer mode (valid in select mode). 0: 1-buffer mode 1: 4-buffer mode 4-buffer mode is prohibited in scan mode.
3	RPS	0	R/W	Selects the repeat number. 0: Single 1: Repeat
2	MS	0	R/W	Selects the operating mode. 0: Scan mode 1: Select mode
1	TRGIN	0	R/W	Selects the trigger input mode. 0: Auto mode 1: Step mode

Bit	Bit Name	Initial Value	R/W	Description
0	TRG	0	R/W	Sets the trigger mode. 0: Software trigger mode*1 1: Hardware trigger mode For details, see **Table 7.10-4**.

Note 1. Set the EGA[1:0] bits to 00 when using software trigger mode.

Table 7.10-4 TRGEN[5:0] Bits and Trigger Source (1/2)

Trigger Mode	Module	Source	Description	TRG Bit	TRGEN[5:0] Bits						EGA[1:0] Bits

		ADTRGA2 or ADTRGB2	Compare match with GPT2.GTADTRA or GPT2.GTADTRB		0	1	1	0	1	1		
		ADTRGA3 or ADTRGB3	Compare match with GPT3.GTADTRA or GPT3.GTADTRB		0	1	1	1	0	0		

7.10.3.3 A/D Converter Mode Register 2 (ADM2)

The ADM2 is a 32-bit register that specifies the analog input channels to be used in A/D conversion. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CHSEL 7	CHSEL 6	CHSEL 5	CHSEL 4	CHSEL 3	CHSEL 2	CHSEL 1	CHSEL 0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
8	—	0	R/W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
7 to 0	CHSEL[7:0]	All 0	R/W	These bits select the A/D analog input channel n (n = 0 to 7). 0: Analog input channel n is not subjected to conversion. 1: Analog input channel n is subjected to conversion.

Note 1. Select only one channel in select mode.

Note 2. If more than one channel is selected in select mode, a channel select error occurs.

7.10.3.4 A/D Converter Mode Register 3 (ADM3)

The ADM3 is a 32-bit register that sets the sampling period of the A/D converter. Be sure to set this register before starting the A/D converter. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADIL7	ADIL6	ADIL5	ADIL4	ADIL3	ADIL2	ADIL1	ADIL0	ADCMP7	ADCMP6	ADCMP5	ADCMP4	ADCMP3	ADCMP2	ADCMP1	ADCMP0

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ADIL[7:0]	All 0	R/W	These bits should be set to H'00.
23 to 16	ADCMP[7:0]	All 0	R/W	These bits should be set to H'1D.
15 to 8	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
7 to 0	ADSMP[7:0]	All 0	R/W	These bits set the sampling period (unit: ADIVCLK cycle). Set above H'47 if select ch.0-7. T stands for the cycle of ADIVCLK (100 MHz).

Note: The ADIL[7:0] bits should be set to H'00 and the ADCMP[7:0] bits should be set to H'1D. If they are set to other values, normal operation cannot be guaranteed.

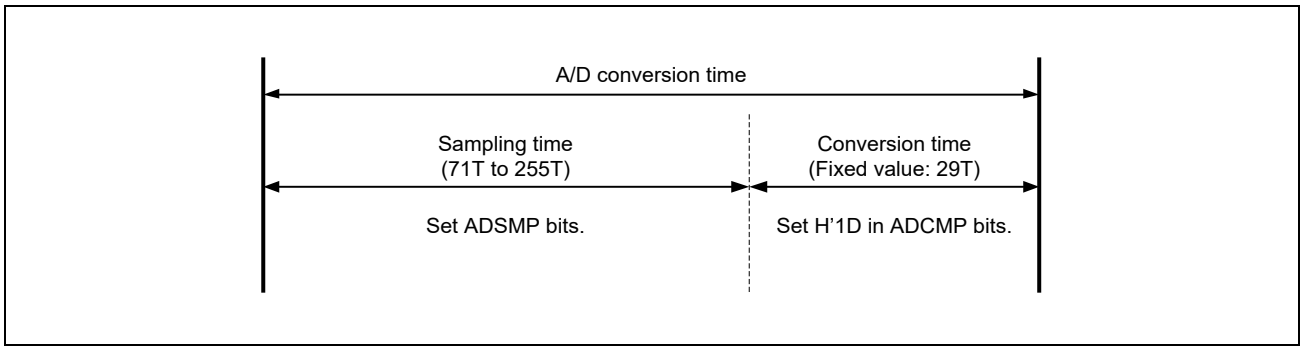

Figure 7.10-2 Correspondence between ADM3 Register and A/D Conversion Time

7.10.3.5 A/D Converter Interrupt Control Register (ADINT)

The ADINT is a 32-bit register that controls interrupts. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INTS	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CSEEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	INTEN 7	INTEN 6	INTEN 5	INTEN 4	INTEN 3	INTEN 2	INTEN 1	INTEN 0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	INTS	0	R/W	Selects the attribute of the interrupt (INTAD) signal. 0: Pulse signal 1: Reserved This bit should be set to 0.
30 to 17	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
16	CSEEN	0	R/W	Enables or disables the A/D conversion channel select error interrupt. 0: Interrupt output is disabled. 1: Interrupt output is enabled.
15 to 12	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
11 to 8	—	All 0	R/W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
7 to 0	INTEN[7:0]	All 0	R/W	These bits enable or disable the conversion end interrupt of channel n (n = 0 to 7). 0: Interrupt output is disabled. 1: Interrupt output is enabled.

The interrupt signal is specified as a pulse and that pulse is output at any of the following timing:

1. An A/D conversion request is detected while the ADM2 register has caused an A/D conversion channel select error
2. Completion of conversion on the channel for which interrupt output has been enabled in the ADINT register
3. An A/D conversion request is detected while 4-buffer mode has been specified in scan mode

7.10.3.6 A/D Converter Status Register (ADSTS)

The ADSTS is a 32-bit register that controls the state of the A/D converter. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRGS	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CSEST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	INTST7	INTST6	INTST5	INTST4	INTST3	INTST2	INTST1	INTST0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	TRGS	0	R/W	• When reading 0: Nothing detected 1: A trigger was detected during the A/D conversion time in **Figure 7.10-2**. • When writing 0: No effect 1: The state is cleared.
30 to 17	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
16	CSEST	0	R/W	Indicates the status of the A/D conversion channel select error interrupt. It is the status of the interrupt for an error that occurs when A/D conversion is started with no channel being specified in the CHSEL[7:0] bits in the ADM2 register as a channel on which A/D conversion proceeds. • When reading 0: No A/D conversion channel select error occurred. 1: An A/D conversion channel select error occurred. • When writing 0: No effect 1: The status is cleared.
15 to 9	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
8	—	0	R/W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
7 to 0	INTST[7:0]	All 0	R/W	Indicates the state of the conversion end interrupt of channel n (n = 0 to 7). • When reading 0: Conversion has not finished. 1: Conversion has finished. • When writing 0: No effect 1: The state is cleared.*1

Note 1. When an interrupt source is generated simultaneously with clearing of the interrupt source, clearing is ignored and the respective bit remains set to 1.

7.10.3.7 A/D Converter External Trigger Pin Filter Control Register (ADFIL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	FILNUM		—	—	—	FILONOFF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
5, 4	FILNUM[1:0]	00	R/W	These bits select the number of stages of the AD external trigger pin filter. The signal to be filtered is ADC0_ADCLK(P20ϕ) (100 MHz). 00: 10.0 ns (100 MHz) × 4 stages 01: 10.0 ns (100 MHz) × 8 stages 10: 10.0 ns (100 MHz) × 12 stages 11: 10.0 ns (100 MHz) × 16 stages
3 to 1	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
0	FILONOFF	0	R/W	Enables or disables the AD external trigger pin filter 0: Filter is disabled. 1: Filter is enabled.

7.10.3.8 A/D Conversion Result Registers 7 to 0 (ADCR7 to ADCR0)

The ADCR7 to ADCR0 are 32-bit registers that hold the A/D conversion results. The A/D converter has eight 32-bit registers. These registers are read from in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	AD11	AD10	AD9	AD8	AD7	AD6	AD5	AD4	AD3	AD2	AD1	AD0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
11 to 0	AD[11:0]	All 0	R	These bits hold the A/D conversion results.

Analog Input Channel	ADCR7 to ADCR0 Registers	
	Select Mode with 1-Buffer Mode Selected or Scan Mode	Select Mode with 4-Buffer Mode Selected
0	ADCR0	ADCR3 to ADCR0
1	ADCR1	
2	ADCR2	
3	ADCR3	
4	ADCR4	ADCR7 to ADCR4
5	ADCR5	
6	ADCR6	
7	ADCR7	

The following formula indicates the relationship between the analog input voltage that is input to analog input pins (ADC_CH7 to ADC_CH0) and the A/D conversion results (A/D conversion result registers (ADCR7 to ADCR0)).

$$\mathrm{ADCR} = \mathrm{INT}\left[\frac{\mathrm{Vin}}{\mathrm{ADC_AVREF}} \times 2^{\mathrm{d}} + 0.5\right]$$

or

$$(\mathrm{ADCR} - 0.5) \times \frac{\mathrm{ADC_AVREF}}{2^{\mathrm{d}}} \leq \mathrm{Vin} < (\mathrm{ADCR} + 0.5) \times \frac{\mathrm{ADC_AVREF}}{2^{\mathrm{d}}}$$

INT[ ]:	Function that returns the integer portion of the value enclosed in [ ]
Vin:	Analog input voltage
ADC_AVREF:	Voltage of power supply pin (VAA18_ADC) for the analog unit
ADCR:	Value of A/D conversion result registers (ADCR7 to ADCR0)
d:	Resolution of A/D converter (d = 12 in this LSI)

The relationship between the analog input voltage and A/D conversion result is shown in the figure below.

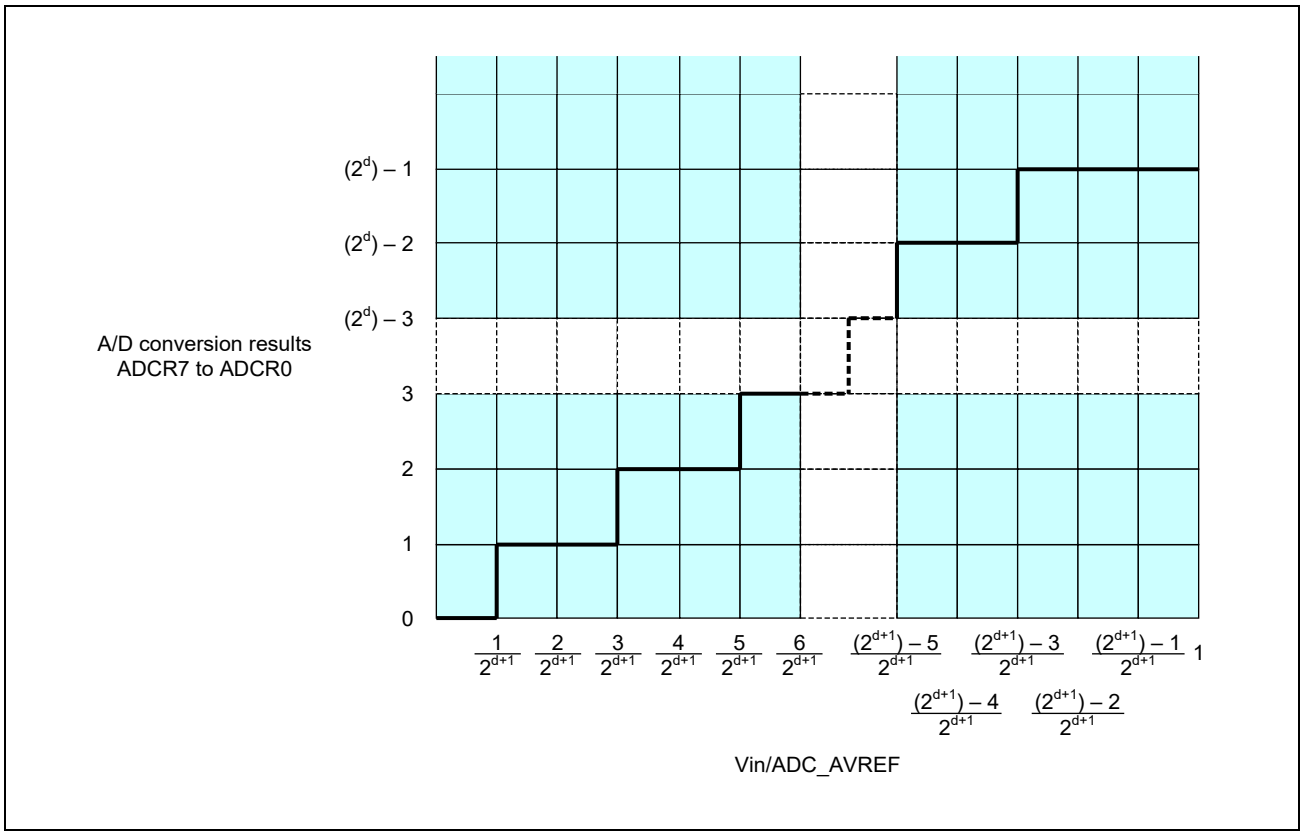

Figure 7.10-3 Relationship between Analog Input Voltage and A/D Conversion Result

7.10.4 Operation

7.10.4.1 Types of A/D Conversion Modes

The following A/D conversion modes can be specified. A/D conversion modes can be set in the ADM1 register.

Table 7.10-5 A/D Conversion Modes

Trigger Mode	Trigger Input Mode	Operating Mode	Conversion Count	Buffer Count	Operation	Example of A/D Conversion for Reference
Software trigger	—	Select	Single	1 buffer	Selected 1 channel × 1-time conversion	**7.10.4.4.1 Example of A/D Conversion in Select Mode with Single Mode Selected**
				4 buffers	Selected 1 channel × 4-time conversion	—
			Repeat	1 buffer	(Selected 1 channel × 1-time conversion) × repeated	**7.10.4.4.2 Example of A/D Conversion in Select Mode with Repeat Mode Selected**
				4 buffers	(Selected 1 channel × 4-time conversion) × repeated	**7.10.4.4.3 Example of A/D Conversion in 4-Buffer Mode**
		Scan	Single	1 buffer	All selected channels × 1-time conversion	**7.10.4.4.4 Example of A/D Conversion in Scan Mode with Single Mode Selected**
				4 buffers	(Setting prohibited)	
			Repeat	1 buffer	(All selected channels × 1-time conversion) × repeated	**7.10.4.4.5 Example of A/D Conversion in Scan Mode with Repeat Mode Selected**
				4 buffers	(Setting prohibited)	
Hardware trigger	Auto (started with a single trigger input)	Select	Single	1 buffer	Selected 1 channel × 1-time conversion	—
				4 buffers	Selected 1 channel × 4-time conversion	—
			Repeat	1 buffer	(Selected 1 channel × 1-time conversion) × repeated	—
				4 buffers	(Selected 1 channel × 4-time conversion) × repeated	—
		Scan	Single	1 buffer	All selected channels × 1-time conversion	**7.10.4.4.6 Example of A/D Conversion in Auto Mode**
				4 buffers	(Setting prohibited)	
			Repeat	1 buffer	(All selected channels × 1-time conversion) × repeated	—
				4 buffers	(Setting prohibited)	
	Step (conversion proceeds at every trigger input)	Select	Single	1 buffer	Selected 1 channel × 1-time conversion	—
				4 buffers	Selected 1 channel × 4-time conversion	—
			Repeat	1 buffer	(Selected 1 channel × 1-time conversion) × repeated	—
				4 buffers	(Selected 1 channel × 4-time conversion) × repeated	—
		Scan	Single	1 buffer	All selected channels × 1-time conversion	**7.10.4.4.7 Example of A/D Conversion in Step Mode**
				4 buffers	(Setting prohibited)	
			Repeat	1 buffer	(All selected channels × 1-time conversion) × repeated	—
				4 buffers	(Setting prohibited)	

Note: When 4-buffer mode is set in scan mode, a channel select error occurs.

7.10.4.1.1 Trigger Modes

Software trigger mode and hardware trigger mode are the two types of trigger modes in which the trigger is the timing for starting the A/D conversion processing. These trigger modes can be set by the TRG bit in the ADM1 register.

(1) Software Trigger Mode

In software trigger mode, A/D conversion is started for the input of the ADC_CH7 to ADC_CH0 pins by setting the ADCE bit in the ADM0 register to 1. The ADBSY bit in the ADM0 register is 1 while the converter is operating.

The hardware trigger is invalid when software trigger mode is set. Set the EGA[1:0] bits in the ADM1 register to 00 when using software trigger mode. When a hardware trigger is input, A/D conversion is not started and the TRGS bit in the ADSTS register retains 0.

(2) Hardware Trigger Mode

There are two triggers in hardware trigger mode: asynchronous trigger using the ADC_TRG pin as the activation source and synchronous trigger using the multi-function timer pulse unit 3 (MTU3a) or general purpose PWM timer (GPT) as the activation source.

The valid edge of the selected hardware trigger can be set by the EGA[1:0] bits in the ADM1 register.

When the ADCE bit in the ADM0 register is set to 1, the A/D converter enters a standby state for a hardware trigger after 250 ns as passed and will start conversion operation upon detection of a valid edge. The ADBSY bit in the ADM0 register remains to be 1 during conversion operation.

The status of the TRGS bit in the ADSTS register can be cleared by writing 1 to the TRGS bit.

In hardware trigger mode, the available trigger input modes are auto mode and step mode. The trigger input mode can be set in the TRGIN bit in the ADM1 register.

(a) Auto mode

When a hardware trigger is input once, A/D conversion is repeated automatically for the conversion count in accordance with the specified conversion settings.

(b) Step mode

A/D conversion proceeds every time a hardware trigger is input. For example, if select mode, single mode, and 4-buffer mode are selected, conversion finishes when a hardware trigger has been input four times.

7.10.4.1.2 Operating mode

There are two operating modes: select mode and scan mode. The select mode has 1-buffer mode and 4-buffer mode as sub-modes. These modes can be set in the BS and MS bits in the ADM1 register.

(1) Select Mode

A/D conversion proceeds for the analog input specified in the CHSEL[7:0] bits in the ADM2 register. The A/D conversion results are stored in the ADCR7 to ADCR0 registers corresponding to the ADC_CH7 to ADC_CH0 pins. In select mode, 1-buffer mode or 4-buffer mode can be used as the method for storing the A/D conversion results.

Only one channel is selectable for A/D conversion in select mode.

If more than one analog input channel is selected in select mode, a channel select error occurs.

(a) 1-buffer mode

A/D conversion proceeds only once for the analog input specified in the ADM2 register and the conversion result is stored in the ADCR7 to ADCR0 registers corresponding to the ADC_CH7 to ADC_CH0 pins.

The ADC_CH7 to ADC_CH0 pins correspond with the ADCR7 to ADCR0 registers on a one-on-one basis. If interrupt output is enabled in the INTEN[7:0] bits in the ADINT register for the channels on which A/D conversion proceeds, an A/D conversion end interrupt (INTAD) occurs on completion of a single conversion.

This mode is usable for reading the result of a single conversion.

(b) 4-buffer mode

A/D conversion proceeds four times for the analog input specified in the ADM2 register and the conversion results are stored in the ADCR7 to ADCR4 or ADCR3 to ADCR0 registers. See **Table 7.10-7** for the correspondence between the analog inputs and A/D conversion result registers.

If interrupt output is enabled in the INTEN[7:0] bits in the ADINT register for the channels corresponding to the ADC7 to ADCR0 registers where the A/D conversion result is to be stored in 1-buffer mode, an A/D conversion end interrupt (INTAD) occurs when the A/D conversion result is stored in the ADCR7 to ADCR0 registers. For example, to generate an interrupt on the fourth A/D conversion when ADC_CH0 is selected, set the INTEN[3] bit in the ADINT register to 1.

See **Table 7.10-6** for the relationship between the setting of the ADINT register and the output of an A/D conversion end interrupt in 4-buffer mode.

This mode is usable for obtaining the average of the A/D conversion results.

Table 7.10-6 ADINT Setting and Generation of A/D Conversion End Interrupt in 4-Buffer Mode

Channel for A/D Conversion	ADINT Register Setting		A/D Conversion End Interrupt
1 channel is selected from ADC_CH3 to ADC_CH0	INTEN[0]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 0.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 0.
	INTEN[1]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 1.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 1.
	INTEN[2]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 2.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 2.
	INTEN[3]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 3.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 3.
1 channel is selected from ADC_CH7 to ADC_CH4	INTEN[4]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 4.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 4.
	INTEN[5]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 5.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 5.
	INTEN[6]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 6.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 6.
	INTEN[7]	1: Interrupt is enabled	An interrupt is output on completion of A/D conversion on channel 7.
		0: Interrupt is disabled	No interrupt is output on completion of A/D conversion on channel 7.

Table 7.10-7 Correspondence between Analog Inputs and A/D Conversion Result Registers in 4-Buffer Mode

Analog Input	A/D Conversion Result Register
1 channel is selected from ADC_CH3 to ADC_CH0	ADCR0 (first time)
	ADCR1 (second time)
	ADCR2 (third time)
	ADCR3 (fourth time)
1 channel is selected from ADC_CH7 to ADC_CH4	ADCR4 (first time)
	ADCR5 (second time)
	ADCR6 (third time)
	ADCR7 (fourth time)

(2) Scan Mode

A/D conversion proceeds for the analog inputs of channels selected in the ADM2 register, in ascending order of channel number. The A/D conversion results are stored in the ADCR7 to ADCR0 registers corresponding to the analog inputs. If interrupt output is enabled in the INTEN[7:0] bits in the ADINT register for the channels on which A/D conversion proceeds, an A/D conversion end interrupt (INTAD) occurs when A/D conversion on the relevant channel finishes.

This mode is usable for constantly monitoring multiple analog signals.

In scan mode, only 1-buffer mode can be specified. If 4-buffer mode is specified in scan mode, a channel select error occurs.

7.10.4.1.3 Conversion Mode

Single mode and repeat mode are available. Use the RPS bit in the ADM1 register to set the conversion mode.

(1) Single Mode

When A/D conversion for the number of times of the conversion count finishes, the ADCE bit in the ADM0 register is automatically cleared to 0. For the number of times of conversion, see the description of operation in **Table 7.10-5**.

(2) Repeat Mode

When 1 is written to the ADCE bit in the ADM0 register, A/D conversion repeatedly proceeds in the A/D conversion mode specified in the ADM1 register. Immediately after 0 is written to the ADCE bit in the ADM0 register, A/D conversion is finished.

For the number of times of conversion, see the description of operation in **Table 7.10-5**.

7.10.4.2 Interrupt Functions

Table 7.10-8 lists the interrupt sources of the A/D converter and the conditions for generating them and the methods for confirming and clearing the interrupt sources.

The INTS bit in the ADINT register is used to set the operation for outputting an interrupt request of the INTAD.

Table 7.10-8 List of Interrupt Functions

Interrupt Source	Condition for Generation	Enabling Interrupt ADINT Register	Confirming Interrupt Source ADSTS Register*1	Method for Clearing Interrupt Source ADSTS Register
A/D conversion end	When A/D conversion on the specified channel is completed	INTEN[7:0]*2	INTST[7:0]	Write 1 to the bits that were 1 when the register was read.
A/D conversion channel select error	• When all of the CHSEL[7:0] bits in the ADM2 register were 0 at the start of A/D conversion*3 • When multiple analog input channels are selected in select mode*3 • When 4-buffer mode is specified in scan mode*3	CSEEN	CSEST	Write 1 to the CSEST bit.

Note 1. If an interrupt source is generated regardless of the settings of the INTEN[7:0] and CSEEN bits in the ADINT register, the bit corresponding to the interrupt source is set to 1 in the ADSTS register.

Note 2. The A/D conversion end interrupt can be enabled or disabled individually for each channel.

Note 3. When an A/D conversion channel select error occurs, the ADCE bit in the ADM0 register becomes 0 and A/D conversion operation is stopped.

7.10.4.3 Procedures of A/D Conversion

Follow the procedures given below for A/D conversion.

(1) Procedure for starting A/D conversion

After the A/D converter is released from the software reset state, use the ADM3 to ADM0 registers*1 to select the analog input channels on which A/D conversion proceeds and specify the trigger mode (software trigger or hardware trigger), operating mode (select or scan), etc.

Setting the ADCE bit in the ADM0 register to 1 will start A/D conversion in software trigger mode, whereas the A/D converter will enter a standby state for a trigger*2 in hardware trigger mode.

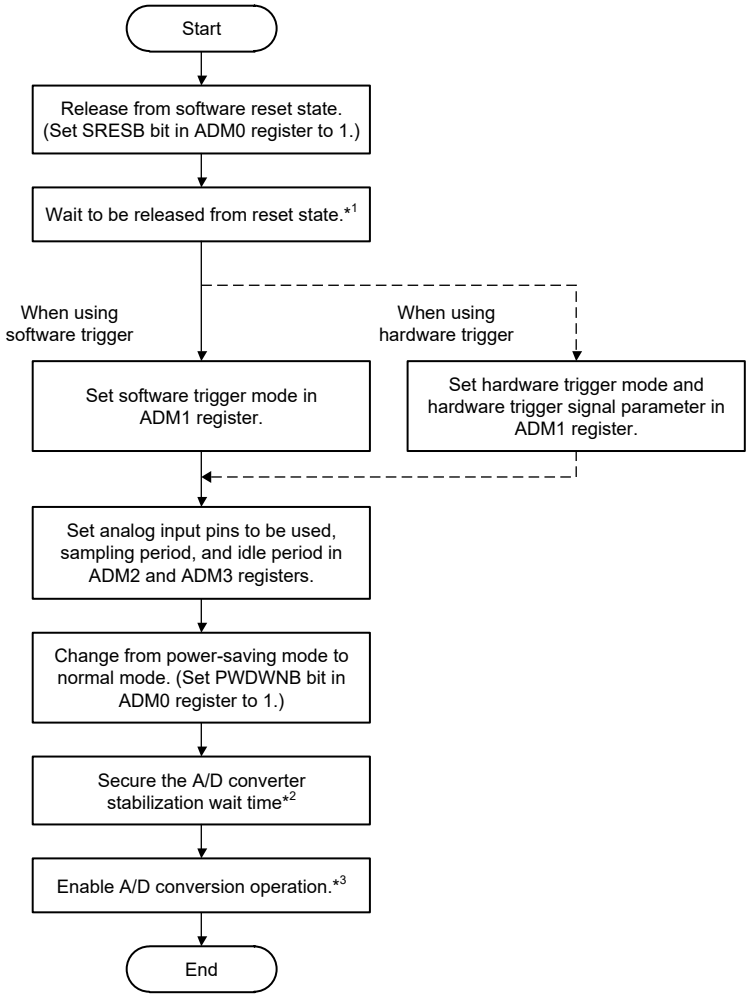
Note 1. Set the ADM3 to ADM0 registers when conversion by the A/D converter is stopped (ADBSY bit in the ADM0 register is 0).

Note 2. If the ADCE bit in the ADM0 register is set to 1 in hardware trigger mode, a transition is made to a trigger standby state. A/D conversion is started (ADBSY bit in ADM0 register is 1) by a hardware trigger signal and the A/D converter returns to the trigger standby state (ADBSY bit in ADM0 register is 0) on completion of A/D conversion.

A/D conversion operation is enabled.

After the A/D converter makes a transition from power-saving mode to normal mode, a period as long as the stabilization wait time is required. The stabilization wait time is 1 μs.

After the stabilization wait time has passed, set the ADCE bit in the ADM0 register to 1.



In software trigger mode, setting the ADCE bit to 1 starts A/D conversion.

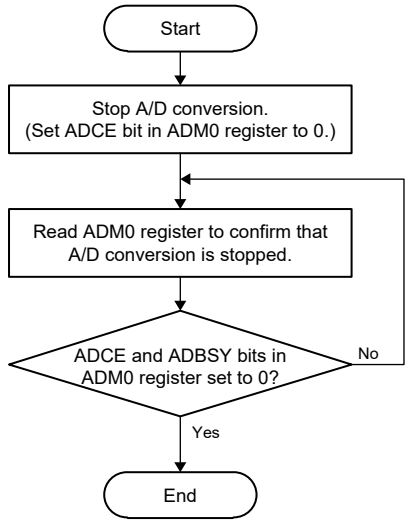
In hardware trigger mode, setting the ADCE bit to 1 makes the A/D converter enter a standby state for a hardware trigger after 250 ns has passed, and conversion operation is started upon detection of a valid edge.

(2) When A/D conversion is finished, the A/D conversion results are stored in the ADCR7 to ADCR0 registers. Also, an A/D conversion end interrupt (INTAD) occurs on completion of A/D conversion on the channels specified in the INTEN[7:0] bits in the ADINT register.

7.10.4.3.1 Procedure for Starting A/D Conversion

Use the following flowchart to start A/D conversion.

Note 1. The time waiting for the A/D converter to be released from the reset state is 2 × ADC0_ADCLK(P20ϕ).



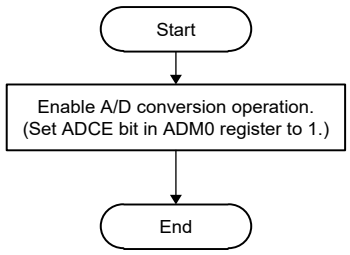
Note 2. The stabilization wait time is 1 μs.

Note 3. In software trigger mode, A/D conversion is started by setting the ADCE bit to 1.
In hardware trigger mode, after the ADCE bit is set to 1, A/D conversion is started upon detection of a valid edge.

Figure 7.10-4 Procedure for Starting A/D Conversion

7.10.4.3.2 Procedure for Stopping A/D Conversion

Use the following flowchart to stop A/D conversion.



Note: For details on the operation for stopping conversion by writing 0 to the ADCE bit, see **Table 7.10-10**.

Figure 7.10-5 Procedure for Stopping A/D Conversion

7.10.4.3.3 Procedure for Stopping and Restarting A/D Conversion

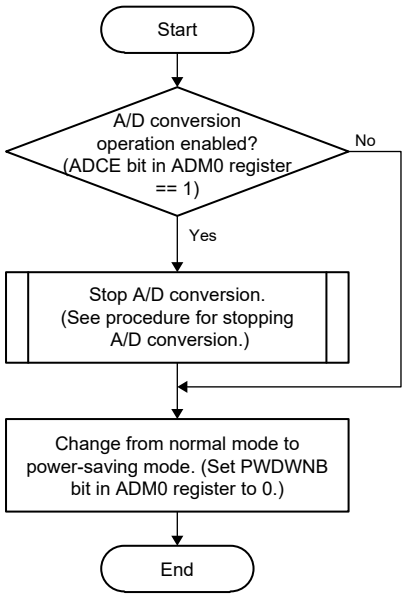
Use the following flowchart to restart A/D conversion after it has been stopped with the procedure for stopping A/D conversion.

Note: For details on the operation for restarting conversion, see **Table 7.10-10**.

Figure 7.10-6 Procedure for Stopping and Restarting A/D Conversion

7.10.4.3.4 Procedure for Entering Power-saving Mode

Use the following flowchart to make a transition to the power-saving mode.



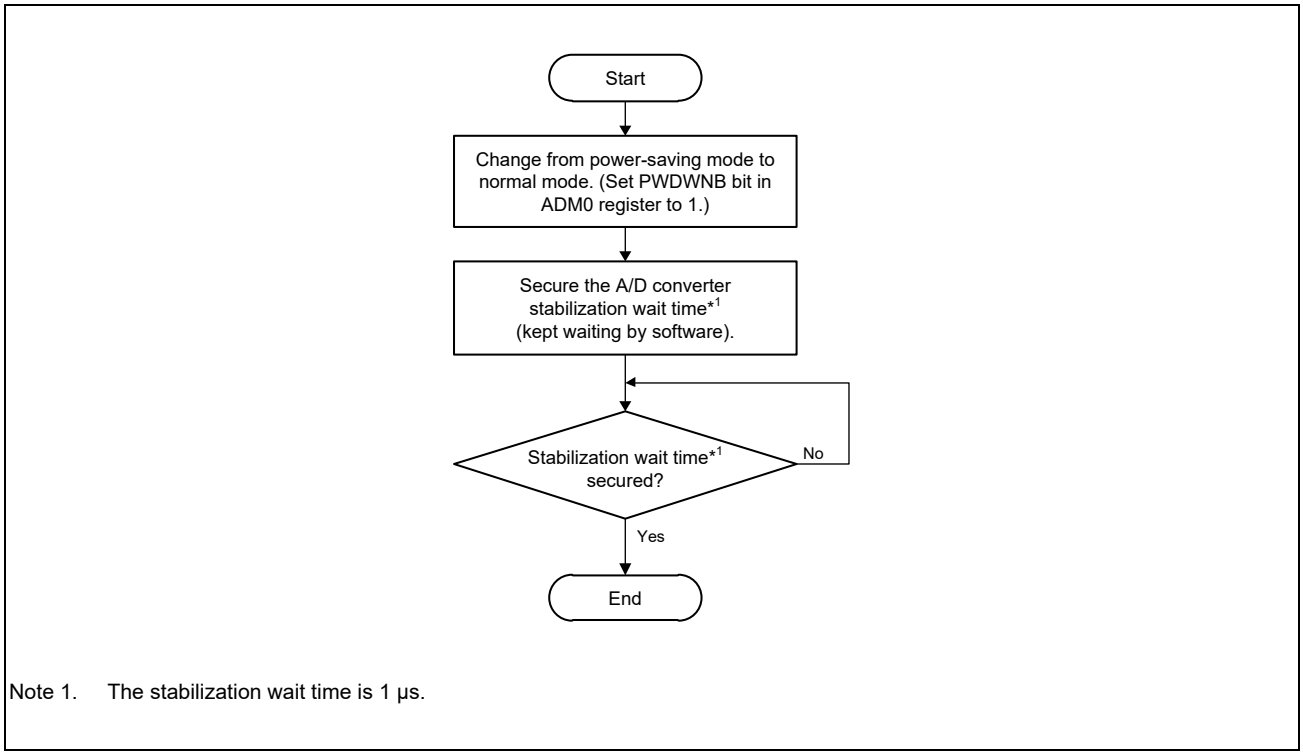


Figure 7.10-7 Procedure for Entering Power-Saving Mode

7.10.4.3.5 Procedure for Releasing from Power-saving Mode

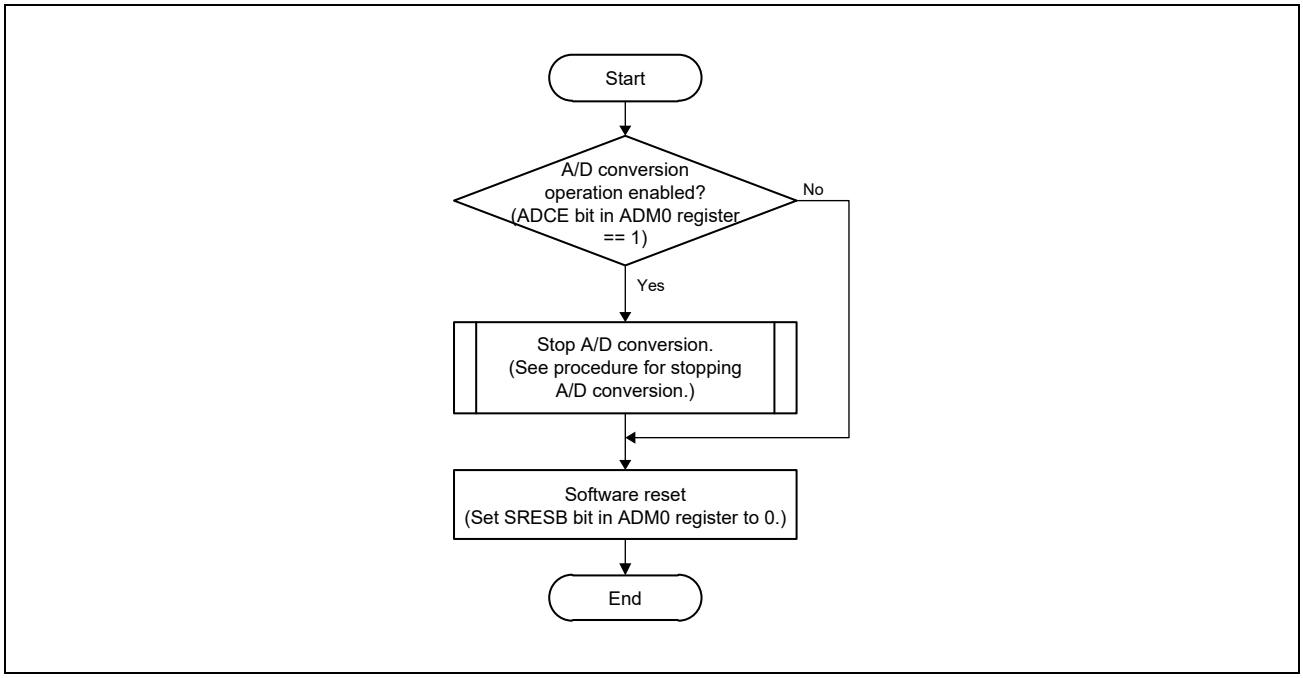
Use the following flowchart to release the A/D converter from the power-saving mode.

Note 1. The stabilization wait time is 1 µs.

Figure 7.10-8 Procedure for Releasing from Power-Saving Mode

7.10.4.3.6 Procedure for a Software Reset

Use the following flowchart to execute a software reset.



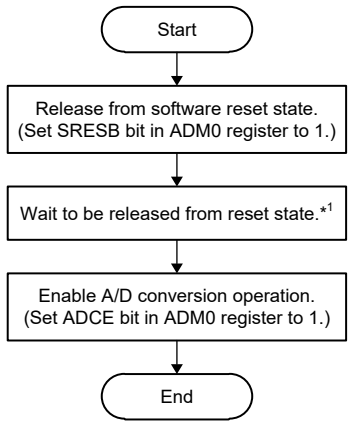


Figure 7.10-9 Procedure for a Software Reset

7.10.4.3.7 Procedure for Restarting A/D Conversion after a Software Reset

Use the following flowchart to start A/D conversion, then execute a software reset with the procedure for a software reset, and finally restart A/D conversion.

Note 1. The time waiting for the A/D converter to be released from the reset state is 2 × ADC0_ADCLK(P20ϕ).

Figure 7.10-10 Procedure for Restarting A/D Conversion after a Software Reset

7.10.4.3.8 Procedure for Interrupt Processing

Use the flowchart in **Figure 7.10-11** to process an interrupt request that was output by the A/D converter.

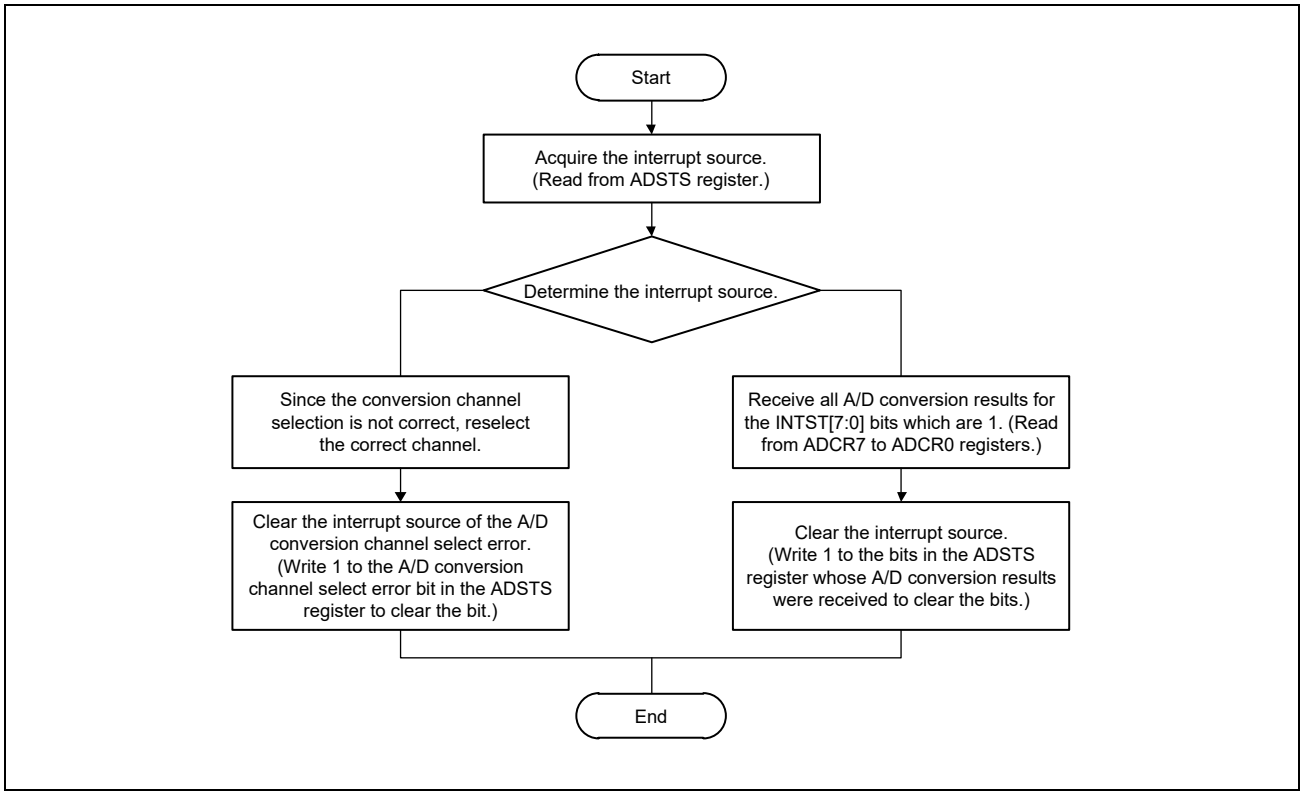

Figure 7.10-11 Procedure for Interrupt Processing

7.10.4.4 Examples of A/D Conversion

This section gives examples of A/D conversion.

1) Example of A/D conversion in select mode with single mode selected
2) Example of A/D conversion in select mode with repeat mode selected
3) Example of A/D conversion in 4-buffer mode
4) Example of A/D conversion in scan mode with single mode selected
5) Example of A/D conversion in scan mode with repeat mode selected
6) Example of A/D conversion in auto mode
7) Example of A/D conversion in step mode

Note to confirm the differences between modes shown below because not all possible combinations are included in this manual.

- For the differences between 1-buffer mode and 4-buffer mode, refer to 1) and 3).
- For the differences between single mode and repeat mode, refer to 1) and 2).
- For the differences between select mode and scan mode, refer to 1) and 4) or 2) and 5)
- For the differences between auto mode and step mode, refer to 6) and 7)
- For the differences between software trigger mode and hardware trigger mode, refer to 4) and 6).

7.10.4.4.1 Example of A/D Conversion in Select Mode with Single Mode Selected

Figure 7.10-12 shows an example of A/D conversion with software trigger mode, select mode, single mode and 1-buffer mode are selected. In the example in **Figure 7.10-12**, conversion proceeds with the analog input changed from ADC_CH1 to ADC_CH2.

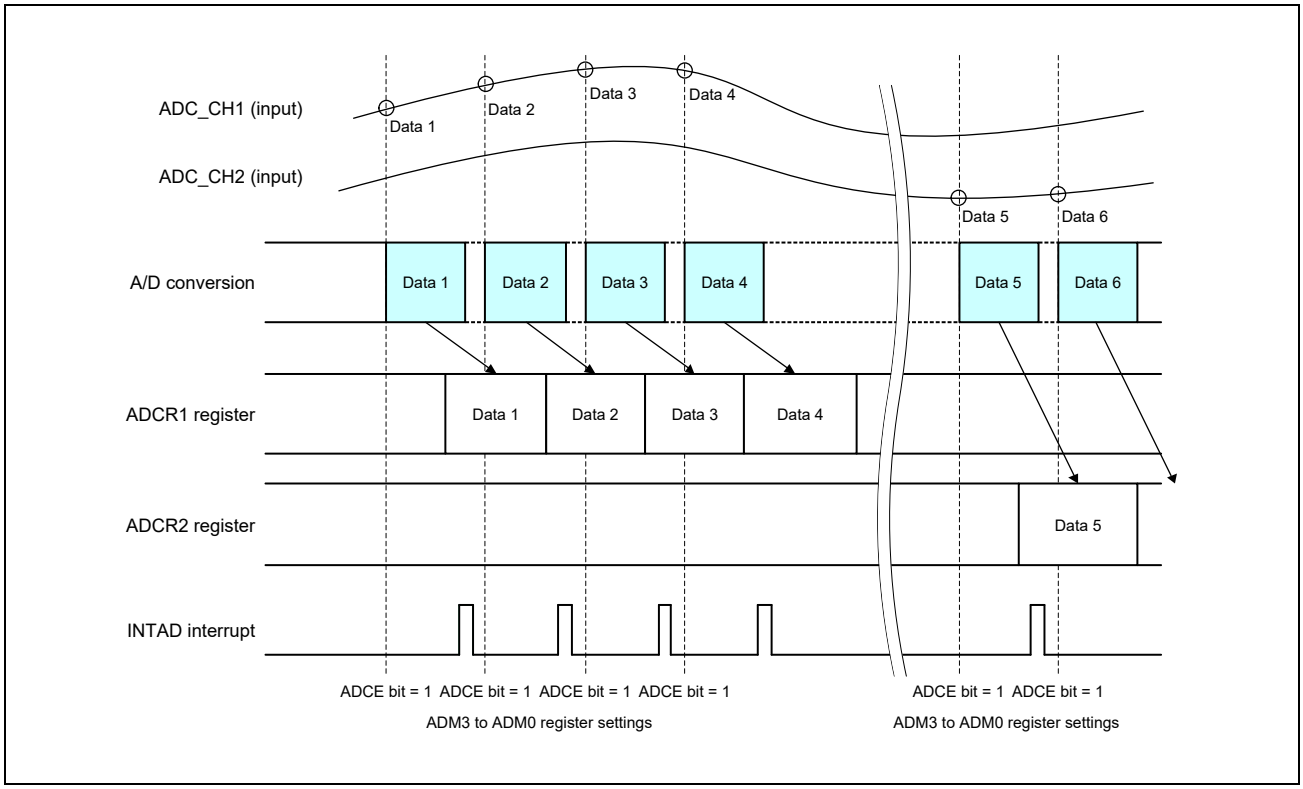

Figure 7.10-12 Example of A/D Conversion in Select Mode with Single Mode Selected

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, software trigger mode, select mode, single mode, and 1-buffer mode are selected, and analog input pin ADC_CH1 is set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 1 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*1 by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
8. A/D conversion proceeds on ADC_CH1 (A/D conversion result is stored in the ADCR1 register).
9. An INTAD interrupt occurs.
10. Steps 7 to 9 above are repeated.
11. A/D conversion operation is stopped by setting the ADCE bit in the ADM0 register to 0.
12. In the ADM3 to ADM0 registers, software trigger mode, select mode, single mode, and 1-buffer mode are selected, and analog input pin ADC_CH2 is set.

13. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
14. A/D conversion proceeds on ADC_CH2 (A/D conversion result is stored in the ADCR2 register).
15. An INTAD interrupt occurs.
16. Steps 13 to 15 above are repeated.

Note 1. The stabilization wait time is 1 μs.

7.10.4.4.2 Example of A/D Conversion in Select Mode with Repeat Mode Selected

Figure 7.10-13 shows an example of A/D conversion with software trigger mode, select mode, repeat mode, and 1-buffer mode are selected. In the example in **Figure 7.10-13**, conversion proceeds with the analog input changed from ADC_CH1 to ADC_CH2.

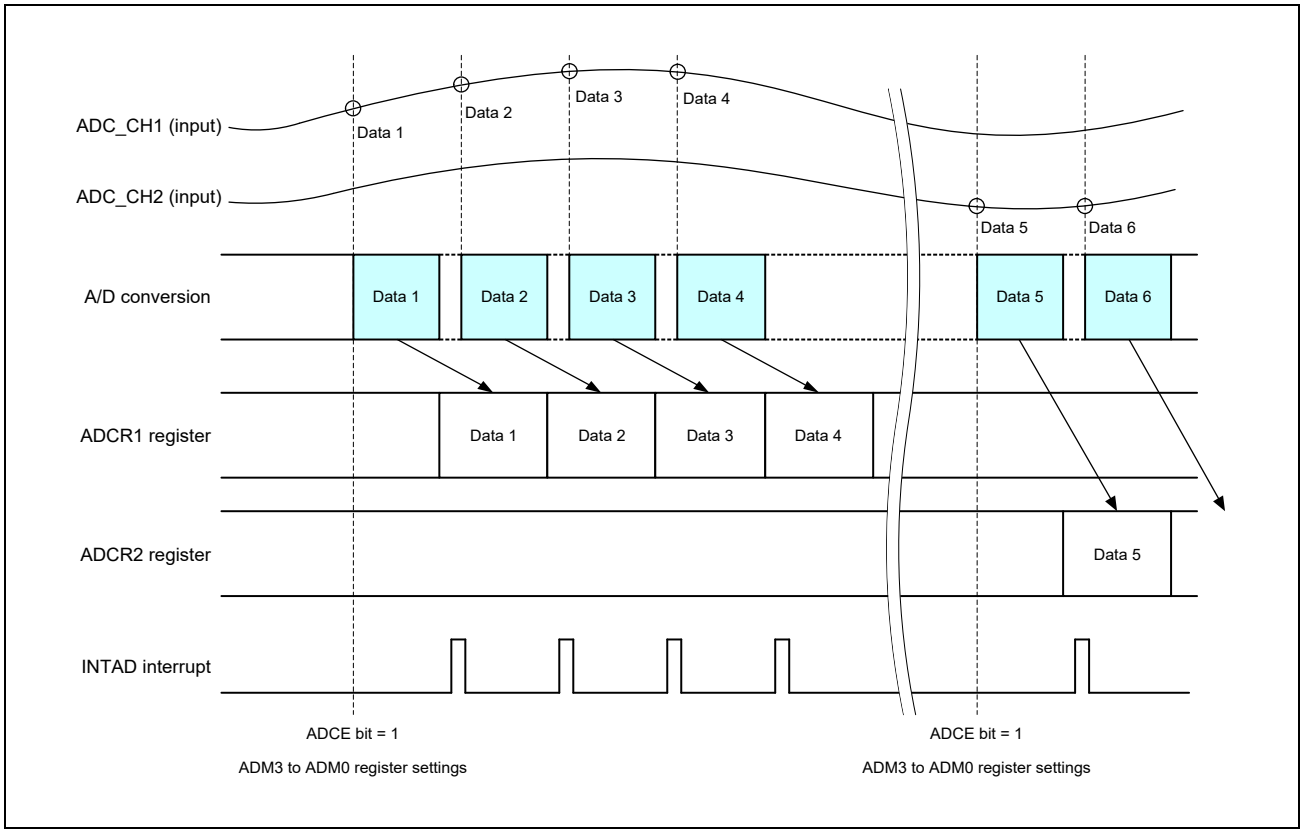

Figure 7.10-13 Example of A/D Conversion in Select Mode with Repeat Mode Selected

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, software trigger mode, select mode, repeat mode, and 1-buffer mode are selected, and analog input pin ADC_CH1 is set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 1 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*1 by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
8. A/D conversion proceeds on ADC_CH1 (A/D conversion result is stored in the ADCR1 register).
9. An INTAD interrupt occurs.
10. Steps 8 and 9 above are repeated automatically.
11. A/D conversion operation is stopped by setting the ADCE bit in the ADM0 register to 0.

12. In the ADM3 to ADM0 registers, software trigger mode, select mode, repeat mode, 1-buffer mode are selected, and analog input pin ADC_CH2 is set.
13. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
14. A/D conversion proceeds on ADC_CH2 (A/D conversion result is stored in the ADCR2 register).
15. An INTAD interrupt occurs.
16. Steps 14 and 15 above are repeated.

Note 1. The stabilization wait time is 1 μs.

7.10.4.4.3 Example of A/D Conversion in 4-Buffer Mode

Figure 7.10-14 shows an example of A/D conversion with software trigger mode, select mode, repeat mode, and 4-buffer mode are selected. In the example in **Figure 7.10-14**, conversion proceeds with the analog input changed from ADC_CH2 to ADC_CH4.

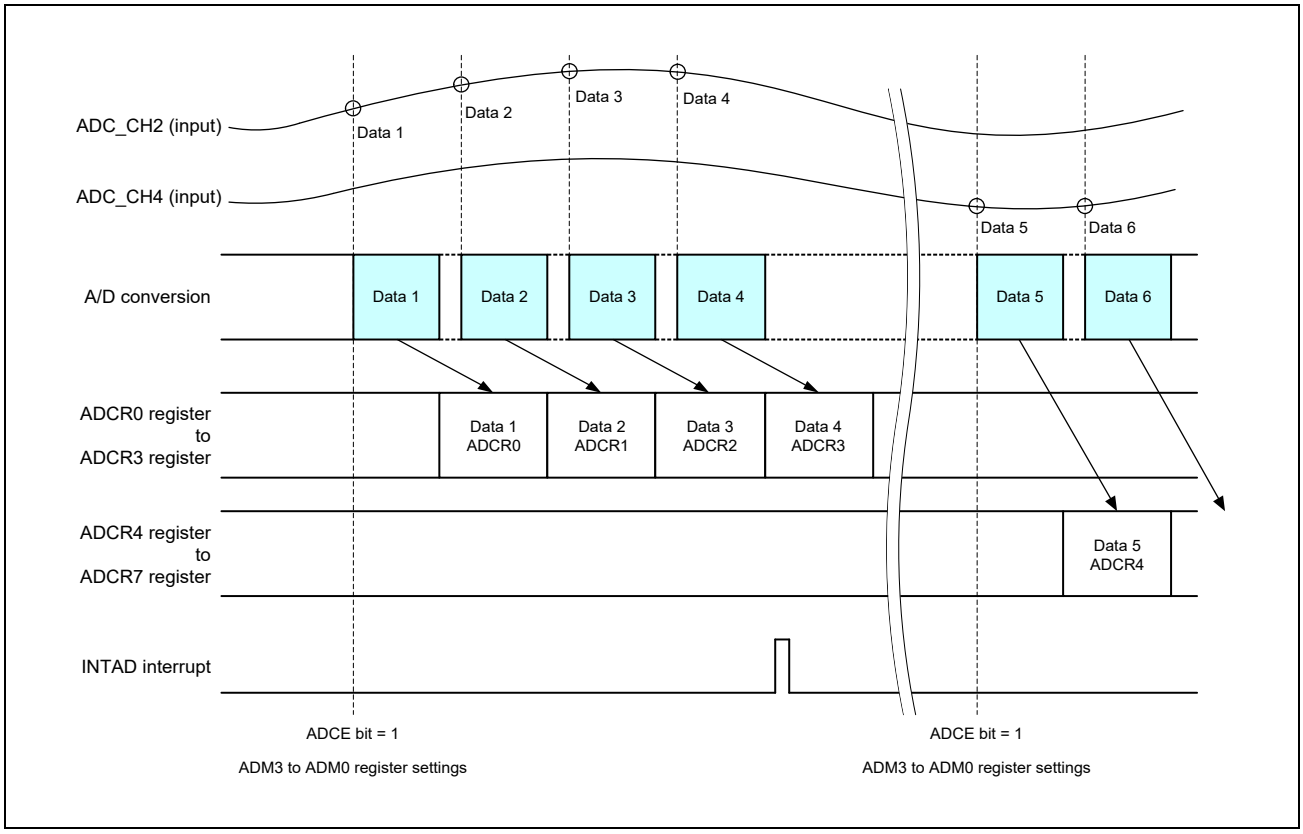

Figure 7.10-14 Example of A/D Conversion in 4-Buffer Mode

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, software trigger mode, select mode, repeat mode, and 4-buffer mode are selected, and analog input pin ADC_CH2 is set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 3 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*1 by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
8. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 1) is stored in the ADCR0 register).
9. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 2) is stored in the ADCR1 register).
10. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 3) is stored in the ADCR2 register).
11. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 4) is stored in the ADCR3 register).
12. An INTAD interrupt occurs.

13. Steps 8 to 12 above are repeated automatically.
14. A/D conversion operation is stopped by setting the ADCE bit in the ADM0 register to 0.
15. In the ADM3 to ADM0 registers, software trigger mode, select mode, repeat mode, and 4-buffer mode are selected, and analog input pin ADC_CH4 is set.
16. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
17. A/D conversion proceeds on ADC_CH4 (A/D conversion result (data 5) is stored in the ADCR4 register).
18. A/D conversion proceeds on ADC_CH4 (A/D conversion result (data 6) is stored in the ADCR5 register).

...

Note 1. The stabilization wait time is 1 μs.

7.10.4.4.4 Example of A/D Conversion in Scan Mode with Single Mode Selected

Figure 7.10-15 shows an example of A/D conversion with software trigger mode, scan mode, and single mode are selected. In the example in **Figure 7.10-15**, conversion proceeds with ADC_CH3 to ADC_CH0 selected.

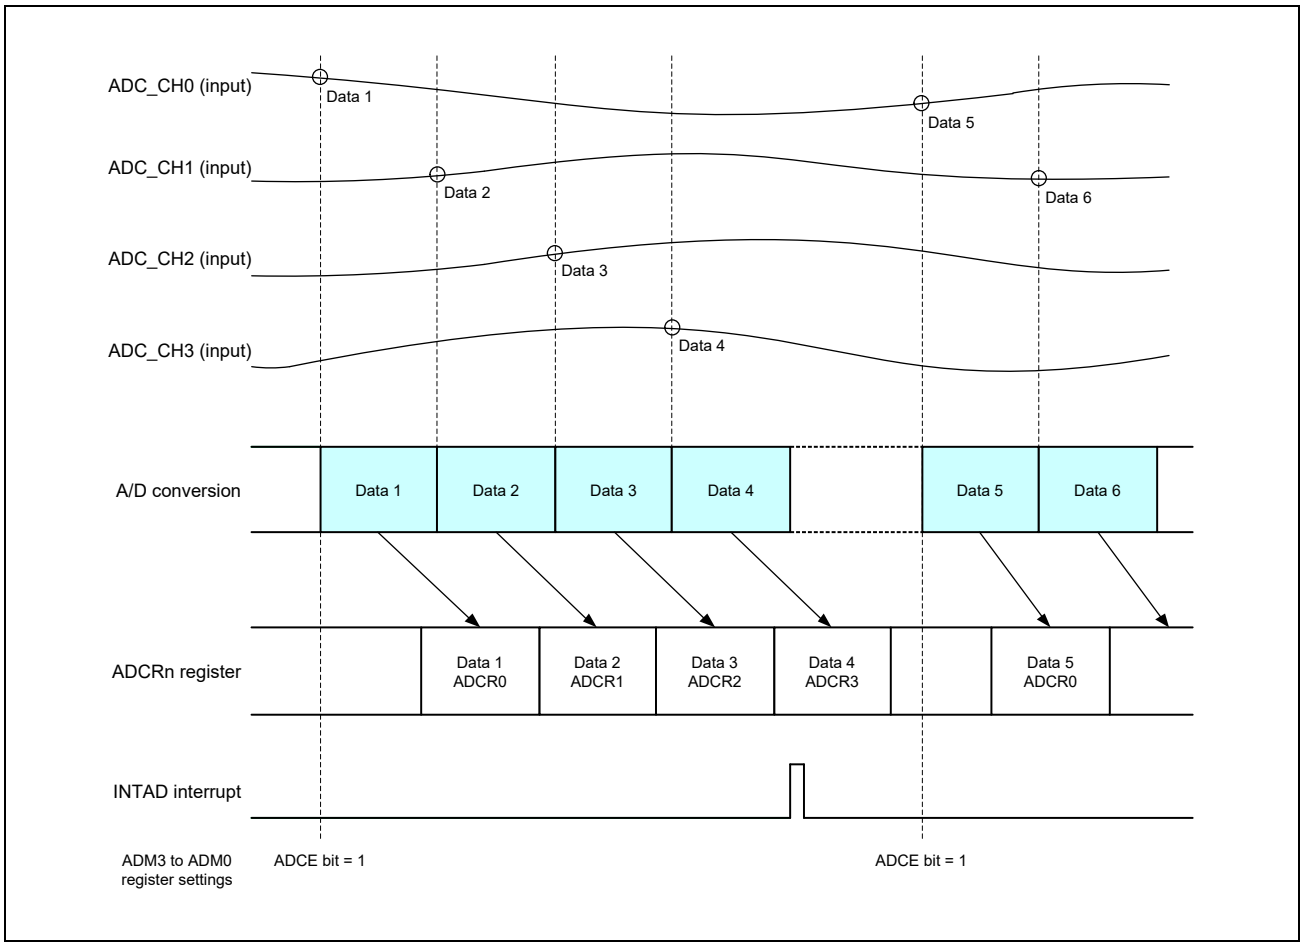

Figure 7.10-15 Example of A/D Conversion in Scan Mode with Single Mode Selected

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, software trigger mode, scan mode, and single mode are selected, and analog input pins ADC_CH3 to ADC_CH0 are set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 3 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*[1] by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
8. A/D conversion proceeds on ADC_CH0 (A/D conversion result (data 1) is stored in the ADCR0 register).
9. A/D conversion proceeds on ADC_CH1 (A/D conversion result (data 2) is stored in the ADCR1 register).
10. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 3) is stored in the ADCR2 register).

11. A/D conversion proceeds on ADC_CH3 (A/D conversion result (data 4) is stored in the ADCR3 register).
12. An INTAD interrupt occurs.
13. Steps 7 to 12 above are repeated.

Note 1. The stabilization wait time is 1 μs.

7.10.4.4.5 Example of A/D Conversion in Scan Mode with Repeat Mode Selected

Figure 7.10-16 shows an example of A/D conversion with software trigger mode, scan mode, and repeat mode are selected. In the example in **Figure 7.10-16**, conversion proceeds with ADC_CH3 to ADC_CH0 selected.

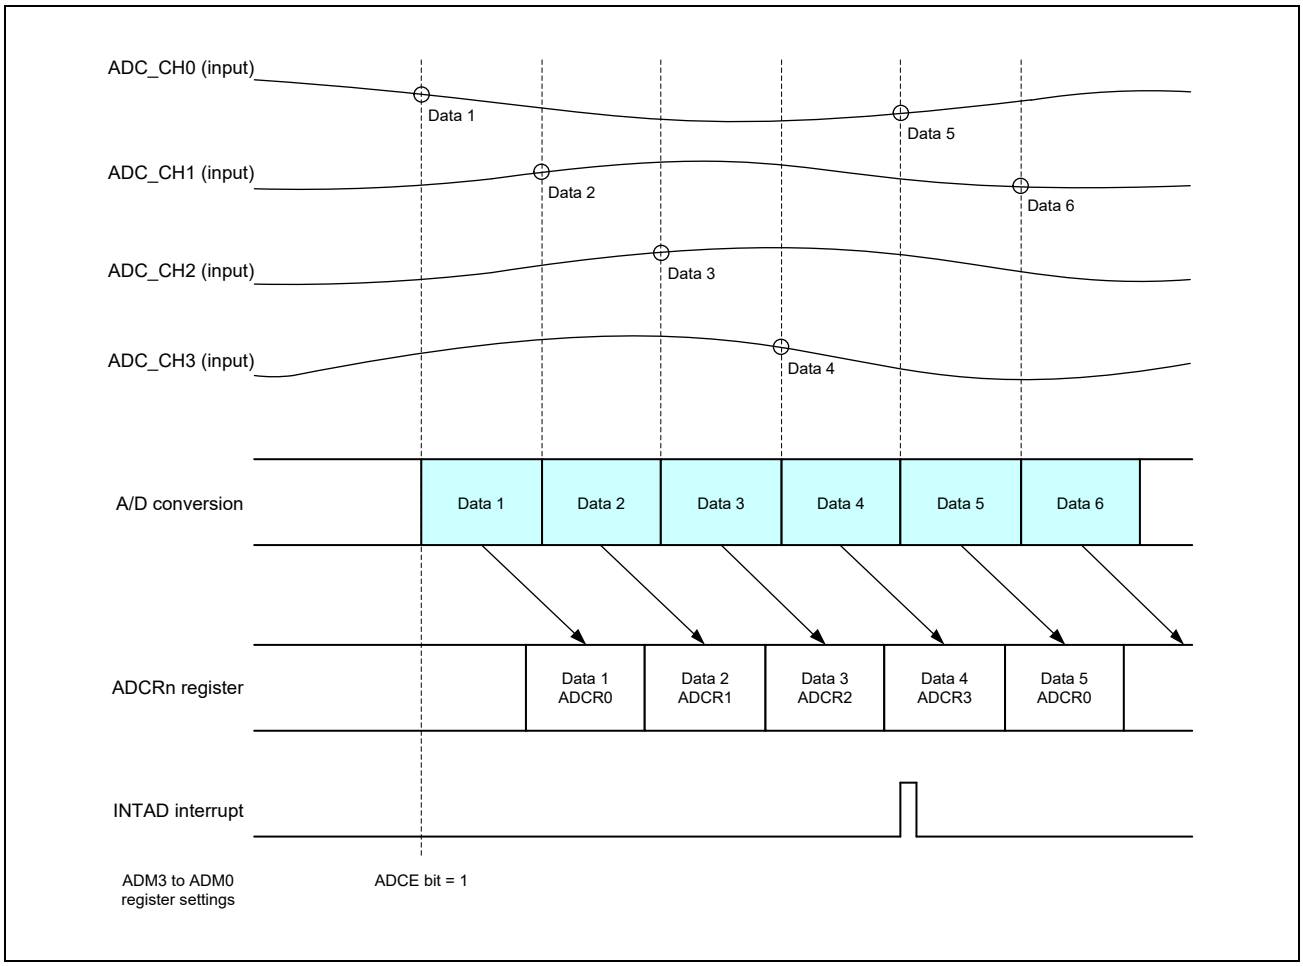

Figure 7.10-16 Example of A/D Conversion in Scan Mode with Repeat Mode Selected

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, software trigger mode, scan mode, and repeat mode are selected and analog input pins ADC_CH3 to ADC_CH0 are set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 3 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*1 by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).
8. A/D conversion proceeds on ADC_CH0 (A/D conversion result (data 1) is stored in the ADCR0 register).
9. A/D conversion proceeds on ADC_CH1 (A/D conversion result (data 2) is stored in the ADCR1 register).
10. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 3) is stored in the ADCR2 register).

11. A/D conversion proceeds on ADC_CH3 (A/D conversion result (data 4) is stored in the ADCR3 register).
12. An INTAD interrupt occurs.
13. Steps 8 to 12 above are repeated automatically.

Note 1. The stabilization wait time is 1 µs.

7.10.4.4.6 Example of A/D Conversion in Auto Mode

Figure 7.10-17 shows an example of A/D conversion with hardware trigger mode, auto mode, scan mode, and single mode are selected. In the example in **Figure 7.10-17**, conversion proceeds with ADC_CH3 to ADC_CH0 selected.

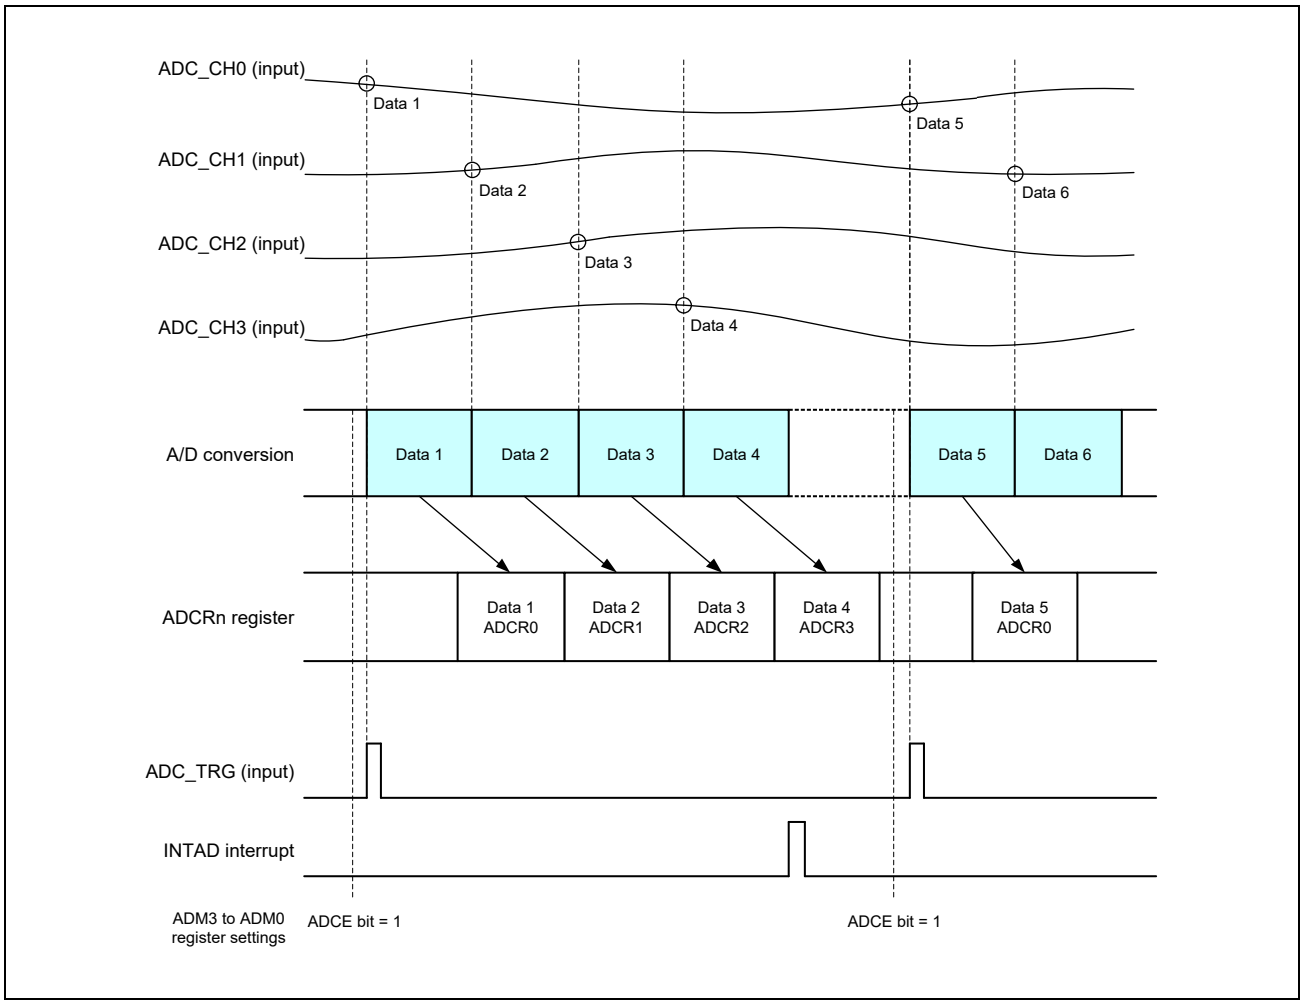

Figure 7.10-17 Example of A/D Conversion in Auto Mode

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, hardware trigger mode, auto mode, scan mode, and single mode are selected, and analog input pins ADC_CH3 to ADC_CH0 are set, the trigger of the ADC_TRG pin is enabled, and rising-edge detection of the hardware trigger is set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 3 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*[1] by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1 (A/D conversion is started).

8. After 250 ns that is the period it takes for accepting a trigger, a rising edge of the pulse is input to the ADC_TRG pin (A/D conversion is started).
9. A/D conversion proceeds on ADC_CH0 (A/D conversion result (data 1) is stored in the ADCR0 register).
10. A/D conversion proceeds on ADC_CH1 (A/D conversion result (data 2) is stored in the ADCR1 register).
11. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 3) is stored in the ADCR2 register).
12. A/D conversion proceeds on ADC_CH3 (A/D conversion result (data 4) is stored in the ADCR3 register).
13. An INTAD interrupt occurs.
14. Steps 7 to 13 above are repeated.

Note 1. The stabilization wait time is 1 µs.

7.10.4.4.7 Example of A/D Conversion in Step Mode

Figure 7.10-18 shows an example of A/D conversion with hardware trigger mode, step mode, scan mode, and single mode are selected. In the example in **Figure 7.10-18**, conversion proceeds with ADC_CH3 to ADC_CH0 selected.

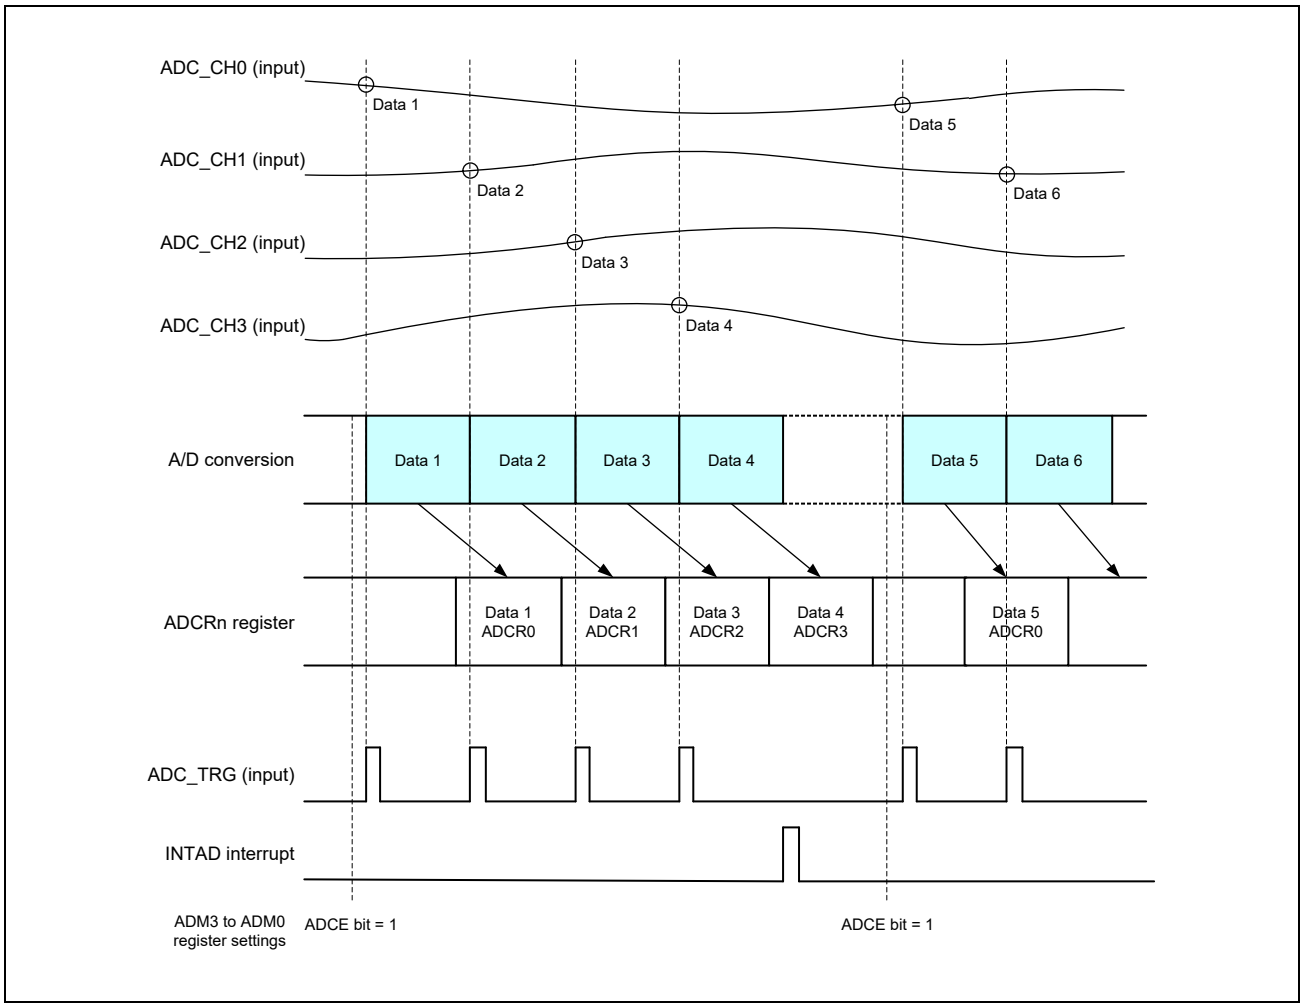

Figure 7.10-18 Example of A/D Conversion in Step Mode

1. The SRESB bit in the ADM0 register is set to 1 to release the A/D converter from the software reset state.
2. The A/D converter waits to be released from the reset state (wait time is 2 × ADC0_ADCLK(P20ϕ)).
3. In the ADM3 to ADM0 registers, hardware trigger mode, step mode, scan mode, and single mode are selected, analog input pins ADC_CH3 to ADC_CH0 are set, the trigger of the ADC_TRG pin is enabled, and rising-edge detection of the hardware trigger is set.
4. In the ADINT and ADSTS registers, the interrupt signal is set as a pulse and interrupt output of channel 3 is enabled.
5. Normal mode is selected by setting the PWDWNB bit in the ADM0 register to 1.
6. The A/D converter is kept waiting for a period equal to or longer than the stabilization wait time*[1] by software.
7. A/D conversion operation is enabled by setting the ADCE bit in the ADM0 register to 1.
8. After 250 ns that is the period it takes for accepting a trigger, a rising edge of the pulse is input to the ADC_TRG pin (A/D conversion is started).

9. A/D conversion proceeds on ADC_CH0 (A/D conversion result (data 1) is stored in the ADCR0 register).
10. After 250 ns that is the period it takes for accepting a trigger, a rising edge of the pulse is input to the ADC_TRG pin (A/D conversion is started).
11. A/D conversion proceeds on ADC_CH1 (A/D conversion result (data 2) is stored in the ADCR1 register).
12. After 250 ns that is the period it takes for accepting a trigger, a rising edge of the pulse is input to the ADC_TRG pin (A/D conversion is started).
13. A/D conversion proceeds on ADC_CH2 (A/D conversion result (data 3) is stored in the ADCR2 register).
14. After 250 ns that is the period it takes for accepting a trigger, a rising edge of the pulse is input to the ADC_TRG pin (A/D conversion is started).
15. A/D conversion proceeds on ADC_CH3 (A/D conversion result (data 4) is stored in the ADCR3 register).
16. An INTAD interrupt occurs.
17. Steps 7 to 16 above are repeated.

Note 1. The stabilization wait time is 1 µs.

7.10.5 Notes

7.10.5.1 Interval of Hardware Trigger

The interval (interval of input time) of a trigger in hardware trigger mode must be longer than the A/D conversion time. For the A/D conversion time, see **7.10.3.4 A/D Converter Mode Register 3 (ADM3)**.

7.10.5.2 Timing Restrictions

This A/D converter has restrictions on the timing interval, which are caused by the asynchronism countermeasure circuit. The restrictions shown in **Table 7.10-9** need to be met. If an access is made in a period shorter than this interval, the register values on the ADC0_PCLK (P20ϕ) side are not reflected in the registers on the ADC0_ADCLK (P20ϕ) side because the notification of register update does not reach the ADC0_ADCLK (P20ϕ) side.

Table 7.10-9 Restrictions on Timing Interval

Condition	Restriction
Writing to the same register successively	(Interval of write access) ≥ (6 × ADC0_PCLK(P20ϕ) + 6 × ADC0_ADCLK(P20ϕ))
Interval of A/D conversion	(A/D conversion time) ≥ (6 × ADC0_PCLK(P20ϕ) + 6 × ADC0_ADCLK(P20ϕ))

Note: For the A/D conversion time, see **Figure 7.10-2**.

7.10.5.3 Restrictions on ADC0_PCLK(P20ϕ) and ADC0_ADCLK(P20ϕ) Cycles

The ADC0_PCLK(P20ϕ) and ADC0_ADCLK(P20ϕ) cycles need to satisfy the relation in the following formula.

$$\mathrm{ADC0_ADCLK(P20\phi)} \leq \frac{(\mathrm{A/D\ conversion\ time})}{6} - \mathrm{ADC0_PCLK(P20\phi)}$$

Note: For the A/D conversion time, see **Figure 7.10-2**.

7.10.5.4 Operation when Stopping or Restarting A/D Conversion

When 0 is written to the ADCE bit in the ADM0 register, the A/D converter stops A/D conversion. A/D conversion is restarted by writing 0 to the ADCE bit in the ADM0 register once and then writing 1 to the same bit. Even though there was an instruction to stop A/D conversion, A/D conversion may not stop immediately. **Table 7.10-10** shows the operation for stopping conversion and also the operation for restarting conversion after it has been stopped.

Table 7.10-10 Operation when Stopping or Restarting A/D Conversion with the ADCE Bit

A/D Conversion Modes					Timing for Stopping Conversion when Stop is Instructed with ADCE = 0	Operation for Restarting Conversion
Trigger		Operating Mode	Conversion Count	Buffer Count		
Mode	Input					
Software	—	Select	Single	1	Stopped on completion of 1-time conversion.	Conversion proceeds on the channel selected in the ADM2 register.
				4	Stopped on completion of conversion in which there was an instruction to stop in the middle of 4-time conversion.	Same as above
			Repeat	1	Stopped on completion of 1-time conversion.	Same as above
				4	Stopped on completion of conversion in which there was an instruction to stop in the middle of 4-time conversion.	Same as above
		Scan	Single	1	Stopped on completion of conversion in which there was an instruction to stop in the middle of scanning.	Conversion proceeds from the smallest channel number selected in the ADM2 register.
				4	(Setting prohibited)	(Setting prohibited)
			Repeat	1	Stopped on completion of conversion in which there was an instruction to stop in the middle of scanning.	Conversion proceeds from the smallest channel number selected in the ADM2 register.
				4	(Setting prohibited)	(Setting prohibited)

SECTION 7 LOW-SPEED INTERFACE

7.11 Thermal Sensor Unit (TSU)

This LSI chip incorporates a thermal sensor unit (TSU) that measures the temperature inside the LSI.

7.11.1 Overview

7.11.1.1 Features

- This LSI has a single TSU.
- The thermal sensor in this unit measures temperatures in the range from −40°C to 125°C with an accuracy of ±7°C.
- The analog output of TSU is connected to channel 8 of ADC1. By controlling ADC1, it converts the analog output with 12bit digital data and outputs the result. (See **7.12 A/D Converter for TSU (ADC1)**.)

7.11.1.2 Block Diagram

Figure 7.11-1 is a block diagram of the TSU.

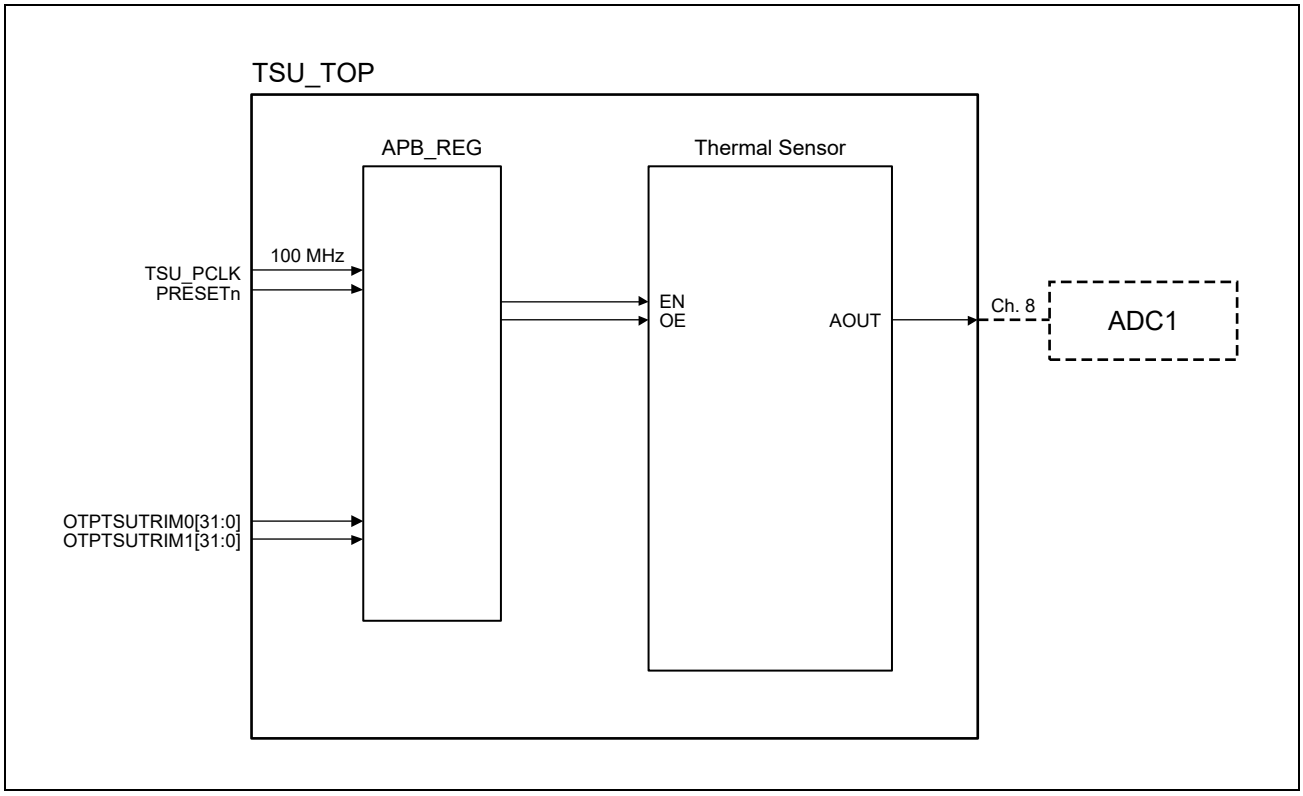

Figure 7.11-1 Block Diagram of the TSU

The TSU consists of the following blocks.

- APB_REG
- Thermal Sensor

7.11.1.2.1 APB_REG

- The APB_REG block provides an external interface for the TSU.
- This block contains control and status registers for the thermal sensor.

7.11.1.2.2 Thermal Sensor

- The thermal sensor block includes the internal probe, A/D converter and other items.
- The analog output of TSU is connected to channel 8 of ADC1. By controlling ADC1, it converts the analog output with 12bit digital data.

7.11.1.3 External Pins

The TSU has no external pins.

7.11.1.4 Interrupts

The TSU has no interrupts.

7.11.2 Register Configuration

This section describes the registers for use in controlling the TSU.

Base Address: H'0_108D_0000 (Cortex-A55 Address Space)
Base Address: H'508D_0000 (Cortex-M33 Address Space Non-Secure)
Base Address: H'408D_0000 (Cortex-M33 Address Space Secure)

7.11.2.1 List of Register

Table 7.11-1 lists the TSU registers. All registers are accessible in 32-bit units.

Table 7.11-1 List of the TSU Registers

Register Name	Abbreviation	R/W	Initial Value	Offset Address	Access Size
Sensor Mode Register	TSU_SM	R/W	H'0000_0000	H'00	32
TSU OTP Calibration Register 0	OTPTSUTRIM0_REG	R	—	H'18	32
TSU OTP Calibration Register 1	OTPTSUTRIM1_REG	R	—	H'1C	32

7.11.3 Register Descriptions

7.11.3.1 Sensor Mode Register (TSU_SM)

This register is used to specify the operating mode of the thermal sensor.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OE	EN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
1	OE	0b	R/W	TS IP Output Enable 1b: output enable 0b: output disable
0	EN	0b	R/W	TS IP Enable 1b: Thermal sensor enable 0b: Thermal sensor disable

7.11.3.2 TSU OTP Calibration Register 0 (OTPTSUTRIM0_REG)

This register holds the correction value for calibration to be used in calculating the temperature.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTPTSUTRIM0_EN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	OTPTSUTRIM0											
Initial Value	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	OTPTSUTRIM0_EN	—	R	This bit indicates whether [11:0] OTPTSUTRIM0 is valid or invalid. 0b: [11:0] OTPTSUTRIM0 is invalid. 1b: [11:0] OTPTSUTRIM0 is valid.
30 to 12	—	—	R	Reserved When read, the value is indefinite value. The written value will be ignored.
11 to 0	OTPTSUTRIM0	—	R	These bits hold the correction value for calibration to be used in calculating the temperature.

7.11.3.3 TSU OTP Calibration Register 1 (OTPTSUTRIM1_REG)

This register holds the correction value for calibration to be used in calculating the temperature.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTPTSUTRIM1_EN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	OTPTSUTRIM1											
Initial Value	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	OTPTSUTRIM1_EN	—	R	This bit indicates whether [11:0] OTPTSUTRIM1 is valid or invalid. 0b: [11:0] OTPTSUTRIM1 is invalid. 1b: [11:0] OTPTSUTRIM1 is valid.
30 to 12	—	—	R	Reserved When read, the value is indefinite value. The written value will be ignored.
11 to 0	OTPTSUTRIM1	—	R	These bits hold the correction value for calibration to be used in calculating the temperature.

7.11.4 Operation

7.11.4.1 Procedure for Starting the TSU

This section describes the procedure for starting the TSU.

1. Set the EN bit in the TSU_SM register to 1b to place the thermal sensor in the normal operating mode.
2. Wait for 30 µs or more, set the OE bit in the TSU_SM register to 1b to enable the output.
3. Wait for 50 µs or more to stable the output level.
4. ADC1 to convert 12bit digital data.
5. Read converted data from ADC1 register.

7.11.4.2 Procedure for Stopping the TSU

This section describes the procedure for stopping the TSU.

1. Set the EN and OE bits in the TSU_SM register to 0 at the same time to place the thermal sensor in the standby mode.

7.11.4.3 Setting A/D Converter

See **7.12 A/D Converter for TSU (ADC1)** for more information.

7.11.4.4 Procedure for Measuring the Temperature

To calculate the temperature Tj, read registers ADCR of ADC1, OTPTSUTRIM0_REG, and OTPTSUTRIM1_REG of TSU, and follow the procedure below.

1. Read the value of the ADCR of ADC1 register eight times every at least 3 µs. The read values are defined as TSCode[0] to TSCode[7].

2. Calculate the average of the values read, TSCodeAVE, by using the following formula.

$$\mathrm{TSCodeAVE} = \frac{(\mathrm{TSCode}[0] + \cdots + \mathrm{TSCode}[7])}{8}$$

3. Read the correction values for use in calibration from registers OTPTSUTRIM0_REG and OTPTSUTRIM1_REG and use the following formula to calculate Tj.

$$\mathrm{Tj} = (\mathrm{TSCodeAVE} - \mathrm{OTPTSUTRIM1}) \times \left(\frac{165}{(\mathrm{OTPTSUTRIM0} - \mathrm{OTPTSUTRIM1})}\right) - 40$$

Note: If the ADC_AVDD18 is not 1.80 V on board, use the following formula to calculate the corrected TSCode.
Corrected TSCode = (ADC_AVDD18 voltage / 1.80) × TSCodeAve

$$\mathrm{Tj} = (\mathrm{Corrected\ TSCode} - \mathrm{OTPTSUTRIM1}) \times \left(\frac{165}{(\mathrm{OTPTSUTRIM0} - \mathrm{OTPTSUTRIM1})}\right) - 40$$

7.11.5 Usage Note

- Do not set OE to 1 during EN = 0.

SECTION 7 LOW-SPEED INTERFACE

7.12 A/D Converter for TSU (ADC1)

7.12.1 Features

This LSI has a successive approximation A/D converter with 12-bit accuracy. This unit is used for TSU.

■ **Resolution**

12 bits

■ **One dedicated input channel to TSU**

■ **Input voltage range**

0 V to 1.8 V

■ **Minimum conversion time**

2.84 µs per channel (when A/D conversion clock ADC1_ADCLK is 100 MHz)

■ **Sample-and-hold function**

■ **Trigger mode**

- Software trigger mode to start A/D conversion by software

■ **Operating mode**

- Select mode is available.
- Select mode to convert the dedicated TSU input channel.
  - 1-buffer mode can be specified for storing the A/D conversion result.

■ **Conversion mode**

- Repeat mode is available.
- Repeat mode to repeatedly proceed A/D conversion

■ **A single interrupt source**

- An A/D conversion end interrupt (INTAD) can be generated on completion of A/D conversion.
  - In the select mode with 1-buffer mode selected, an A/D conversion end interrupt is generated on completion of a single conversion.

Table 7.12-1 shows the outline of the functions of the A/D converter.

Table 7.12-1 Functions of A/D Converter

Item			Source
Analog Input Channel			ADC_CH8(TSU)
Conditions for starting A/D conversion	Software	Software trigger	(Enabled by software)

Table 7.12-2 lists the I/O pins used in the A/D converter.

Table 7.12-2 I/O Pins of A/D Converter

Pin Name	Input/Output	Functional Description
VAA18_ADC	Input	A/D converter power supply pin
AVSS_ADC	Input	A/D converter ground pin

7.12.2 List of Registers

Table 7.12-3 shows the register list of this module.

The base address is as follows.

Base address: H'0_108C_0000 (Cortex-A55 Address Space)
Base address: H'408C_0000 (Cortex-M33 Address Space Secure)
Base address: H'508C_0000 (Cortex-M33 Address Space Non-Secure)

Table 7.12-3 List of Registers of A/D Converter

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
A/D converter mode register 0	ADM0	R/W	H'0000	H'0	32
Reserved	—	R/W	H'0000	H'4	32
Reserved	—	R/W	H'0000	H'8	32
A/D converter mode register 3	ADM3	R/W	H'0000	H'C	32
A/D converter of TSU	TSUMODE	R/W	H'0000	H'10	32
Reserved	—	R	H'0000	H'14 to 1F	32
A/D converter interrupt control register	ADINT	R/W	H'0000	H'20	32
A/D converter status register	ADSTS	R/W	H'0000	H'24	32
Reserved	—	R/W	H'0000	H'28 to H'2C	32
Reserved	—	R	H'0000	H'30 to H'4C	32
A/D conversion result register 8	ADCR8	R	H'0000	H'50	32
Reserved	—	R	H'0000	H'54 to 6C	32
Renesas reserved area*1	—	R/W	Undefined	H'70 to 7F	32

Note: When writing successively to the same register, the notes in **7.12.5.1 Timing Restrictions**, need to be observed.

Note 1. Writing to a Renesas reserved area is prohibited.

7.12.3 Register Descriptions

7.12.3.1 A/D Converter Mode Register 0 (ADM0)

The ADM0 is a 32-bit register that controls A/D conversion and the power-saving mode of the A/D converter, and also executes a software reset. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRESB	—	—	—	—	—	—	—	—	—	—	—	—	PWDWNB	ADBSY	ADCE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
15	SRESB	0	R/W	Issues a software reset to the A/D converter. Circuits (e.g. registers) other than those of the A/D converter will not be reset. To release the A/D converter from the reset state, write 1 to this bit. 0: A/D converter is reset. 1: A/D converter is released from the reset state. The A/D converter enters the power-saving mode when this bit is used to execute a reset.
14 to 3	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
2	PWDWNB	0	R/W	Specifies the A/D converter to enter or exit the power-saving mode. 0: Power-saving mode 1: Normal mode
1	ADBSY	0	R	Indicates the status of the A/D converter. This bit is read-only. Writing to this bit is ignored. 0: A/D converter is stopped. 1: A/D converter is busy. For operation of the ADBSY bit, see **Figure 7.12-1**.
0	ADCE	0	R/W	Stops or enables the A/D converter. 0: A/D converter is stopped. 1: A/D converter is enabled. When 0 is written to the ADCE bit, the A/D converter stops operating. For operation of the ADCE bit at reading, see **Figure 7.12-1**.

Note: Notes regarding the ADM0 register are given on the next page.

NOTES

1. To enable A/D conversion operation using the ADCE bit, first switch from PWDWNB = 0 (power-saving mode) to PWDWNB = 1 (normal mode) and then wait for a period equal to or longer than the stabilization wait time before setting the ADCE bit to 1. The stabilization wait time is 1 µs.
2. To make a transition to the power-saving mode using the PWDWNB bit, first stop operation of the A/D converter (ADCE = 0) and then confirm that A/D conversion is completed (ADBSY = 0) before setting the PWDWNB bit to 0.

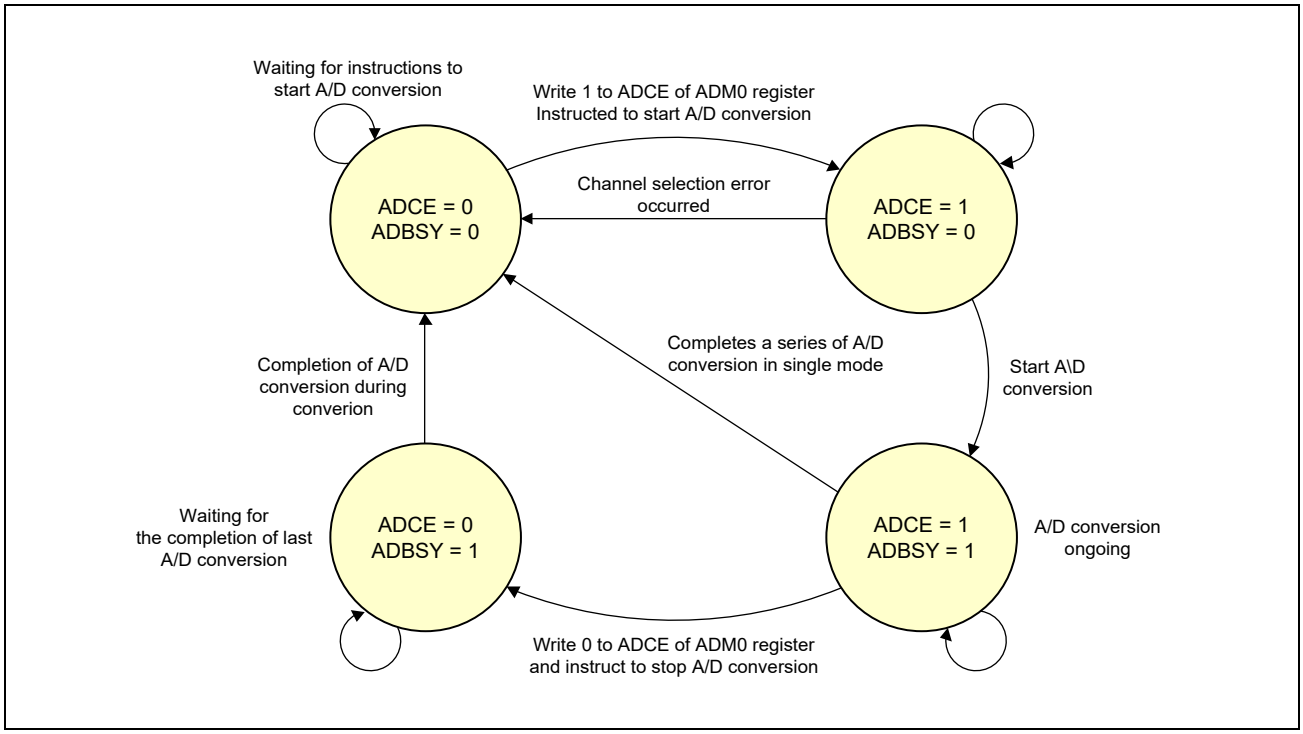

Figure 7.12-1 State Transitions of ADCE Bit and ADBSY Bit

7.12.3.2 A/D Converter Mode Register 3 (ADM3)

The ADM3 is a 32-bit register that sets the sampling period of the A/D converter. Be sure to set this register before starting the A/D converter. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ADIL[7:0]	All 0	R/W	These bits should be set to H'00.
23 to 16	ADCMP[7:0]	All 0	R/W	These bits should be set to H'1D.
15 to 8	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
7 to 0	ADSMP[7:0]	All 0	R/W	These bits set the sampling period (unit: ADIVCLK cycle). Set H'FF if measure TSU. T stands for the cycle of ADIVCLK (100 MHz).

Note: The ADIL[7:0] bits should be set to H'00 and the ADCMP[7:0] bits should be set to H'1D. If they are set to other values, normal operation cannot be guaranteed.

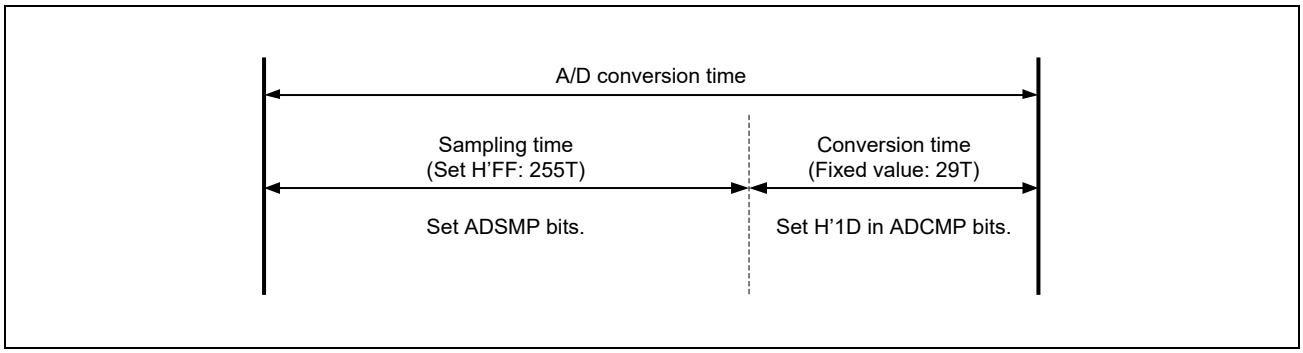

Figure 7.12-2 Correspondence between ADM3 Register and A/D Conversion Time

7.12.3.3 TSU Conversion Mode Register (TSUMODE)

The TSUMODE is a 32-bit register that control TSU conversion. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSUEN	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
1	TSUEN	0	R/W	This bit set the TSU conversion mode. 0: TSU conversion mode is disabled.. 1: TSU conversion mode is enabled.
0	—	0	R	Reserved When read, the initial value is read. The written value will be ignored.

7.12.3.4 A/D Converter Interrupt Control Register (ADINT)

The ADINT is a 32-bit register that controls interrupts. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INTS	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	INTEN8	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	INTS	0	R/W	Selects the attribute of the interrupt (INTAD) signal. 0: Pulse signal 1: Reserved This bit should be set to 0.
30 to 17	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
16	—	0	R/W	Reserved This bit should be set to 0.
15 to 12	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
11 to 9	—	All 0	R/W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
8	INTEN[8]	0	R/W	This bit enable or disable the conversion end interrupt of channel n (n = 8). 0: Interrupt output is disabled. 1: Interrupt output is enabled.
7 to 0	—	All 0	R/W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.

Note: The interrupt signal is output as a pulse when conversion is completed.

7.12.3.5 A/D Converter Status Register (ADSTS)

The ADSTS is a 32-bit register that controls the state of the A/D converter. This register can be read from and written to in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	INST8	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R/W	Reserved This bit should be set to 0.
30 to 17	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
16	—	0	R/W	Reserved This bit should be set to 0.
15 to 9	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
8	INTST[8]	0	R/W	Indicates the state of the conversion end interrupt of channel. • When reading 0: Conversion has not finished. 1: Conversion has finished. • When writing 0: No effect 1: The state is cleared.*1
7 to 0	—	All 0	R/W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.

Note 1. When an interrupt source is generated simultaneously with clearing of the interrupt source, clearing is ignored and the respective bit remains set to 1.

7.12.3.6 A/D Conversion Result Register 8 (ADCR8)

The ADCR8 is 32-bit registers that hold the A/D conversion results. These registers are read from in 32-bit units.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					AD11	AD10	AD9	AD8	AD7	AD6	AD5	AD4	AD3	AD2	AD1	AD0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved When read, the initial value is read. The written value will be ignored.
11 to 0	AD[11:0]	All 0	R	These bits hold the A/D conversion results.

The following formula indicates the relationship between the analog input voltage that is input to analog input pins (ADC_CH8) and the A/D conversion results (A/D conversion result register (ADCR8)).

$$\mathrm{ADCR} = \mathrm{INT}\left[\frac{\mathrm{Vin}}{\mathrm{ADC_AVREF}} \times 2^{\mathrm{d}} + 0.5\right]$$

or

$$(\mathrm{ADCR} - 0.5) \times \frac{\mathrm{ADC_AVREF}}{2^{\mathrm{d}}} \leq \mathrm{Vin} < (\mathrm{ADCR} + 0.5) \times \frac{\mathrm{ADC_AVREF}}{2^{\mathrm{d}}}$$

INT[ ]:	Function that returns the integer portion of the value enclosed in [ ]
Vin:	Analog input voltage
ADC_AVREF:	Voltage of power supply pin (VAA18_ADC) for the analog unit
ADCR:	Value of A/D conversion result register (ADCR8)
d:	Resolution of A/D converter (d = 12 in this LSI)

The relationship between the analog input voltage and A/D conversion result is shown in the figure below.

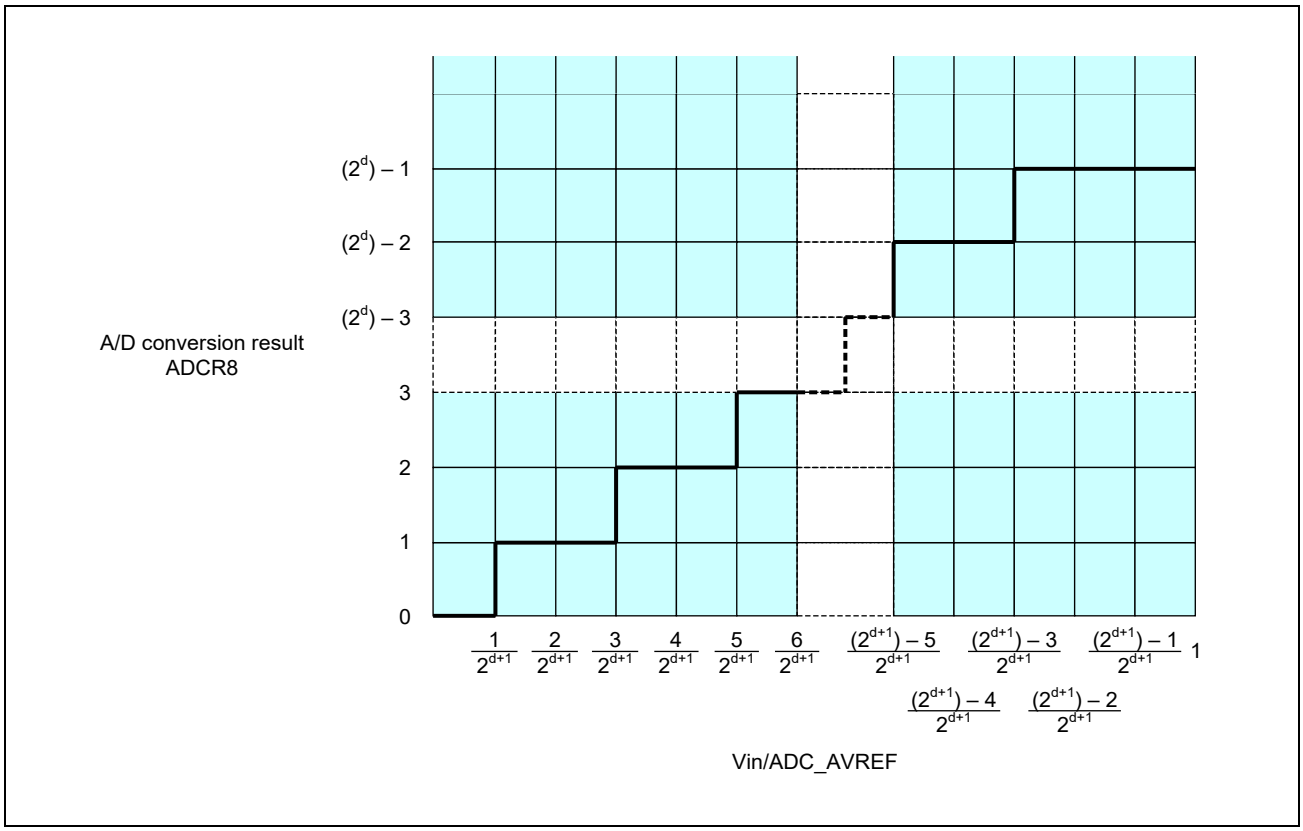

Figure 7.12-3 Relationship between Analog Input Voltage and A/D Conversion Result

7.12.4 Operation

7.12.4.1 Types of A/D Conversion Modes

The following A/D conversion modes can be specified. A/D conversion mode is set by setting the TSUEN bit in the TSUMODE register to 1.

Table 7.12-4 A/D Conversion Modes

Trigger Mode	Trigger Input Mode	Operating Mode	Conversion Count	Buffer Count	Operation
Software trigger	—	Select	Repeat	1 buffer	(TSU channel × 1-time conversion) × repeated

7.12.4.1.1 Trigger Modes

This unit is used software trigger mode.

(1) Software Trigger Mode

In software trigger mode, A/D conversion is started for the input of the TSU by setting the ADCE bit in the ADM0 register to 1. The ADBSY bit in the ADM0 register is 1 while the converter is operating.

7.12.4.1.2 Operating mode

Operating mode is select mode and 1-buffer mode. Operating mode is set by setting the TSUEN bit in the TSUMODE register to 1.

(1) Select Mode

A/D conversion is performed only once for the TSU input, and the conversion result is stored in the ADCR8 register. If interrupt output is enabled in the INTEN[8] bit in the ADINT register for the channels on which A/D conversion proceeds, and A/D conversion and interrupt (INTAD) occurs on completion of a single conversion.

This mode is usable for reading the result of a single conversion.

7.12.4.1.3 Conversion Mode

Repeat mode is available. Repeat mode is set by setting the TSUEN bit in the TSUMODE register to 1.

(1) Repeat Mode

When 1 is written to the ADCE bit in the ADM0 register, A/D conversion repeatedly proceeds. Immediately after 0 is written to the ADCE bit in the ADM0 register, A/D conversion is finished.

For the number of times of conversion, see the description of operation in **Table 7.12-4**.

7.12.4.2 Interrupt Function

Table 7.12-5 shows the interrupt source of the A/D converter, the condition for generation, and the method for confirming and clearing the interrupt source.

The INTS bit in the ADINT register is used to set the operation for outputting an interrupt request of the INTAD.

Table 7.12-5 List of Interrupt Function

Interrupt Source	Condition for Generation	Enabling Interrupt	Confirming Interrupt Source	Method for Clearing Interrupt Source
		ADINT Register	ADSTS Register*1	ADSTS Register
A/D conversion end	When A/D conversion on the TSU channel is completed	INTEN[8]	INTST[8]	Write 1 to this bit when its value is 1.

Note 1. If an interrupt source is generated regardless of the settings of the INTEN[8] bit in the ADINT register, the bit corresponding to the interrupt source is set to 1 in the ADSTS register.

7.12.4.3 Procedures of A/D Conversion

Follow the procedures given below for A/D conversion.

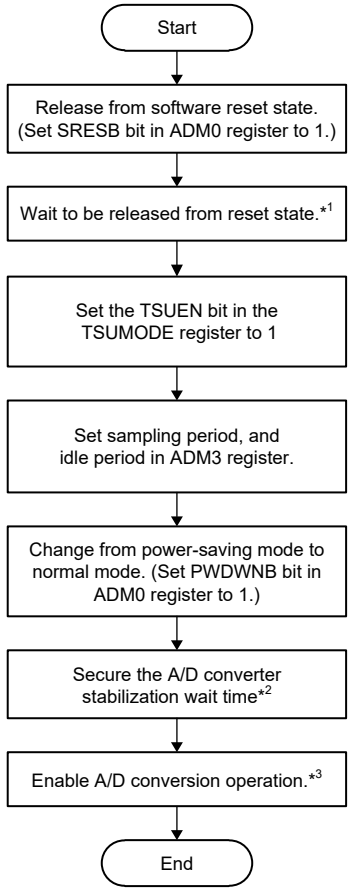
(1) Procedure for starting A/D conversion

After the A/D converter is released from the software reset state, set the ADM0 and ADM3 registers*[1]. Setting the ADCE bit in the ADM0 register to 1 will start A/D conversion in software trigger mode.

Note 1. Set the ADM0 and ADM3 registers when conversion by the A/D converter is stopped (ADBSY bit in the ADM0 register is 0).

A/D conversion operation is enabled.

After the A/D converter makes a transition from power-saving mode to normal mode, a period as long as the stabilization wait time is required. The stabilization wait time is 1 µs.



After the stabilization wait time has passed, set the ADCE bit in the ADM0 register to 1.

In software trigger mode, setting the ADCE bit to 1 starts A/D conversion.

(2) When A/D conversion is finished, the A/D conversion result is stored in the ADCR8 register. Also, an A/D conversion end interrupt (INTAD) occurs on completion of A/D conversion on the channels specified in the INTEN[8] bit in the ADINT register.

7.12.4.3.1 Procedure for Starting A/D Conversion

Use the following flowchart to start A/D conversion.

Note 1. The time waiting for the A/D converter to be released from the reset state is 2 × ADC1_ADCLK(P20ϕ).

Note 2. The stabilization wait time is 1 μs.

Note 3. In software trigger mode, A/D conversion is started by setting the ADCE bit in ADM0 register to 1.

Figure 7.12-4 Procedure for Starting A/D Conversion

7.12.4.3.2 Procedure for Stopping A/D Conversion

Use the following flowchart to stop A/D conversion.

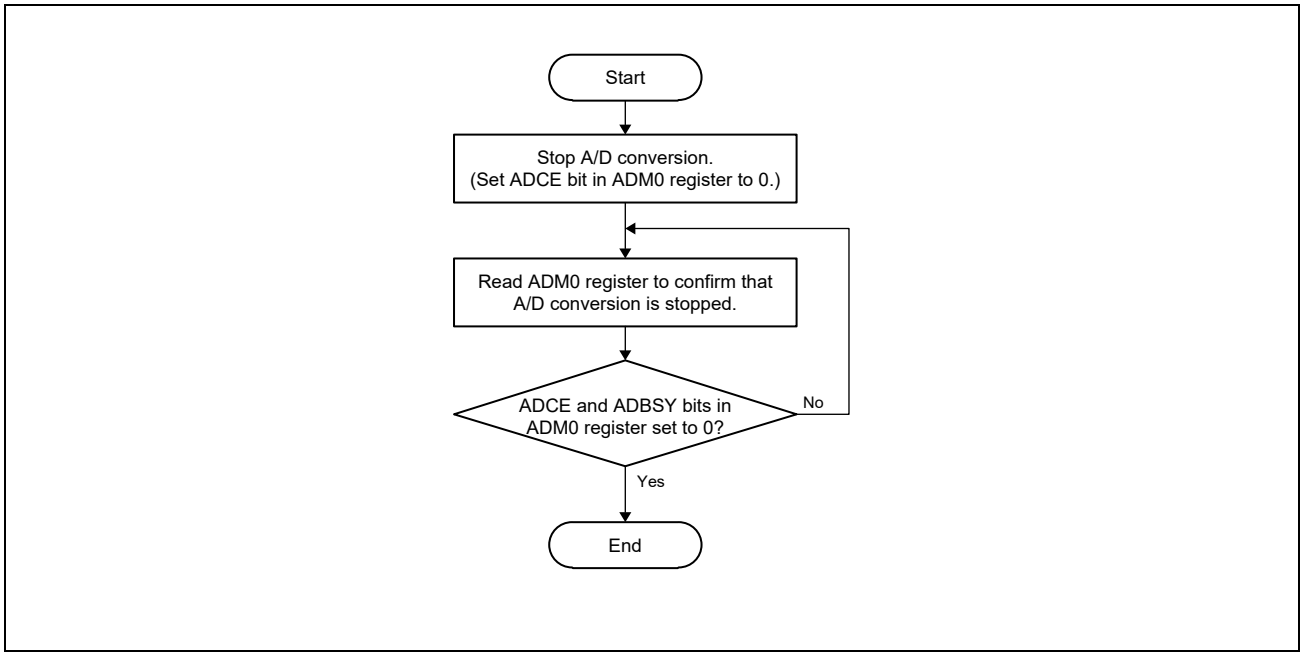


Figure 7.12-5 Procedure for Stopping A/D Conversion

7.12.4.3.3 Procedure for Stopping and Restarting A/D Conversion

Use the following flowchart to restart A/D conversion after it has been stopped with the procedure for stopping A/D conversion.

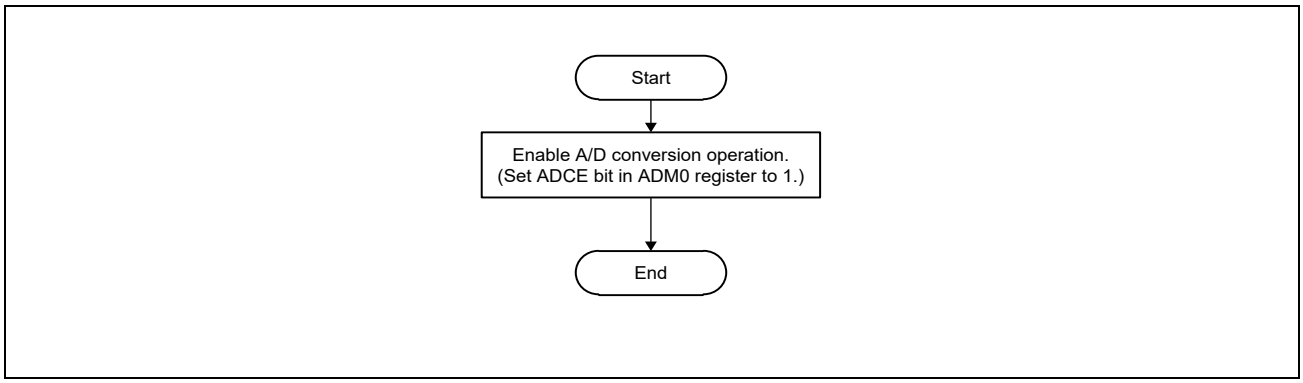

Figure 7.12-6 Procedure for Stopping and Restarting A/D Conversion

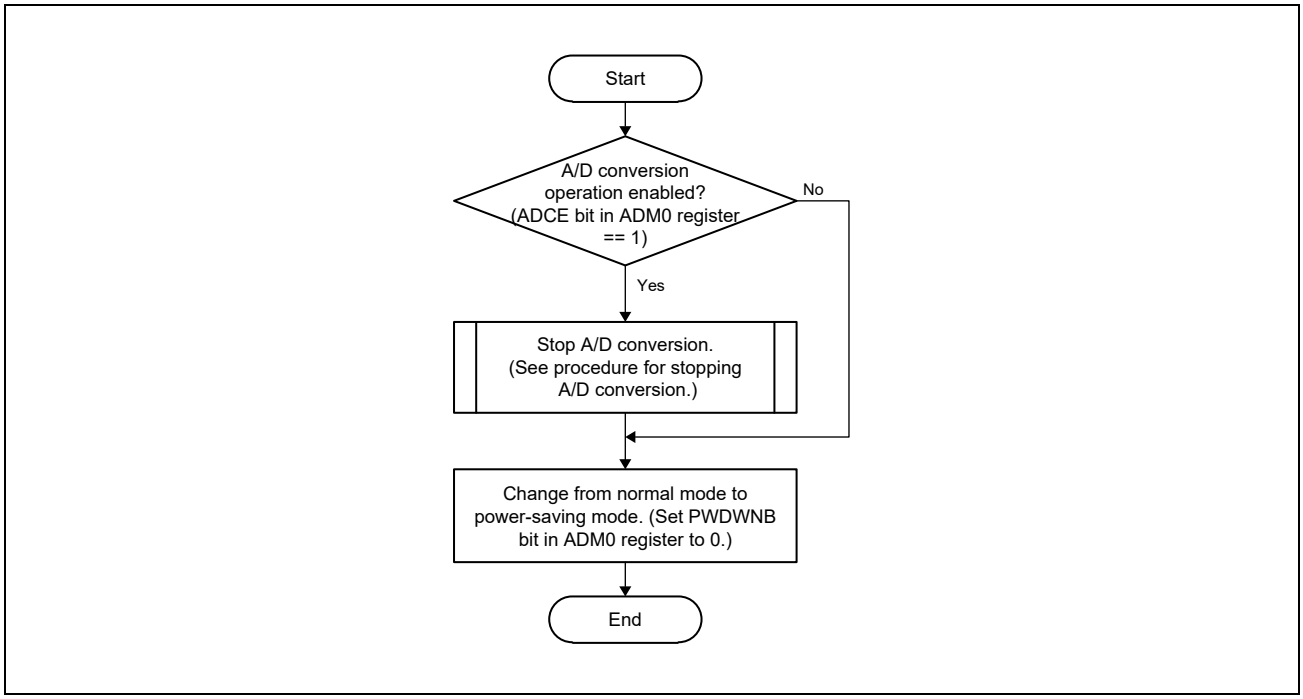
7.12.4.3.4 Procedure for Entering Power-saving Mode

Use the following flowchart to make a transition to the power-saving mode.



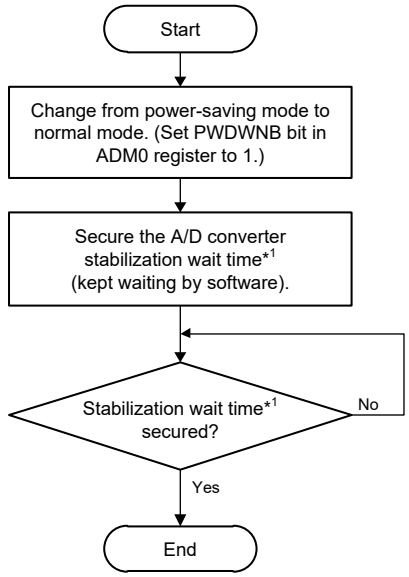


Figure 7.12-7 Procedure for Entering Power-Saving Mode

7.12.4.3.5 Procedure for Releasing from Power-saving Mode

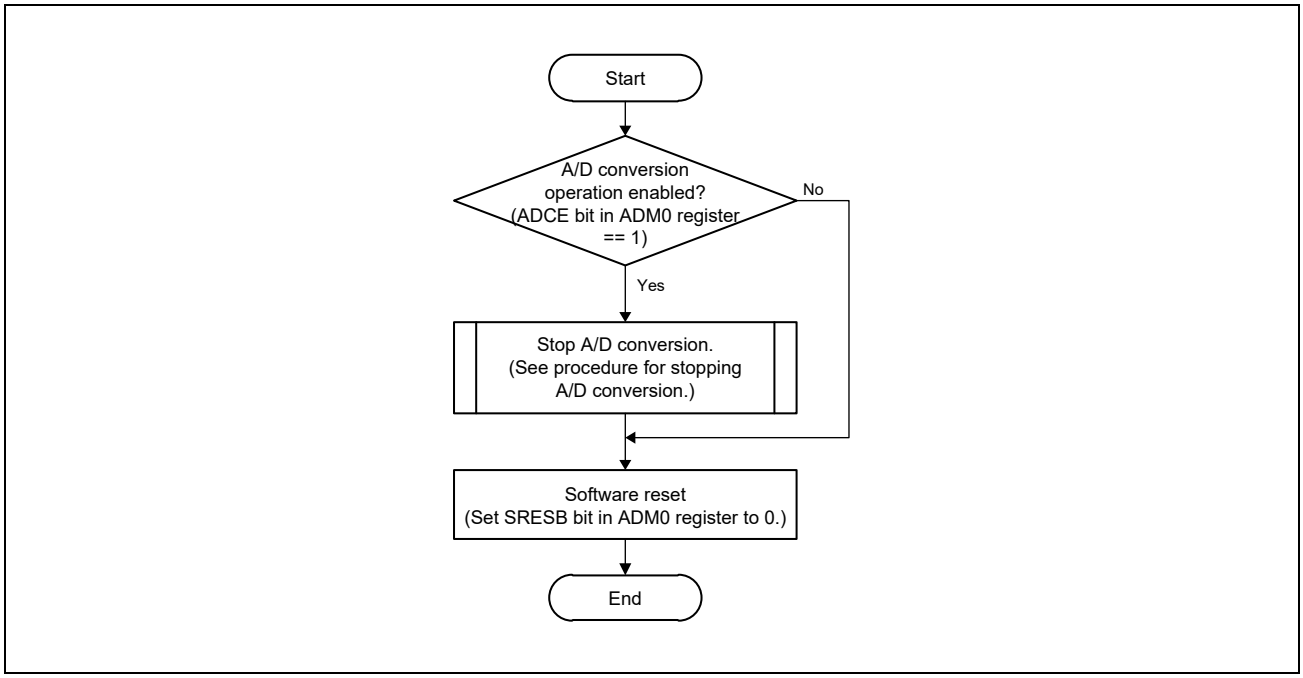
Use the following flowchart to release the A/D converter from the power-saving mode.

Note 1. The stabilization wait time is 1 µs.

Figure 7.12-8 Procedure for Releasing from Power-Saving Mode

7.12.4.3.6 Procedure for a Software Reset

Use the following flowchart to execute a software reset.



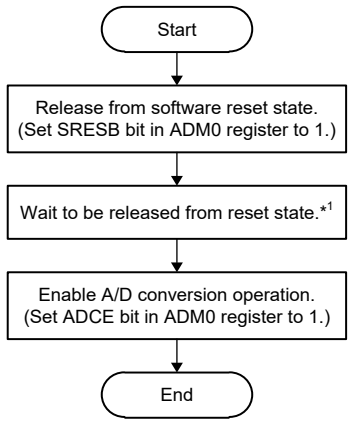


Figure 7.12-9 Procedure for a Software Reset

7.12.4.3.7 Procedure for Restarting A/D Conversion after a Software Reset

Use the following flowchart to start A/D conversion, then execute a software reset with the procedure for a software reset, and finally restart A/D conversion.

Note 1. The time waiting for the A/D converter to be released from the reset state is 2 × ADC1_ADCLK(P20ϕ).

Figure 7.12-10 Procedure for Restarting A/D Conversion after a Software Reset

7.12.4.3.8 Procedure for Interrupt Processing

Use the flowchart in **Figure 7.12-11** to process an interrupt request that was output by the A/D converter.

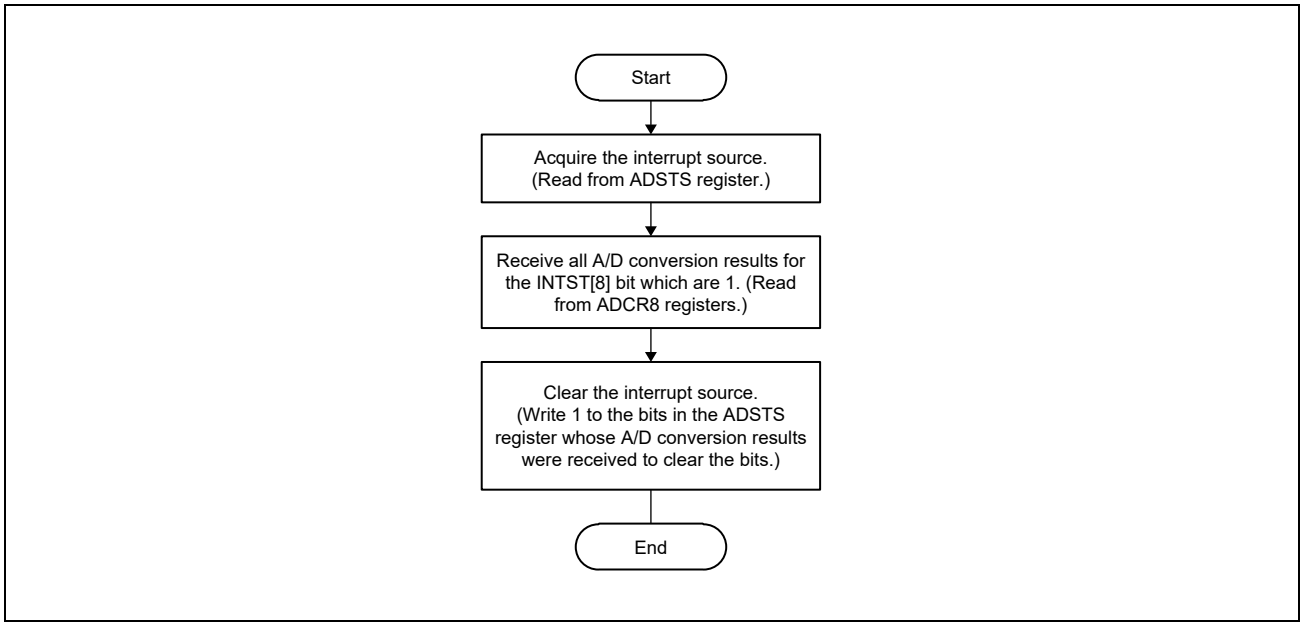

Figure 7.12-11 Procedure for Interrupt Processing

7.12.4.4 TSU Conversion

ADC converts the temperature that TSU IP outputs to 12bit data. Start and stop the TSU each time temperature measurement is required, or keep the TSU always on.(For details on TSU control, see the chapter “TSU”.)

7.12.4.4.1 TSUMODE register

1. Stop an operation of ADC. (See **7.12.4.3.2 Procedure for Stopping A/D Conversion**)
   If the temperature sensor is not operating, start control from the temperature sensor register.
2. Set TSUMODE.TSUEN to 1b.
3. Set ADM3.ADSMP[7:0] to H’FF.
4. Set ADM0.ADCE to 1b to start ADC operation.
   The temperature data is converted every 2.84 µs, and 12-bit conversion data is stored in ADCR8 register.
5. Read data from ADCR8 register. Calculate the temperature with Tj correction. (See the section “Procedure for Measuring the Temperature” in chapter TSU)
6. After temperature calculation, set ADM0.ADCE to 0b to stop ADC operation.
7. Set TSUMODE.TSUEN to 0b.
   In the case of stopping the temperature sensor, stop it with temperature sensor register.

7.12.5 Notes

7.12.5.1 Timing Restrictions

This A/D converter has restrictions on the timing interval, which are caused by the asynchronism countermeasure circuit. The restrictions shown in **Table 7.12-6** need to be met. If an access is made in a period shorter than this interval, the register values on the ADC1_PCLK (P20ϕ) side are not reflected in the registers on the ADC1_ADCLK (P20ϕ) side because the notification of register update does not reach the ADC1_ADCLK (P20ϕ) side.

Table 7.12-6 Restrictions on Timing Interval

Condition	Restriction
Writing to the same register successively	(Interval of write access) ≥ (6 × ADC1_PCLK(P20ϕ) + 6 × ADC1_ADCLK(P20ϕ))
Interval of A/D conversion	(A/D conversion time) ≥ (6 × ADC1_PCLK(P20ϕ) + 6 × ADC1_ADCLK(P20ϕ))

Note: For the A/D conversion time, see **Figure 7.12-2**.

7.12.5.2 Restrictions on ADC1_PCLK(P20ϕ) and ADC1_ADCLK(P20ϕ) Cycles

The ADC1_PCLK(P20ϕ) and ADC1_ADCLK(P20ϕ) cycles need to satisfy the relation in the following formula.

$$\mathrm{ADC1_ADCLK(P20\phi)} \leq \frac{(\text{A/D conversion time})}{6} - \mathrm{ADC1_PCLK(P20\phi)}$$

Note: For the A/D conversion time, see **Figure 7.12-2**.

7.12.5.3 Operation when Stopping or Restarting A/D Conversion

When 0 is written to the ADCE bit in the ADM0 register, the A/D converter stops A/D conversion. A/D conversion is restarted by writing 0 to the ADCE bit in the ADM0 register once and then writing 1 to the same bit. Even though there was an instruction to stop A/D conversion, A/D conversion may not stop immediately. **Table 7.12-7** shows the operation for stopping conversion and also the operation for restarting conversion after it has been stopped.

Table 7.12-7 Operation when Stopping or Restarting A/D Conversion with the ADCE Bit

A/D Conversion Modes					Timing for Stopping Conversion when Stop is Instructed with ADCE = 0	Operation for Restarting Conversion
Trigger		Operating Mode	Conversion Count	Buffer Count		
Mode	Input					
Software	—	Select	Repeat	1	Stopped on completion of 1-time conversion.	TSU conversion proceeds

SECTION 8 AUDIO

8.1 Audio Overview

This section describes the audio unit modules of this LSI, refer to the section of each unit.

■ Serial Sound Interface (SSIF-2) (See 8.5)

This LSI equips 4 channels of SSIF-2. The SSIF-2 transmits and receives audio data to and from various devices that are compatible with I2S format, monaural format and TDM format.

■ SPDIF Interface (SPDIF) (See 8.6)

This LSI equips 1 channel of SPDIF. The SPDIF is an interface that complies with the IEC60958 standard.

■ Pulse Density Modulation (PDM) (See 8.7)

The PDM has 3 PDM function channels and allows independent operation of each channel.

SECTION 8 AUDIO

8.5 Serial Sound Interface (SSIF-2)

8.5.1 Overview

The serial sound interface (SSIF-2) transmits and receives audio data to and from various devices that are compatible with I^2S format, monaural format and TDM format.

8.5.1.1 Features

Table 8.5-1 Features of SSIF-2 (1/2)

Item		Description
Number of interfaces		4
Communication mode		• Master/slave • Full-duplex communication is available.
Communication format		• I^2S format • Monaural format • TDM format
Serial data		• MSB first • Data can be left-justified or right-justified. • Data delay (one clock cycle) or no delay selectable for the period from SSI_RCK to SSI_TXD/SSI_RXD • System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits • Data word length: 8, 16, 18, 20, 22, 24, or 32 bits • Padding polarity: Low or high
Bit clock (SSIBCK)	In master mode	• Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128. • Supply/stop of SSI_BCK is selectable while communication is halted.
	In slave mode	SSI_BCK input method: Direct input or via the noise canceller
	In master/slave mode	Polarity: Rising/falling edge canceler
Left and right clock/frame synchronization (SSILRCK/SSIFS)	In master mode	• Polarity: Low/high level selectable • Supply/stop of SSI_RCK is selectable while communication is halted.
	In slave mode	Two input methods: Direct input or via the noise canceller
Transmit data (SSITxD) and receive data (SSIRxD)	Transmission	Mute: Transmission of transmit FIFO data or fixed value 0 selectable
	Reception (in slave mode)	Two input methods: Direct input or via the noise canceller
FIFO	Capacity	• Transmit FIFO/receive FIFO: 4 bytes × 32 stages, • Receive FIFO: 4 bytes × 32 stages
	Data alignment	Method of data transfer between FIFO and shift register (Left-justification and right-justification) selectable.

Table 8.5-1 Features of SSIF-2 (2/2)

Item		Description
Interrupt	Interrupt output	• Communication error/idle mode error (level) • Receive data full interrupt (edge) • Transmit data empty interrupt (edge) • Receive data full/transmit data empty interrupt (edge)
	Interrupt capture spilling solution function	Edge Interrupt supports inhibition function of capture spilling.
Low power consumption function		Supply/stop of audio clock is selectable in master-mode communication.

The definition of words and phrases used by the format of the communication of SSIF-2 is as follows.

Table 8.5-2 Word Definition List

Word	Definition
Start trigger	The first edge that reaches value that set to LRCKP in SSI_RCK pin after SSIF-2 permit communication.
Frame boundary	When SSIF-2 begins to transmit the first data of one frame. When SSIF-2 forwarding ends final data of one frame.
Frame word number	Sound channel number in one frame
System word length	Bit length in one frame.
Data word length	Effective bit length in one frame.
Control bit of communication format	• SSICR register: FRM,DWL,SWL,LRCKP,SPDP,SDTA,PDTA,DEL • SSIFCR register: BSW • SSIOFR register: OMOD • SSISCR register: TDES, RDFS

Figure 8.5-3 shows the clock configuration of SSIF-2.

[Legend]

SSICR: Control register

SSIFCR: FIFO control register

Note: Switch the above SFRs while communication is halted.

Note 1. N.C. (Noise canceller)

Figure 8.5-3 SSIF-2 Clock Configuration

8.5.2 Input/Output Pins

Table 8.5-3 shows the pin configuration

Table 8.5-3 Pin Configuration

Interface	Pin Name	Signal name in this section	Input/Output	Functional description
Common	AUDIO_CLK_B	AUDIO_CLK1	Input	External clock1 for audio (The oversampling clock signal is input.)
	AUDIO_CLK_C	AUDIO_CLK2	Input	External clock2 for audio (The oversampling clock signal is input.)
0, 1, 2, 3 (n = 0,1, 2, 3)	SSIFn_RXD	SSIn_RXD	Input	Serial data input
	SSIFn_BCK	SSIn_BCK	I/O	Bit clock
	SSIFn_RCK	SSIn_RCK	I/O	LR clock/frame synchronization
	SSIFn_TXD	SSIn_TXD	Output	Serial data output

8.5.3 List of Registers

Table 8.5-4 shows the register configuration of SSIF-2. The address of the SSIF-2 register is represented by the offset address from the base address. SSIF-2 base address is as follows:

- SSIF-2 base address: H'0_100E_4000 (ch0), H'0_100E_4400 (ch1), H'0_100E_4800 (ch2), H'0_100E_4C00 (ch3) (Overall Address Space)
- SSIF-2 base address: H'400E_4000 (ch0), H'400E_4400 (ch1), H'400E_4800 (ch2), H'400E_4C00 (ch3) (Cortex-M33 Address Space Secure)
- SSIF-2 base address: H'500E_4000 (ch0), H'500E_4400 (ch1), H'500E_4800 (ch2), H'500E_4C00 (ch3) (Cortex-M33 Address Space Non-Secure)

Table 8.5-4 List of Control Registers (1/2)

Channel	Register Name	Symbol	R/W	Initial Value	Address	Access Size
0	Control register	SSICR	RW	H'0000_0000	H'00	32 bits
	Status register *Note*: Bits 31, 30, and 25 to 0 are read only.	SSISR	RW	H'0200_0000	H'04	32 bits
	FIFO control register	SSIFCR	RW	H'0000_0000	H'10	32 bits

Table 8.5-4 List of Control Registers (2/2)

Channel	Register Name	Symbol	R/W	Initial Value	Address	Access Size
2	Control register	SSICR	RW	H'0000_0000	H'00	32 bits
	Status register *Note*: Bits 31, 30, and 25 to 0 are read only.	SSISR	RW	H'0200_0000	H'04	32 bits
	FIFO control register	SSIFCR	RW	H'0000_0000	H'10	32 bits
	FIFO status register *Note*: Bits 31 to 17 and 15 to 1 are read only.	SSIFSR	RW	H'0001_0000	H'14	32 bits
	Transmit FIFO data register	SSIFTDR	W	H'0000_0000	H'18	32 bits, 16 bits, 8 bits
	Receive FIFO data register	SSIFRDR	R	H'0000_0000	H'1C	32 bits, 16 bits, 8 bits
	Audio format register	SSIOFR	RW	H'0000_0000	H'20	32 bits
	Status control register	SSISCR	RW	H'0000_0000	H'24	32 bits
3	Control register	SSICR	RW	H'0000_0000	H'00	32 bits
	Status register *Note*: Bits 31, 30, and 25 to 0 are read only.	SSISR	RW	H'0200_0000	H'04	32 bits
	FIFO control register	SSIFCR	RW	H'0000_0000	H'10	32 bits
	FIFO status register *Note*: Bits 31 to 17 and 15 to 1 are read only.	SSIFSR	RW	H'0001_0000	H'14	32 bits
	Transmit FIFO data register	SSIFTDR	W	H'0000_0000	H'18	32 bits, 16 bits, 8 bits
	Receive FIFO data register	SSIFRDR	R	H'0000_0000	H'1C	32 bits, 16 bits, 8 bits
	Audio format register	SSIOFR	RW	H'0000_0000	H'20	32 bits
	Status control register	SSISCR	RW	H'0000_0000	H'24	32 bits

Note: Access to the addresses other than those listed above is prohibited.

8.5.4 Function Details

8.5.4.1 Register Descriptions

8.5.4.1.1 Control Register (SSICR)

This is a 32-bit readable/writable register. With this register, select an audio clock, control IRQ, select data formats, and set an operation mode.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	—	0	R	Reserved. Write 0. The read value is 0.
14	MST	0	RW	Master enable*1 0: Slave-mode communication 1: Master-mode communication
13	BCKP	0	RW	Selects bit clock polarity*1 0: SSILRCK/SSIFS and SSIFTxD/SSIFRxD change at a falling edge (sampling SSILRCK/SSIFS and SSIFRxD at a rising edge of SSIBCK). 1: SSILRCK/SSIFS and SSIFTxD/SSIFRxD change at a rising edge (sampling SSILRCK/SSIFS and SSIFRxD at a falling edge of SSIBCK).
12	LRCKP	0	RW	Selects the initial value and polarity of LRCK/FS*1 0: The initial value is at a high level For SSILRCK/SSIFS, one frame start trigger is falling edge of SSILRCK/SSIFS. 1: The initial value is at a low level For SSILRCK/SSIFS, one frame start trigger is rising edge of SSILRCK/SSIFS.
11	SPDP	0	RW	Selects serial padding polarity*1 0: Padding data is at a low level 1: Padding data is at a high level
10	SDTA	0	RW	Selects serial data alignment*1 0: Transmits and receives serial data first and then padding bits. 1: Transmit and receives padding bits first and then serial data.
9	PDTA	0	RW	Selects placement data alignment*1 0: Left-justifies placement data (SSIFTDR, SSIFRDR) 1: Right-justifies placement data (SSIFTDR, SSIFRDR)
8	DEL	0	RW	Selects serial data delay*1 0: Delay of one cycle of SSIBCK between SSILRCK/SSIFS and SSIFTxD/SSIFRxD. 1: No delay between SSILRCK/SSIFS and SSIFTxD/SSIFRxD. This bit control SSILRCK/SSIFS in monaural format (Refer to **8.5.4.2.2 Monaural Format** for details).

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	CKDV[3:0]	H'0	RW	Selects bit clock division ratio*1 CKDV[3:0] 0000: AUDIO_MCK 0001: AUDIO_MCK/2 0010: AUDIO_MCK/4 0011: AUDIO_MCK/8 0100: AUDIO_MCK/16 0101: AUDIO_MCK/32 0110: AUDIO_MCK/64 0111: AUDIO_MCK/128 1000: AUDIO_MCK/6 1001: AUDIO_MCK/12 1010: AUDIO_MCK/24 1011: AUDIO_MCK/48 1100: AUDIO_MCK/96 1101: Setting prohibited 1110: Setting prohibited 1111: Setting prohibited
3	MUEN	0	RW	Mute (silent) enable 0: Disables muting on the next frame boundary. 1: Enables muting on the next frame boundary.
2	—	0	R	Reserved. Write 0. The read value is 0.
1	TEN	0	RW	Transmission and reception enable*2
0	REN	0	RW	(TEN, REN): Operating 00: Disables transmission and reception 01: Enables reception (starts reception) 10: Enables transmission (starts transmission) 11: Enables transmission and reception (starts transmission and reception)

Note 1. Writing to these bits while SSIF-2 is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If written, the operation performed immediately after writing is not guaranteed. For example, after enabling operation, make sure that SSISR.IIRQ = 0 and after disabling operation, make sure that SSISR.IIRQ = 1.

CKS Bit

This bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in **8.5.4.1.3 FIFO Control Register (SSIFCR)** for detailed timing.

TUIEN Bit

This bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

TOIEN Bit

This bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

RUIEN Bit

This bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

ROIEN Bit

This bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROIRQ = 1.

IIEN Bit

This bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

FRM[1:0] Bits

These bits set system word number in one frame of the communication formats.

Rewrite these bits when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in **8.5.4.1.7 Audio Format Register (SSIOFR)** for the output operation of the LR clock.

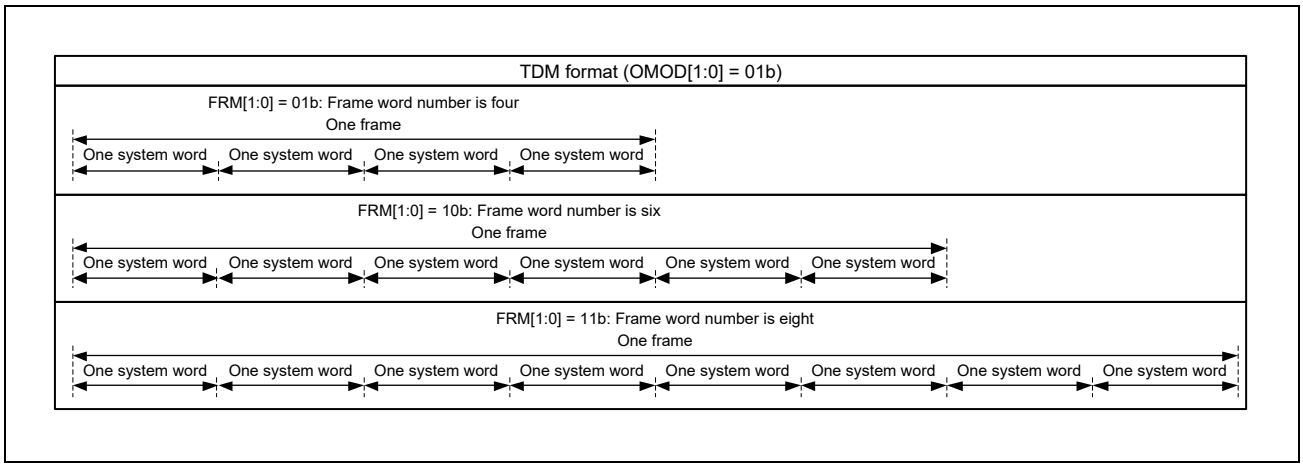

Figure 8.5-4 Frame Word Number

DWL[2:0] Bits

These bits set the number of bits in one data word. The setting whose number of data of system word lengths is shorter than that of the data word length is a prohibition. Refer to **Table 8.5-13** in **8.5.4.2 Communication Formats** for details.

SWL[2:0] Bits

These bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See **Table 8.5-13** in **8.5.4.2 Communication Formats** for details.

Rewrite these bits when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in **8.5.4.1.7 Audio Format Register (SSIOFR)** for the output operation of the LR clock.

MST Bit

This bit sets master-/slave-mode communication.

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in **8.5.4.1.3 FIFO Control Register (SSIFCR)** for detailed timing.

BCKP Bit

This bit sets the bit clock polarity (**Table 8.5-5**).

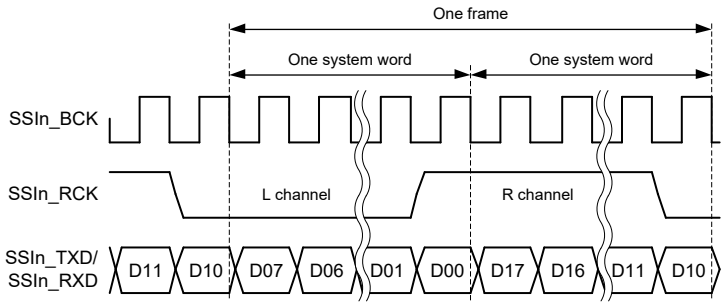
To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in **8.5.4.1.3 FIFO Control Register (SSIFCR)** for detailed timing.

Table 8.5-5 Bit Clock Polarity

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Reception	Slave	At SSILRCK/SSIFS sampling	SSIBCK rising edge	SSIBCK falling edge
	Master/slave	At SSIFRxD sampling	SSIBCK rising edge	SSIBCK falling edge
Transmission	Master	At change of SSILRCK/SSIFS output	SSIBCK falling edge	SSIBCK rising edge
	Master/slave	At change of SSIFTxD output	SSIBCK falling edge	SSIBCK rising edge

LRCKP Bit

This bit sets the initial value and polarity of SSILRCK/SSIFS. Set this bit according to the communication format to be used in SSIF-2 (**Table 8.5-6**). Only the start trigger is used at slave communication (MST=0).



Rewrite this bit when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in **8.5.4.1.7 Audio Format Register (SSIOFR)** for the output operation of the LR clock.

Table 8.5-6 Initial Output Value and Polarity of SSILRCK/SSIFS Pin

Communication Format	Expected Initial State	Setting Value of LRCKP
I^2S	H	0
Monaural	L	1
TDM	L	1

Note: Do the setting that can be communicated respectively to I^2S, monaural, and TDM at the compatible format.

System word length: 8 bits (SWL = 000b), Data word length: 8 bits (DWL = 000b),
LR clock polarity: L channel = low, R channel = high (LRCKP = 0)
Other control bits of communication format are at their initial values.

System word length: 8 bits (SWL = 000b), Data word length: 8 bits (DWL = 000b),
LR clock polarity: L channel = high, R channel = low (LRCKP = 1)
Other control bits of communication format are at their initial values.

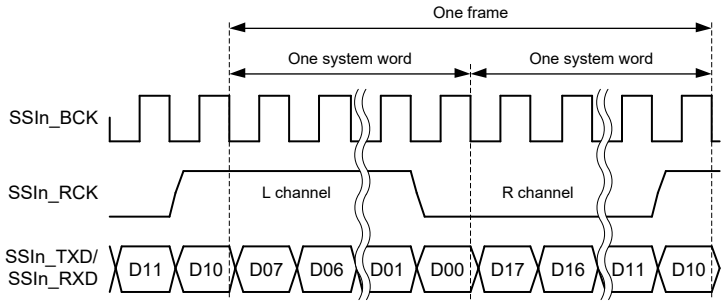


Figure 8.5-5 LRCK/FS Polarity Setting

SPDP Bit

This bit sets polarity of padding bits.

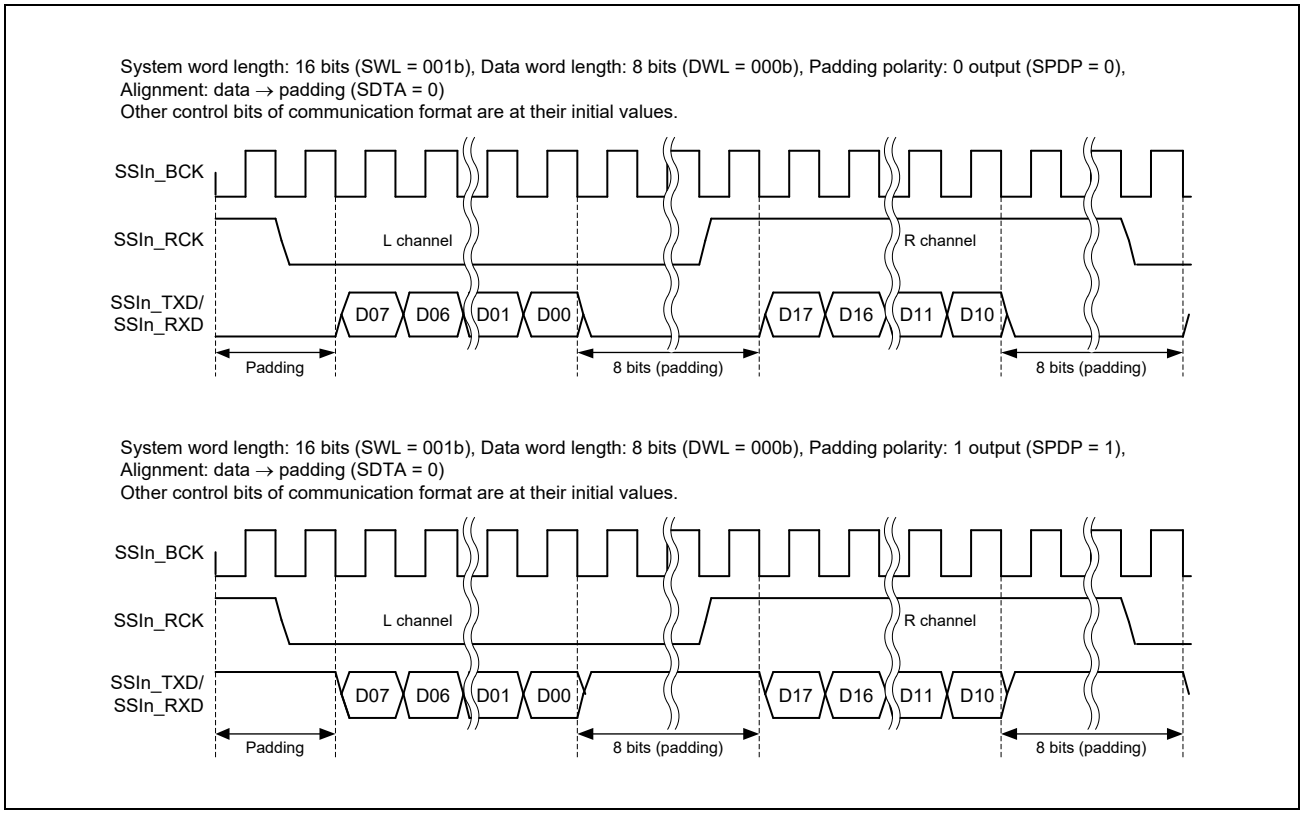

Figure 8.5-6 Padding Bit Polarity

SDTA Bit

This bit sets alignment of serial data (data bits and padding bits). For communication without padding bits, this bit is invalid.

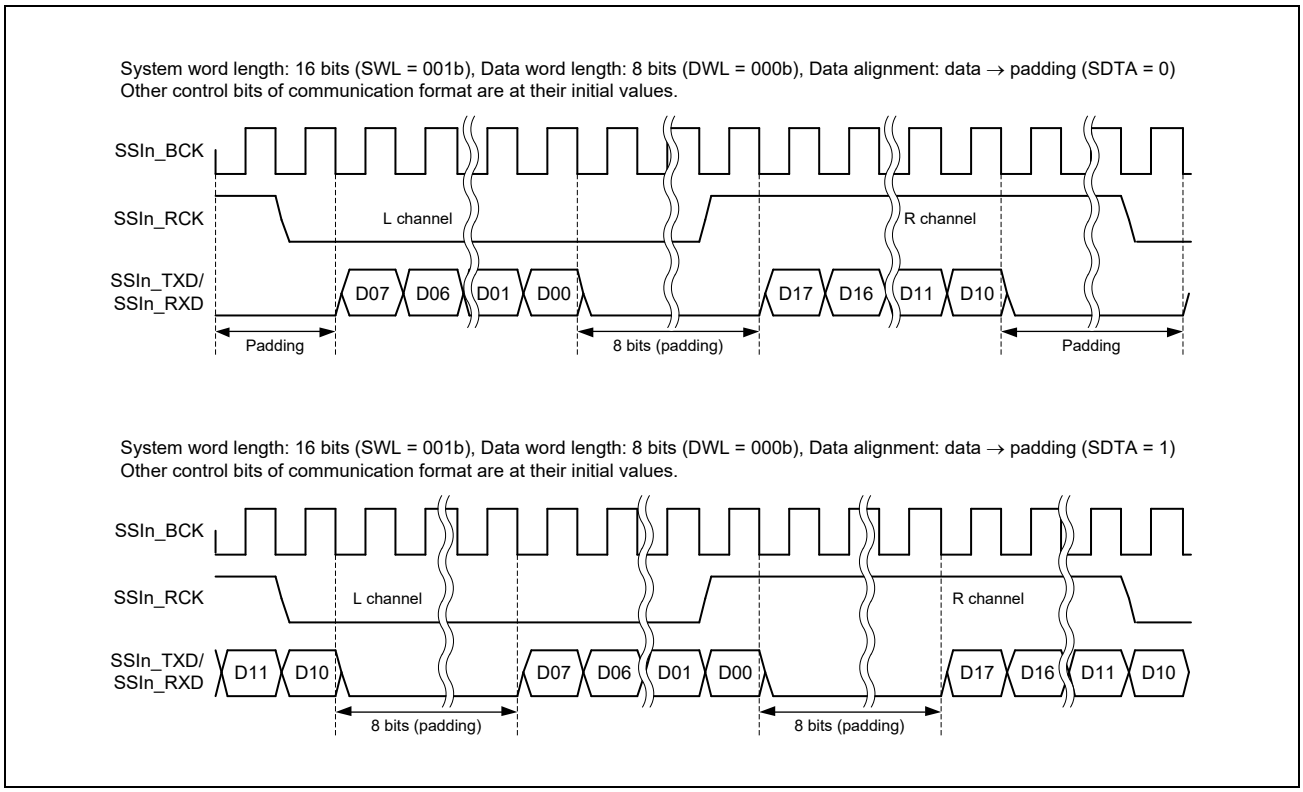

Figure 8.5-7 Alignment Setting of Serial Data with Padding Bits

PDTA Bit

This bit sets alignment of placement data. With the setting of data word length as 32 bits (DWL[2:0] = 110b), this bit is invalid.

- At transmission:

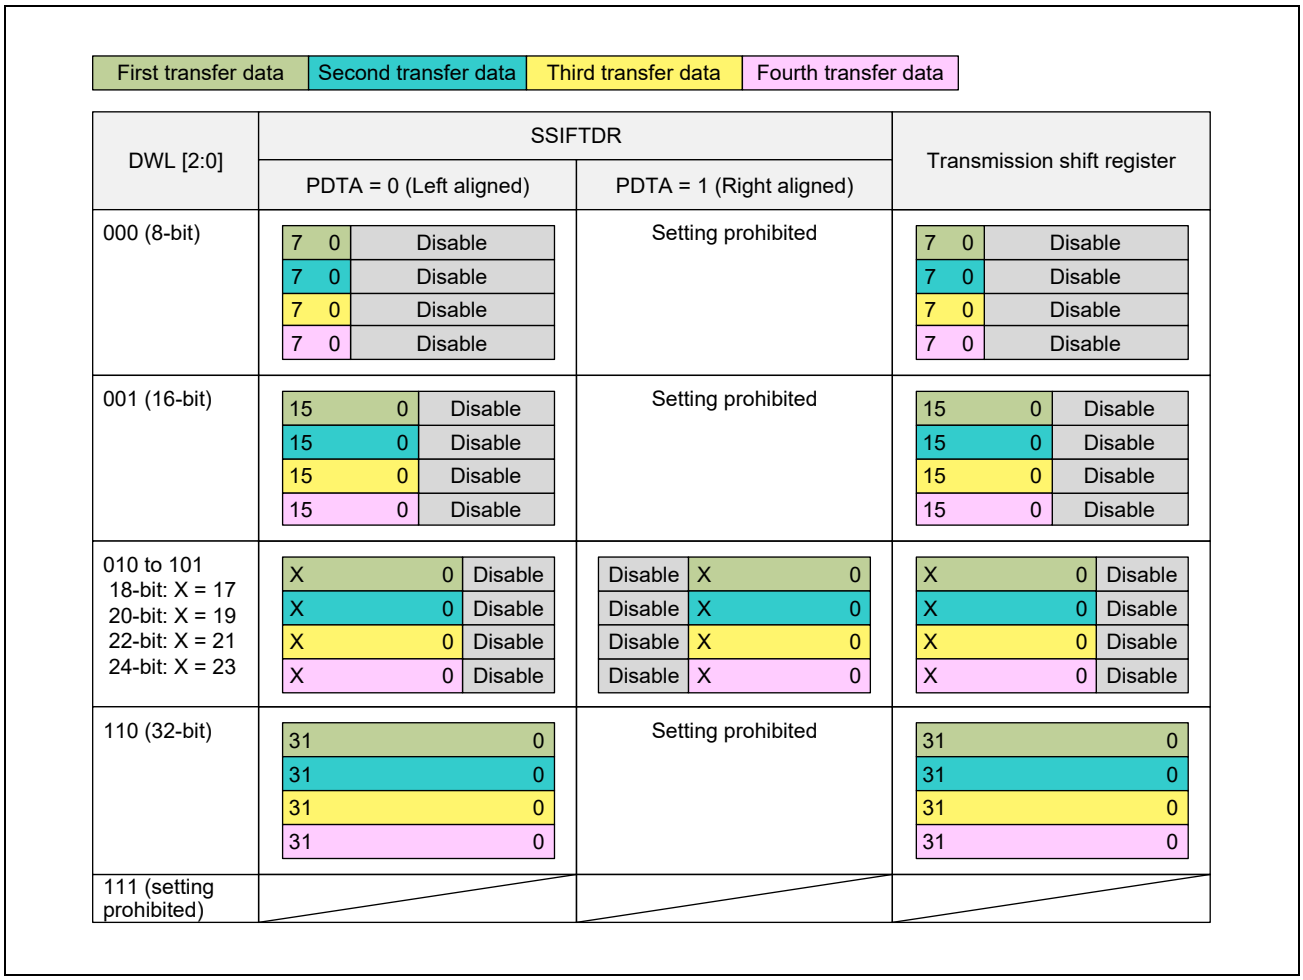

Figure 8.5-8 Alignment Setting of Placement Data in Transmission

- At reception:

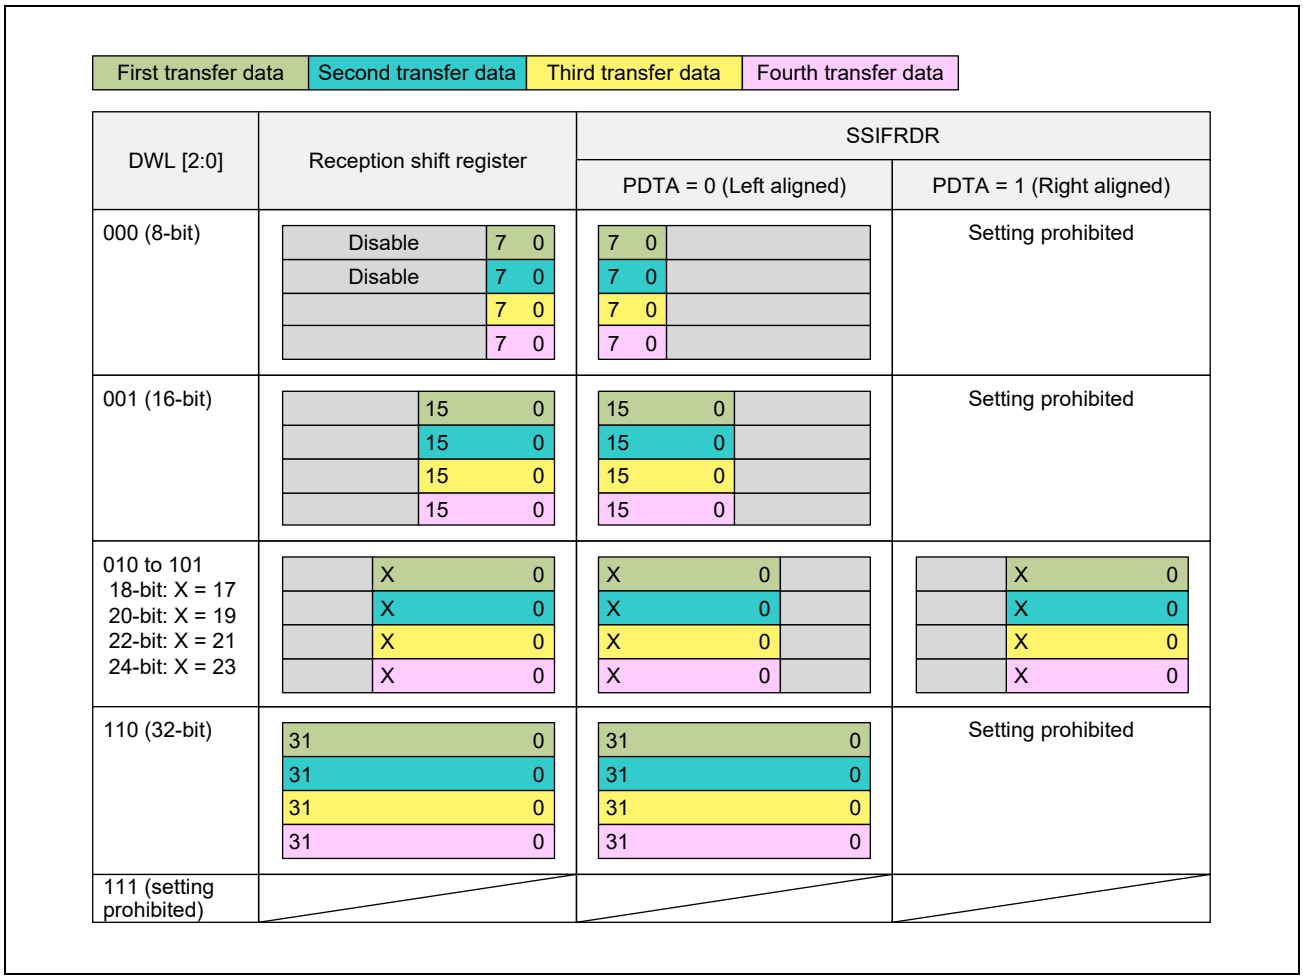

Figure 8.5-9 Alignment Setting of Placement Data in Reception

DEL Bit

This bit sets whether or not there will be a delay between SSILRCK/SSIFS and SSITxD/SSIRxD.

With the I²S format and TDM format, set 0 to DEL (**Figure 8.5-10**). With the monaural format, this bit changes the high period width. Refer to **8.5.4.2.2 Monaural Format** for details. Do the setting that can be communicated at the compatible communication format.

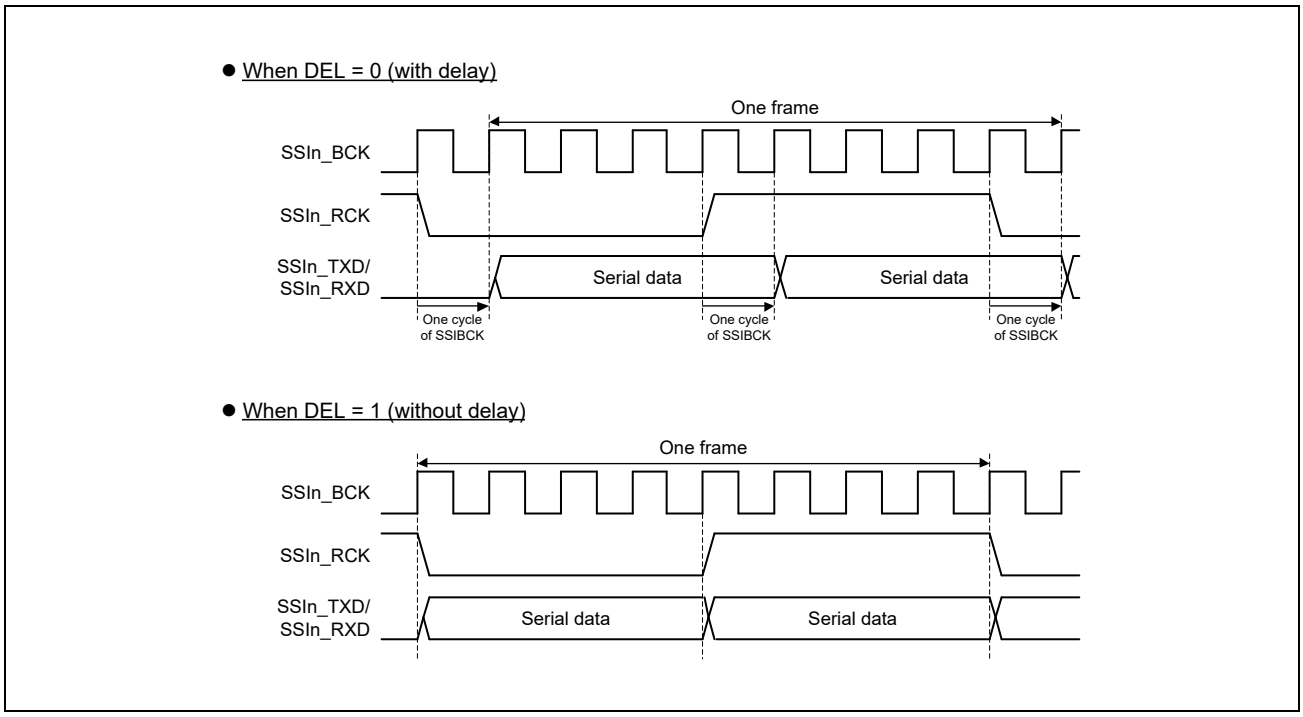

Figure 8.5-10 Setting of Delay in Serial Data

CKDV[3:0] Bits

These bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST = 1) (**Figure 8.5-11**). In slave-mode communication (MST = 0), setting of these bits are invalid.

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in **8.5.4.1.3 FIFO Control Register (SSIFCR)** for detailed timing.

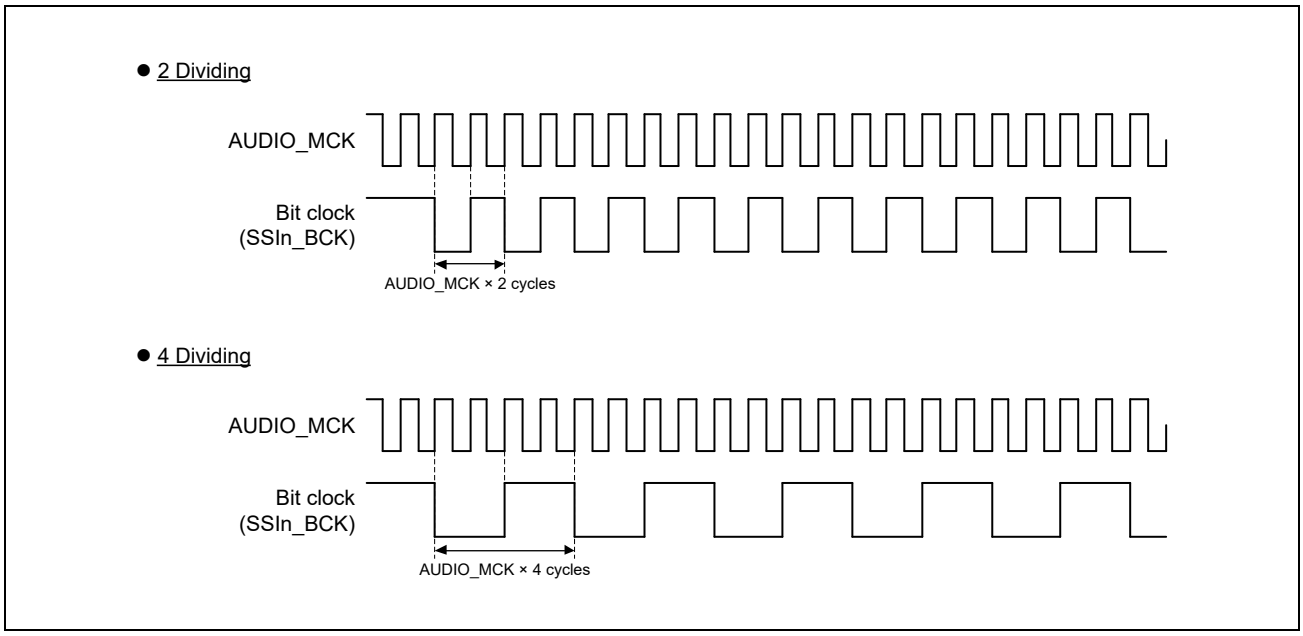

Figure 8.5-11 Sampling Frequencies in Master-mode Communication

MUEN Bit

This bit sets/clears the mute function for the data output from the terminal SSITxD. When you set this bit to 1, the output value of SSITxD becomes 0 from the next frame boundary. When you set this bit to 0, the output value of SSITxD can be made the data of the FIFO transmission data register from the following frame boundary.

Note that this bit controls data only. Status flags and interrupt signals are normally generated. Set this bit after setting completing the communication format.

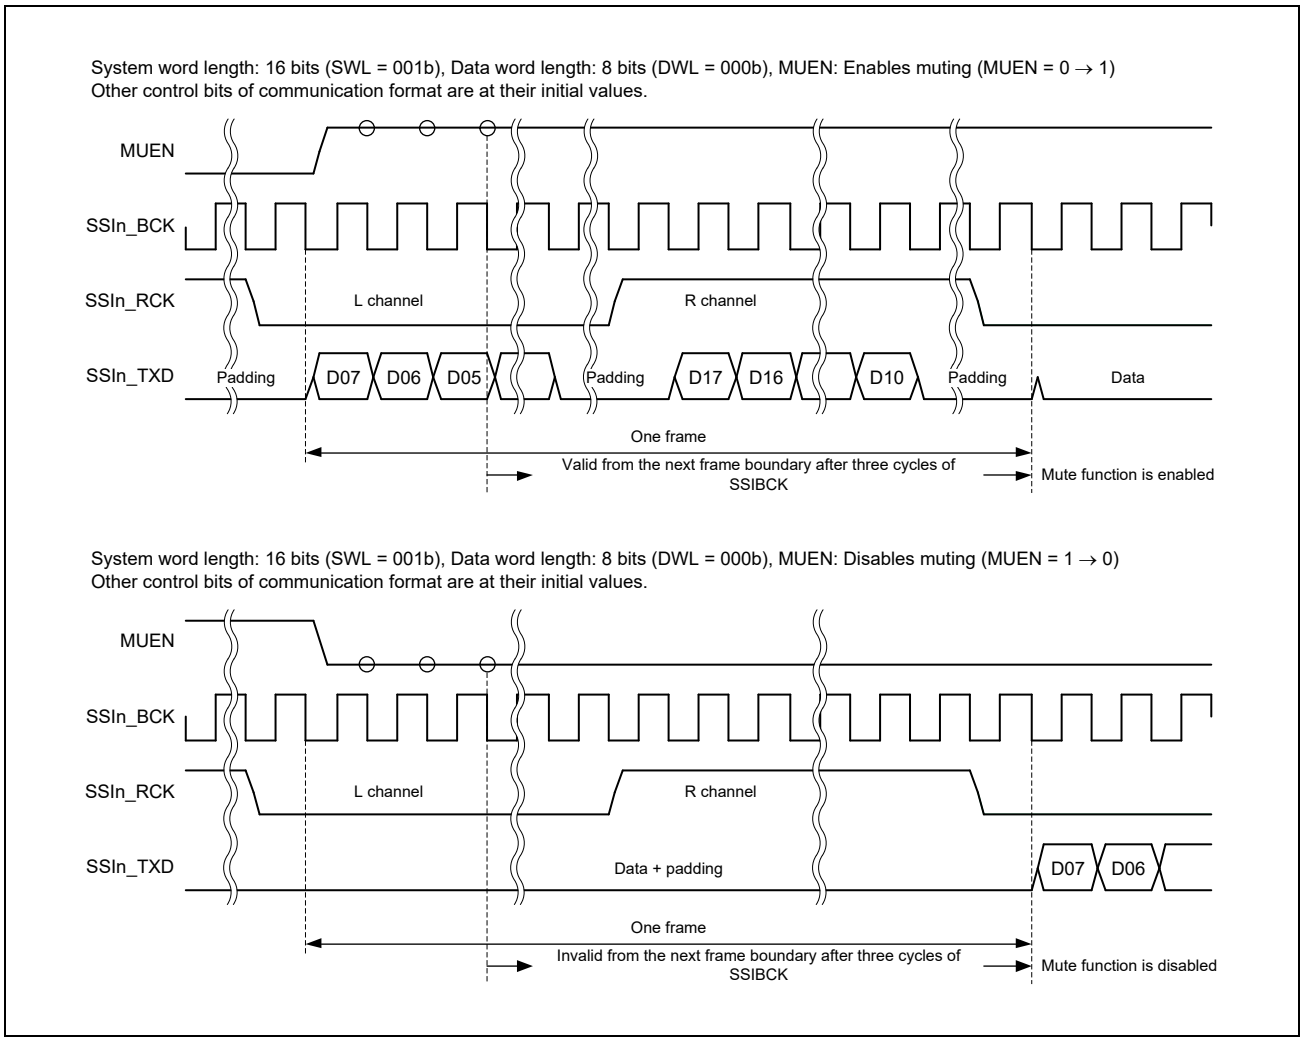

Figure 8.5-12 Transmit Data with the Mute Function Set

TEN and REN Bits

These bits enable/disable transmission and reception. Writing 1 to these bits, transmission starts in synchronization with start trigger. Refer to **8.5.5.2.2 Transmission**, **8.5.5.2.3 Reception**, and **8.5.5.2.4 Transmission and Reception** for details. Writing 0 to these bits, transmission stops in synchronization with next frame boundary. Set 1 at the same time when you use SSIF-2 as transmission and reception. To stop communication, make sure to stop transmission and reception (TEN = 0 and REN = 0).

To stop communication without waiting for the frame boundary, follow the software reset procedure.

8.5.4.1.2 Status Register (SSISR)

This is a readable/writable 32-bit register. It is configured with status flags that indicate SSIF-2 operational state.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W0	R/W0	R/W0	R/W0	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	00b	R	Reserved. Write 0. The read value is 0.
29	TUIRQ	0	RW0	Transmit underflow error status flag 0: No transmit underflow error is generated. 1: A transmit underflow error is generated.
28	TOIRQ	0	RW0	Transmit overflow error status flag 0: No transmit overflow error is generated. 1: A transmit overflow error is generated.
27	RUIRQ	0	RW0	Receive underflow error status flag 0: No receive underflow error is generated. 1: A receive underflow error is generated.
26	ROIRQ	0	RW0	Receive overflow error status flag 0: No receive overflow error is generated. 1: A receive overflow error is generated.
25	IIRQ	1	R	Idle mode status flag 0: In the communication state 1: In the idle state
24 to 0	—	H'000_0000	R	Reserved. Write 0. The read value is 0.

TUIRQ Bit

This is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing serial data necessary for one frame to SSIFTDR was slower than one frame of the transmission operation. Even if this flag is cleared after this flag becomes '1', the output value of SSIFTxD is 0. Follow the communication stop procedure (**Figure 8.5-55**) and the error procedure (**Figure 8.5-56**) to output the data written in transmission FIFO data register (SSIFTDR) to the terminal SSIFTxD. See **8.5.5.2.6 Error Handling** for the error recovery procedure. This flag is not cleared by transmission FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following is approved.

(1) Writing 0 to this flag after reading this flag as 1.*2

(2) When you do the communication permission (SSICR.TEN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this flag after reading this flag as 1 (**Figure 8.5-13**).

(2) Write 1 in SSICR.TEN, complete, and after one cycle of P0ϕ (**Figure 8.5-13**).

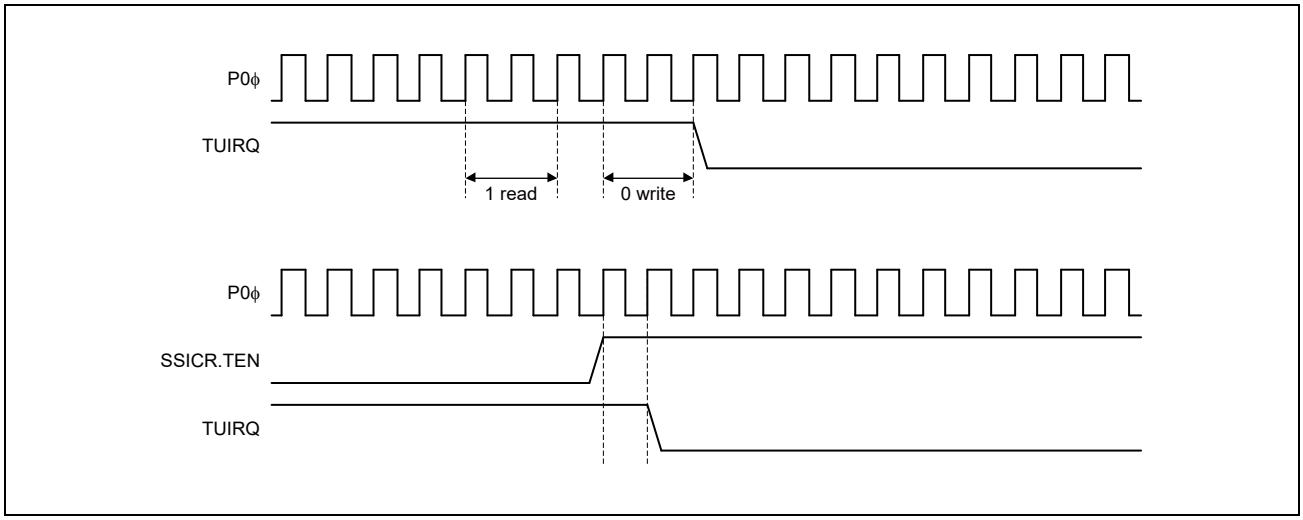

Figure 8.5-13 TUIRQ Clearing Timing

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:
- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P0ϕ elapsing after the completion of writing 1 to SSICR.TEN.

Remark After the communication is permitted (SSICR.TEN is written and '1' is written from '0'), the transmission error flag (TOIRQ and TUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the transmission error flag might not be able to be read.

[Setting condition]

When data to be transmitted in the next frame is not fully written to SSIFTDR at the frame boundary of continuance communication.

[Setting timing]

After three cycles of P0ϕ from frame boundary (**Figure 8.5-14**).

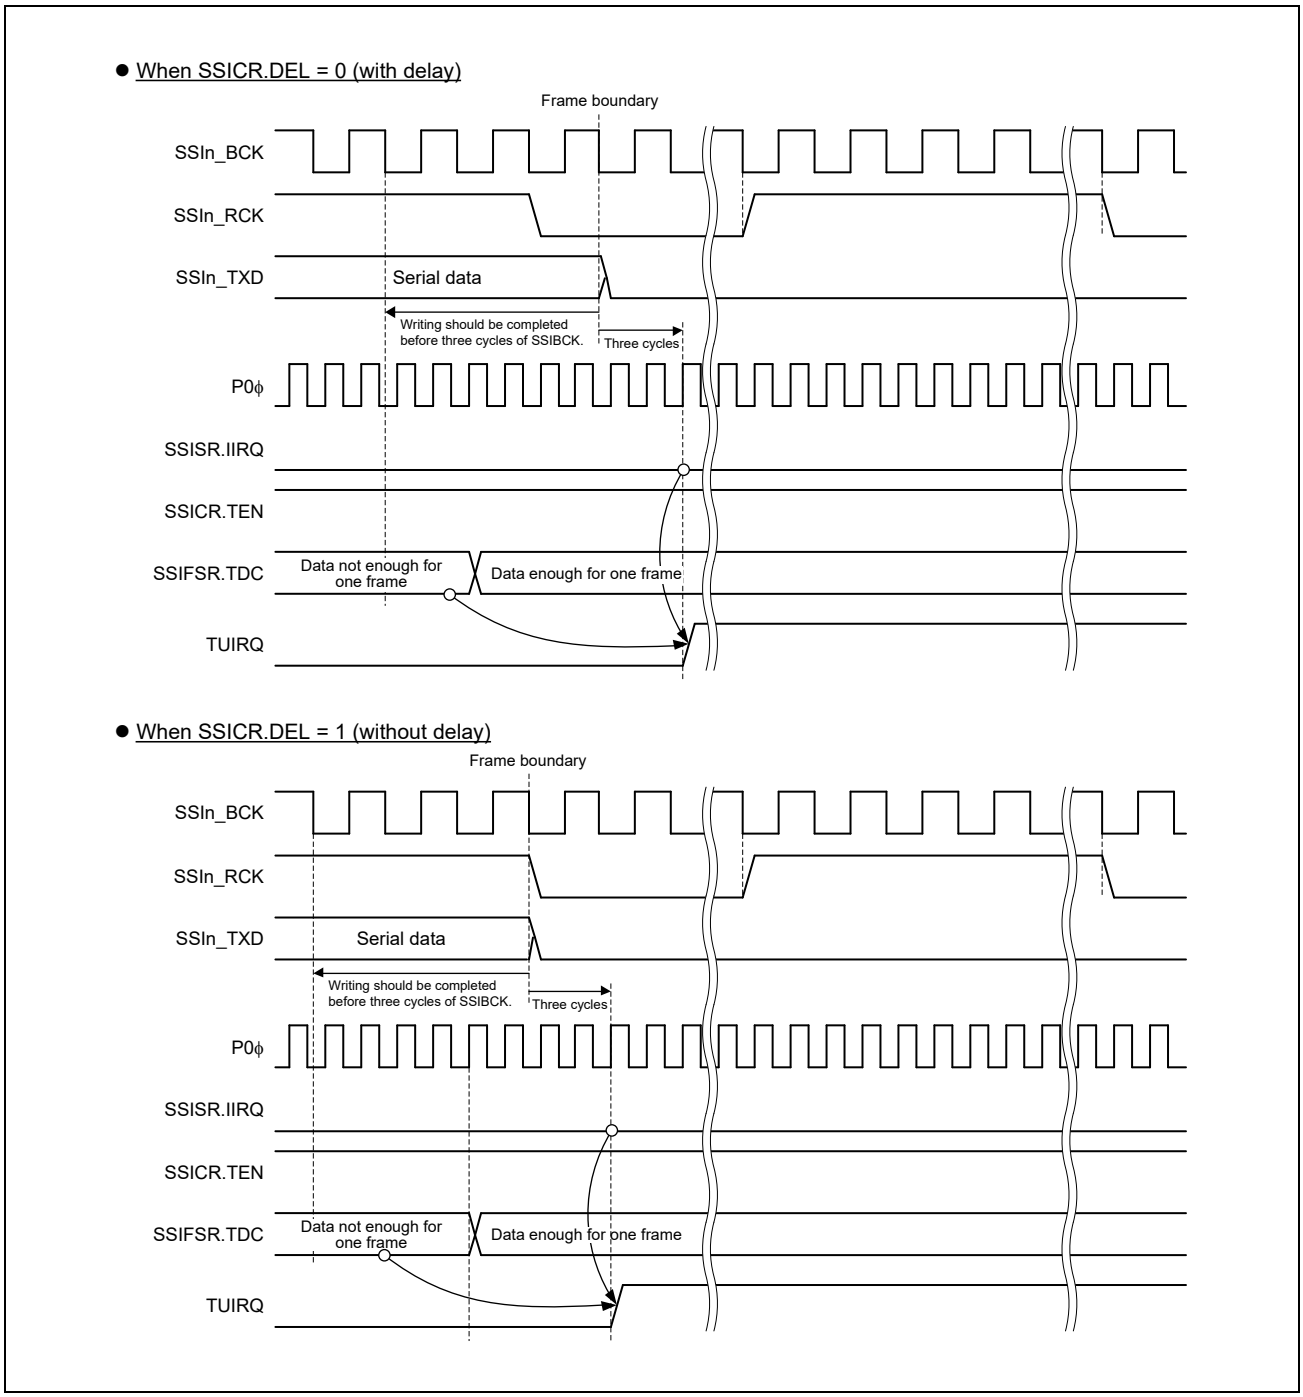

Figure 8.5-14 TUIRQ Setting Timing (when you continue communicating)

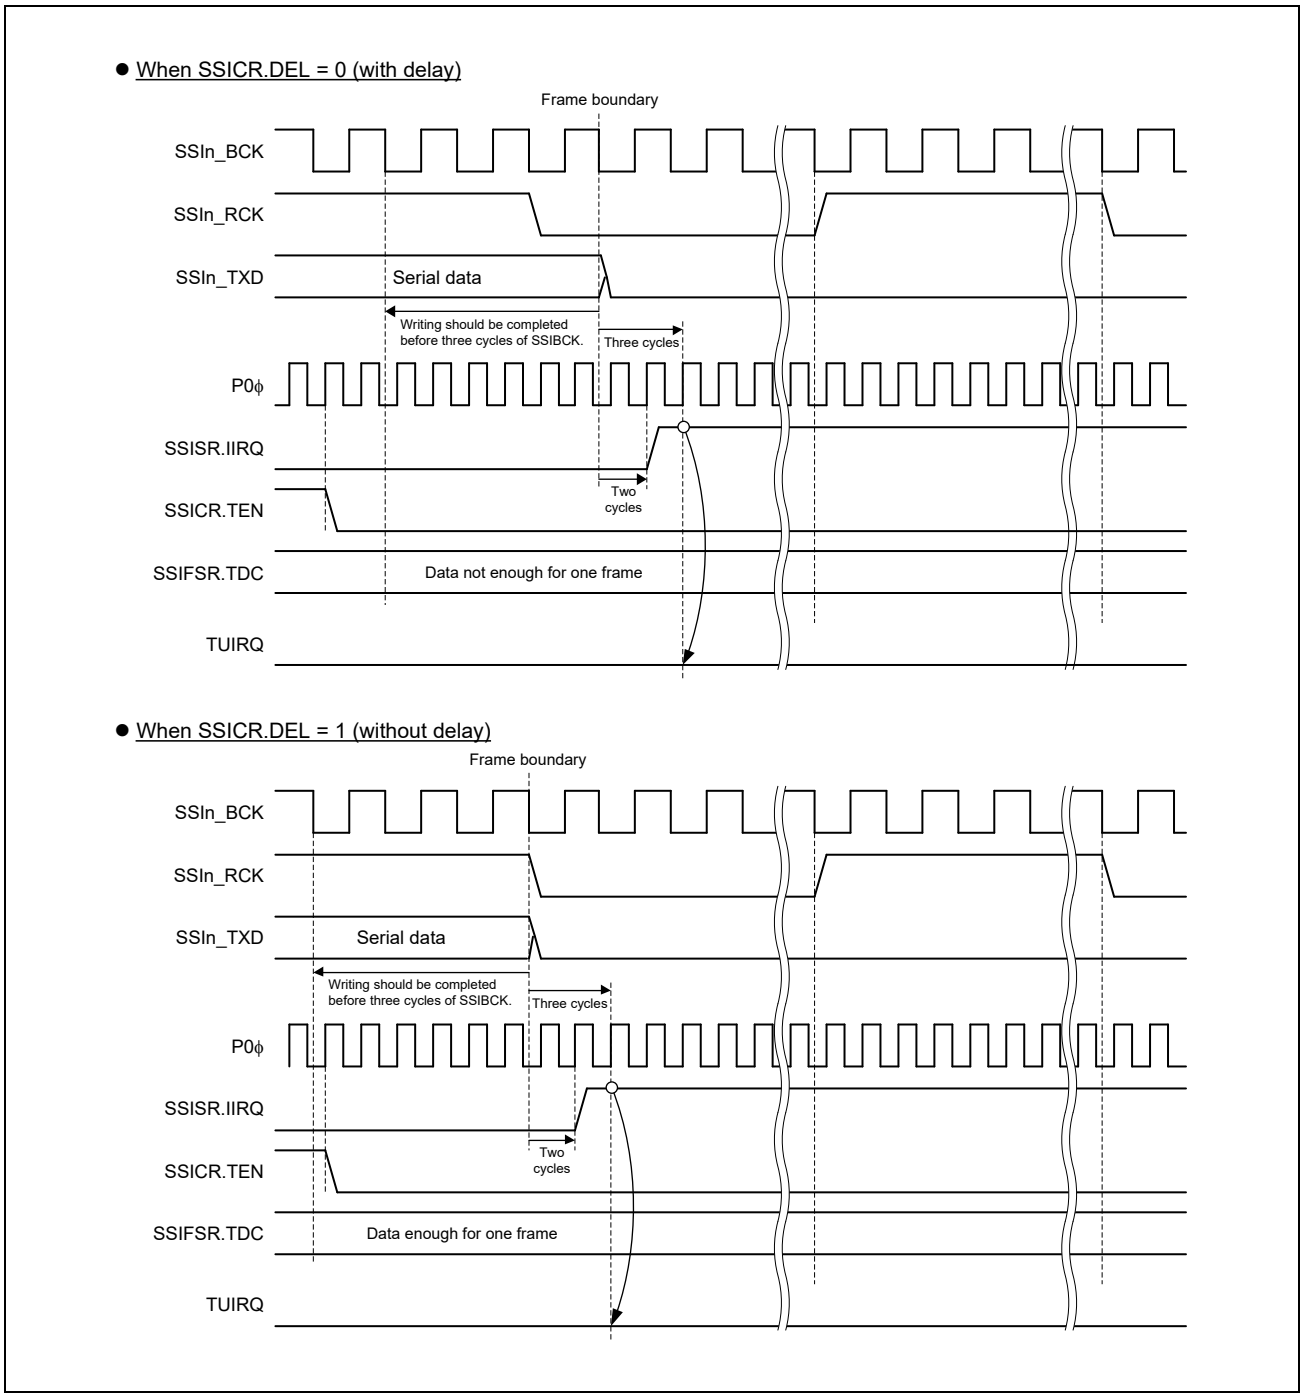

Figure 8.5-15 TUIRQ Setting Timing (when you stop communicating)

TOIRQ Bit

This is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that serial data is written to SSIFTDR when it is full during transmission (SSICR.TEN=1). Data is not written to SSIFTDR where a transmit overflow error is generated. See **8.5.5.2.6 Error Handling** for the error recovery procedure. This flag is not cleared by transmission FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following is approved.

(1) Writing 0 to this flag after reading this flag as 1.*2

(2) When you do the communication permission (SSICR.TEN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this flag after reading this flag as 1 (same as **Figure 8.5-13**).

(2) Write 1 in SSICR.TEN, complete, and after one cycle of P0ϕ (same as **Figure 8.5-13**).

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:
- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P0ϕ elapsing after the completion of writing 1 to SSICR.TEN.

Remark After the communication is permitted (SSICR.TEN is written and '1' is written from '0'), the transmission error flag (TOIRQ and TUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the transmission error flag might not be able to be read.

[Setting condition]

During transmission operation (SSICR.TEN = 1), data is written to SSIFTDR while it is full.

[Setting timing]

At completion of writing to SSIFTDR (**Figure 8.5-16**)

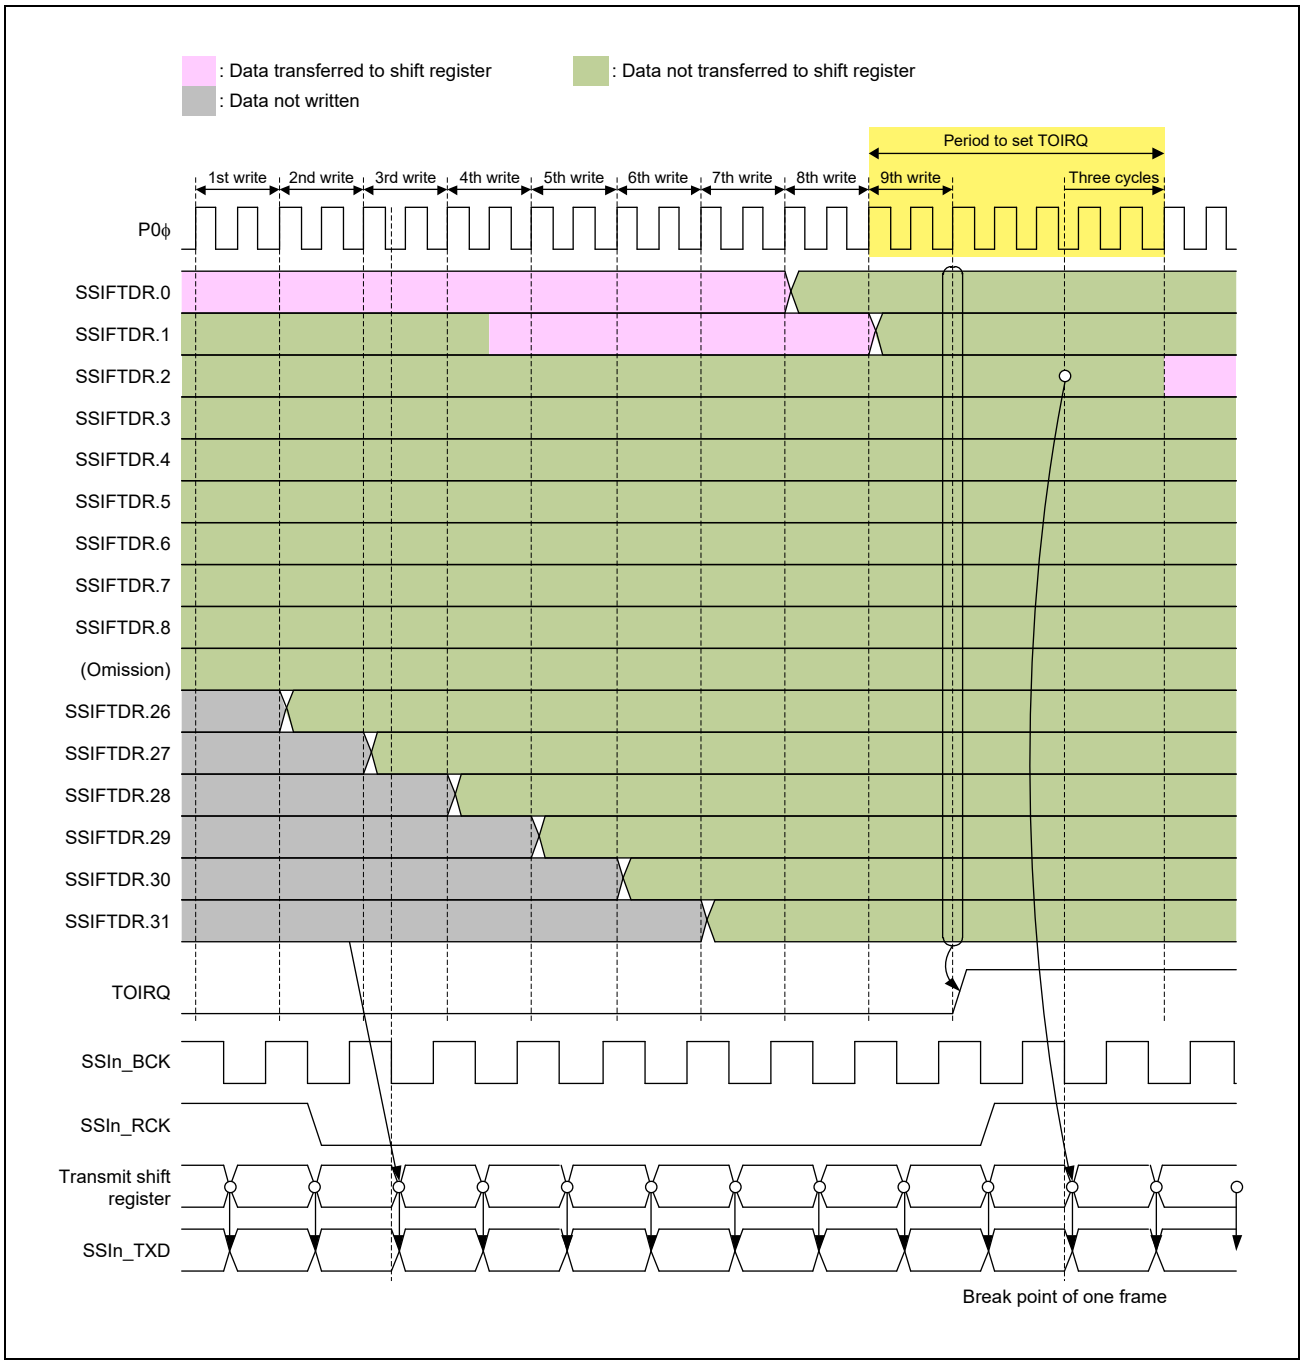

Figure 8.5-16 TOIRQ Setting Timing

RUIRQ Bit

This is a status flag that indicates a receive underflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See **8.5.5.2.6 Error Handling** for the error recovery procedure. This flag is not cleared by reception FIFO data register reset (SSIFCR.RFRST). Even if SSIFRDR is read to (SSIFCR.RFRST=1) while resetting reception FIFO data register, it doesn't set 1.

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following is approved.

(1) Writing 0 to this flag after reading this flag as 1.*2

(2) When you do the communication permission (SSICR.REN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this flag after reading this flag as 1 (same as **Figure 8.5-13**).

(2) Write 1 in SSICR.REN, complete, and after one cycle of P0ϕ (same as **Figure 8.5-13**).

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:
- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P0ϕ elapsing after the completion of writing 1 to SSICR.TEN.

Remark After the communication is permitted (SSICR.REN is written and '1' is written from '0'), the transmission error flag (ROIRQ and RUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the reception error flag might not be able to be read.

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR (**Figure 8.5-17**).

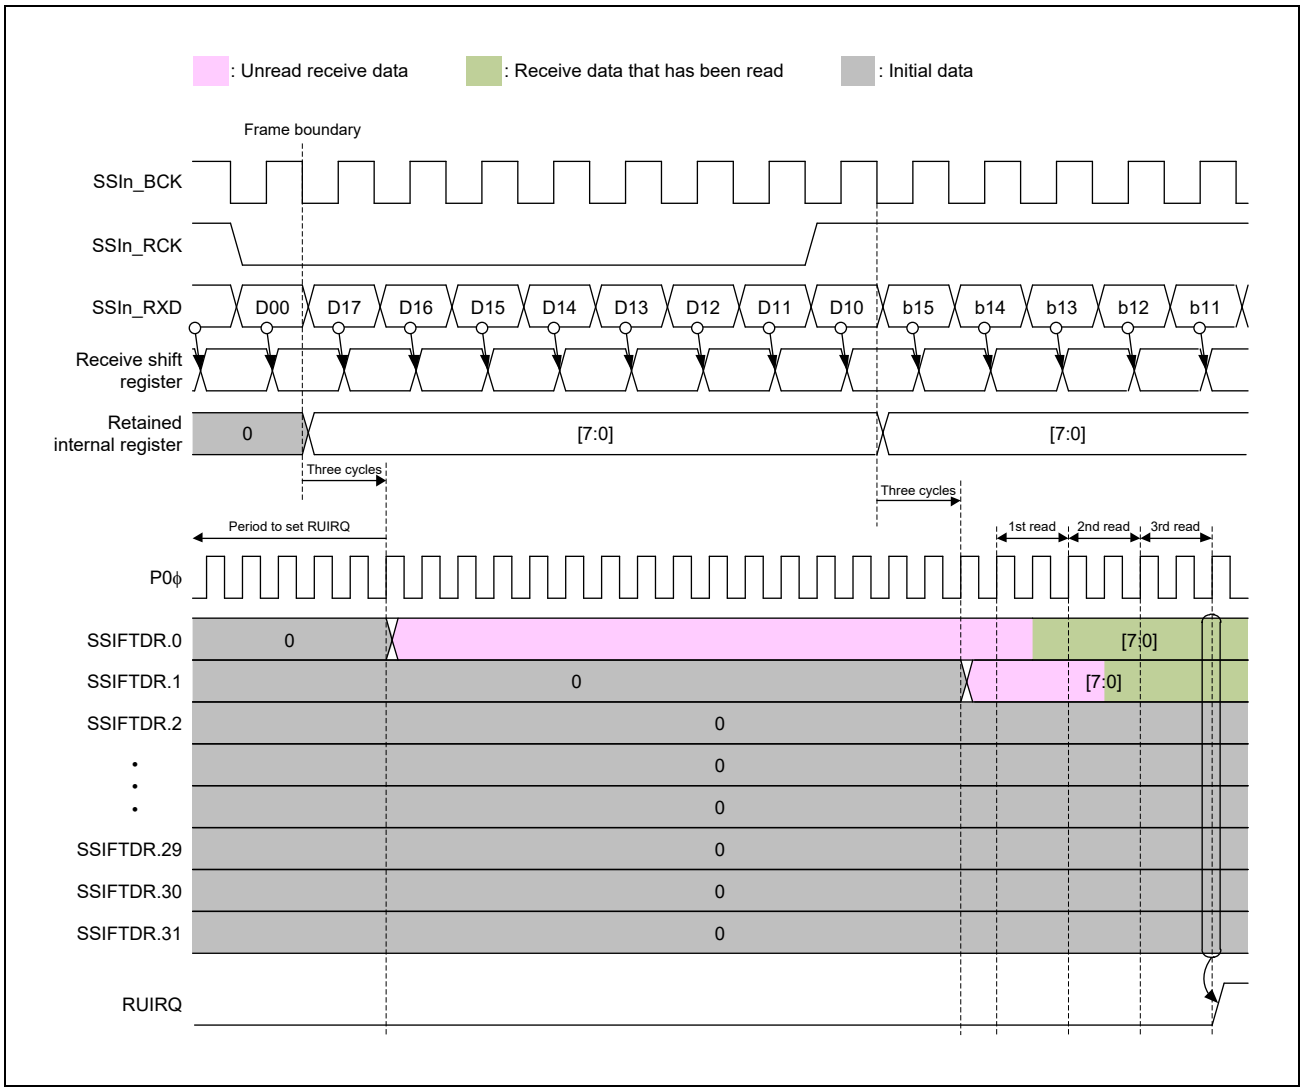

Figure 8.5-17 RUIRQ Setting Timing

ROIRQ Bit

This is a status flag that indicates a receive overflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. See **8.5.5.2.6 Error Handling** for the error recovery procedure. This flag is not cleared by reception FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.

[Clearing condition]

Writing 0 to this flag after reading this flag as 1.

[Clearing timing]

At completion of writing 0 after reading 1 from an SFR (same as **Figure 8.5-13**).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following is approved.

(1) Writing 0 to this flag after reading this flag as 1.*2

(2) When you do the communication permission (SSICR.REN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this flag after reading this flag as 1 (same as **Figure 8.5-13**).

(2) Write 1 in SSICR.REN, complete, and after one cycle of P0ϕ (same as **Figure 8.5-13**).

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:
- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P0ϕ elapsing after the completion of writing 1 to SSICR.TEN.

Remark After the communication is permitted (SSICR.REN is written and '1' is written from '0'), the transmission error flag (ROIRQ and RUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the reception error flag might not be able to be read.

[Setting condition]

At completion of receiving new data while SSIFRDR is full.

[Setting timing]

Three cycles of P0ϕ after reception is completed (**Figure 8.5-18**).

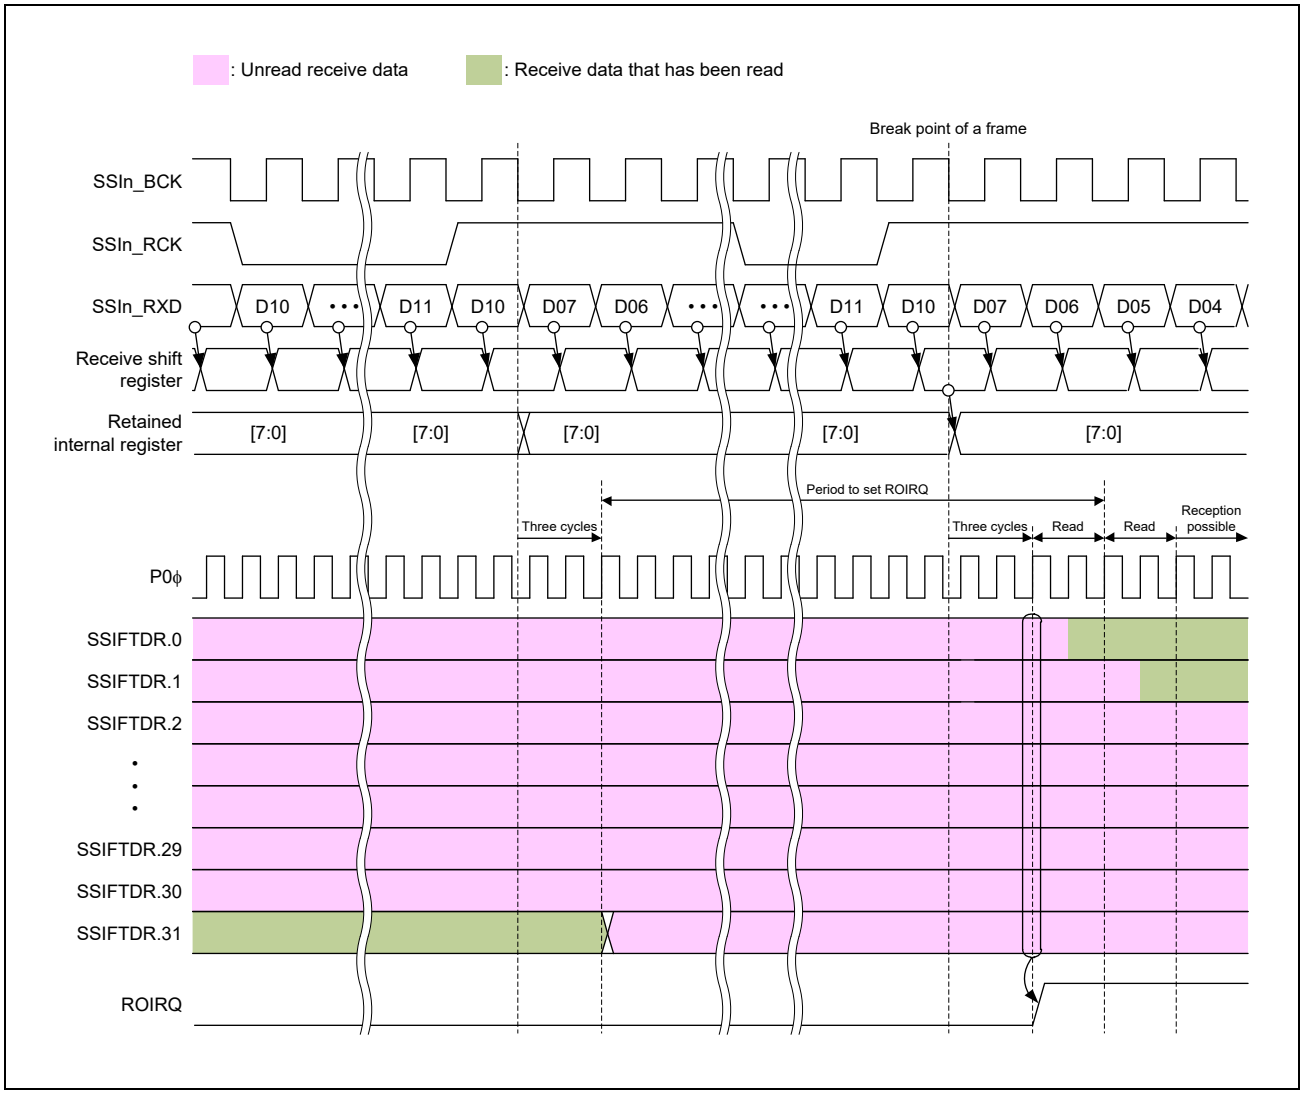

Figure 8.5-18 ROIRQ Setting Timing

IIRQ Bit

This is a status flag that indicates the idle state. It indicates whether SSIF-2 is in the idle state or communication state (**Figure 8.5-19** and **Figure 8.5-20**).

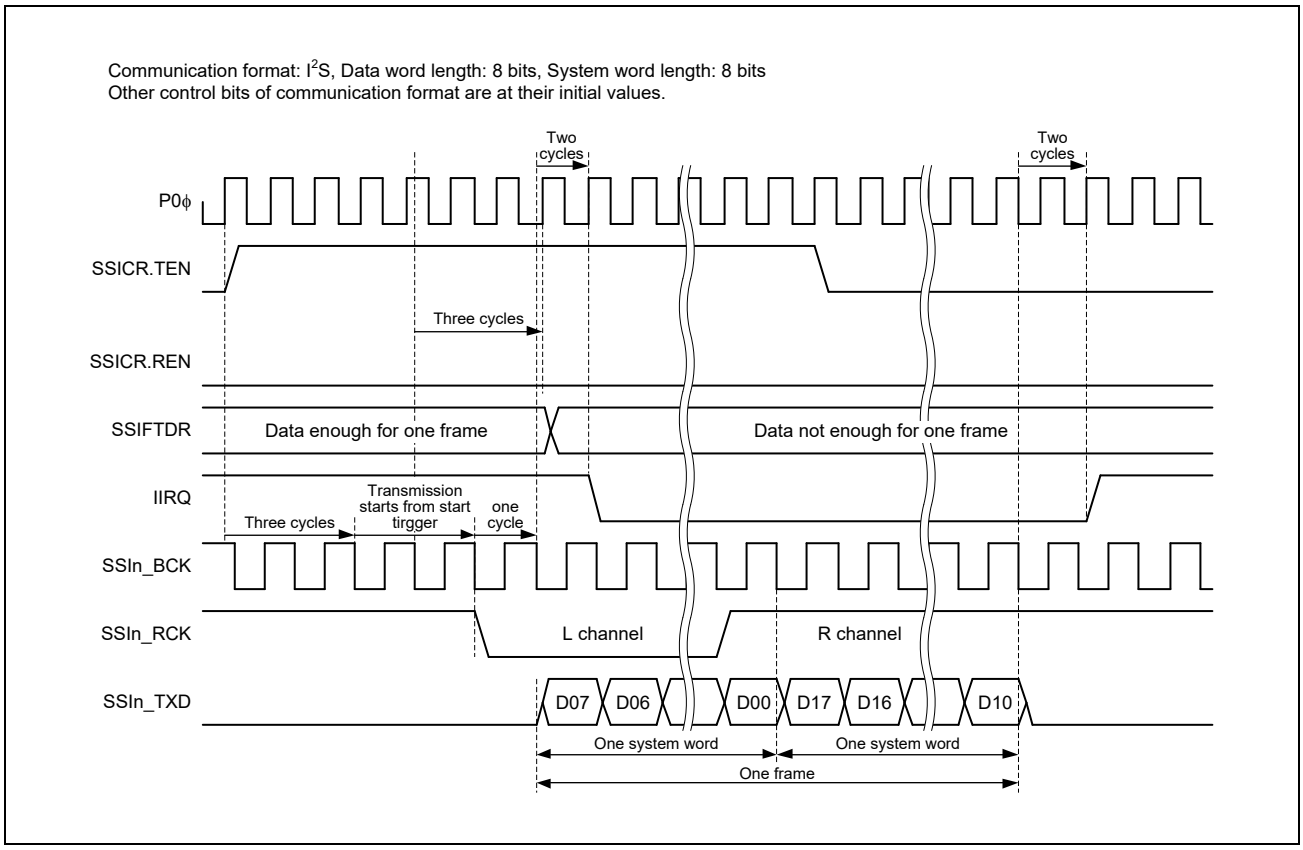

Figure 8.5-19 IIRQ Setting Timing (Transmission)

Transmitter (dedicated to transmission)

[Clearing condition]

While transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), one frame of data to be transmitted has been written to SSIFTDR, and a start trigger is generated in SSILRCK/SSIFS.

[Clearing timing]

Two cycles of P0ϕ after one cycle of SSIBCK where a start trigger is generated.

[Setting condition]

One frame of data has been transmitted while transmission and reception are disabled (SSICR.TEN = 0 and SSICR.REN = 0).

[Setting timing]

Two cycles of P0ϕ after transmission is complete according to the setting condition (frame boundary).

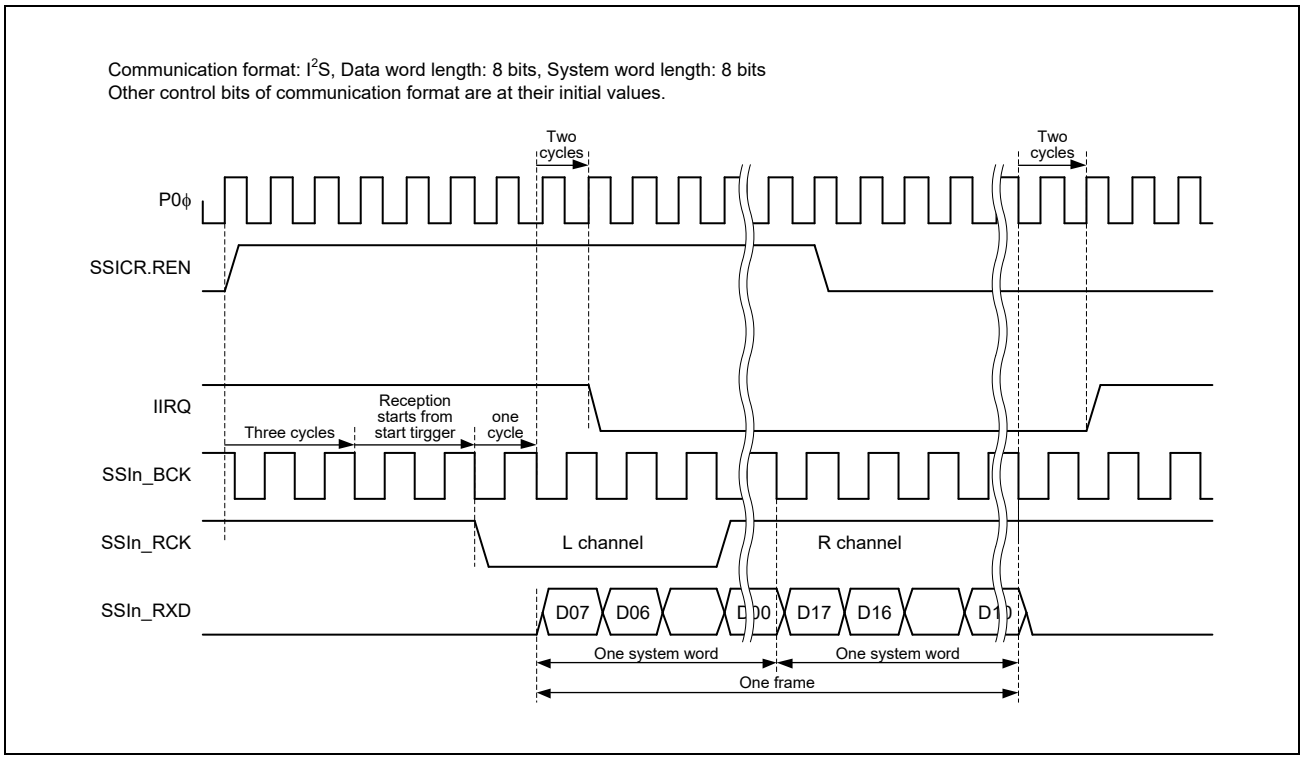

Figure 8.5-20 IIRQ Setting Timing (Reception)

Receiver (dedicated to reception)

[Clearing condition]

While reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), and a start trigger is generated in SSILRCK/SSIFS.

[Clearing timing]

Two cycles of P0ϕ after one cycle of SSIBCK when a start trigger of the clearing condition is generated.

[Setting condition]

One frame of data has been received while transmission and reception are disabled (SSICR.TEN = 0 and SSICR.REN = 0).

[Setting timing]

Two cycles of P0ϕ after reception of the setting condition is completed (frame boundary).

Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), one frame of data to be transmitted has been written to SSIFTDR, and a start trigger is generated in SSILRCK/SSIFS.

[Clearing timing]

Two cycles of P0ϕ after one cycle of SSIBCK when a start trigger of the clearing condition is generated.

[Setting condition]

One frame of data has been transmitted while transmission and reception are disabled (SSICR.TEN = 0 and SSICR.REN = 0).

[Setting timing]

Two cycles of P0ϕ after transmission is completed according to the setting condition (frame boundary).

8.5.4.1.3 FIFO Control Register (SSIFCR)

This is a readable/writable 32-bit register. It sets a software reset, byte swap, noise canceller, and enable/disable of interrupt requests.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AUCKE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSIRST

0	RFRST	0	RW	Receive FIFO data register reset*1 0: Clears a receive data FIFO reset condition 1: Sets a receive data FIFO reset condition

Note 1. Writing to these bits while SSIF-2 is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Note 2. This bit can only be set to 1 in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1'. Be sure to clear this bit to 0 in master-mode communication (SSICR.MST = '1') or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

AUCKE Bit

This bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1). Select AUDIO_MCK (SSICR.CKS bit) before writing 1 to this bit.

Rewrite this bit after completing the setting (CKS, MST, BCKP, and CKDV of the SSICR register) that relates to AUDIO_MCK.

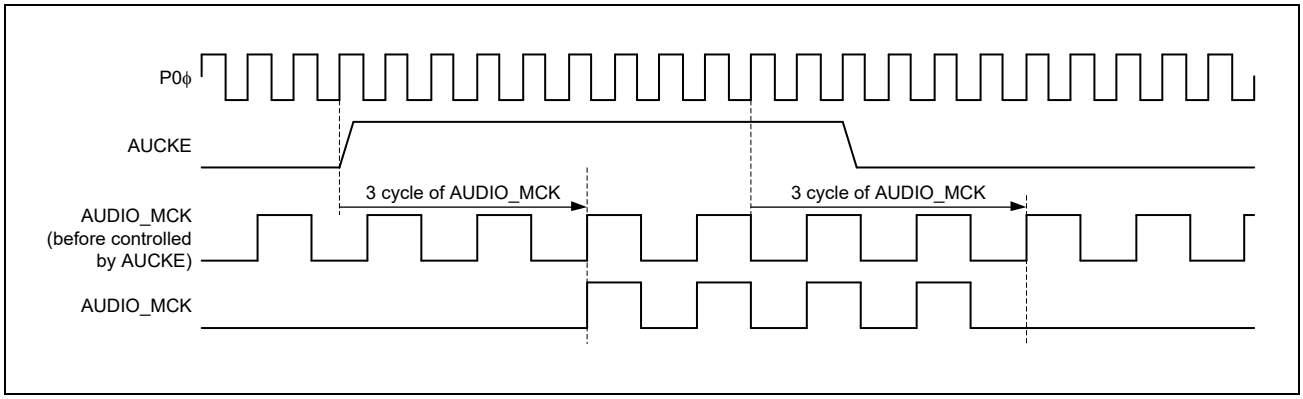

Figure 8.5-21 Stop/Resume of AUDIO_MCK

CAUTION

- In slave-mode communication (SSICR.MST = 0), SSIF-2 needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIF-2 becomes idle, take the procedure to start communication (**Figure 8.5-52**) or wait for an idle state by taking the procedure to resume communication (**Figure 8.5-57**).
- In master-mode communication (SSICR.MST = 1), SSIF-2 operates with the audio clock (AUDIO_MCK). To stop SSIF-2 completely, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.ADCKE. If 0 is written to SSIFCR.ADCKE before SSIF-2 becomes idle, take the procedure to start communication (**Figure 8.5-52**) or wait for the idle state by taking the procedure to resume communication (**Figure 8.5-57**).

Figure 8.5-22 and **Figure 8.5-23** show timing until outputting it to the terminal SSIBCK after this bit is set to '1'.

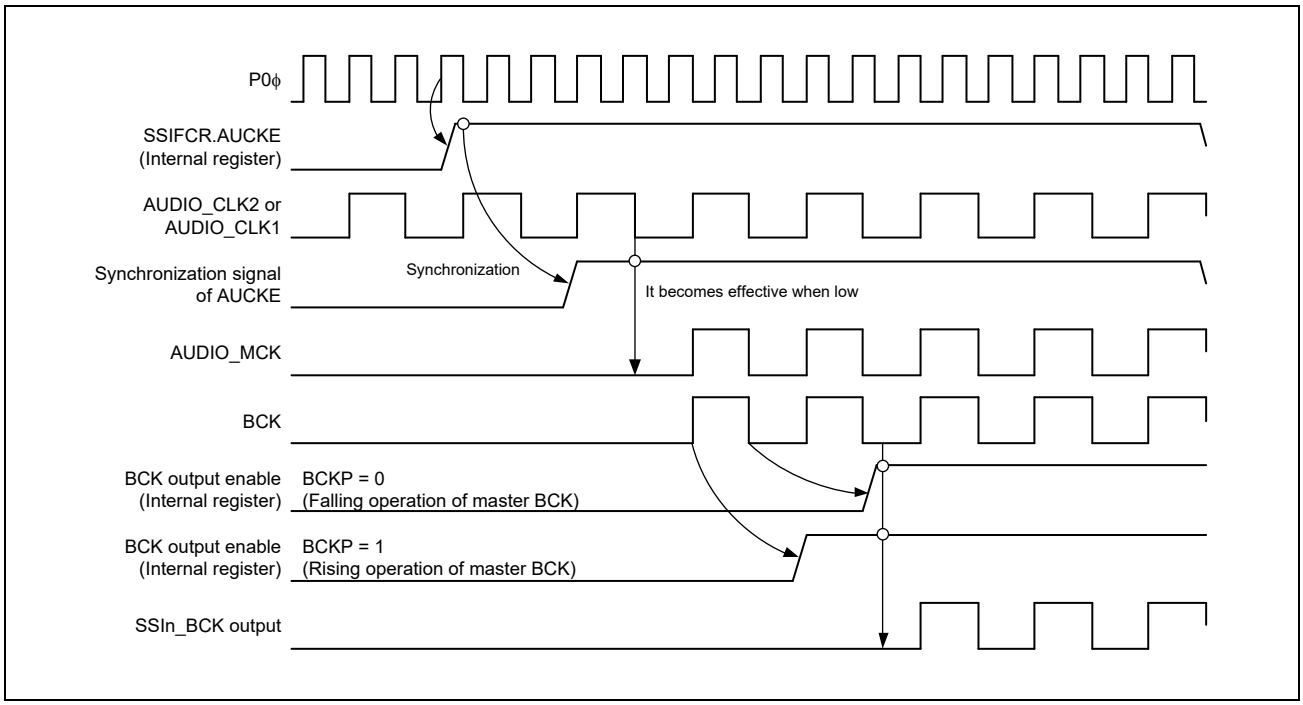

Figure 8.5-22 Timing Chart when It begins to Communicate Master from System Reset

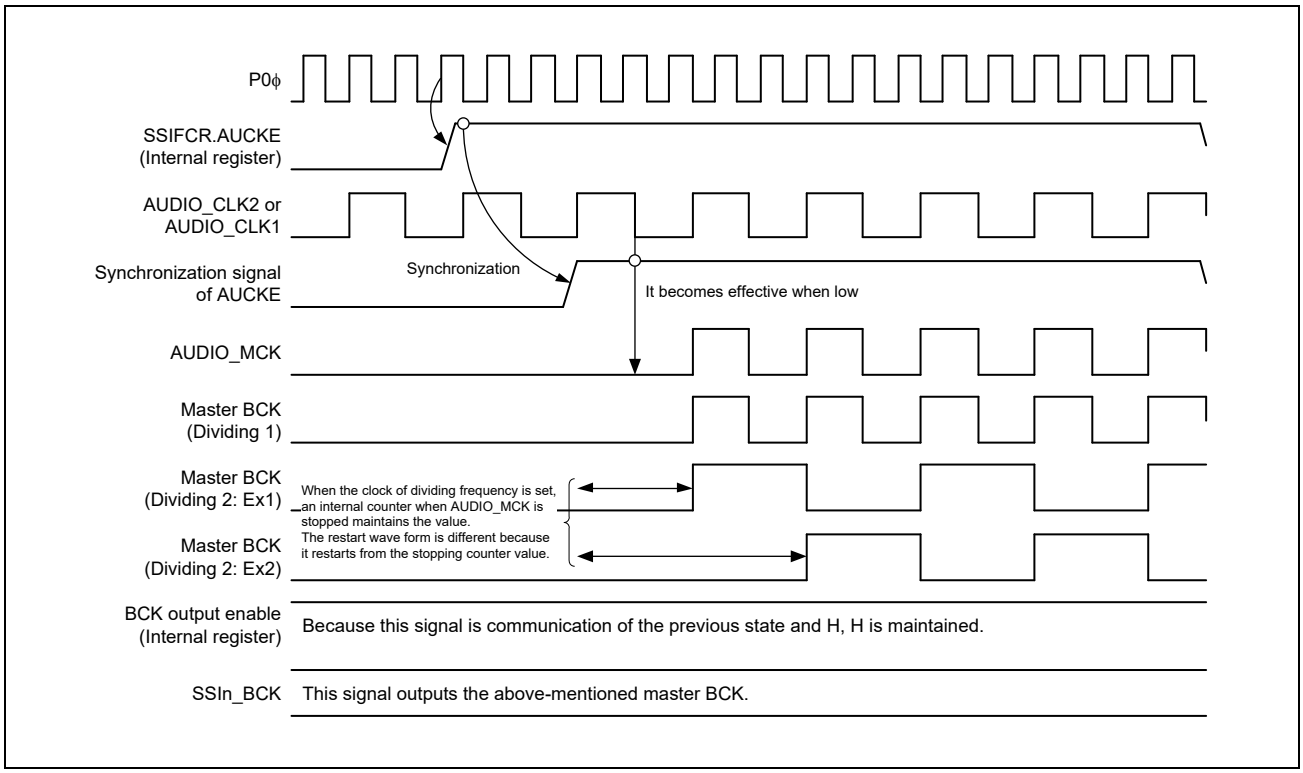

Figure 8.5-23 Timing Chart when It begins to Communicate Master from Communication Stop

Remark When the supply of AUDIO_MCK is stopped, the terminal SSIBCK maintains the value. The terminal SSIBCK might stop in the state of "H".

SSIRST Bit

This bit sets a software reset of SSIF-2. Writing 1 to this bit initializes the internal state of SSIF-2. After a reset by writing 1, write 0 to release the reset because this bit is not automatically cleared to 0. After writing 0 to this bit, make sure that the bit becomes 0 before the next procedure.

To stop communication of SSIF-2 immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 8.5-7 Bits Initialized by Software Reset of the SSIFCR.SSIRST Bit

Symbol	Address (Base+)		+0								+1							
			31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BSW Bit

This bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR (**Figure 8.5-24**).

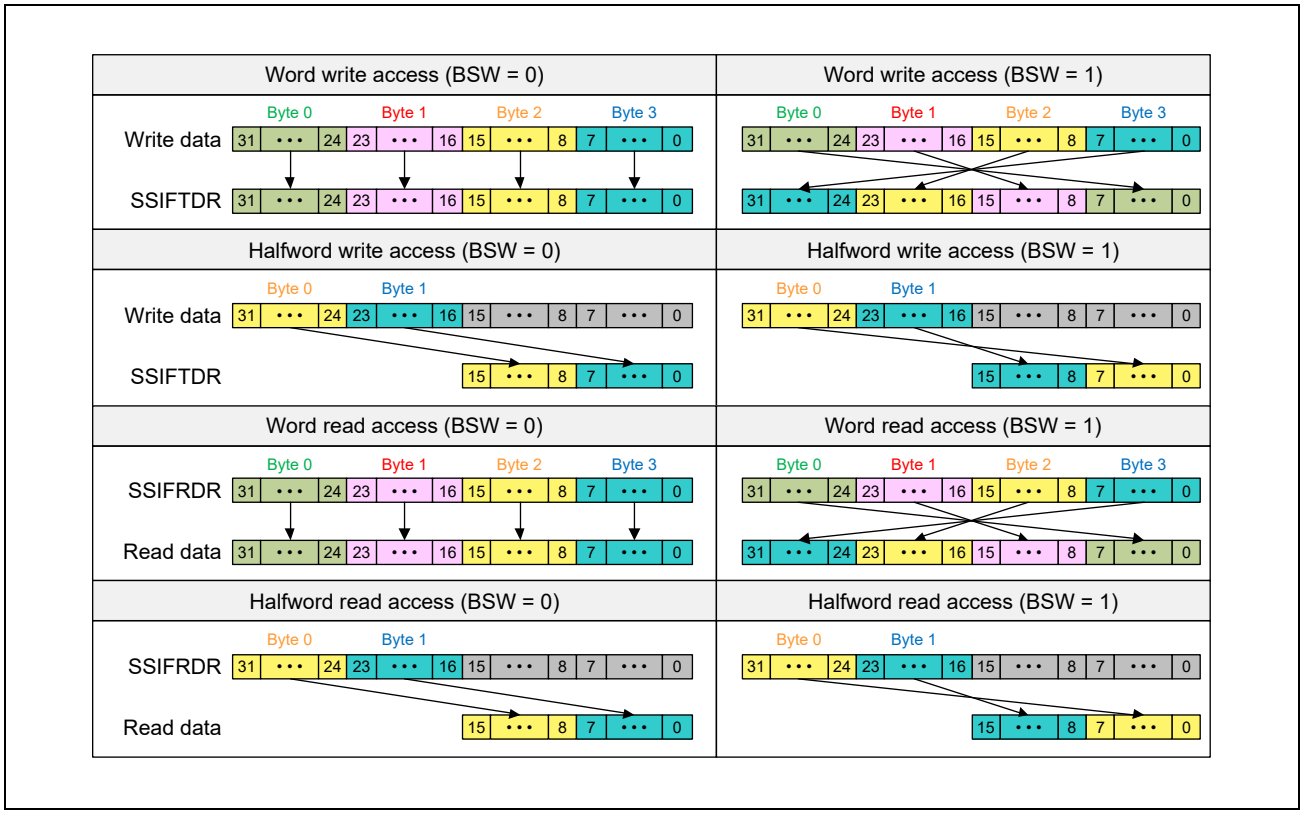

Figure 8.5-24 Operation Example of Byte Swap

BCKNCE Bit

This bit enables or disables the noise cancellation function supporting the suppression of transients 15-ns in length (typ.) in input signals on the SSIBCK pin in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1'. The setting of this bit in master-mode communication (SSICR.MST = '1') is disabled.

Be sure to clear this bit to 0 in master-mode communication or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

LRCKNCE Bit

This bit enables or disables the noise cancellation function supporting the suppression of transients 15-ns in length (typ.) in input signals on the SSILRCK and SSIFS pins in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1'. The setting of this bit in master-mode communication (SSICR.MST = '1') is disabled.

Be sure to clear this bit to 0 in master-mode communication or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

RXDNCE Bit

This bit enables or disables the noise cancellation function supporting the suppression of transients 15-ns in length (typ.) in input signals on the SSIRxD pin in slave-mode communication (SSICR.MST = ‘0’) except in the case of transmission (SSICR.TEN = ‘1’) while SSICR.DEL = ‘1’ and while reception is enabled (SSICR.REN = ‘1’).

The setting of this bit in master-mode communication (SSICR.MST = ‘1’) or while reception is disabled (SSICR.REN = ‘0’) is disabled.

Be sure to clear this bit to 0 in master-mode communication or during transmission in slave mode (SSICR.MST = ‘0’, SSICR.TEN = ‘1’) while SSICR.DEL = ‘1’. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

TIE Bit

This bit enables/disables output of transmit data empty interrupts. Transmission data empty interrupt is used as an interrupt factor written in the FIFO transmission data register. Set this bit to 1 after setting set condition (SSISCR.TDES) of transmission data empty interrupt. See **Figure 8.5-25** for the generation timing of a transmit data empty interrupt.

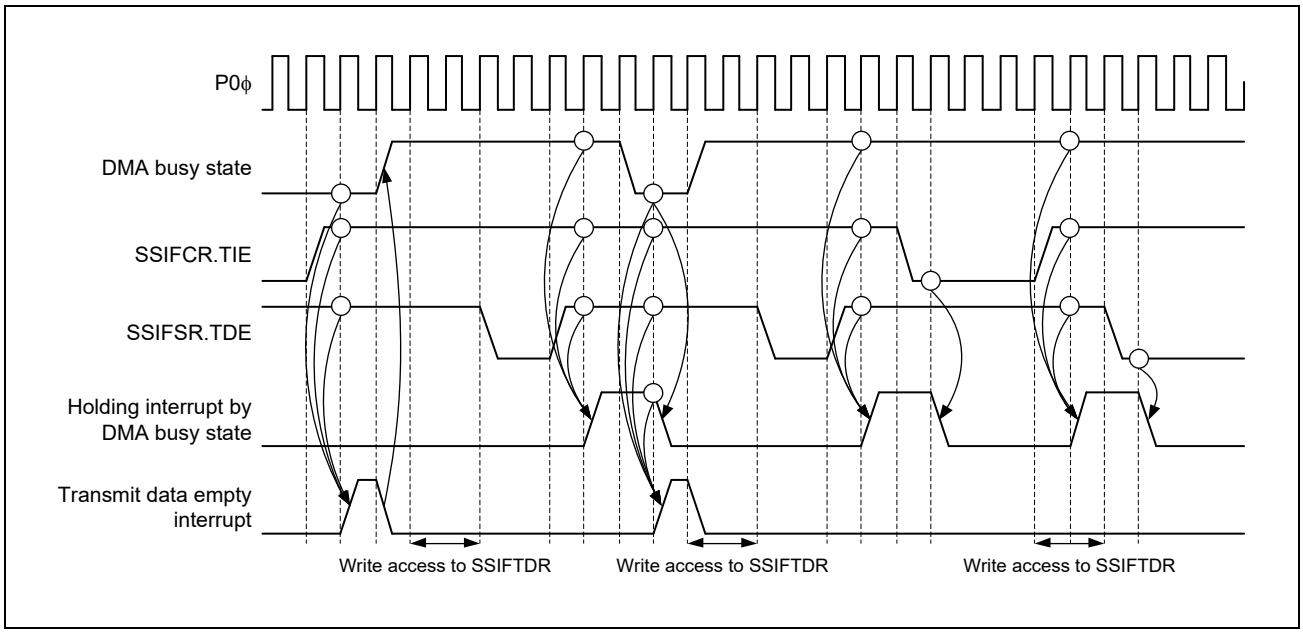

Figure 8.5-25 Generation Timing of Transmit Data Empty Interrupt

RIE Bit

This bit enables/disables output of receive data full interrupts. Receive data empty interrupt is used as an interrupt factor to read the FIFO receive data register. Set this bit to 1 after setting set condition (SSISCR.RDFS) of Receive data empty interrupt. See **Figure 8.5-26** for the generation timing of a receive data full interrupt.

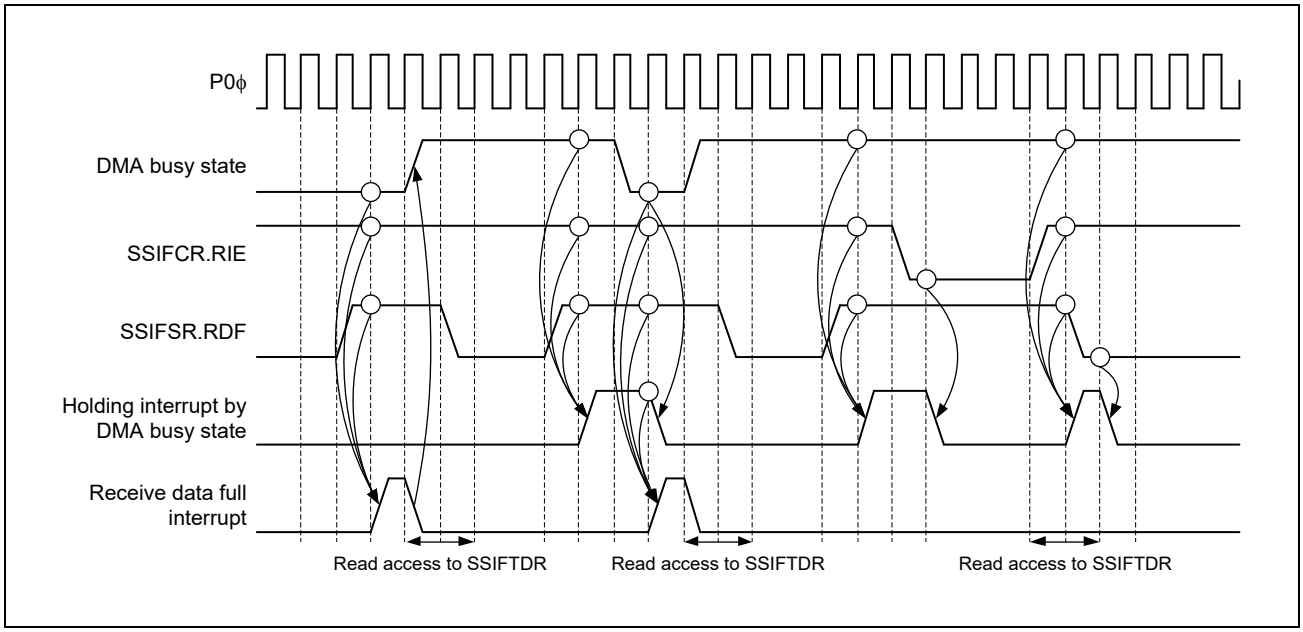

Figure 8.5-26 Generation Timing of Receive Data Empty Interrupt

TFRST Bit

This bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. See **Table 8.5-8** for the registers to which this software reset is applied. After a reset by writing 1, write 0 to clear the reset condition because this bit is not automatically cleared to 0. After writing 0 to this bit, make sure that the bit becomes 0 before the next procedure.

This bit is a bit of SSIRST for reset. Software reset by SSIRST becomes and writing this bit becomes invalid because of priority.

Table 8.5-8 Bits Initialized by Software Reset of the SSIFCR.TFRST Bit

RFRST Bit

This bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. After a reset by writing 1, write 0 to clear the reset condition because this bit is not automatically cleared to 0. After writing 0 to this bit, make sure that the bit becomes 0 before the next procedure.

This bit is a bit of SSIRST for reset. Software reset by SSIRST becomes and writing this bit becomes invalid because of priority.

8.5.4.1.4 FIFO Status Register (SSIFSR)

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	TDC[5:0]						—	—	—	—	—	—	—	TDE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RDC[5:0]						—	—	—	—	—	—	—	RDF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W0

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	H'0	R	Reserved. Write 0. The read value is 0.
29 to 24	TDC[5:0]	H'00	R	Number of Transmit FIFO Data Indication Flag
23 to 17	—	H'00	R	Reserved. Write 0. The read value is 0.
16	TDE	1	RW0	Transmit Data Empty Flag 0: The free space of SSIFTDR is not more than the value of SSISCR.TDES 1: The free space of SSIFTDR is not less than the value of SSISCR.TDES plus one.
15, 14	—	H'0	R	Reserved. Write 0. The read value is 0.
13 to 8	RDC[5:0]	H'00	R	Number of Receive FIFO Data Indication Flag
7 to 1	—	H'00	R	Reserved. Write 0. The read value is 0.
0	RDF	0	RW0	Receive Data Full Flag 0: The size of received data in SSIFRDR is not more than the value of SSISCR.RDFS 1: The size of received data in SSIFRDR is not less than the value of SSISCR.RDFS plus one.

TDC[5:0] Bits

These bits indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With this flag as H'0, there is no data to be transmitted. With H'20, there is no space to write data.

TDE Bit

This bit indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSISCR.TDES bit plus one. This flag is set by automatic determination but it must be cleared by register access.
[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

(1) Writing 0 to this bit after reading this bit as 1.*2

(2) When writing data to SSIFTDR.

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this bit after reading this bit as 1 (**Figure 8.5-13**).

(2) When writing data to SSIFTDR.

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following four conditions being met:
- Software reset (SSIFCR.SSIRST = 1)
- Resetting of the transmit FIFO data register (SSIFCR.TFRST = 1)
- Completion of writing 0 to this flag after having read it as 1.
- When writing data to SSIFTDR.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSISCR.TDES bit plus one.

[Setting timing]

While operating on P0ϕ, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

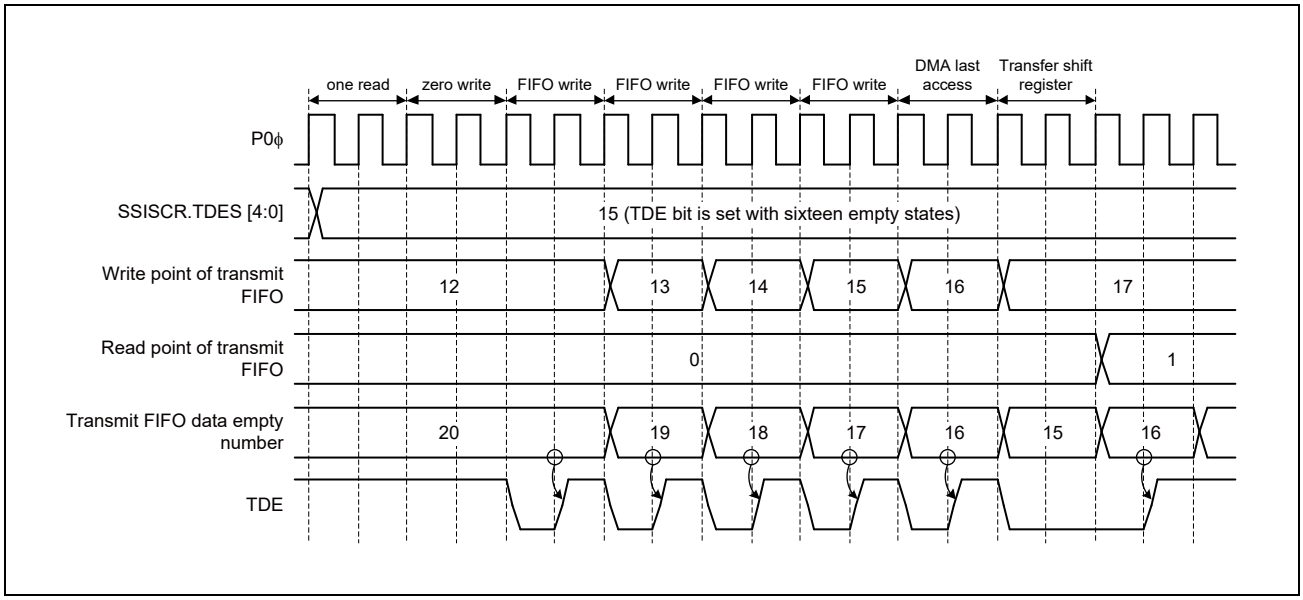

Figure 8.5-27 Set Timing and Clear Timing of TDE

RDC[5:0] Bits

These bits indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With this flag as H’0, there is no received data. With H’20, the register is filled with received data and there is no free space.

RDF Bit

This bit indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

(1) Writing 0 to this bit after reading this bit as 1.*2

(2) When reading data from SSIFRDR.

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this bit after reading this bit as 1 (**Figure 8.5-13**).

(2) After reading data from SSIFRDR.

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Clearing conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

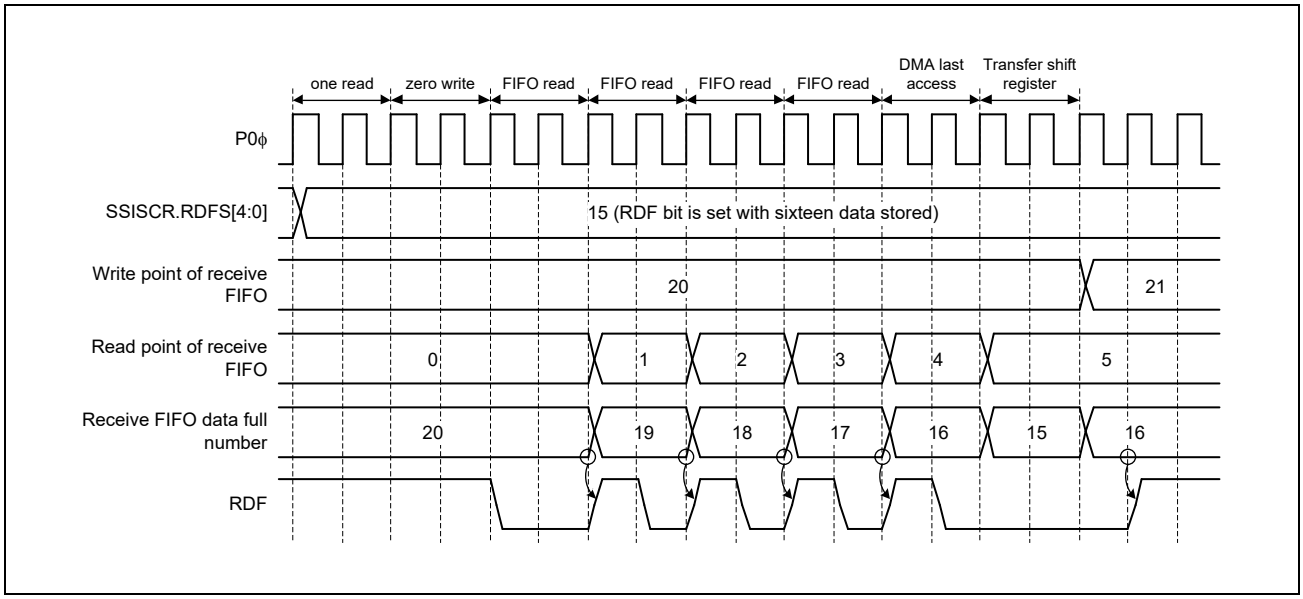
Note 2. The state of reading this bit as one is cleared by any of the following four conditions being met:
- Software reset (SSIFCR.SSIRST = 1)
- Receive FIFO data register reset (SSIFCR.RFRST = 1)
- Completion of writing 0 to this flag after having read it as 1.
- When reading data from SSIFRDR.

[Setting condition]

SSIFRDR has data not less than the amount set with the SSISCR.RDFS bit plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bit plus one.



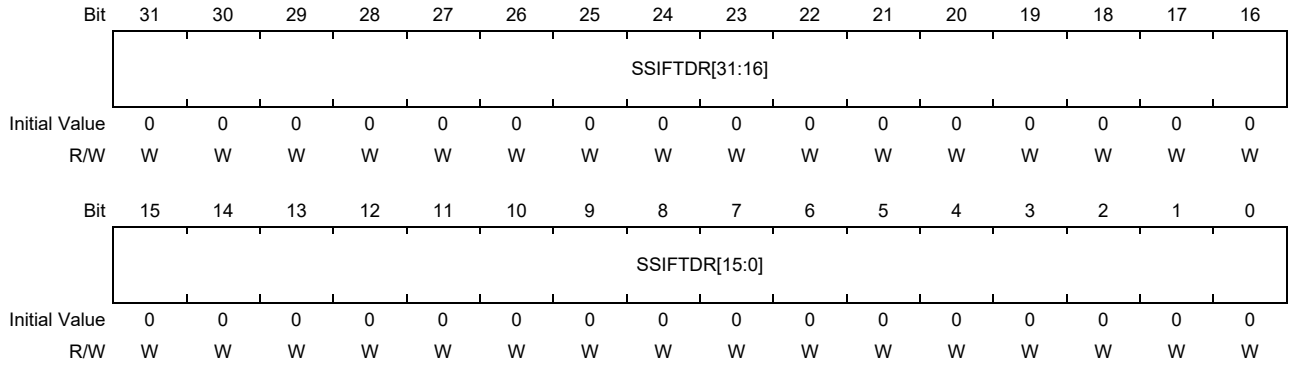


Figure 8.5-28 Set Timing and Clear Timing of RDF

8.5.4.1.5 Transmit FIFO Data Register (SSIFTDR)

This is a 32-bit writable register. 0 is returned when this register is read. This register stores data to be serially transmitted.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SSIFTDR[31:0]	H'0000_0000	W	Transmit FIFO data

To use this register for transmission, set DMA operation handling of a transmit data empty interrupt as writing to this register. Determine the access size to this register according to the data word length to be communicated (**Table 8.5-10**).

Table 8.5-10 Register Access Restriction to FIFOs

Access Size				
SSICR.DWL[2:0]	Data Word Length	Byte	Halfword	Word
000b	8	✓	—	—
001b	16	—	✓	—
010b	18	—	—	✓
011b	20	—	—	✓
100b	22	—	—	✓
101b	24	—	—	✓
110b	32	—	—	✓
111b	Setting prohibited	—	—	—

Figure 8.5-29 shows register access to the transmit FIFO data register.

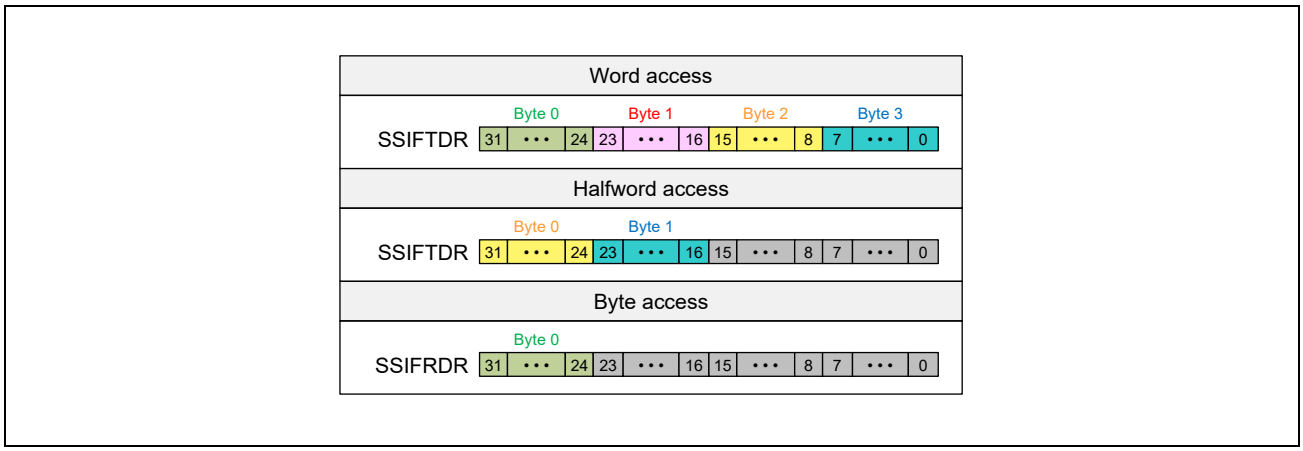

Figure 8.5-29 Example of Register Access to the Transmit FIFO Data Register

Figure 8.5-30 shows the configurations and operation examples of the transmit FIFO data register and transmit shift register. The configurations are for storing data to FIFO and not related with communication.

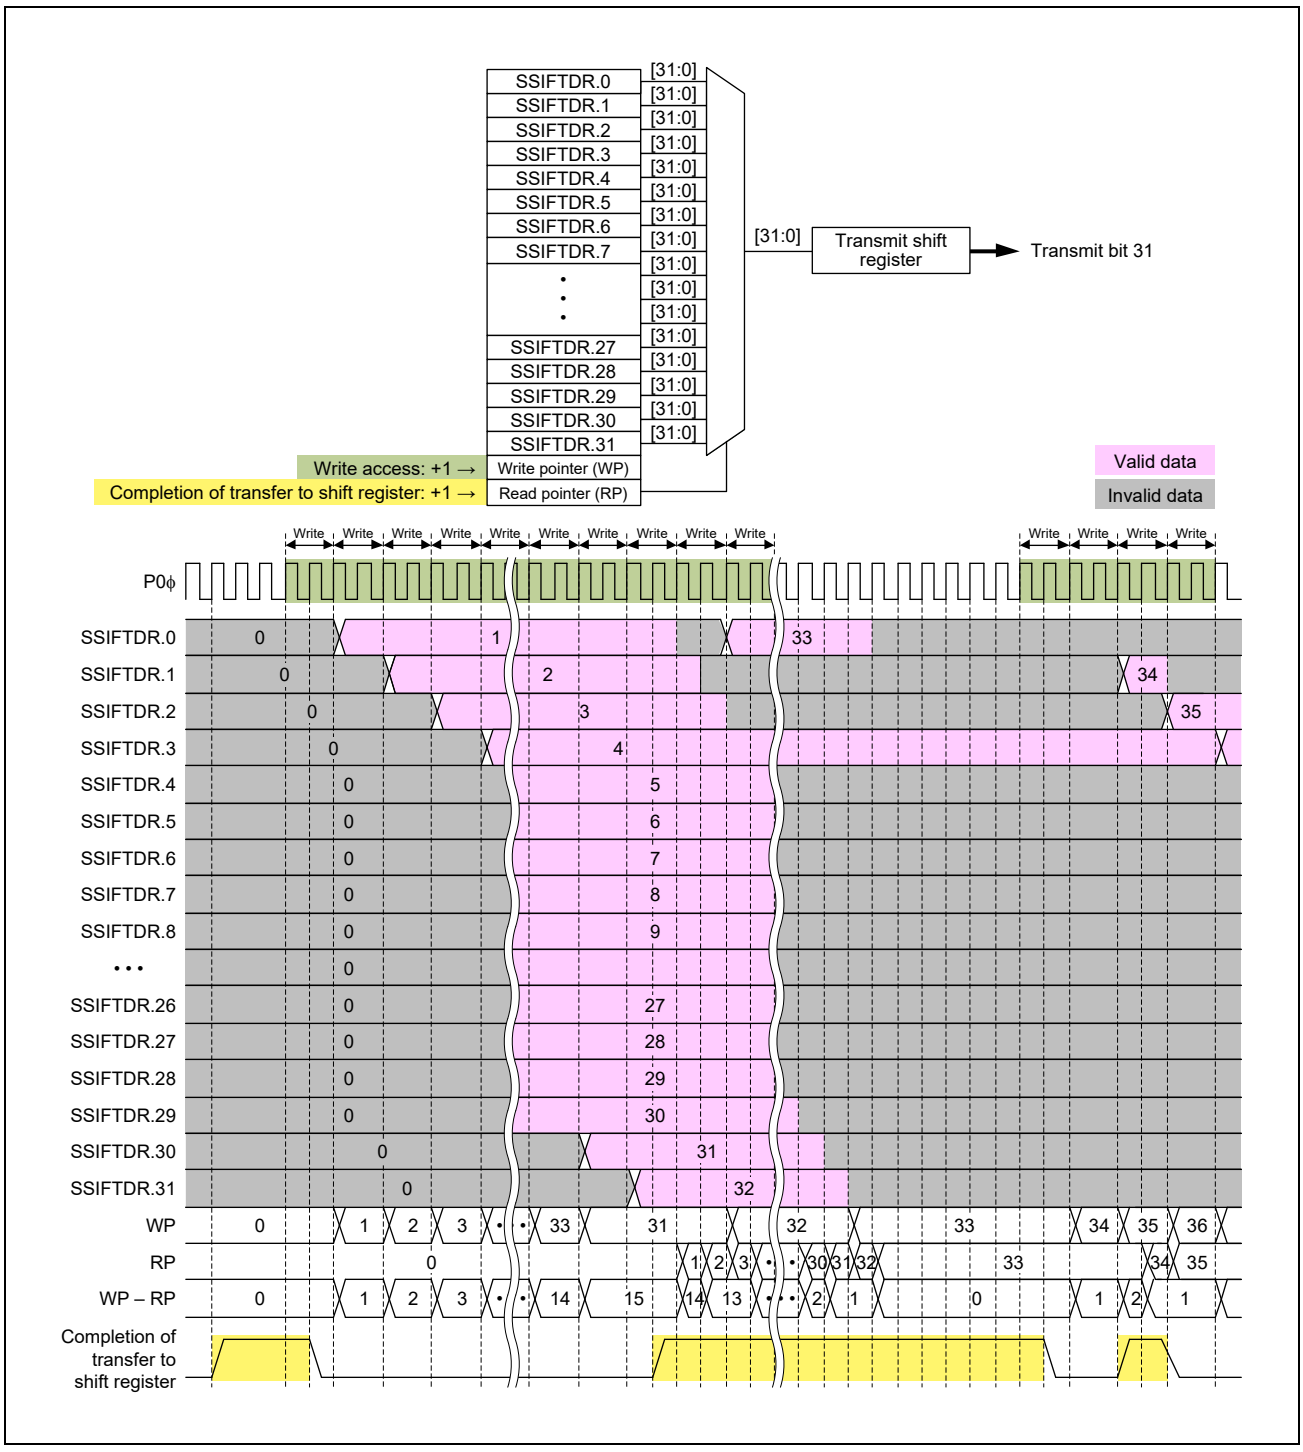

Figure 8.5-30 Configuration of the Transmit FIFO Data Register and Transmit Shift Register, and FIFO Operation Example

8.5.4.1.6 Receive FIFO Data Register (SSIFRDR)

This is a readable 32-bit register. This register stores received serial data.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSIFRDR[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SSIFRDR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SSIFRDR [31:0]	H'0000_0000	R	Receive FIFO data

To use this register for reception, set DMA operation handling of a receive data full interrupt as reading from this register. Determine the access size to this register according to the data word length to be communicated (**Table 8.5-10**). Register access to the receive FIFO data register is same as for the transmit FIFO data register (**Figure 8.5-29**).

Figure 8.5-31 shows the configurations and operation examples of the receive FIFO data register and receive shift register.

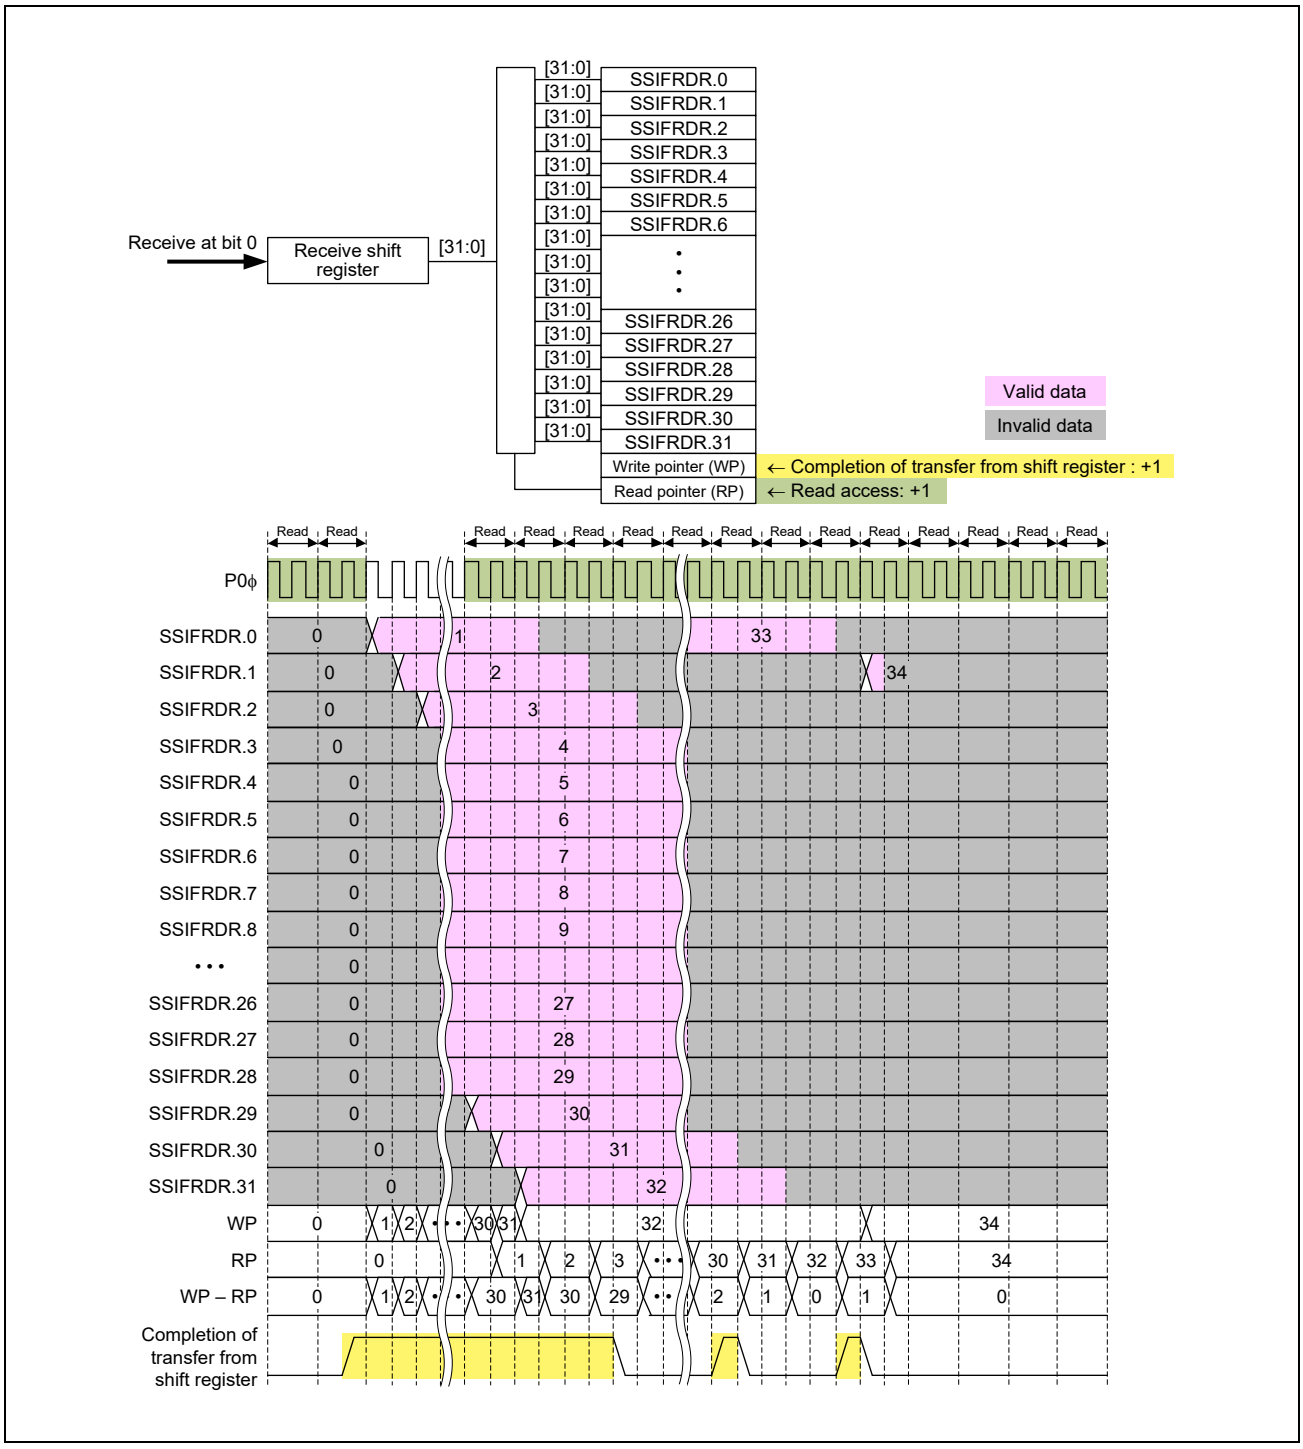

Figure 8.5-31 Configuration of the Receive FIFO Data Register and Receive Shift Register, and FIFO Operation Example

8.5.4.1.7 Audio Format Register (SSIOFR)

This is a readable/writable 32-bit register. It sets an audio format including the communication format, LRCK/FS continuation mode, and BCK output stop.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	BCKSTP	LRCONT	—	—	—	—	—	—	OMOD[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	H'00_0000	R	Reserved. Write 0. The read value is 0.
9	BCKASTP	0	RW	BCK Output Stop Enable*1,*2 0: Enables output of BCK 1: Disables output of BCK
8	LRCONT	0	RW	LRCK/FS Continuation Enable*1,*2 0: Disables LRCK continuation 1: Enables LRCK continuation
7 to 2	—	H'00	R	Reserved. Write 0. The read value is 0.
1, 0	OMOD[1:0]	0	RW	Audio Format Select*3,*4 OMOD[1:0]: Format 00: I²S format 01: TDM format 10: Monaural format 11: Setting prohibited

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. BCKASTP=1 and LRCONT=1 is prohibitions.

Note 3. Writing in this bit is a prohibition when SSIF-2 is communication state (SSISR.IIRQ=0). Operation is not guaranteed when rewriting it.

Note 4. Use the communication format setting that can be communicated when the format of the communication of the opposing device is compatible format of SSIF-2.

BCKASTP Bit

This bit turns on or off the function to output BCK to the SSIBCK pin according to the communication shown in **Figure 8.5-32** and **Figure 8.5-33** in master-mode communication (SSICR.MST = 1). Set this bit after setting completing the communication format.

This bit must defend the following usage. Start communication with BCKASTP = 0, and set 1 to BCKASTP while communicating. As a result, the bit clock output to the terminal SSIBCK stops by the automatic operation when the communication stop is done. When you will restart the communication, set 0 to BCKASTP with idle state (SSICR.IIRQ=1) and the AUDIO_MCK supply state (SSIFCR.AUCKE = 1)

When master communication (SSICR.MST=1) and idle state (SSICR.IIRQ=1).

Table 8.5-11 BCKASTP State, and Output state of SSIBCK Pin

BCKASTP bit	Output State of SSIBCK Pin
0	Enable
1	Disable

Note: When the opposing device who is the slave needs the clock of the terminal SSIBCK before the communication operates, it is not possible to use it. Use it to stop clocking after the communication ends (**Figure 8.5-33**). Refer to **Figure 8.5-32** for timing that the function becomes effective.

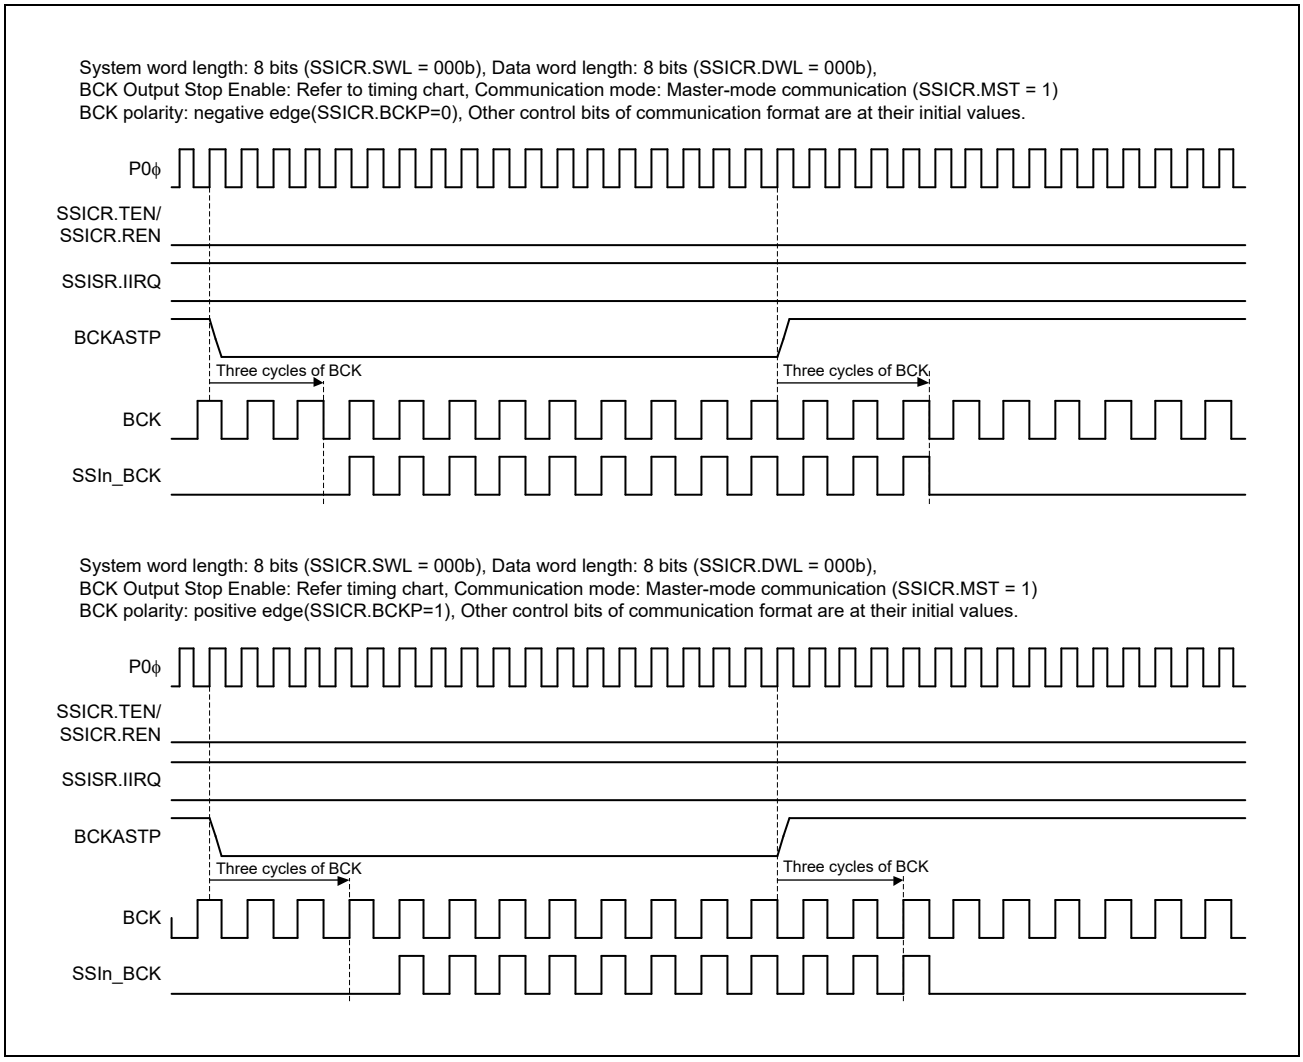

Figure 8.5-32 Example Operation of the BCKASTP Bit (in Idle State)

When master communication (SSICR.MST=1) and the BCK output automatic operation stop function (BCKASTP = 1) (**Figure 8.5-33**).

Details of the BCK output to SSIBCK pin are as follows.

- Output start timing: To generate an effective edge in timing that LRCK/FS is changed into the valid value, BCK is output.
- Output stop timing: Frame boundary from 1 to 1.5 clock

Refer to the timing chart of **Figure 8.5-33** for detailed timing.

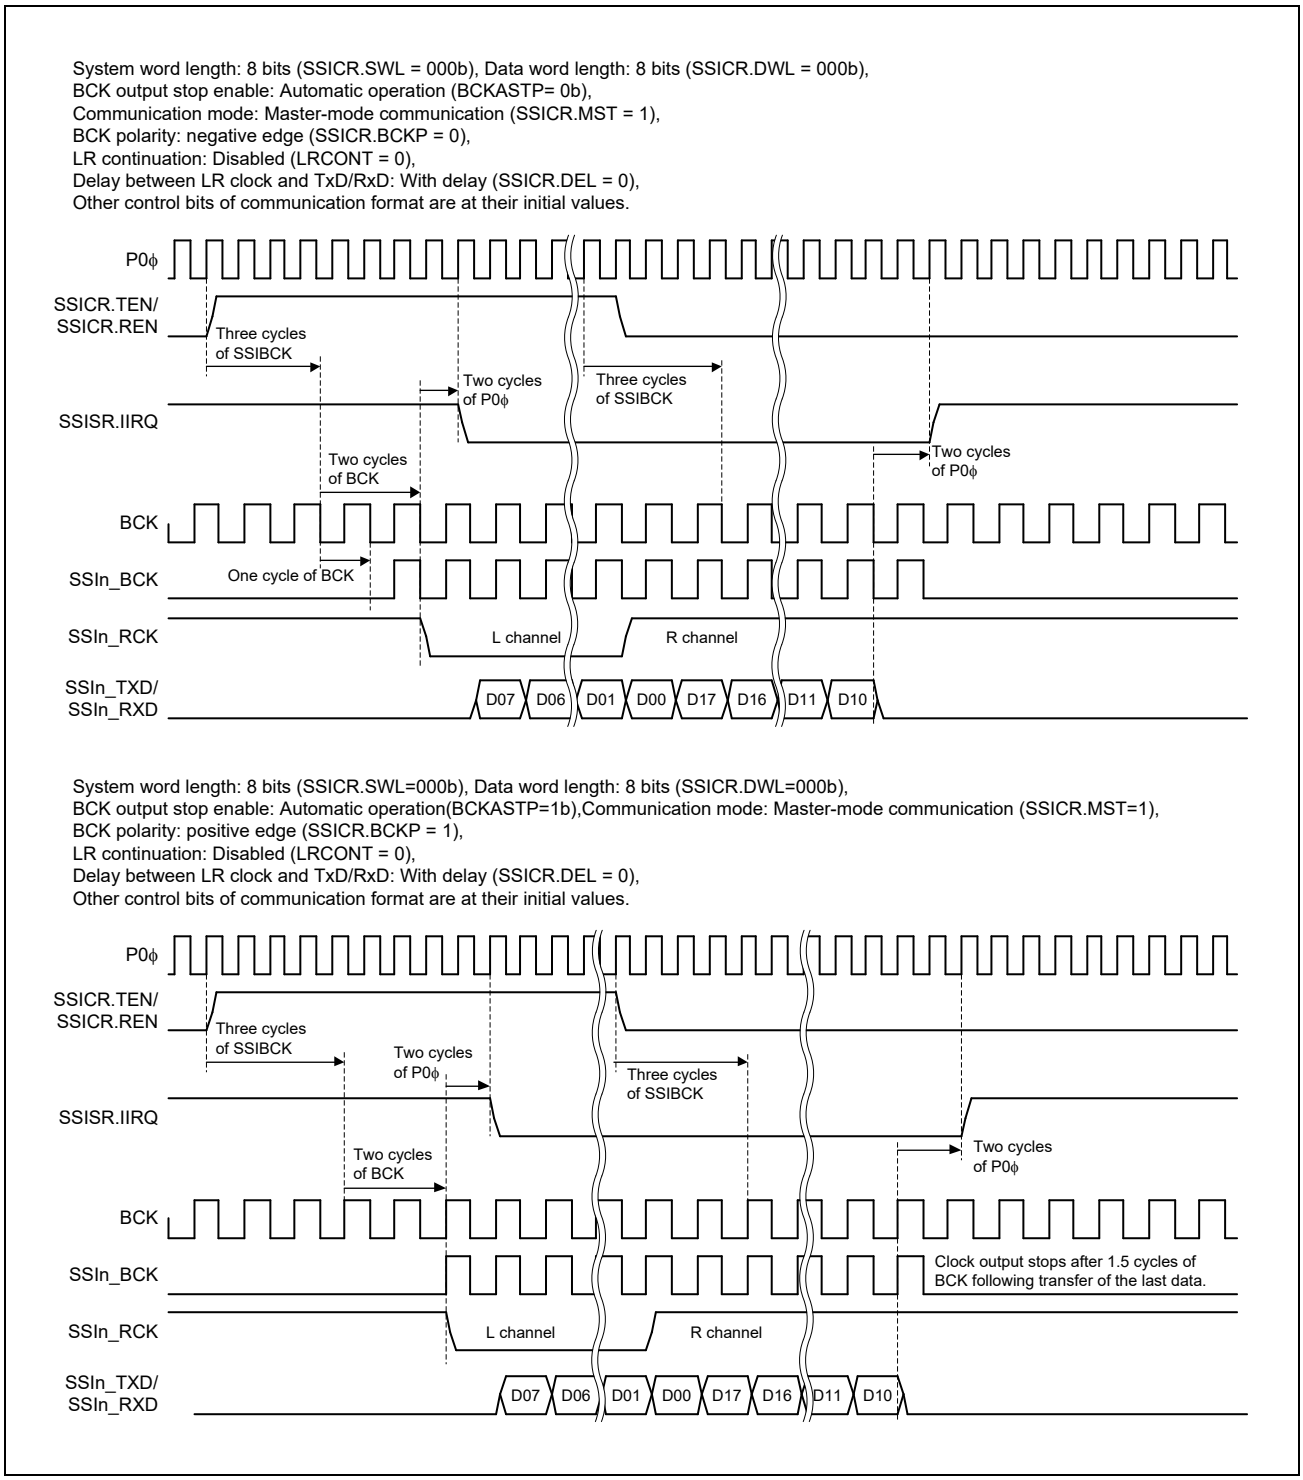

Figure 8.5-33 Example Operation of the BCKASTP Bit (Communication behavior in BCKASTP=1)

LRCONT Bit

This bit enables/disables the output from the SSILRCK/SSIFS pin when SSIF-2 is master communication (SSICR.MST=1) and idle state (SSISR.IIRQ=1). Writing 1 to this bit (enables LRCK/FS continuation) in master mode (SSICR.MST = 1) enables continuation of the output from the SSILRCK/SSIFS pins even when idle state.

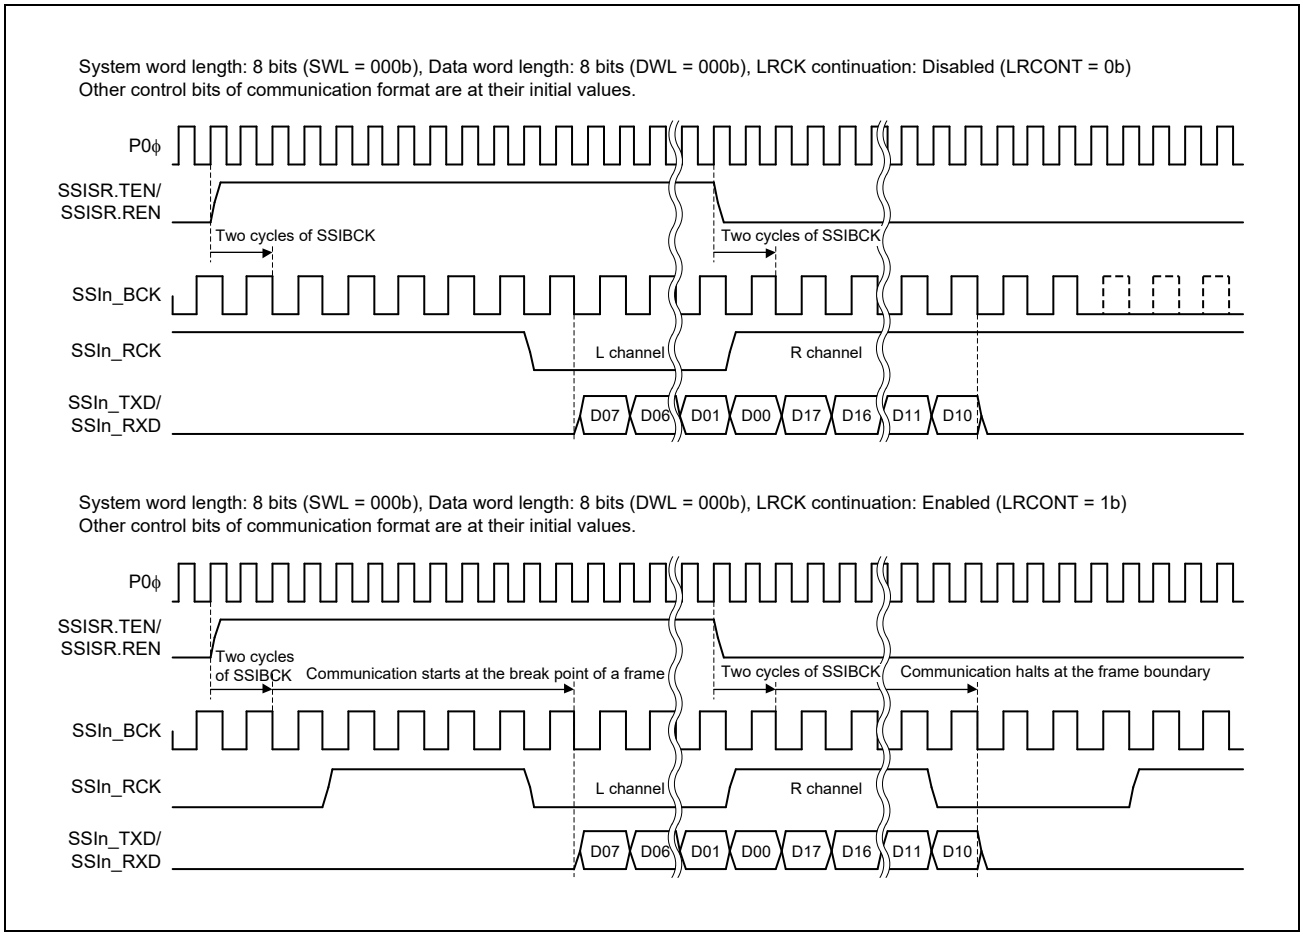

Figure 8.5-34 Operation Example of LRCK/FS Continuation (in Idle State)

OMOD[1:0] Bits

These bits set an audio format.

Rewrite this bit when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in **8.5.4.1.7 Audio Format Register (SSIOFR)** for the output operation of the LR clock.

8.5.4.1.8 Status Control Register (SSISCR)

This is a readable/writable 32-bit register. It sets the operation of the TDE and RDF flags.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	TDES[4:0]					—	—	—	RDFS[4:0]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	H'0_0000	R	Reserved. Write 0. The read value is 0.
12 to 8	TDES[4:0]	H'00	RW	TDE Setting Condition Select*1 TDES[4:0]: Operation 00000b: SSIFTDR has one stage or more free space 00001b: SSIFTDR has two stages or more free space (snip) 11110b: SSIFTDR has thirty-one stages or more free space 11111b: SSIFTDR has thirty-two stages or more free space
7 to 5	—	H'0	R	Reserved. Write 0. The read value is 0.
4 to 0	RDFS[4:0]	H'00	RW	RDF Setting Condition Select*1 RDFS[4:0]: Operation 00000b: SSIFRDR has one stage or more data size 00001b: SSIFRDR has two stages or more data size (snip) 01110b: SSIFRDR has thirty-one or more data size 01111b: SSIFRDR has thirty-two stages or more data size

Note 1. Writing to these bits while SSIF-2 is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

TDES[4:0] Bits

These bits set the setting condition of the transmit data empty flag (TDE). Set these bits in byte units.

RDFS[4:0] Bits

These bits set the setting condition of the receive data full flag (RDF). Set these bits in byte units.

8.5.4.2 Communication Formats

SSIF-2 supports three communication formats (**Table 8.5-12**).

Table 8.5-12 Supported Communication Formats

Communication Format	SSIOFR.OMOD[1:0]
I^2S format	00
TDM format	01
Monaural format	10

The following figure shows the serial data configuration common to communication formats. Serial data is determined according to the system word length (SSICR.SWL[2:0]) and the data word length (SSICR.DWL[2:0]). When the system word length is longer than the data word length, padding bits are transferred (**Figure 8.5-35**).

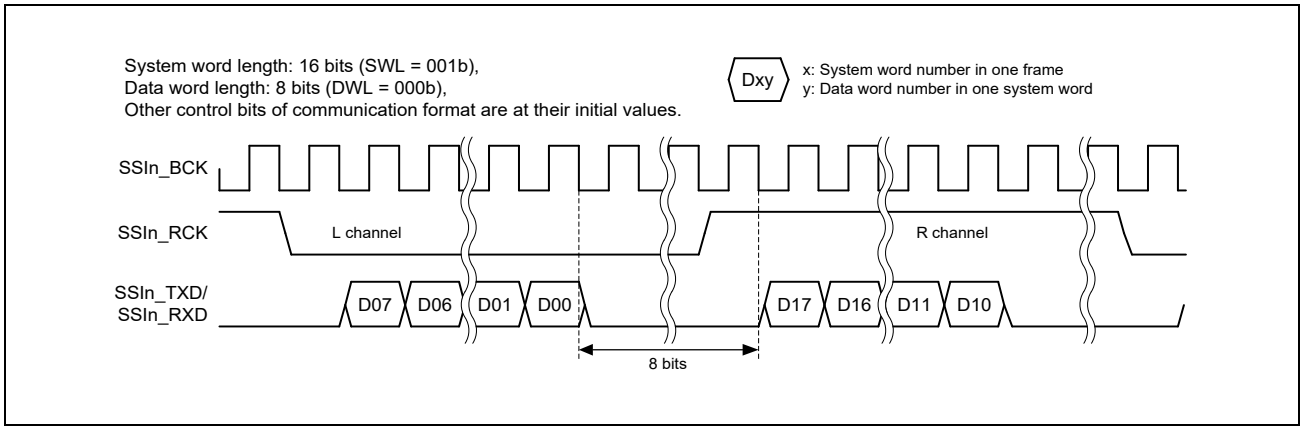

Figure 8.5-35 Example of Padding Bit Transfer (I^2S Format: System Word Length > Data Word Length)

Table 8.5-13 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). "-" indicates that the setting is prohibited.

Table 8.5-13 Number of Padding Bits

	SSICR.DWL[2:0]	000b	001b	010b	011b	100b	101b	110b	111b
SSICR.SWL[2:0]	System Word Length	8	16	18	20	22	24	32	Set Prohibition
000b	8	0	—	—	—	—	—	—	—
001b	16	8	0	—	—	—	—	—	—
010b	24	16	8	6	4	2	0	—	—
011b	32	24	16	14	12	10	8	0	—
100b	48	40	32	30	28	26	24	16	—
101b	64	56	48	46	44	42	40	32	—
110b	128	120	112	110	108	106	104	96	—
111b	256	248	240	238	236	234	232	224	—

8.5.4.2.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCK/SSIFS signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. **Figure 8.5-36** shows the I²S format without padding. See **Figure 8.5-35** for the format with padding.

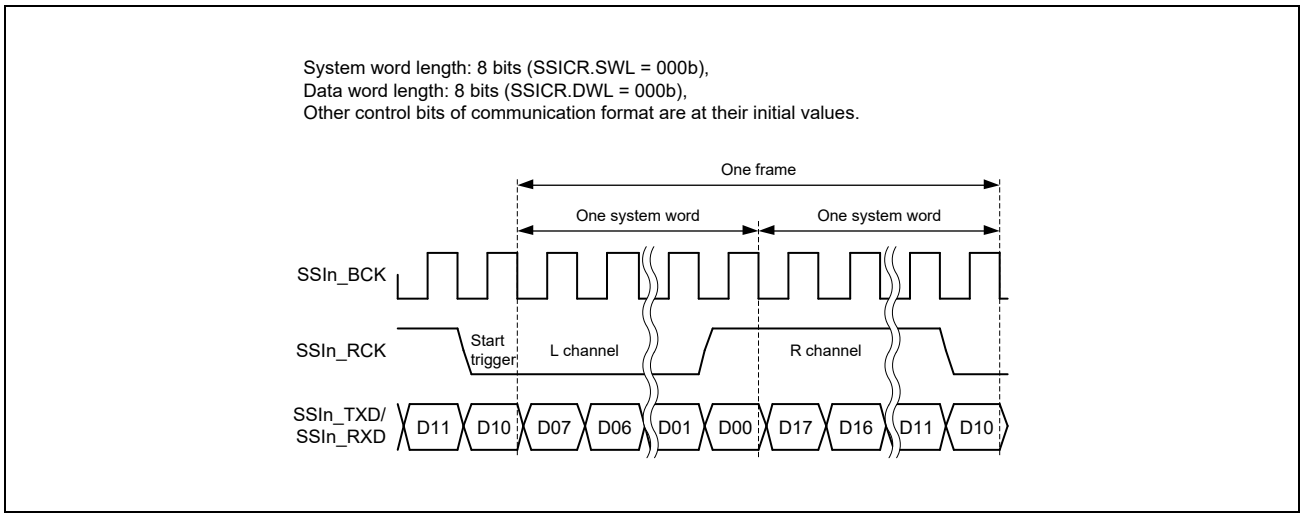

Figure 8.5-36 I²S Format (without Padding: System Word Length = Data Word Length)

For the state of external pins when SSIF-2 is in the idle state, see **8.5.5.1.1 Idle State**.

NOTE

SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/ SSIFS only as a communication start trigger.

8.5.4.2.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 10b), one frame is configured with the number of system words set with the SSICR.FRM[1:0] bits (**Figure 8.5-37**). A rising of the SSILRCK/SSIFS signal means a start trigger. **Figure 8.5-37** and **Figure 8.5-38** respectively show the monaural formats without and with padding.

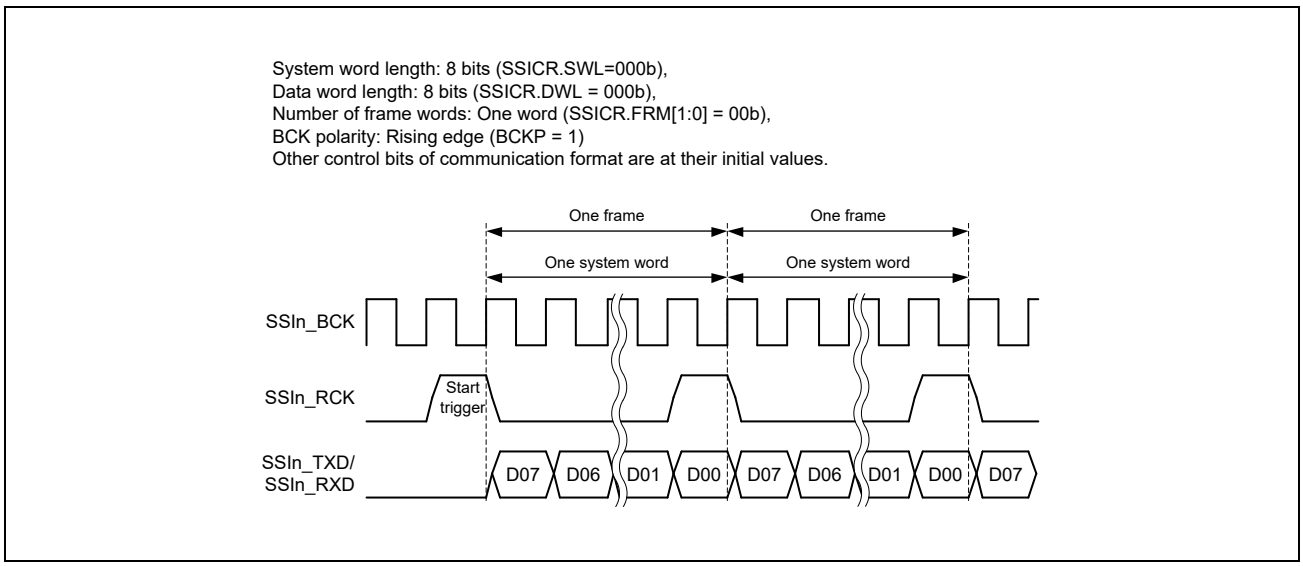

Figure 8.5-37 Short Frame in Monaural Format (without Padding: System Word Length = Data Word Length)

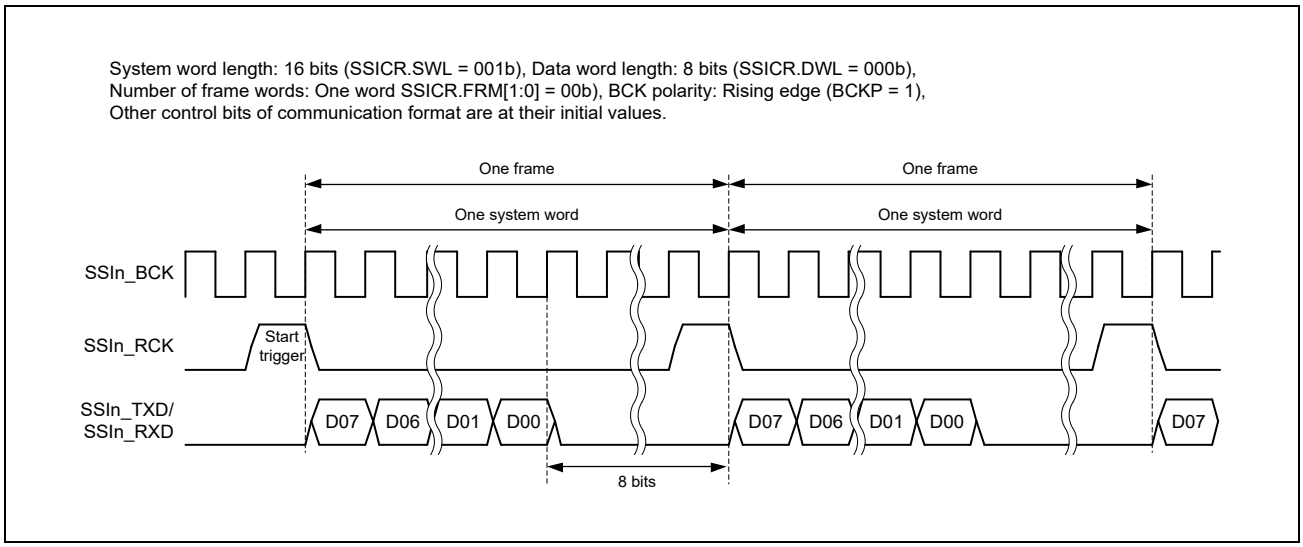

Figure 8.5-38 Short Frame in Monaural Format (with Padding: System Word Length > Data Word Length)

The monaural formats supported by SSIF-2 consist of short frames and long frames. See **8.5.4.2.2 (1) Short Frame** and **8.5.4.2.2 (2) Long Frame** for the difference between these two frames.

For the state of external pins state when SSIF-2 is in the idle state, see **8.5.5.1.1 Idle State**.

NOTE

SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/SSIFS only as a communication start trigger.

(1) Short Frame

With the short frame (SSICR.DEL = 0), the SSILRCK/SSIFS signal that indicates a start of serial data is at a high level for one cycle of SSIBCK. Data transfer starts at the falling edge of the signal **Figure 8.5-37** and **Figure 8.5-38**).

(2) Long Frame

With the long frame (SSICR.DEL = 1), the SSILRCK/SSIFS signal that indicates a start of serial data is at a high level for two cycles of SSIBCK. Data transfer starts at the rising edge of the signal (**Figure 8.5-39**).

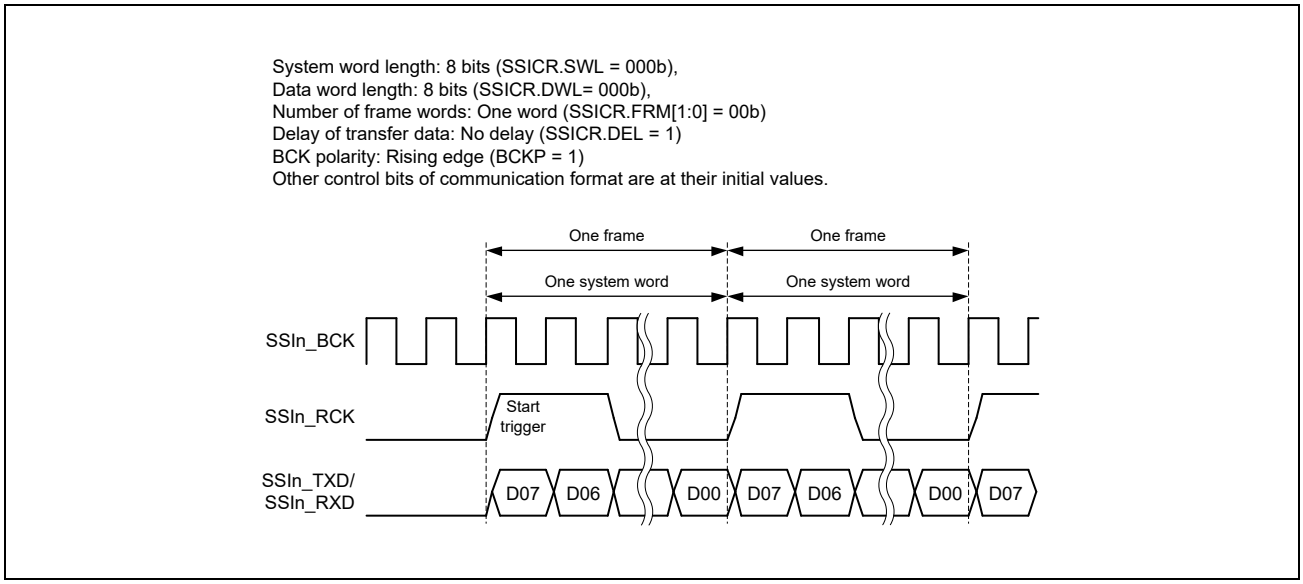

Figure 8.5-39 Long Frame in Monaural Format (without Padding)

8.5.4.2.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCK/SSIFS signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCK/SSIFS signal is defined as the SYNC pulse and its rising edge means a start of one frame. **Figure 8.5-40** and **Figure 8.5-41** respectively show the TDM formats with and without padding.

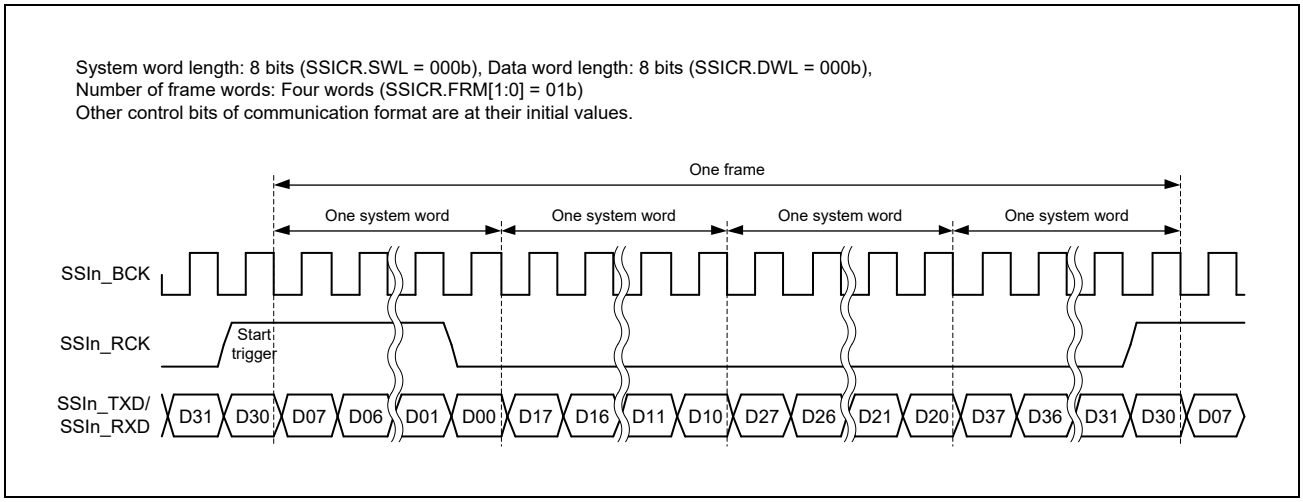

Figure 8.5-40 TDM Format (without Padding: System Word Length = Data Word Length)

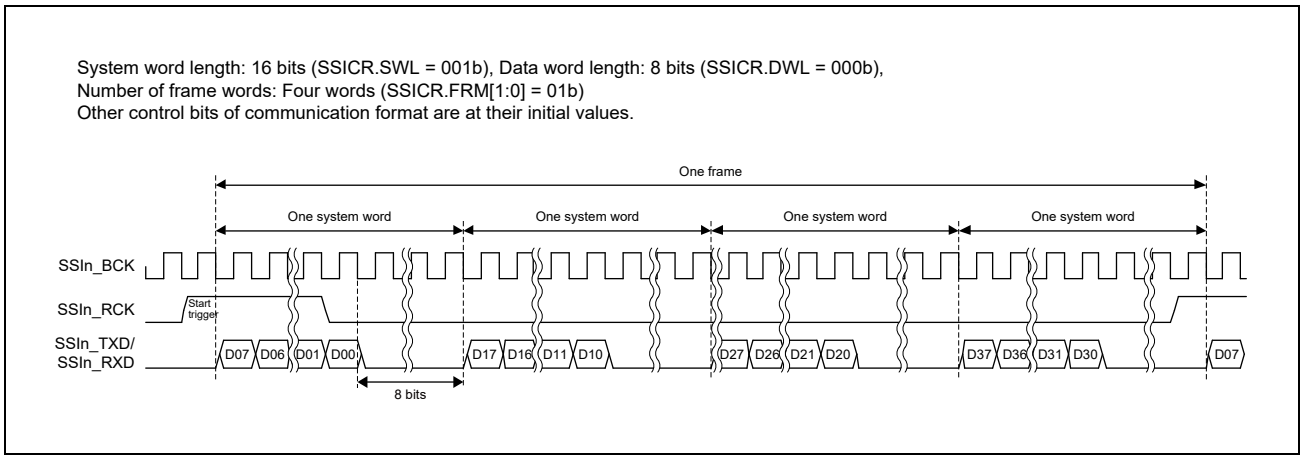

Figure 8.5-41 TDM Format (with Padding: System Word Length > Data Word Length)

For the state of external pins when SSIF-2 is in the idle state, see **8.5.5.1.1 Idle State**.

NOTE

SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/SSIFS only as a communication start trigger.

8.5.4.3 Communication Modes

SSIF-2 supports the following communication modes. **Table 8.5-15** lists the control bits that are not available with each communication mode. See **8.5.4.3.1 Slave-Mode Communication** to **8.5.4.3.5 Transmission and Reception** for details of these communication modes.

Table 8.5-14 Communication Modes

Communication Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transmission and reception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transmission and reception	1	1	1

Table 8.5-15 Control Bits that Cannot be Used in Each Communication Mode

Communication Mode Control Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transmission and Reception	Master-mode Reception	Master-mode Transmission	Master-mode Transmission and Reception

Note 1. Disabled when SSICR.DEL = ‘1’

Note 2. Note 2. Disabled during transmission (SSICR.TEN = ‘1’) when SSICR.DEL = ‘1’

8.5.4.3.1 Slave-Mode Communication

SSIF-2 operates in slave mode with SSICR.MST = 0. Supply the SSIBCK signal and the SSILRCK/SSIFS signal used for the serial data communication from external devices. If these signals do not match the communication format set for SSIF-2, operation is not guaranteed.

8.5.4.3.2 Master-Mode Communication

SSIF-2 operates in master mode with SSICR.MST = 1. The SSIBCK signal and SSILRCK/SSIFS signal used for the serial data communication are internally generated from the audio clock. These signals use the format according to the setting of SSIF-2. If the communication format of another device working as the slave device does not match the communication format set for SSIF-2, operation is not guaranteed.

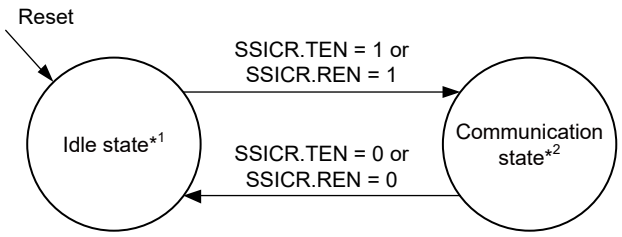
8.5.4.3.3 Transmission

SSIF-2 transmits serial data to opposing device when SSICR.TEN = 1 and SSICR.REN = 0. If the communication format of the opposing device does not match the communication format set for SSIF-2, operation is not guaranteed.

8.5.4.3.4 Reception

SSIF-2 receives serial data from opposing device when SSICR.TEN = 0 and SSICR.REN = 1. If the communication format of the opposing device does not match the communication format set for SSIF-2, operation is not guaranteed.

8.5.4.3.5 Transmission and Reception



SSIF-2 transmits and receives serial data to and from opposing device when SSICR.TEN = 1, SSICR.REN = 1. If the communication format of opposing device does not match the communication format set for SSIF-2, operation is not guaranteed.

8.5.5 Operation

8.5.5.1 Operational State

SSIF-2 has the following two main operation states (**Figure 8.5-42**).

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0)

Note 1. See **8.5.5.1.1 Idle State** for details of the idle state.

Note 2. See **8.5.5.1.2 Communication States** for details of the communication state.

Figure 8.5-42 SSIF-2 State Transition

8.5.5.1.1 Idle State

In this state, communication of SSIF-2 is halted. However, when SSICR.MST = 1, output of BCK and LRCK/FS to external pins is enabled depending on the settings in the SSIOFR.BCKASTP bit and the SSIOFR.LRCONT bit (**Table 8.5-16**). This function is common to all formats.

Table 8.5-16 Output from External Pins in the Idle State

			Output from Pins		
SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	SSIBCK	SSILRCK/SSIFS	SSITxD
0	—	—	Stop	Stop	Stop
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop

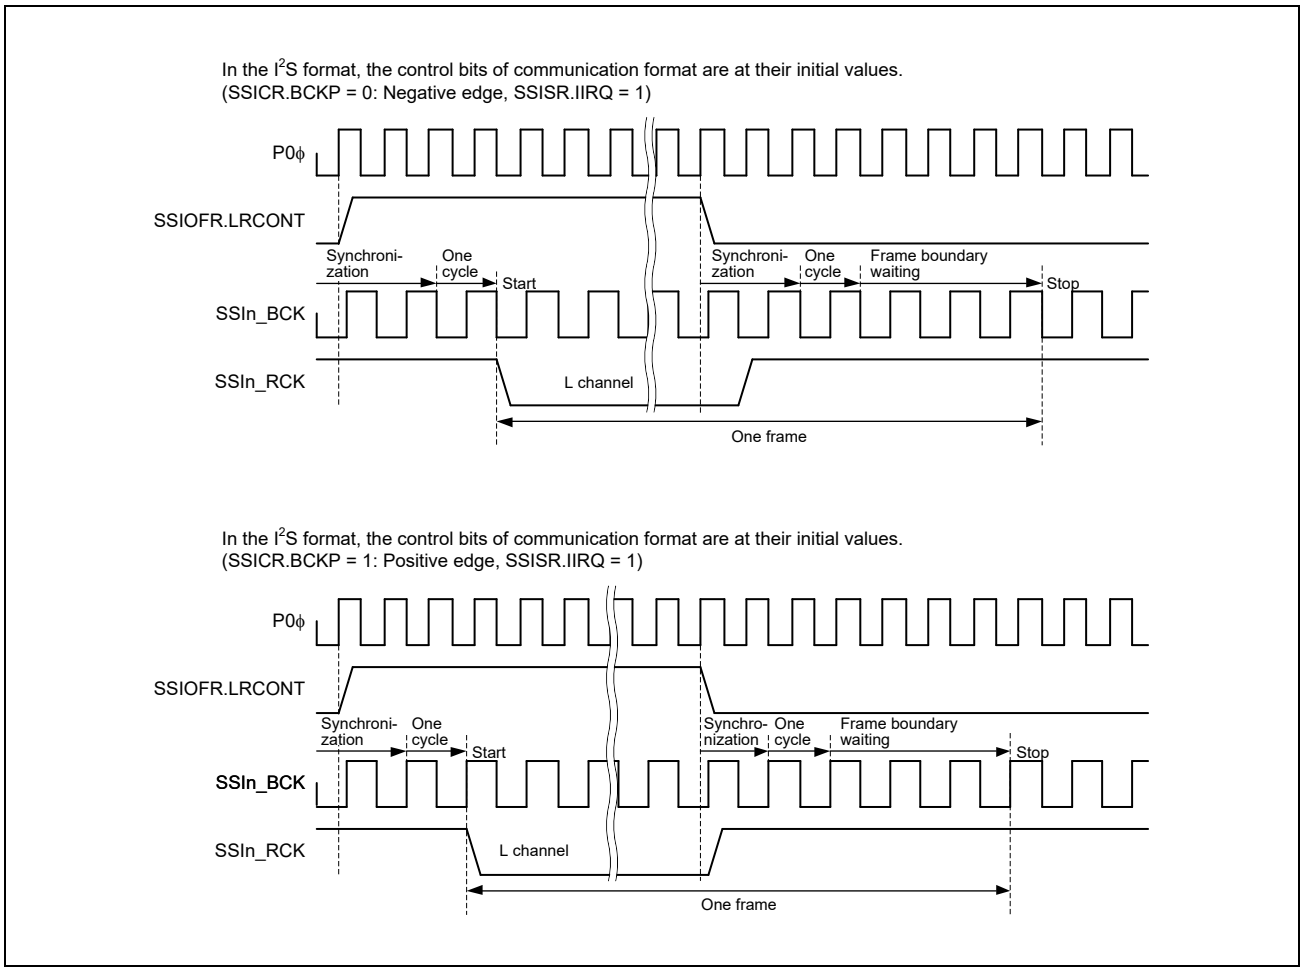


Figure 8.5-43 Example of LRCK/FS Continuation Release with SSIOFR.LRCONT

NOTE

To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIF-2 is in the idle state in master- mode communication (SSICR.MST = 1), note the following: The output stops when 0 is written from 1 to SSIOFR.LRCONT. (**Figure 8.5-43**). Make sure that the remote device is not affected.

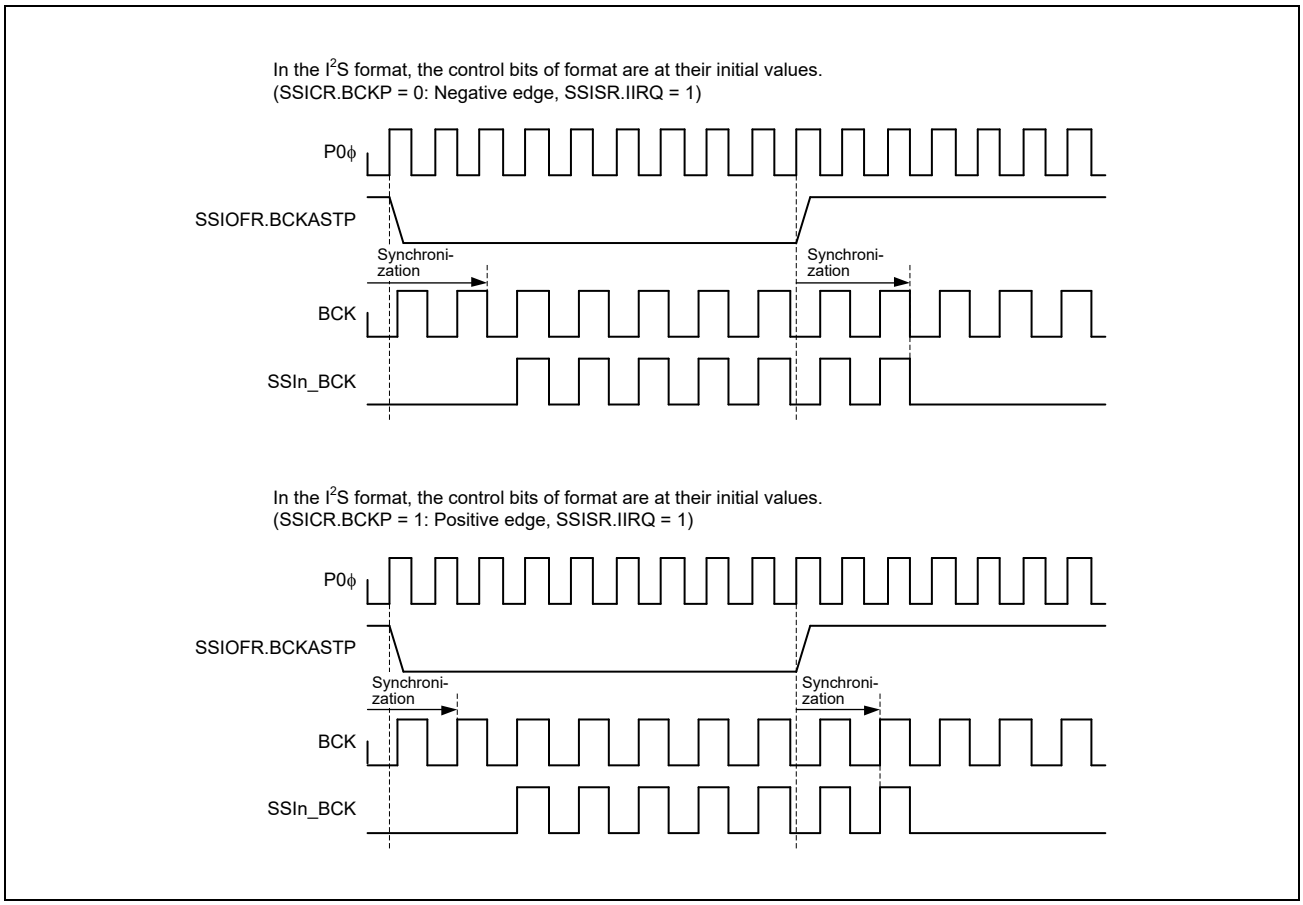

Figure 8.5-44 Example of Stopping SSIBCK with SSIOFR.BCKASTP

NOTE

To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIF-2 is in the idle state, note the following; By writing 0 to SSIOFR.BCKASTP while it is 1, the output stops immediately (**Figure 8.5-44**). So, make sure that the remote device is not affected.

8.5.5.1.2 Communication States

In this state, SSIF-2 is during communication. **Figure 8.5-45** shows transitions of communication states and **Table 8.5-17** lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

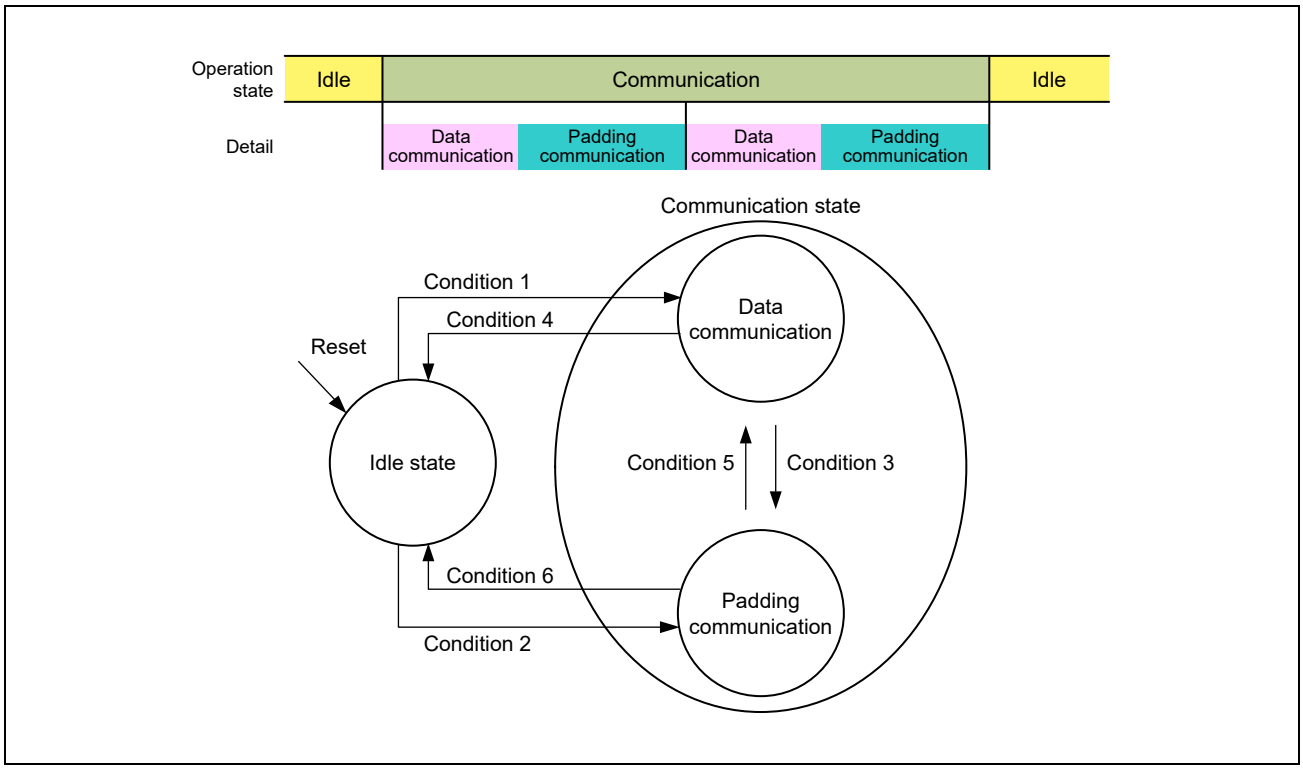

Figure 8.5-45 Communication State Transition

Table 8.5-17 Condition for Communication State Transition

Condition No.	Condition for Transition
1	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits.
2	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits.
3	The following all of three conditions are satisfied: ● SSICR.TEN = 1 or SSICR.REN = 1 ● In the setting without padding bits ● Transfer data words of the last data bit is completed.
4	The following all of two conditions are satisfied: ● SSICR.SDTA = 1 or without padding bits ● Transfer data words of the last data bit of one frame is completed while SSICR.TEN = 0 and SSICR.REN = 0
5	Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1
6	The following all of two conditions are satisfied: ● SSICR.SDTA = 0 and with padding bits ● Transfer of the last data bit of one frame is completed while SSICR.TEN = 0 and SSICR.REN = 0.

See **Table 8.5-13** for the setting with/without padding bits.

(1) Data Communication State

In this state, SSIF-2 is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIF-2 is during data communication for all the time (**Figure 8.5-46**). By disabling transmission and reception (SSICR.TEN = 0 and SSICR.REN = 0), SSIF-2 transits to the idle state (**Figure 8.5-47**).

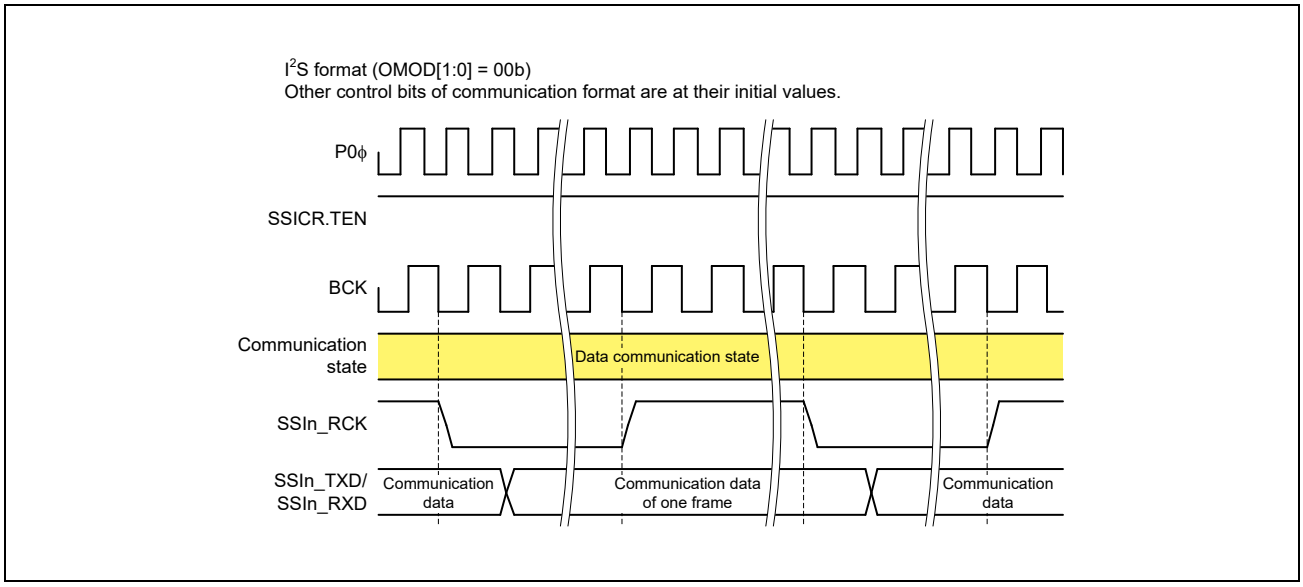

Figure 8.5-46 Continuation of the Data Communication State

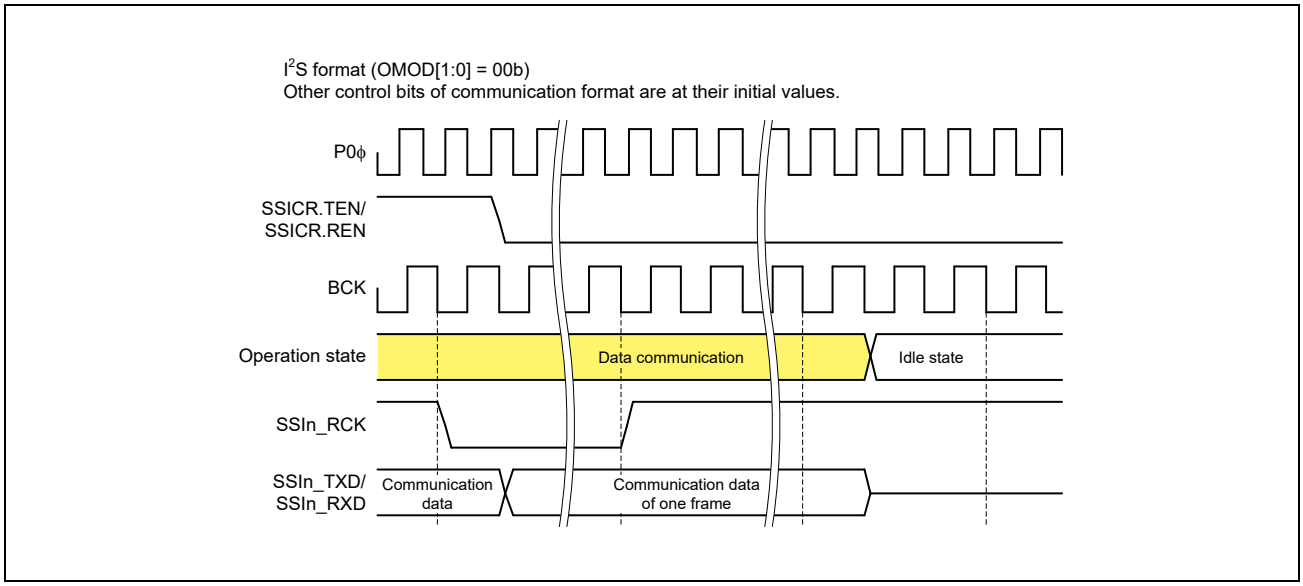

Figure 8.5-47 Halt from the Data Communication State (without Padding Bits)

State Transition in the Setting with Padding Bits

During communication (SSISR.IIRQ = 0), after completing transfer of the last bit of a data word, SSIF-2 transits to the padding communication state from data communication state (**Figure 8.5-48**). By disabling transmission and reception (SSICR.TEN = 0 and SSICR.REN = 0) while SSICR.SDTA = 1, SSIF-2 transits to the idle state from data communication state when the communication stop is done. (**Figure 8.5-49**).

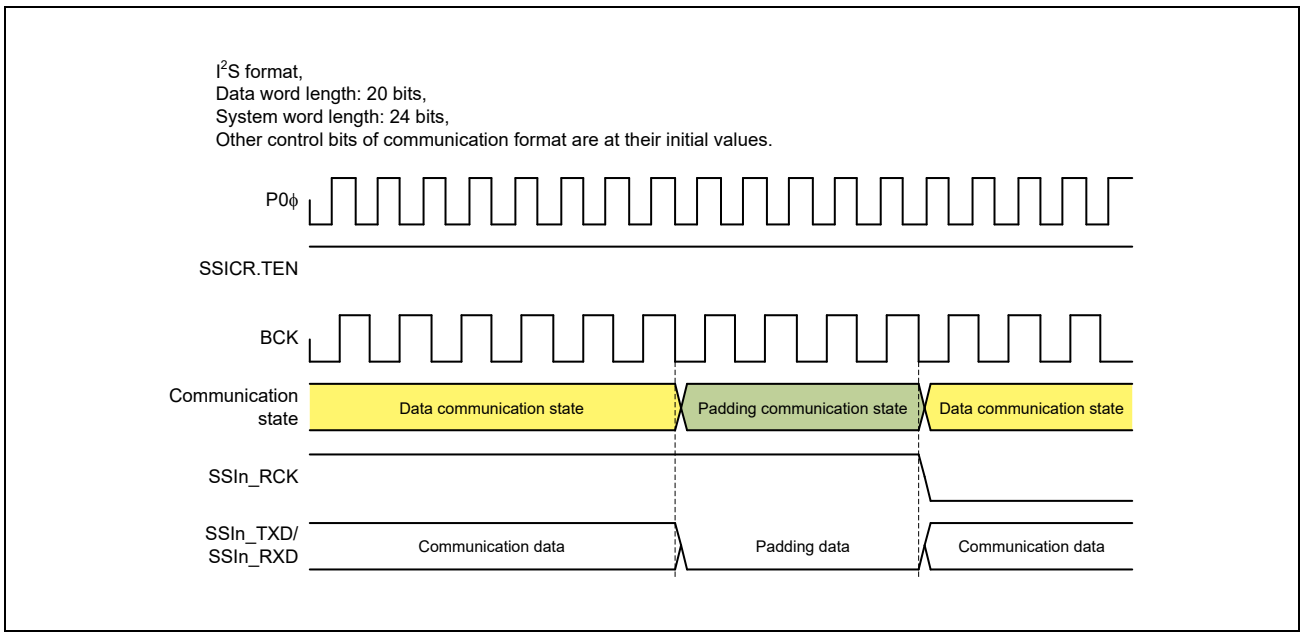

Figure 8.5-48 Transition from Data Communication to Padding Communication

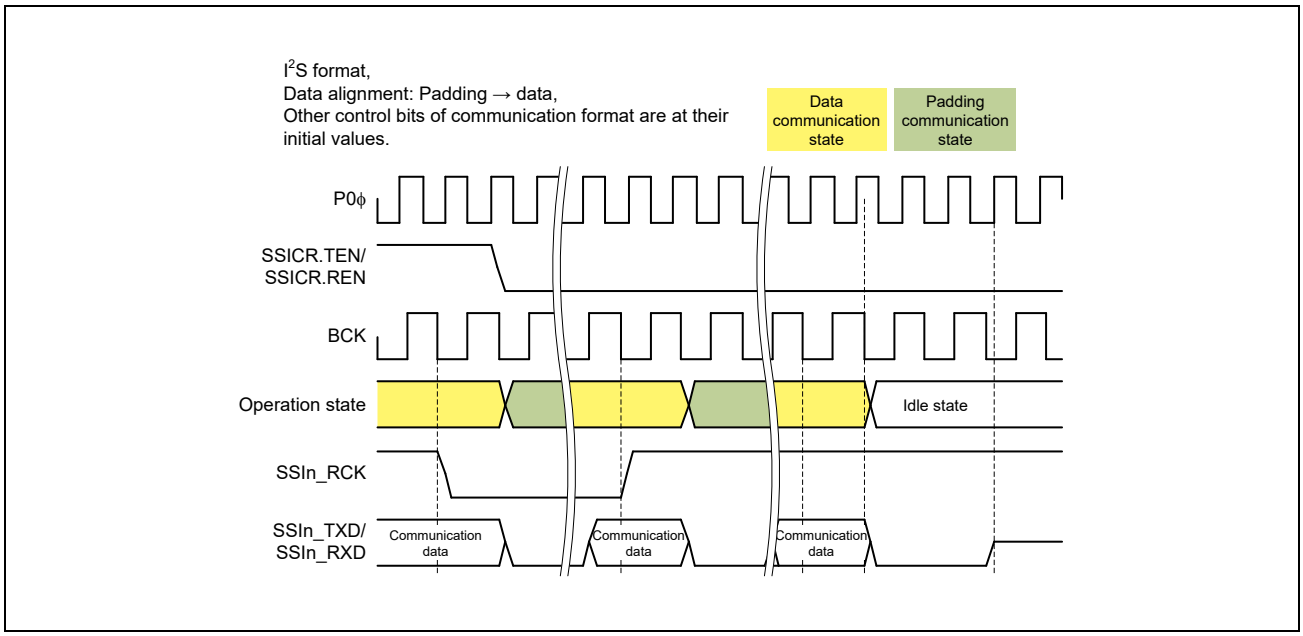

Figure 8.5-49 Halt from Data Communication (with Padding Bits)

(2) Padding Communication State

In this state, SSIF-2 is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

State Transition in the Setting with Padding Bits

During communication (SSISR.IIRQ = 0), after completing transfer of the last padding bit, SSIF-2 transits to data communication state (**Figure 8.5-48**). By disabling transmission and reception (SSICR.TEN = 0 and SSICR.REN = 0) while SSICR.SDTA = 0, SSIF-2 transits to the idle state from padding communication when the communication stop is done. (**Figure 8.5-50**).

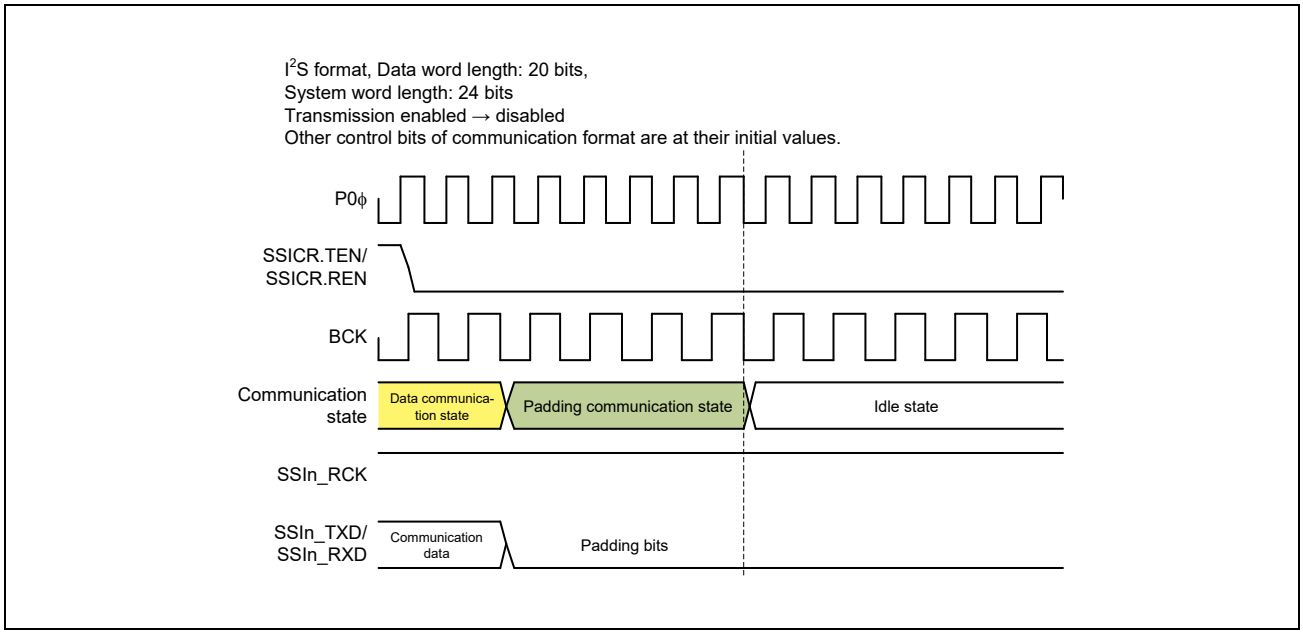

Figure 8.5-50 Halt from the Padding Communication State

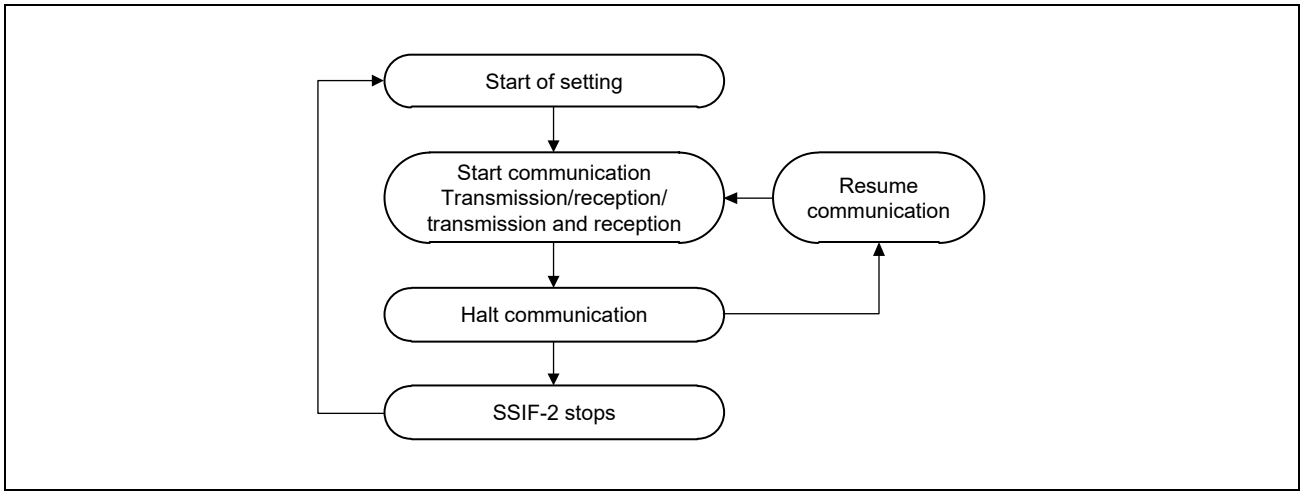
8.5.5.2 Communication Operation

Figure 8.5-51 shows the communication flow of SSIF-2.



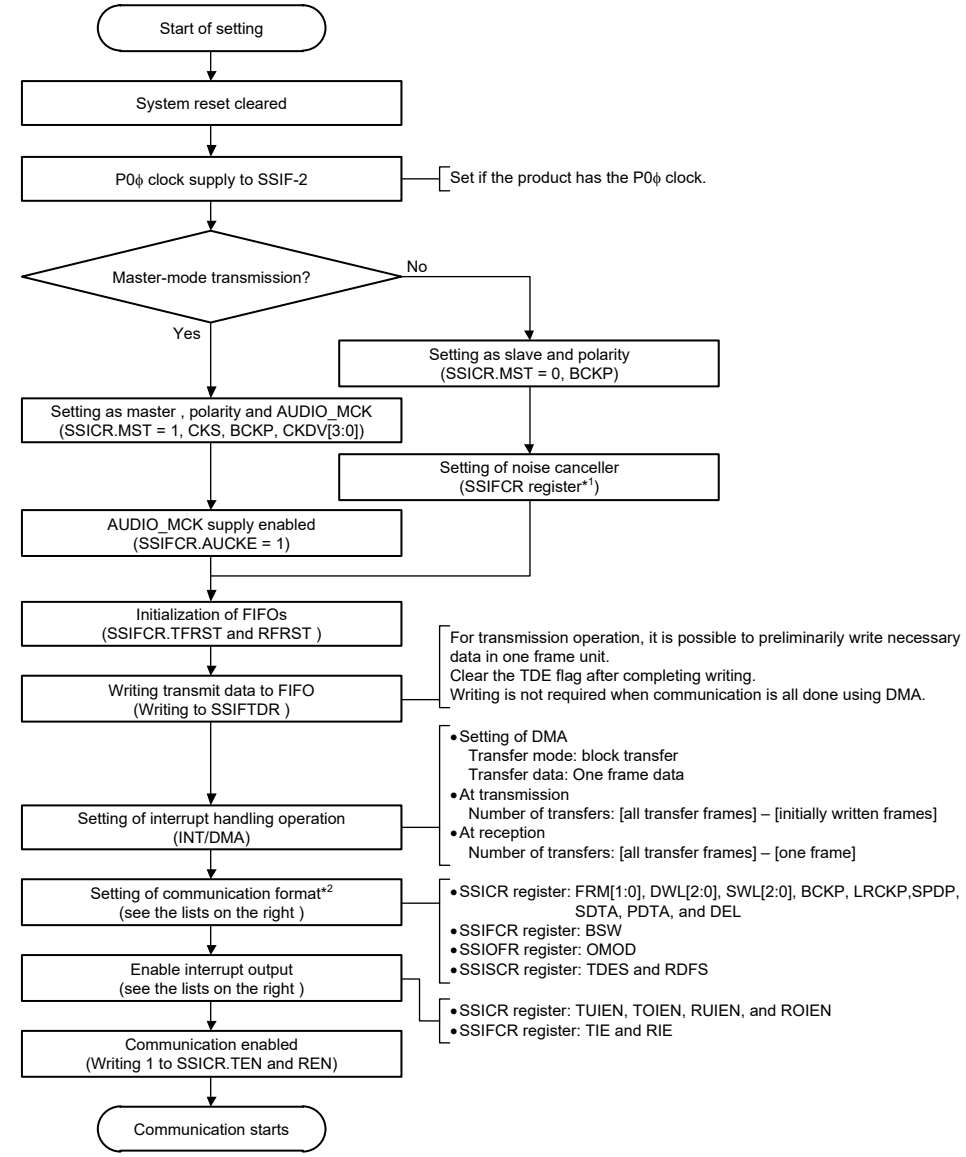


Figure 8.5-51 SSIF-2 Communication Operation

The procedure of each operation is described in **8.5.5.2.1 Start Communication** to **8.5.5.2.7 Resume Communication**.

8.5.5.2.1 Start Communication

This section describes how to start communication of SSIF-2. **Figure 8.5-52** shows the procedure to start communication. Be sure to follow the procedure. See **8.5.5.2.2 Transmission** for transmission operation and **8.5.5.2.3 Reception** for reception operation.

Note 1. BCKNCE, LRCKNCE, LRCKNCE
Change all the settings of the noise cancellation to the same setting.

Note 2. Set SSICR.MUEN, SSIOFR.BCKASTP, and SSIOFR.LRCONT after completing the setting of the communication format.

Figure 8.5-52 Procedure to Start Communication (CPU Procedure)

For SSIF-2 communication, continuous communication is possible with DMA interrupt handling. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

8.5.5.2.2 Transmission

Follow the transmission operation procedure (**Figure 8.5-53**) while the transmission is operating.

Transmission starts in synchronization with the start trigger of the SSILRCK/SSIFS signal while transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0) and while there is one or more frame of serial data in the transmit FIFO data register (SSIFTDR).

SSIF-2 outputs a transmit data empty interrupt to DMA according to the setting condition of TDE (SSISCR.TDES) and transmit data empty interrupt (SSIFCR.TIE) being enabled.

This interrupt requests writing to the transmit FIFO data register (SSIFTDR). By writing to SSIFTDR at each generation of an interrupt, serial data transmission is realized.

In the procedure to start communication, set DMA handling for transmit data empty interrupts as writing to the transmit FIFO data register (SSIFTDR). As a result, SSIF-2 is able not to mediate CPU and to transmit continuous data. When it becomes empty capacity of transmission FIFO data register set with SSISCR.TDES, transmission data empty interrupt is generated. Set the writing number of times according to empty capacity of transmission FIFO data register that transmission data empty interrupt shows. In a case of an error, stop receive procedure (**8.5.5.2.5 Halt Communication**) and then take the error procedure **(8.5.5.2.6 Error Handling**).

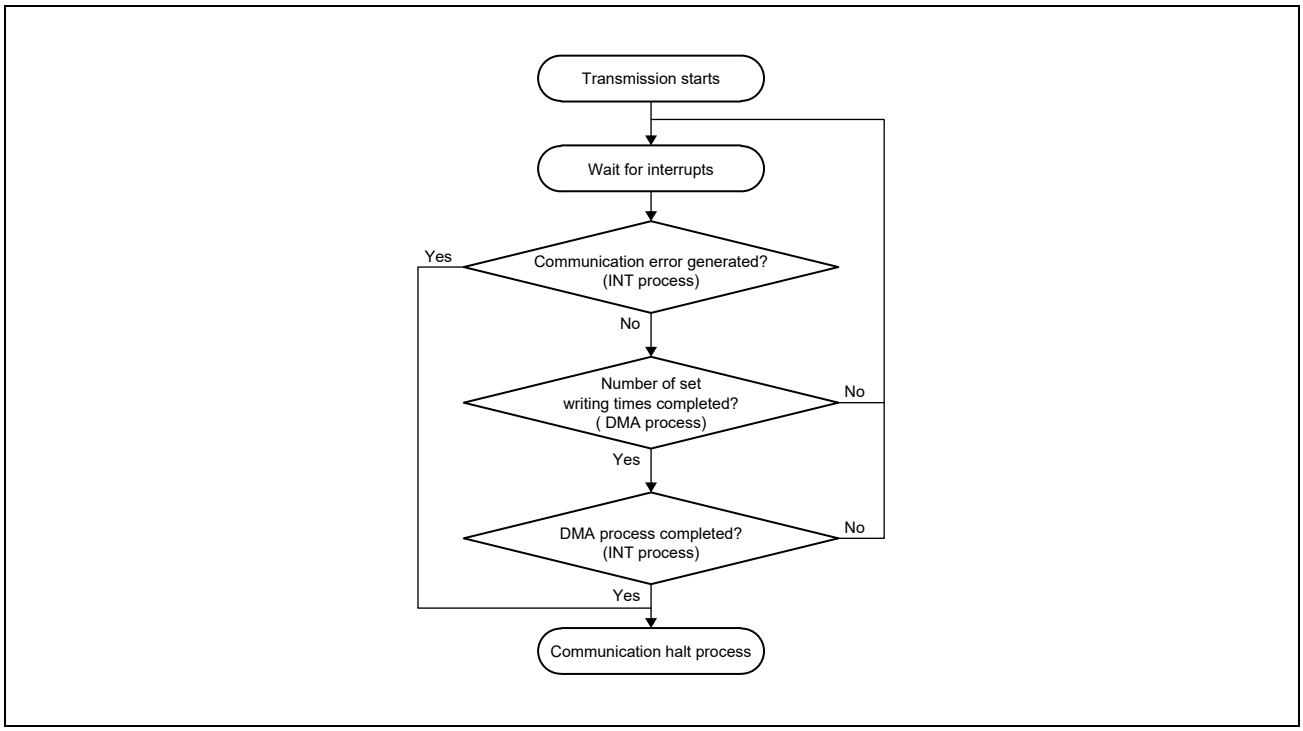

Figure 8.5-53 Transmission Procedure

NOTE

The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe one of SSIFSR.TDE, and write it in SSIFTDR. Follow empty capacity of transmission FIFO data register set with SSISCR.TDES about the number of times written in SSIFTDR detecting 1 of SSIFSR.TDE. After writing the transmission data corresponding to the free space to SSIFTDR, polling '1' of SSIFSR.TDE and repeating this enables continuous transmission operation.

8.5.5.2.3 Reception

Follow the reception operation procedure (**Figure 8.5-54**) while the reception is operating.

Reception starts in synchronization with the start trigger of the SSILRCK/SSIFS signal while reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1). SSIF-2 outputs a receive data full interrupt to DMA according to the setting of RDF (SSISCR.RDFS) and receive data empty interrupt (SSIFCR.RIE) being enabled. This interrupt requests reading from the receive FIFO data register (SSIFRDR). By reading from SSIFRDR at each generation of an interrupt, serial data reception is realized.

In the procedure to start communication, set DMA handling for receive data full interrupts as reading from receive FIFO data register (DDIFRDR). As a result, SSIF-2 is able not to mediate CPU and to receive continuous data. If the data capacity of reception FIFO data register set with SSISCR.RDFS is stored, receive data full interrupt is generated. Set the writing number of times according to the data capacity of reception FIFO data register that receive data full interrupt shows.

In the case of an error, stop the receive operation (**8.5.5.2.6 Error Handling**) and then take the error procedure (**8.5.5.2.6 Error Handling**).

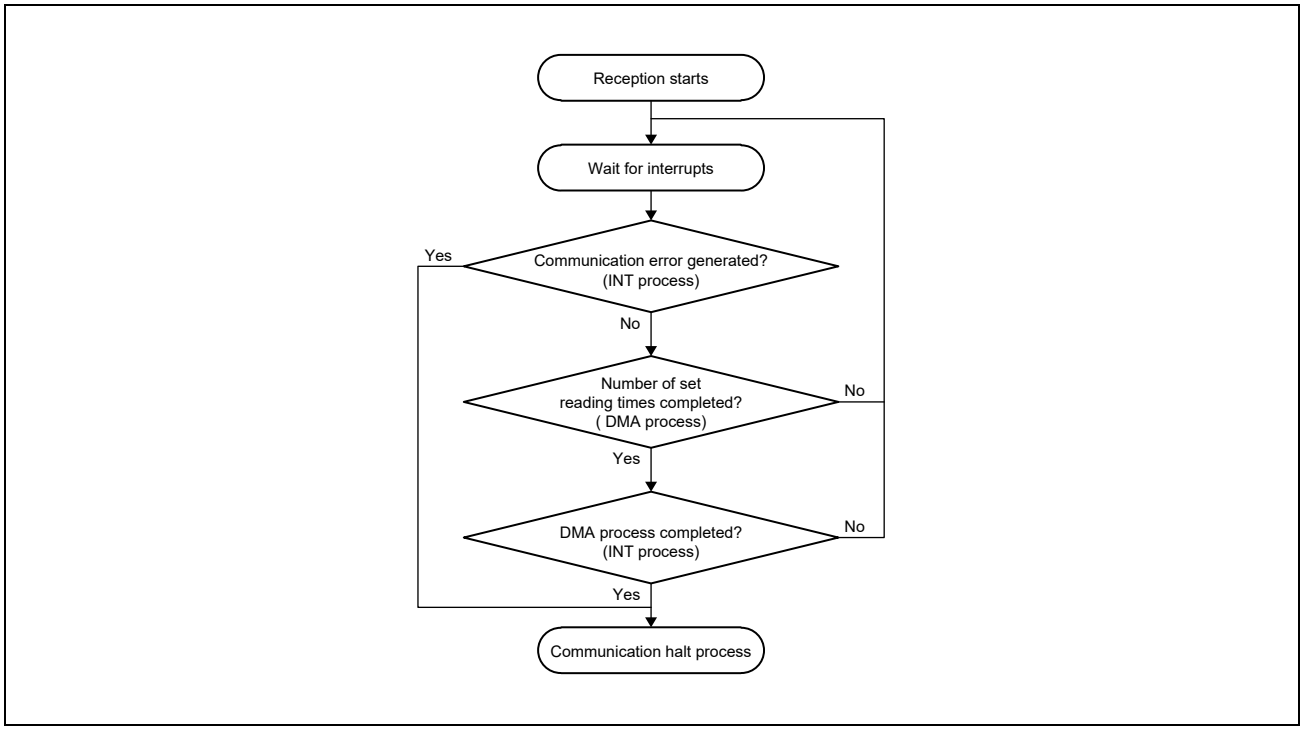

Figure 8.5-54 Reception Procedure

NOTE

The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe 1 of SSIFSR.RDF, and read SSIFRDR. Follow the receive data capacity of reception FIFO data register set with SSISCR.RDFS about the number of times in which SSIFRDR is read detecting 1 of SSIFSR.RDF. After reading the received data from SSIFRDR, Continuous reception operation is possible by polling '1' of SSIFSR.RDF and repeating this.

8.5.5.2.4 Transmission and Reception

Transmission and reception starts in synchronization with the start trigger of the SSILRCK/SSIFS signal while transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1) and while there is one or more frames of serial data in the transmit FIFO data register (SSIFTDR). The transmission and reception operation of SSIF-2 can be transmitted and received continuously by each doing the procedure for showing in the transmission operation (**8.5.5.2.2 Transmission**) and the reception operation (**8.5.5.2.3 Reception**). As transmission and reception are independent in SSIF-2, see sections of transmission and reception respectively. See **8.5.5.2.5 Halt Communication** to halt communication.

8.5.5.2.5 Halt Communication

This section describes how to halt communication of SSIF-2. **Figure 8.5-55** shows the procedure to halt communication. Be sure to follow the procedure.

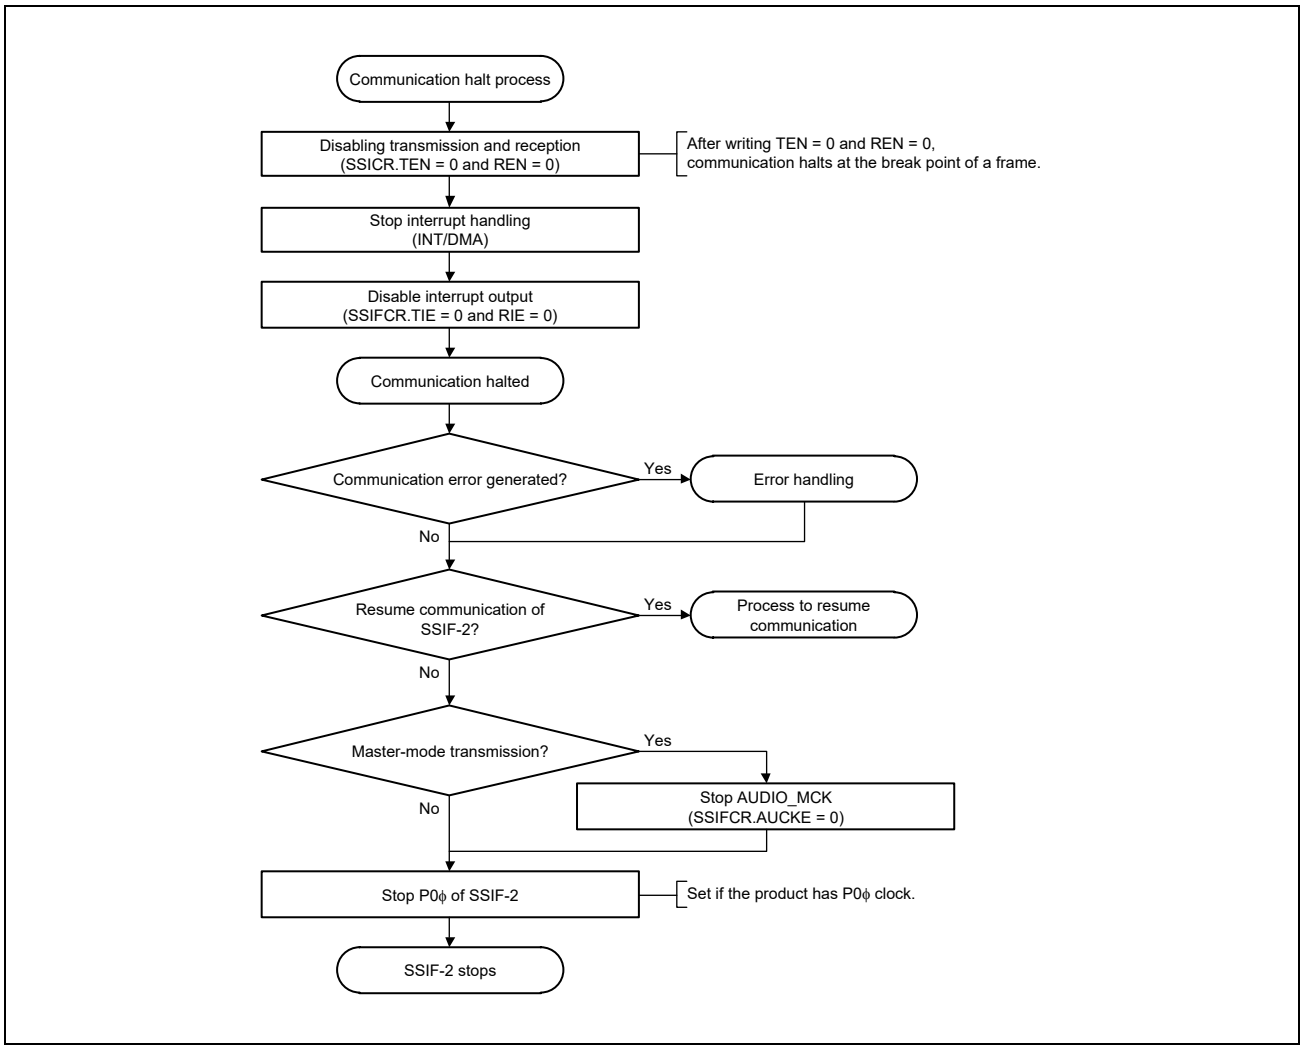

Figure 8.5-55 Procedure to Halt Communication (CPU Procedure)

To halt the communication of SSIF-2, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1

To resume communication of SSIF-2 in the previous setting, see **8.5.5.2.7 Resume Communication**.

NOTE

When communication of SSIF-2 is halted according to the procedure to halt communication in **Figure 8.5-55**, resume communication according to the procedure to start communication in **Figure 8.5-52**.

8.5.5.2.6 Error Handling

SSIF-2 has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIF-2 need to be restarted. Take the error procedure (**Figure 8.5-56**) according to the procedure to halt communication (**Figure 8.5-55**).

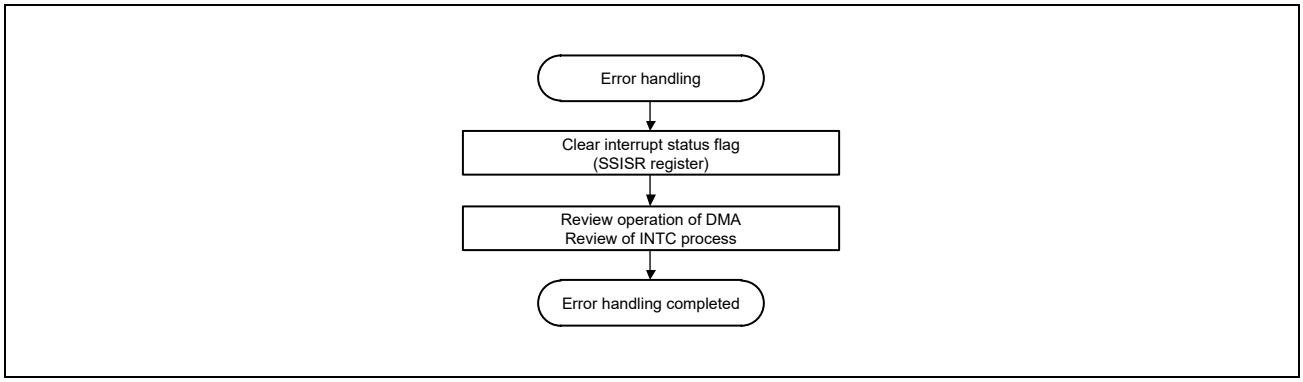

Figure 8.5-56 Error Handling Procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See descriptions of flags in **8.5.4.1.2 Status Register (SSISR)** for the setting conditions of error flags.

(1) Transmit Underflow Error

In the case a transmit underflow error is generated during transmission (SSICR.TEN = 1, SSISR.IIRQ = 0), review the number of write operations to the transmit FIFO data register (SSIFTDR) according to serial data empty interrupts. After generation of a transmit underflow error, data to be transmitted from SSIF-2 are 0 output. To transmit data written to SSIFTxD pin normally, run the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**). When this error is generated, serial data is consumed as usual. To resume transmission of SSIF-2, write data from the beginning of one frame.

(2) Transmit Overflow Error

In the case a transmit overflow error is generated, review the number of write operations to the transmit FIFO data register (SSIFTDR) according to transmit data empty interrupts. Data is not written to SSIFTDR where a transmit overflow error is generated. This error is generated regardless of while the transmission is operating. To resume transmission of SSIF-2, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**). When communication is resumed, consider the lost serial data.

(3) Receive Underflow Error

In the case a receive underflow error is generated, review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. The value read from SSIFRDR is undefined where a receive underflow error is generated. This error is generated regardless of while the reception is operating. To resume reception of SSIF-2, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**).

(4) Receive Overflow Error

In the case a receive overflow error is generated during reception (SSICR.REN = 1, SSISR.IIRQ = 0), review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. Data is not stored in SSIFRDR when a receive overflow error is generated. To resume reception of SSIF-2, take the procedure to halt communication (**Figure 8.5-55**) and then take the error handling procedure (**Figure 8.5-56**).

8.5.5.2.7 Resume Communication

To resume communication of SSIF-2, follow the procedure shown in **Figure 8.5-57**. After communication is halted, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication (**Figure 8.5-52**). For communication after resume, see **8.5.5.2.2 Transmission** and **8.5.5.2.3 Reception**.

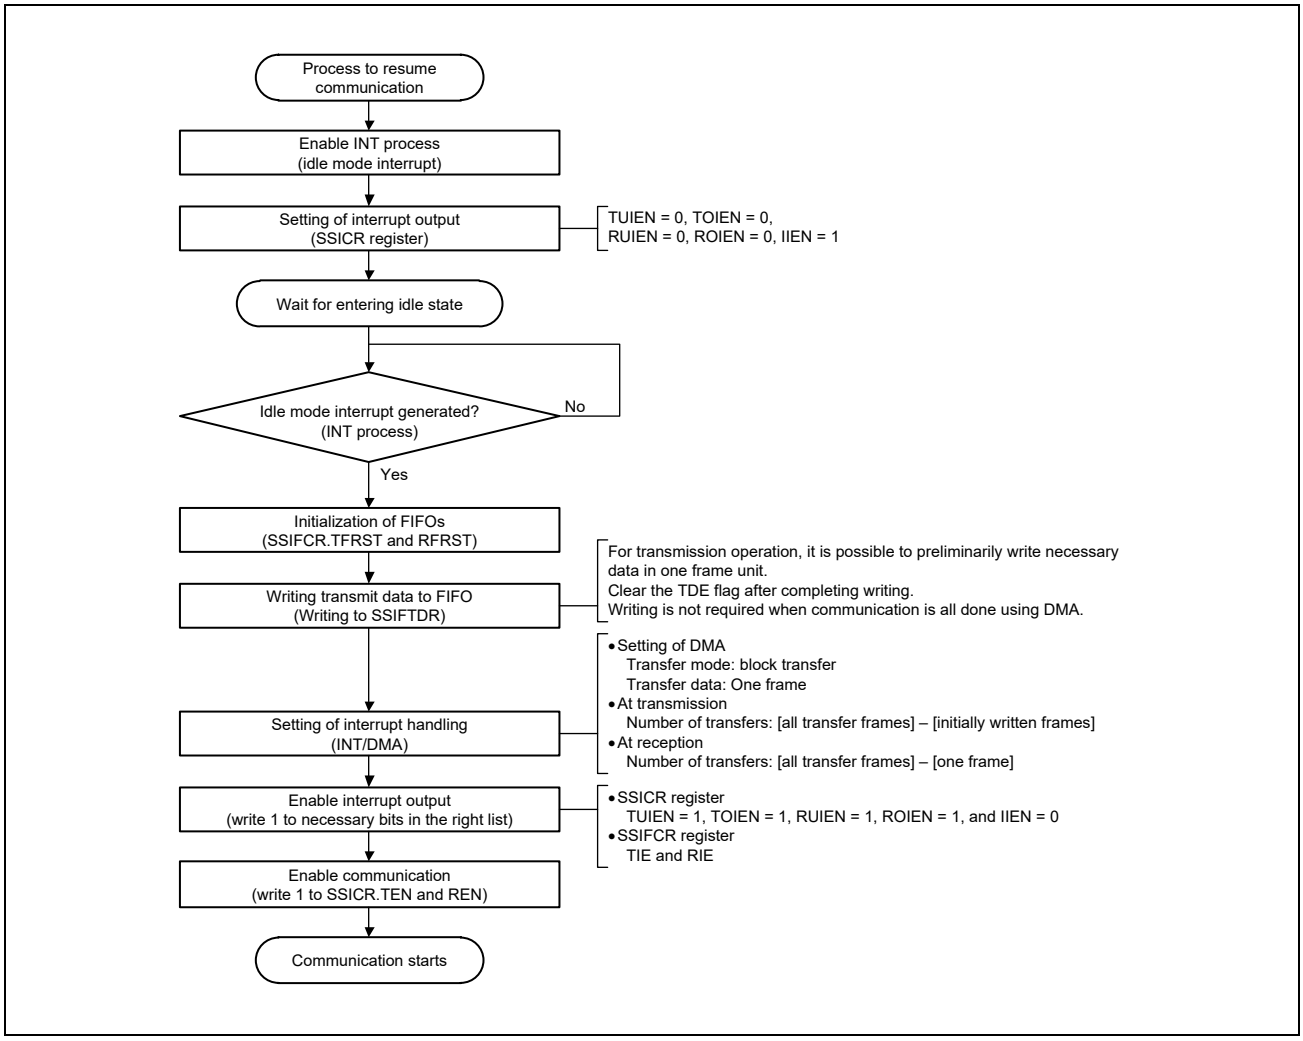

Figure 8.5-57 Procedure to Resume Communication (CPU Procedure)

8.5.5.3 Interrupt Sources

Table 8.5-18 lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and IIEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 8.5-18 Interrupt Sources

Interrupt Source	Interrupt	Interrupt Flag	Interrupt Sense	DMA Activation
INT_ssif_int_req	Transmit underflow interrupt/ Transmit overflow interrupt/ Receive underflow interrupt/ Receive overflow interrupt/ Idle mode interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Level	Not available
INT_ssif_dma_tx	Transmit data empty interrupt	SSIFSR.TDE	Edge	Available
INT_ssif_dma_rx	Receive data full interrupt	SSIFSR.RDF	Edge	Available

8.5.5.3.1 INT_ssif_int_req Interrupt

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIF-2. This interrupt moves from the flag and the output enable permission that five factors have respectively (**Figure 8.5-58**). To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

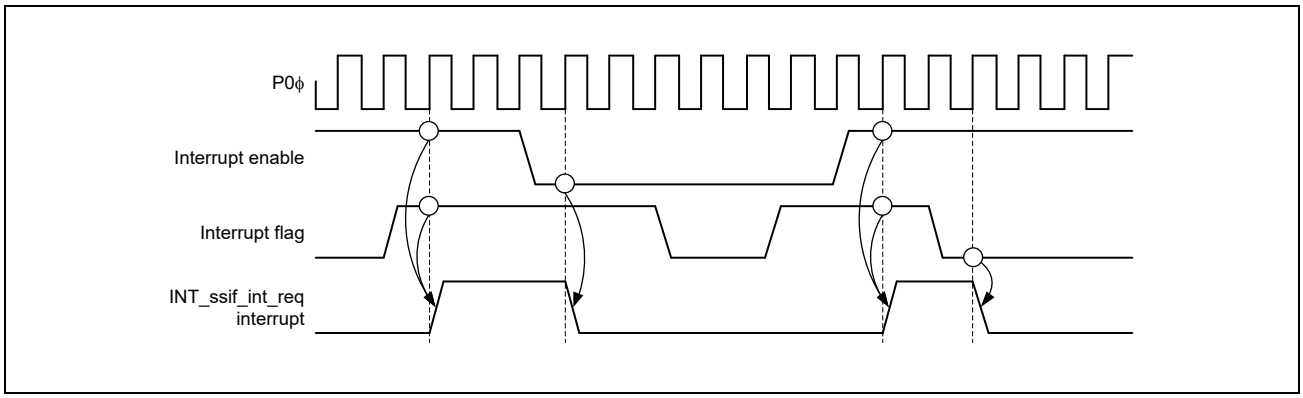

Figure 8.5-58 Timing Chart of the Common Interrupt Source, INT_ssif_int_req

(1) Transmit Underflow Interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. To restart transmission (SSICR.TEN = 1), enable the output of this interrupt (SSICR.TUIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**).

(2) Transmit Overflow Interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIRQ = 1. To restart transmission (SSICR.TEN = 1), enable the output of this interrupt (SSICR.TOIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**).

(3) Receive Underflow Interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIRQ = 1. To restart reception (SSICR.REN = 1), enable the output of this interrupt (SSICR. RUIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**).

(4) Receive Overflow Interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIRQ = 1. To restart reception (SSICR.REN = 1), enable the output of this interrupt (SSICR. ROIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**).

(5) Idle Mode Interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. When the thing that the communication has stopped completely is confirmed, this interrupt is used (**Figure 8.5-57**).

8.5.5.3.2 INT_ssif_dma_tx Interrupt [full-duplex communication]

As the transmit data empty interrupt, a pulse interrupt is output by the following condition.

- SSIFSR.TDE and SSIFCR.TIE becomes 1.
  SSIF-2 operation: SSIFSR.TDE becomes 1 from 0 while SSIFCR.TIE = 1
  CPU operation: SSIFCR.TIE is changed to 1 from 0 while SSIFSR.TDE = 1

An interrupt suppression function is available for this interrupt to prevent the thing that cannot be taken. When the DMA is busy state (Interrupt cannot be accepted), and the interruption condition occurs, output of this interrupt is held. This interrupt is output after the DMA becomes acceptable (**Figure 8.5-59**).

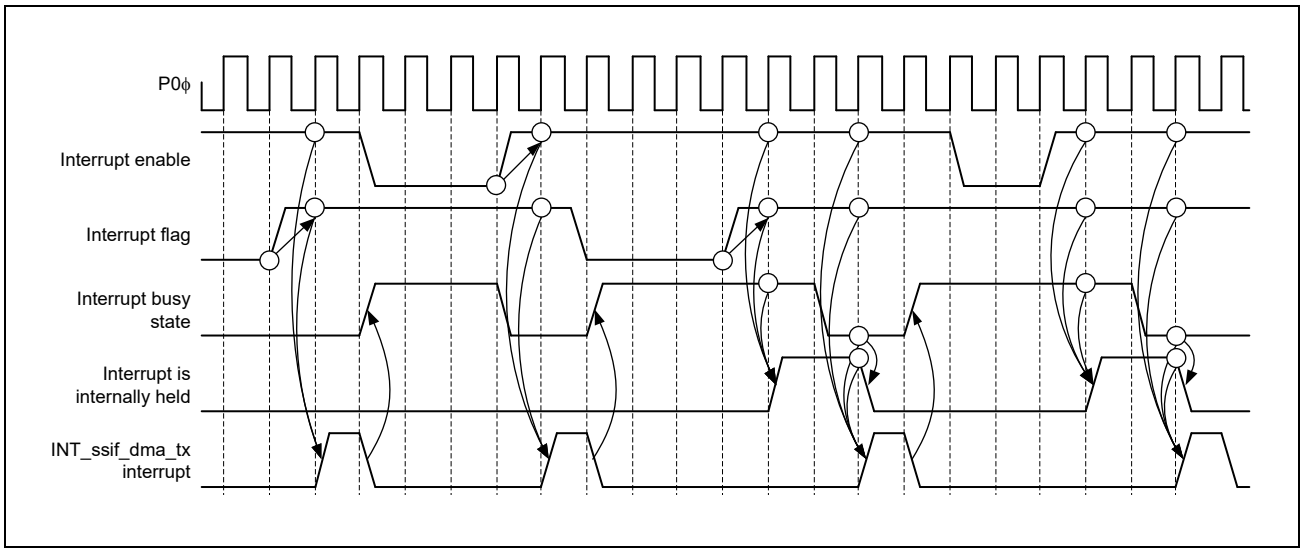

Figure 8.5-59 INT_ssif_dma_tx Interrupt Timing Chart

8.5.5.3.3 INT_ssif_dma_rx Interrupt [full-duplex communication]

As the receive data full interrupt, a pulse interrupt is output by the following condition.

- SSIFSR.RDF and SSIFCR.RIE becomes 1.
  SSIF-2 operation: SSIFSR.RDF becomes 1 from 0 while SSIFCR.RIE = 1.
  CPU operation: SSIFCR.RIE is changed to 1 from 0 while SSIFSR.RDF = 1.

An interrupt suppression function is available for this interrupt to prevent the thing that cannot be taken. When the DMA is busy state (Interrupt cannot be accepted), and the interruption condition occurs, output of this interrupt is held. This interrupt is output after the DMA becomes acceptable. It operates in the same way as in **Figure 8.5-59**.

8.5.5.4 Software Resets

SSIF-2 has three software reset bits to reset its states.

- SSIF-2 software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSICR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST)

It explains the procedure of three software reset.

8.5.5.4.1 Software Reset Procedure

(1) SSIF-2 Software Reset

For the SSIF-2 software reset bit (SSIFCR.SSIRST), follow the procedure shown in **Figure 8.5-60**. After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication (**Figure 8.5-52**). See **8.5.5.2.2 Transmission** and **8.5.5.2.3 Reception** respectively for transmission and reception after communication is resumed.

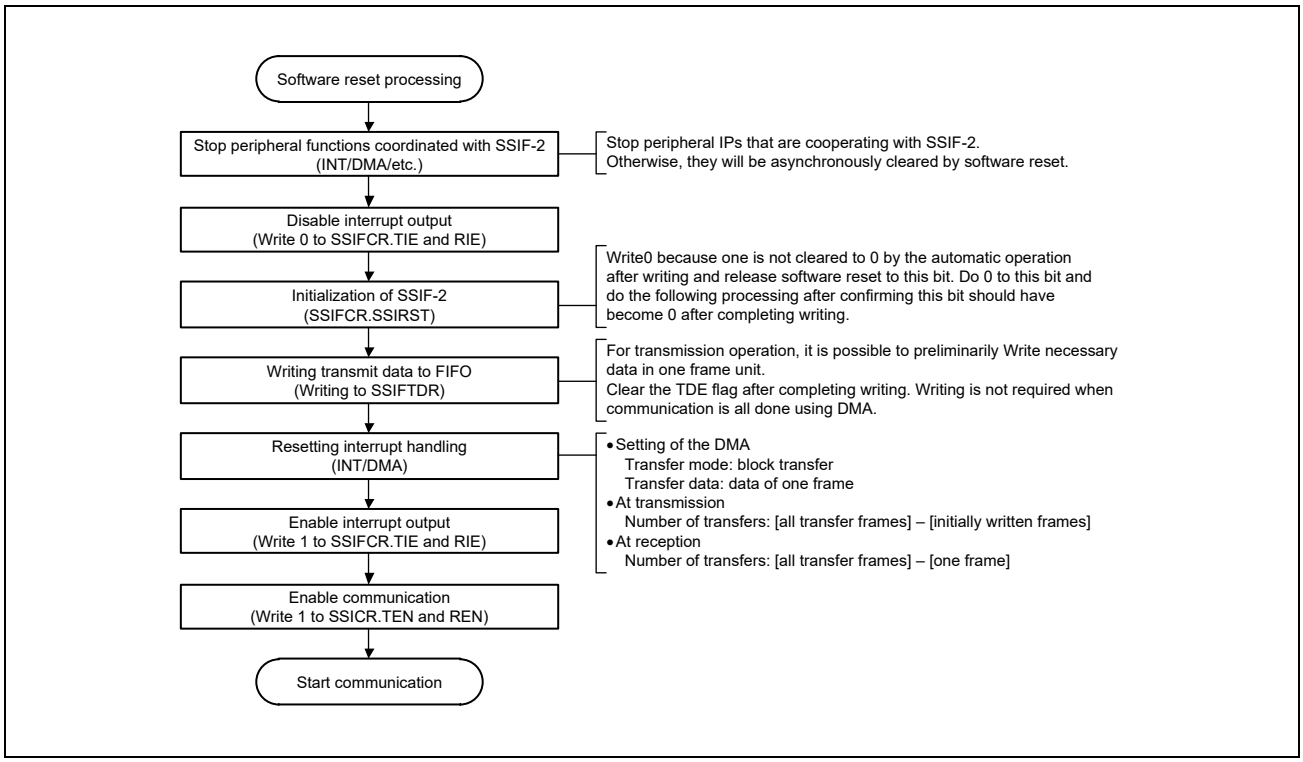

Figure 8.5-60 Software Reset Procedure (CPU Procedure)

(2) Transmit FIFO Data Register Reset

To initiate a transmit FIFO data register reset, follow the procedure to start communication (**Figure 8.5-52**) and resume communication (**Figure 8.5-57**).

(3) Receive FIFO Data Register Reset

To initiate a receive FIFO data register reset, follow the procedure to start communication (**Figure 8.5-52**) and resume communication (**Figure 8.5-57**).

8.5.6 Notes

8.5.6.1 Notes

8.5.6.1.1 Attention by Communication Using DMA

SSIF-2 assumes the DMA access as follows.

Table 8.5-19 Interrupt to Expect DMA Access

Communication Operation	Interrupt	DMA Access	LSI Specification	Remarks
Transmission	INT_ssif_dma_tx	Write to SSIFTDR	Full duplex transmission	
Reception	INT_ssif_dma_rx	Read SSIFRDR	Full duplex transmission	
Transmission and Reception	INT_ssif_dma_tx	Write to SSIFTDR	Full duplex transmission	
	INT_ssif_dma_rx	Read SSIFRDR	Full duplex transmission	

8.5.6.1.2 Notes for Slave-Mode Communication

(1) ADCKE Control

In slave-mode communication (SSICR.MST = 0), SSIF-2 needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIF-2 becomes idle, take the procedure to start communication (**Figure 8.5-52**) or wait for an idle state by taking the procedure to resume communication (**Figure 8.5-57**).

(2) SSI_RCK

SSIF-2 has the terminal SSI_RCK that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSI_RCK only as a communication start trigger.

8.5.6.1.3 Notes for Master-Mode Communication

(1) ADCKE Control

In master-mode communication (SSICR.MST = 1), SSIF-2 operates with the audio clock (AUDIO_MCK). To stop SSIF- 2 completely, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.ADCKE. If 0 is written to SSIFCR.ADCKE before SSIF-2 becomes idle, take the procedure to start communication (**Figure 8.5-52**).

(2) LRCONT Control

To stop the output to the SSI_RCK pin with SSIOFR.LRCONT when SSIF-2 is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when 0 is written from 1 to SSIOFR.LRCONT. (**Figure 8.5-43**). Make sure that the remote device is not affected.

(3) BCKASTP Control

To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIF-2 is in the idle state, note the following; By writing 0 to SSIOFR.BCKASTP while it is 1, the output stops immediately (**Figure 8.5-44**). So, make sure that the remote device is not affected.

NOTE

When the opposing device who is the slave needs the clock of the terminal SSI_BCK before the communication operates, it is not possible to use it.

8.5.6.1.4 Notes for Communication Flow

(1) When an Error Interrupt is Generated

SSIF-2 has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIF-2 need to be restarted. Take the error procedure (**Figure 8.5-56**) according to the procedure to halt communication (**Figure 8.5-55**).

(a) Transmit Underflow Error

In the case a transmit underflow error is generated during transmission (SSICR.TEN = 1, SSISR.IIRQ = 0), review the number of write operations to the transmit FIFO data register (SSIFTDR) according to serial data empty interrupts. After generation of a transmit underflow error, data to be transmitted from SSIF-2 are 0 output. To transmit data written to SSIFTxD pin normally, run the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**). When this error is generated, serial data is consumed as usual. To resume transmission of SSIF-2, write data from the beginning of one frame.

(b) Transmit Overflow Error

In the case a transmit overflow error is generated, review the number of write operations to the transmit FIFO data register (SSIFTDR) according to transmit data empty interrupts. Data is not written to SSIFTDR where a transmit

overflow error is generated. This error is generated regardless of while the transmission is operating. To resume transmission of SSIF-2, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**). When communication is resumed, consider the lost serial data.

(c) Receive Underflow Error

In the case a receive underflow error is generated, review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. The value read from SSIFRDR is undefined where a receive underflow error is generated. This error is generated regardless of while the reception is operating. To resume reception of SSIF-2, take the procedure to halt communication (**Figure 8.5-55**) and then take the error procedure (**Figure 8.5-56**).

(d) Receive Overflow Error

In the case a receive overflow error is generated during reception (SSICR.REN = 1, SSISR.IIRQ = 0), review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. Data is not stored in SSIFRDR when a receive overflow error is generated. To resume reception of SSIF-2, take the procedure to halt communication (**Figure 8.5-55**) and then take the error handling procedure (**Figure 8.5-56**).

(2) Transmit Data Empty Interrupt

The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe one of SSIFSR.TDE, and write it in SSIFTDR. Follow empty capacity of transmission FIFO data register set with SSISCR.TDES about the number of times written in SSIFTDR detecting 1 of SSIFSR.TDE. Clear the transmission data that corresponds to empty capacity and clear the SSIFSR.TDE flag to SSIFTDR after writing. Transmission operation consecutive by the repeated thing is possible. SSIFSR.TDE is not cleared when not clearing.

(3) Receive Data Full Interrupt

The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe 1 of SSIFSR.RDF, and read SSIFRDR. Follow the receive data capacity of reception FIFO data register set with SSISCR.RDFS about the number of times in which SSIFRDR is read detecting 1 of SSIFSR.RDF. Clear data that does the reception completion and clear the SSIFSR.RDF flag from SSIFRDR after reading. Reception operation consecutive by the repeated thing is possible. SSIFSR.RDF is not cleared when not clearing.

(4) Switching Transfer Modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit and the SSICR.REN bit again and resume transfer.

(5) Resume Communication after Halting SSIF-2

When communication of SSIF-2 is halted according to the procedure to halt communication in **Figure 8.5-55**, resume communication according to the procedure to resume communication in **Figure 8.5-52**.

8.5.6.1.5 Write Access Restriction

(1) SSICR Register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If written, the operation performed immediately after writing is not guaranteed. For example, after enabling operation, make sure that SSISR.IIRQ = 0 and after disabling operation, make sure that SSISR.IIRQ = 1.

(a) TEN Bit and REN Bit

Writing 1 to these bits, transmission starts in synchronization with start trigger. Refer to **8.5.5.2.2 Transmission**, **8.5.5.2.3 Reception**, and **8.5.5.2.4 Transmission and Reception** for details. Writing 0 to these bits, transmission stops in synchronization with next frame boundary. Set 1 at the same time when you use SSIF-2 as transmission and reception. To stop communication, make sure to stop transmission and reception (TEN = 0 and REN = 0).

(2) SSICR Register

(a) Clear operation of TUIRQ and TOIRQ

After the communication is permitted (SSICR.TEN is written and '1' is written from '0'), the transmission error flag (TOIRQ and TUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the transmission error flag might not be able to be read.

(b) Clear operation of RUIRQ and ROIRQ

After the communication is permitted (SSICR.REN is written and '1' is written from '0'), the transmission error flag (ROIRQ and RUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the reception error flag might not be able to be read.

(3) Communication State

Writing to the bits with shaded area in **Table 8.5-20** is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 8.5-20 Bits Protected from Writing during Communication

SECTION 8 AUDIO

8.6 Renesas SPDIF Interface

8.6.1 Overview

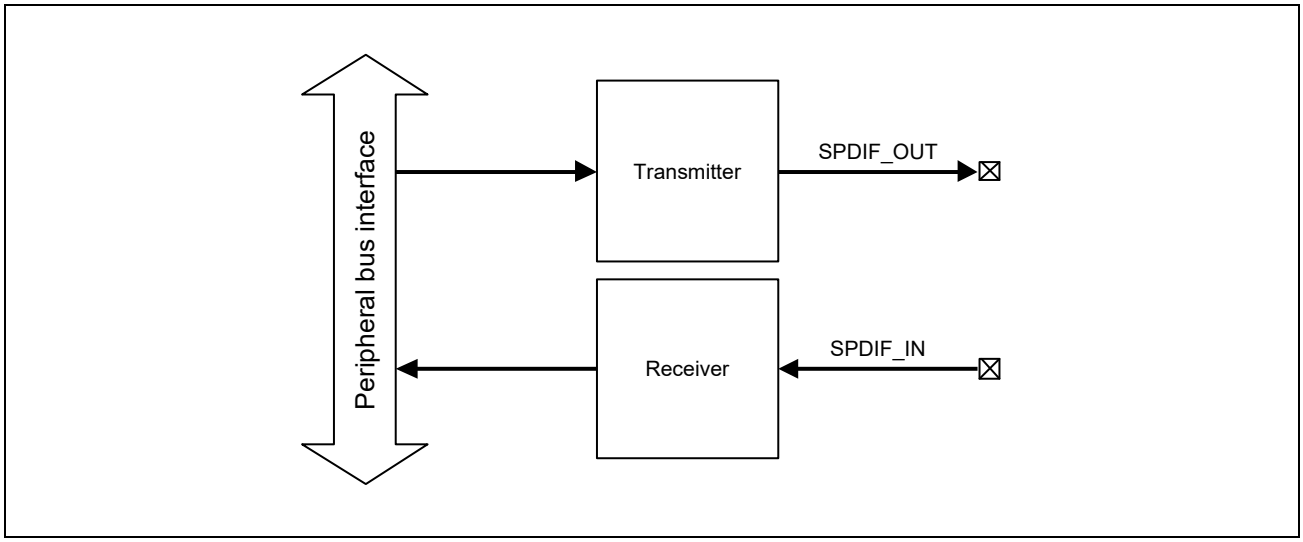

Figure 8.6-1 Overview Block Diagram

8.6.2 Features

- Supports the IEC 60958 standard (stereo and consumer use modes only).
- Supports sampling frequencies of 32 kHz, 44.1 kHz, and 48 kHz.
- Supports audio word sizes of 16 to 24 bits per sample.
- Biphase mark encoding.
- Double buffered data.
- Parity encoded serial data.
- Simultaneous transmit and receive
- Receiver autodetects IEC 61937 compressed mode data

8.6.3 Functional Block Diagram

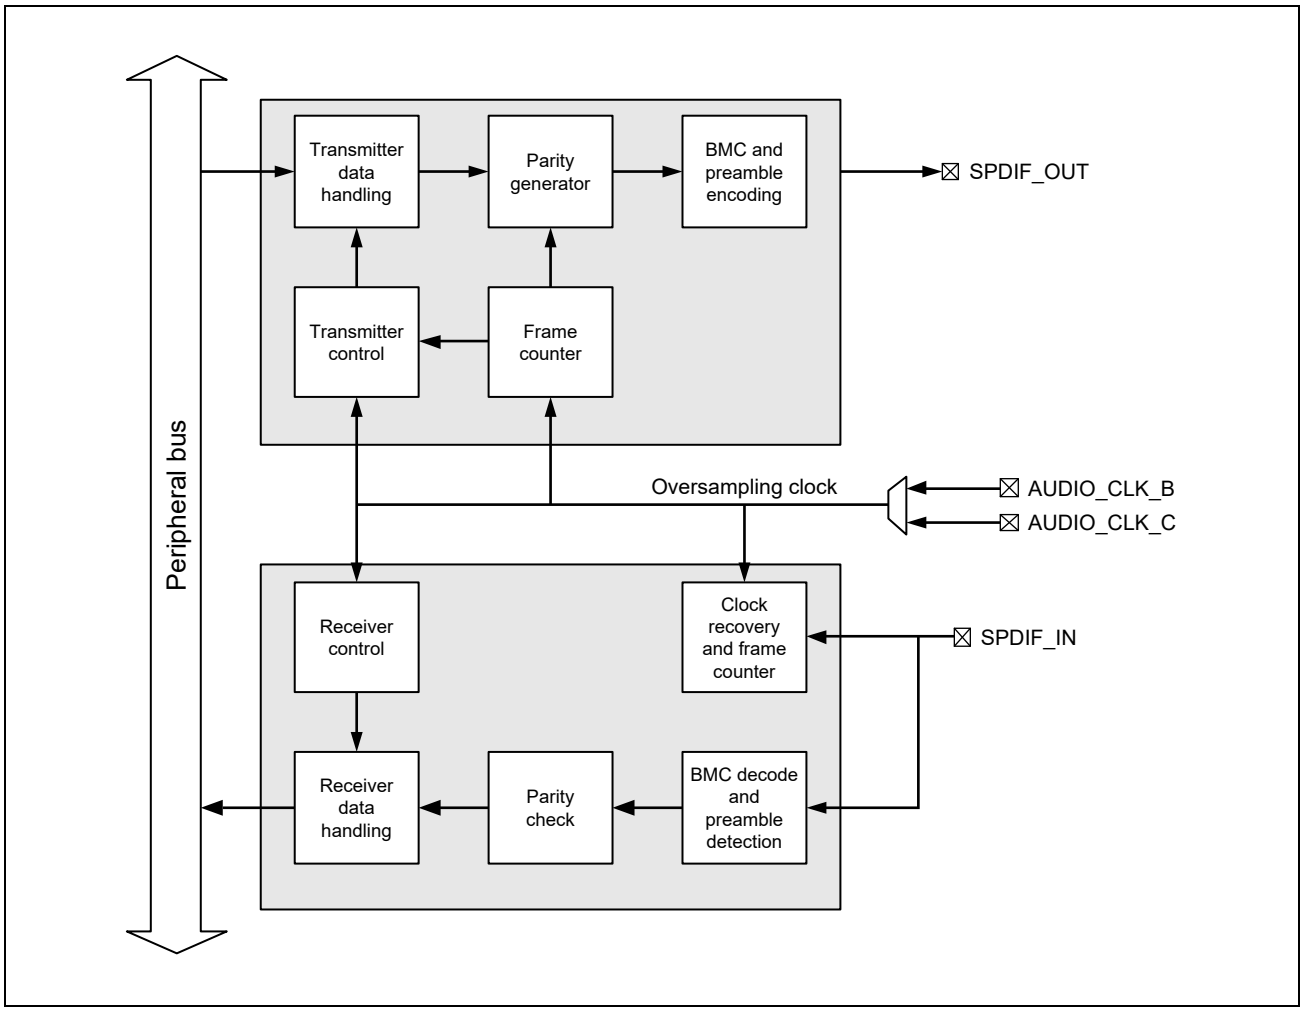

Figure 8.6-2 Functional Block Diagram

8.6.4 Input/Output Pins

Table 8.6-1 shows the pin configuration.

Table 8.6-1 Pin Configuration

Pin Name	Signal Name in This Section	Input/Output	Functional Description
SPDIF_OUT	SPDIF_OUT	Output	Transmitter biphase-mark encoded SPDIF bitstream
SPDIF_IN	SPDIF_IN	Input	Receiver biphase-mark encoded SPDIF bitstream
AUDIO_CLK_B	AUDIO_CLK1	Input	External clock 1 for audio (The oversampling clock signal is input.)
AUDIO_CLK_C	AUDIO_CLK2	Input	External clock 2 for audio (The oversampling clock signal is input.)

8.6.5 Renesas SPDIF (IEC60958) Frame Format

The Renesas SPDIF frame consists of two subframes (for channels 1 and 2), each of which contains a 4-bit preamble, audio data of up to 24 bits, a V flag, a user bit, a channel status bit, and an even parity bit. **Figure 8.6-3** shows the subframe format. According to this format, the Renesas SPDIF performs biphase-mark modulation (channel coding) that will make the transmission line's DC component a minimum value.

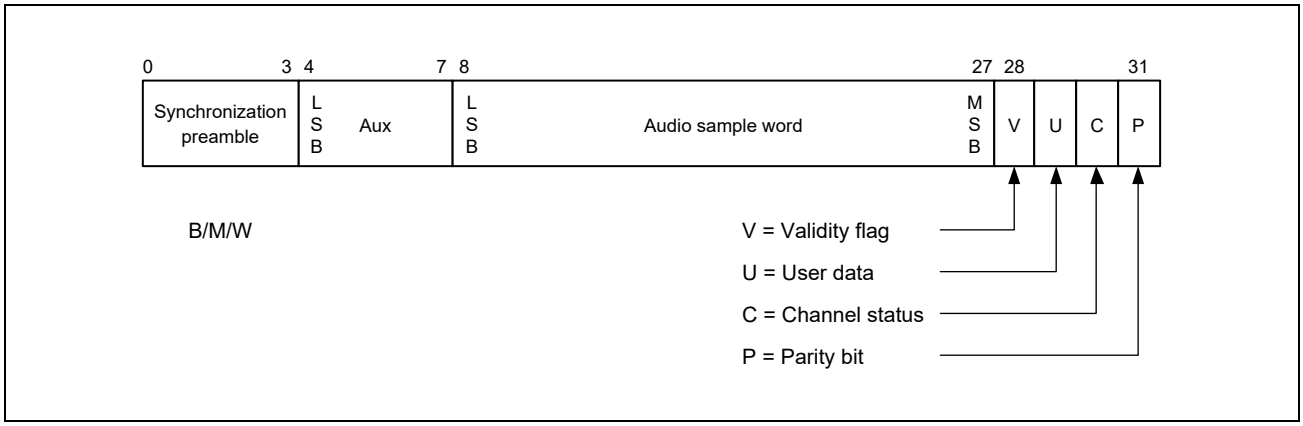

Figure 8.6-3 Subframe Format

Figure 8.6-4 shows the block format, which consists of 192 continuous frames. One block begins at the starting frame (preamble B) and ends at the 192nd frame (frame 191), and the preamble is used to identify all subframes. Each block has a total of 384 subframes, which are classified into three categories: subframe 0 indicating the beginning of a new block, subframe 1 (usually the channel 1), and subframe 2 (usually the channel 2). Usually, the music data sent and received by the SPDIF is continuous so that continuous blocks appear.

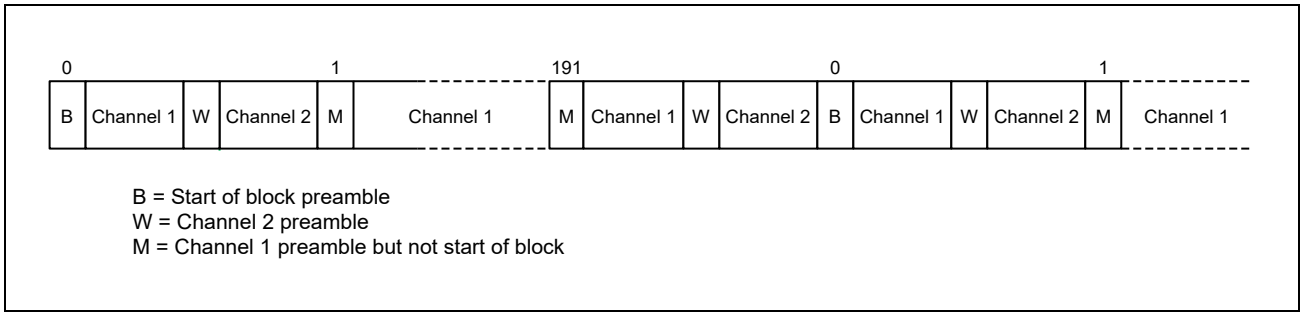

Figure 8.6-4 Block Format

Table 8.6-2 shows the binary values of the Renesas SPDIF preambles. The polarity of these preambles differs depending on the status of the preceding symbol (parity bit).

Table 8.6-2 Binary Preamble Values

Preamble	Preceding Symbol's Status = 0	Preceding Symbol's Status = 1
B	H'1110_1000	H'0001_0111
M	H'1110_0010	H'0001_1101
W	H'1110_0100	H'0001_1011

Note: As shown in **Figure 8.6-3**, the even parity bit at time slot 31 of a subframe determines the type of a preamble for one cycle of transmission. Usually, therefore, any one is selected from the set states that are sent through the Renesas SPDIF. However, IEC60958 requires decoding both types in view of connection with the preamble polarity reversed; the Renesas SPDIF has preambles decoded according to **Table 8.6-2**.

Channel status information is encoded at the rate of one bit per subframe, making the channel status information per block have a total of 192 bits for each of subframes 1 and 2. For the format of the channel status, refer to the IEC 60958 standard.

8.6.6 Register

Table 8.6-3 shows the register configuration. The SPDIF address space is offset from the base address. The base address of SPDIF is as follows.

SPDIF base address: H'0_100A_9000 (Overall Address Space)
SPDIF base address: H'400A_9000 (Cortex-M33 Address Space Secure)
SPDIF base address: H'500A_9000 (Cortex-M33 Address Space Non-Secure)

Table 8.6-3 Register Configuration

Channel	Register Name	Abbreviation	Offset Address	Access size
0 (Transmit)	Transmitter channel 1 audio register	TLCA	H'0000	32
	Transmitter channel 2 audio register	TRCA	H'0004	32
	Transmitter channel 1 status register	TLCS	H'0008	32
	Transmitter channel 2 status register	TRCS	H'000C	32
	Transmitter user data register	TUI	H'0010	32
1 (Receive)	Receiver channel 1 audio register	RLCA	H'0014	32
	Receiver channel 2 audio register	RRCA	H'0018	32
	Receiver channel 1 status register	RLCS	H'001C	32
	Receiver channel 2 status register	RRCS	H'0020	32
	Receiver user data register	RUI	H'0024	32
0, 1 (Common)	Control register	CTRL	H'0028	32
	Status register	STAT	H'002C	32
0, 1 (Common)	Transmitter DMA audio data register	TDAD	H'0030	32
	Receiver DMA audio data register	RDAD	H'0034	32

Note: All registers are longword registers and must be accessed as such.
A register diagram containing a 0 indicates that the write value should always be 0 (if the register is writable) and that the read value should always be 0 (if readable).

8.6.7 Register Descriptions

[Legend]

Initial Value: Register value after reset

—: Undefined value

R/W: Readable/writable register. The write value can be read.

R: Read only register. The write value should always be 0.

R/WC0: Readable/writable register. Writing 0 initializes the bit, but writing 1 is ignored.

R/WC1: Readable/writable register. Writing 1 initializes the bit, but writing 0 is ignored.

W: Write only register. Reading is prohibited. If this bit is reserved, the write value should always be 0.

—/W: Write only, Read value undefined

8.6.7.1 Control Register (CTRL)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
28	CKS	0	R/W	Oversampling clock select Selects oversampling clock supply source. 0: AUDIO_CLK1 1: AUDIO_CLK2
27	—	0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
26	PB	0	R/W	Pass Back Passes transmitter SPDIF output into SPDIF receiver in SPDIF module. 0: Pass Back disabled 1: Pass Back enabled
25, 24	RASS	All 0	R/W	Receiver Audio Sample Bit Size These bits Indicate the receiver audio sample bit size (16, 20, or 24 bits), for data alignment purposes. 00: 16-bit sample 01: 20-bit sample 10: 24-bit sample 11: Reserved
23, 22	TASS	All 0	R/W	Transmitter Audio Sample Bit Size These bits Indicate the transmitter audio sample bit size (16, 20, or 24 bits), for data alignment purposes. 00: 16-bit sample 01: 20-bit sample 10: 24-bit sample 11: Reserved
21	RDE	0	R/W	Receiver DMA Enable Enables DMA requests for the receiver. 0: Receiver DMA disabled 1: Receiver DMA enabled
20	TDE	0	R/W	Transmitter DMA Enable Enables the DMA requests for the transmitter. 0: Transmitter DMA disabled 1: Transmitter DMA enabled
19	NCSI	0	R/W	New Channel Status Information Set this bit to 1 when new channel status information to be corrected is in the transmitter. 0: New channel status information has not been in transmitter 1: New channel status information has been in transmitter

Bit	Bit Name	Initial Value	R/W	Description
18	AOS	0	R/W	Audio Only Samples Clear this bit to 0 when audio channel 1 and channel 2 registers contain user information. When this bit is set to 1, all user bits are cleared to 0. 0: User information present 1: User information not present
17	RME	0	R/W	Receiver Module Enable Enables the receiver module. 0: Receiver module disabled 1: Receiver module enabled
16	TME	0	R/W	Transmitter Module Enable Enables the transmitter module. 0: Transmitter module disabled 1: Transmitter module enabled
15	REIE	0	R/W	Receiver Error Interrupt Enable Enables the receiver error interrupts. 0: Receiver error interrupt disabled 1: Receiver error interrupt enabled
14	TEIE	0	R/W	Transmitter Error Interrupt Enable Enables the transmitter error interrupts. 0: Transmitter error interrupt disabled 1: Transmitter error interrupt enabled
13	UBOI	0	R/W	User Buffer Overrun Interrupt Enable Enables the user buffer overrun interrupts. 0: User buffer overrun interrupt disabled 1: User buffer overrun interrupt enabled
12	UBUI	0	R/W	User Buffer Underrun Interrupt Enable Enables the user buffer underrun interrupts. 0: User buffer underrun interrupt disabled 1: User buffer underrun interrupt enabled
11	CREI	0	R/W	Clock Recovery Error Interrupt Enable Enables the clock recovery error interrupts. 0: Clock recovery error interrupt disabled 1: Clock recovery error interrupt enabled
10	PAEI	0	R/W	Parity Error Interrupt Enable Enables the parity check error interrupts. 0: Parity check error interrupt disabled 1: Parity check error interrupt enabled
9	PREI	0	R/W	Preamble Error Interrupt Enable Enables the preamble check error interrupts. 0: Preamble error interrupt disabled 1: Preamble error interrupt enabled
8	CSEI	0	R/W	Channel Status Error Interrupt Enable Enables the channel status error interrupts. 0: Channel status error interrupt disabled 1: Channel status error interrupt enabled
7	ABOI	0	R/W	Audio Buffer Overrun Interrupt Enable Enables the receiver audio buffer overrun interrupts. 0: Audio buffer overrun interrupt disabled 1: Audio buffer overrun interrupt enabled
6	ABUI	0	R/W	Audio Buffer Underrun Interrupt Enable Enables the transmitter audio buffer underrun interrupts. 0: Audio buffer underrun interrupt disabled 1: Audio buffer underrun interrupt enabled

Bit	Bit Name	Initial Value	R/W	Description
5	RUII	0	R/W	Receiver User Information Interrupt Enable Enables the receiver user information register full interrupts. 0: Receiver user information interrupt disabled 1: Receiver user information interrupt enabled
4	TUII	0	R/W	Transmitter User Information Interrupt Enable Enables the transmitter user information register empty interrupts. 0: Transmitter user information interrupt disabled 1: Transmitter user information interrupt enabled
3	RCSI	0	R/W	Receiver Channel Status Interrupt Enable Enables the receiver channel status register full interrupts. 0: Receiver channel status interrupt disabled 1: Receiver channel status interrupt enabled
2	RCBI	0	R/W	Receiver Channel Buffer Interrupt Enable Enables the receiver audio channel buffer full interrupts. 0: Receiver audio channel interrupt disabled 1: Receiver audio channel interrupt enabled
1	TCSI	0	R/W	Transmitter Channel Status Interrupt Enable Enables the transmitter channel status register empty interrupts. 0: Transmitter channel status interrupt disabled 1: Transmitter channel status interrupt enabled
0	TCBI	0	R/W	Transmitter Channel Buffer Interrupt Enable Enables the transmitter audio channel buffer empty interrupts. 0: Transmitter audio channel interrupt disabled 1: Transmitter audio channel interrupt enabled

8.6.7.2 Status Register (STAT)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	RIS	TIS	UBO	UBU	CE	PARE	PREE	CSE	ABO	ABU	RUIR	TUIR	CSRX	CBRX	CSTX	CBTX
Initial Value	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
16	CMD	0	R	Compressed Mode Data Sets if the data being received is compressed mode data (When bit 1 = 1 in the V flag and channel status). 0: Data is not in compressed mode 1: Data is in compressed mode
15	RIS	1	R	Receiver Idle State Sets if the receiver is in the idle state. 0: Receiver is not in idle state 1: Receiver in idle state
14	TIS	1	R	Transmitter Idle State Sets if the transmitter is in the idle state. 0: Transmitter is not in idle state 1: Transmitter is in idle state
13	UBO	0	R/WC0	User Buffer Overrun*1 Sets if the receiver user buffer overruns. This bit is cleared by writing 0 to the register. If bit REIE and bit UBOI in the control register are set this causes an interrupt. 0: User buffer has not overrun 1: User buffer has overrun
12	UBU	0	R/WC0	User Buffer Underrun*1 Sets if the transmitter user buffer underrun. This bit is cleared by writing 0. If bits TEIE and UBUI in the control register are set this causes an interrupt. 0: User buffer has not underrun 1: User buffer has underrun
11	CE	0	R/WC0	Clock Error*1 Sets when the clock recovery falls out of synchronization. This bit is cleared by writing 0. If bits REIE and CREI in the control register are set this causes an interrupt. 0: Clock recovery stable 1: Clock recovery error
10	PARE	0	R/WC0	Parity Error*1 Sets when the parity checker produces a fail result. This bit is cleared by writing 0. If bits REIE and PAEI in the control register are set this causes an interrupt. 0: Parity check correct 1: Parity error

Bit	Bit Name	Initial Value	R/W	Description
9	PREE	0	R/WC0	Preamble Error*1 Sets when the start of word preamble fails to appear in the correct place. This bit is cleared by writing 0. If bits REIE and PREI in the control register are set this causes an interrupt. 0: Preamble is in the correct place 1: Preamble error *Note*: Only set after a start of block preamble has occurred.
8	CSE	0	R/WC0	Channel Status Error*1 Sets when the channel status information is written before the 32nd frame of the current block. This bit is cleared by writing 0. If bits TEIE and CSEI in the control register are set this causes an interrupt. 0: Channel status correct 1: Channel status error
7	ABO	0	R/WC0	Audio Buffer Overrun*1 Indicates that the receiver audio buffer is full in both the first and second stages and that data has been overwritten. This bit is cleared by writing 0. If bits REIE and ABOI in the control register are set then this causes an interrupt. 0: Receiver audio buffer has not overrun 1: Receiver audio buffer has overrun
6	ABU	0	R/WC0	Audio Buffer Underrun*1 Indicates that the transmitter audio buffer is empty in both the first and second stages and that the last data transmission has been repeated. This bit is cleared by writing 0. If bits TEIE and ABUI in the control register are set then this causes an interrupt. 0: Transmitter audio buffer has not underrun 1: Transmitter audio buffer has underrun
5	RUIR	0	R	Receiver User Information Register Status Indicates the status of the receiver user information register. This bit is cleared by reading from the receiver user register. If bit RUII in the control register is set then this causes an interrupt. 0: Receiver user information register is empty 1: Receiver user information register is full
4	TUIR	0	R	Transmitter User Information Register Status Indicates the status of the transmitter user information register. This bit is cleared by writing to the transmitter user register. If bit TUII in the control register is set then this causes an interrupt. 0: Transmitter user information register is full 1: Transmitter user information register is empty
3	CSRX	0	R	Channel 1 and Channel 2 Status for Receiver Indicates the status of the receiver channel status registers. This bit is cleared by reading from the receiver channel status registers. If bit RCSI in the control register is set this causes an interrupt. 0: Receiver channel status registers are empty 1: Receiver channel status registers are full
2	CBRX	0	R	Channel 1 and Channel 2 Buffers for Receiver Indicates the status of the receiver audio channel registers. This bit is cleared by reading from the receiver audio channel registers. If bit RCBI in the control register is set this causes an interrupt. 0: Receiver audio channel registers are empty 1: Receiver audio channel registers are full

Bit	Bit Name	Initial Value	R/W	Description
1	CSTX	0	R	Channel 1 and Channel 2 Status for Transmitter Indicates the status of the transmitter channel status registers. This bit is cleared by writing to the transmitter channel status registers. If bit TCSI in the control register is set this causes an interrupt. 0: Transmitter channel status register is full 1: Transmitter channel status register is empty
0	CBTX	0	R	Channel 1 and Channel 2 Buffers for Transmitter Indicates the status of the transmitter audio channel registers. This bit is cleared by writing to the transmitter audio channel registers. If bit TCBI in the control register is set this causes an interrupt. 0: Transmitter audio channel registers are full 1: Transmitter audio channel registers are empty

Note 1. When an error bit is detected during DMA transfer, DMA transfer settings must be made again. In this case, the Renesas SPDIF's module enable bit (either the RME or TME bit) and the DMA enable bit (either the RDE or TDE bit) must be disabled and the error status must be cleared before making DMA transfer settings again. Then the module enable bit should be set and DMA transfer can be started again.

8.6.7.3 Transmitter Channel 1 Audio Register (TLCA)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.6.7.6 Transmitter User Data Register (TUI)

U-bit data in subframes is written into this register. Because U-bit data is transmitted in a sequence of subframes 1 and 2, you need to update the data on a 16-frame basis. For the contents of the user bytes refer to the appropriate standard for the device in use. The user bits to be transmitted are set in sequence starting at the LSB.

8.6.7.7 Transmitter Channel 1 Status Register (TLCS)

The 30-bit register stores the channel status information to be transmitted. For each channel, channel status information per frame consists of 192 bits. Because necessary data covers only the 30 bits that are set in the following register, zeros continue to be sent after the transmission of the first 30 bits.

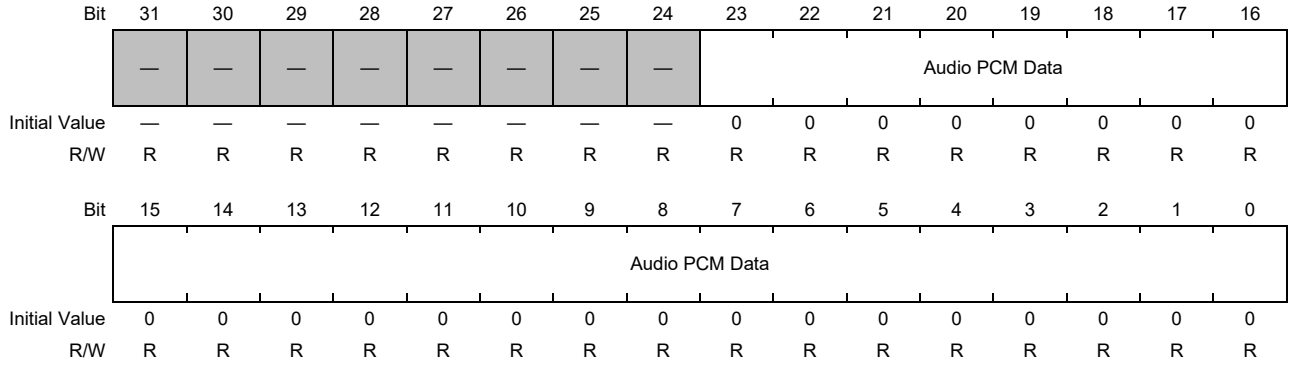
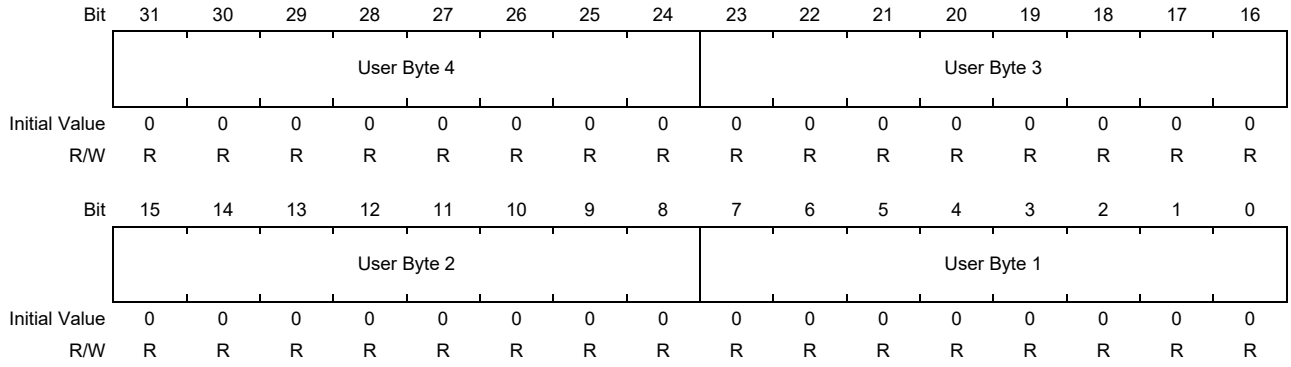
8.6.7.9 Receiver Channel 1 Audio Register (RLCA)



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	—	R	Reserved
23 to 0	Audio PCM Data	All 0	R	Audio PCM Data LSB aligned PCM encoded audio data.

8.6.7.10 Receiver Channel 2 Audio Register (RRCA)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	—	R	Reserved
23 to 0	Audio PCM Data	All 0	R	Audio PCM Data LSB aligned PCM encoded audio data.



8.6.7.11 Receiver DMA Audio Data (RDAD)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	—	R	Reserved
23 to 0	Audio PCM Data	All 0	R	Audio PCM Data LSB aligned PCM encoded audio data.

8.6.7.12 Receiver User Data Register (RUI)

The register stores the U-bit data received through the Renesas SPDIF. Because U-bit data is stored in a sequence of subframes 1 and 2 starting at the LSB, you need to read the data on a 16-frame basis. For the contents of the user bytes refer to the appropriate standard for the device in use.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	User Byte 4	All 0	R	U-bit information is stored here.
23 to 16	User Byte 3	All 0	R	
15 to 8	User Byte 2	All 0	R	
7 to 0	User Byte 1	All 0	R	

8.6.7.13 Receiver Channel 1 Status Register (RLCS)

The channel status is stored starting at the register's LSB in a way that subframe 1 received from the beginning of the block is stored. For the contents of the channel status register, refer to the IEC-60958 standard.

0	—	0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.

8.6.8 Functional Description — Transmitter

8.6.8.1 Transmitter Module

The transmitter module transmits PCM data and auxiliary information after encoding it according to the method of biphase-mark modulation that complies with the IEC60958 standard (SPDIF).

The clock for the transmitter module is an oversampling clock supplied from the outside. This clock usually selects a value that serves as an oversample at a frequency eight times larger than the clock frequency required for biphase-mark encoding. In this case, the clock frequency required to transmit 32 time slots in a subframe is 512 times as large as the sample frequency for audio data.

Audio data and channel status information are first written into the module's channel 1 and then into channel 2. Generally, the channel status need to be written only when the information changes. The SPDIF module requests that the channel status be written in 30 frames -- when all the current channel status data have been transmitted. You need to write somewhere between frame 31 and the beginning of the next block of 192 frames.

The audio data is stored in a double buffer arrangement. To make sure that the first stage buffer is empty, you can send an interrupt request or poll the status register. DMA transfers send channel 1 audio data on the first request and channel 2 data on the second.

The channel status information is stored in the 30-bit registers of channels 1 and 2. For each channel, the channel status information per frame consists of 192 bits. Because necessary data covers only 30 bits, zeros continue to be sent after the transmission of the first 30 bits until the block is completed.

User data forms a 32-bit double buffer arrangement. You can make sure that the first stage buffer is empty by either sending an interrupt request or polling the status register. Usually, information about the user data will become insufficient with the length of data between blocks. Transmission takes place in a sequence of channels 1 and 2. For the user data within a block, 384 bits are transmitted before the next block is continuously transmitted.

The audio data handled by the Renesas SPDIF module is a linear PCM, making it possible to set up to 24 bits. For this reason, the V flag indicating that audio data is a linear PCM remains to be 0. The V flag involves no register-based setting. An even parity is created for each 32 bits of serial output data (excluding the preamble).

NOTE

When transmitter user buffer underrun occurs, the current data in the buffer data of SPDIF is transmitted until the next data is filled.

8.6.8.2 Transmitter Module Initialization

The device defaults to an idle state when it comes out of reset, or can be put into an idle state when 0 is written to the TME bit in the CTRL register. When the transmitter module is idle, it has the following settings:

- The transmitter idle status bit (TIS) is set to 1, all other status bits are cleared to 0.
- Preamble generation is invalid.
- Synchronization between channels 1 and 2 is set to 0 (0 for channel 1, 1 for channel 2).
- Both word_count and frame_count are set to 0.
- The output from the biphase-mark encoder is set to 0.

Channel status, user and audio data registers will retain its value prior to putting the module into idle. To exit the idle state the user must write 1 to the TME bit in the CTRL register.

8.6.8.3 Initial Settings for Transmitter Module

When the TME bit is set to 1, the TUIR and CSTX bits are set to 1. After that, if data is written in the order of 1) TUI and 2) TLCS and TRCS, a channel status error will occur. To avoid this, be sure to write data in the order of 1) TLCS and TRCS and 2) TUI.

Before writing the first audio data (write access to TLCA or TRCA by the CPU or write access to TDAD by the DMA transfer) after setting the TME bit to 1, be sure to check that the CSTX and TUIR bits are cleared by writing to TLCS, TRCS, and TUI.

8.6.8.4 Transmitter Module Data Transfer

Once the transmitter module has left the idle state, it is ready for data transfer. Data transfer timing can be achieved in three ways. Either the transfer is done by interrupts, DMA requests or by polling the status register. There is a shared interrupt line (for both transmit and receive) and a single transmitter DMA request line.

Figure 8.6-5 shows a data transfer with an interrupt for the transmitter.

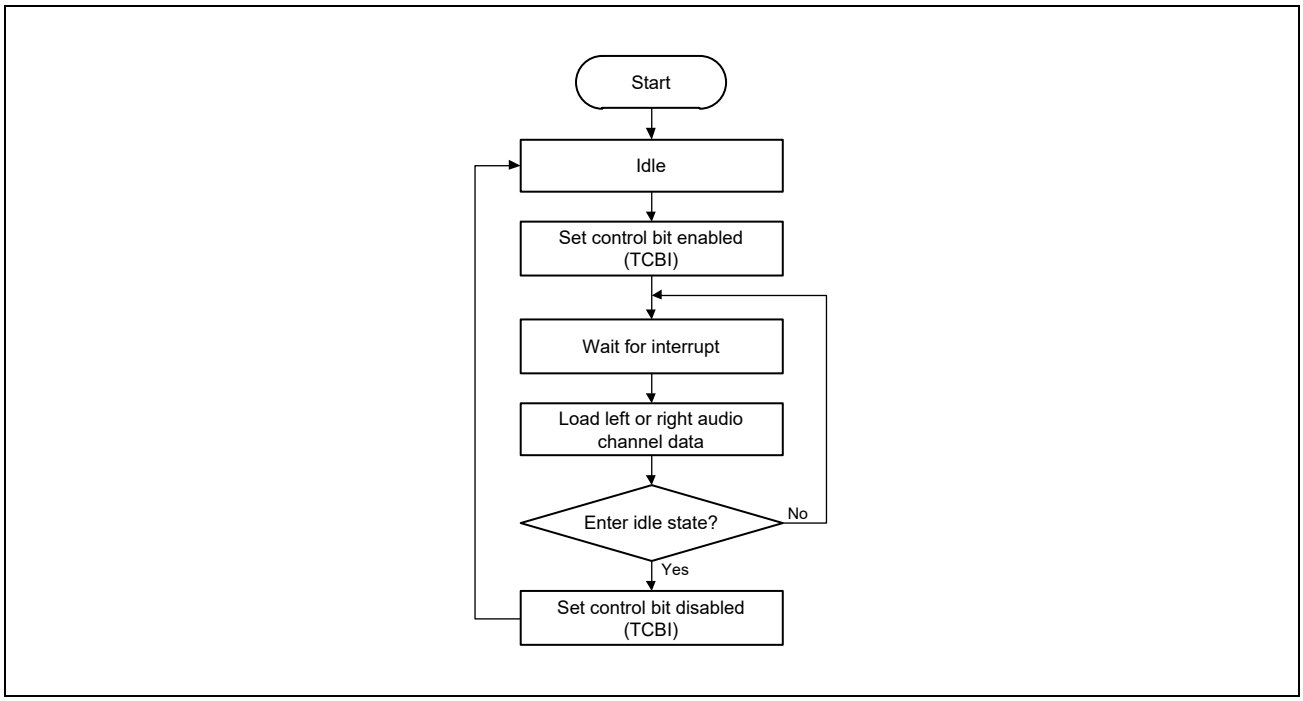

Figure 8.6-5 Transmitter Data Transfer Flow Diagram - Interrupt Driven

Figure 8.6-6 shows a data transfer with a DMA transfer for the transmitter.

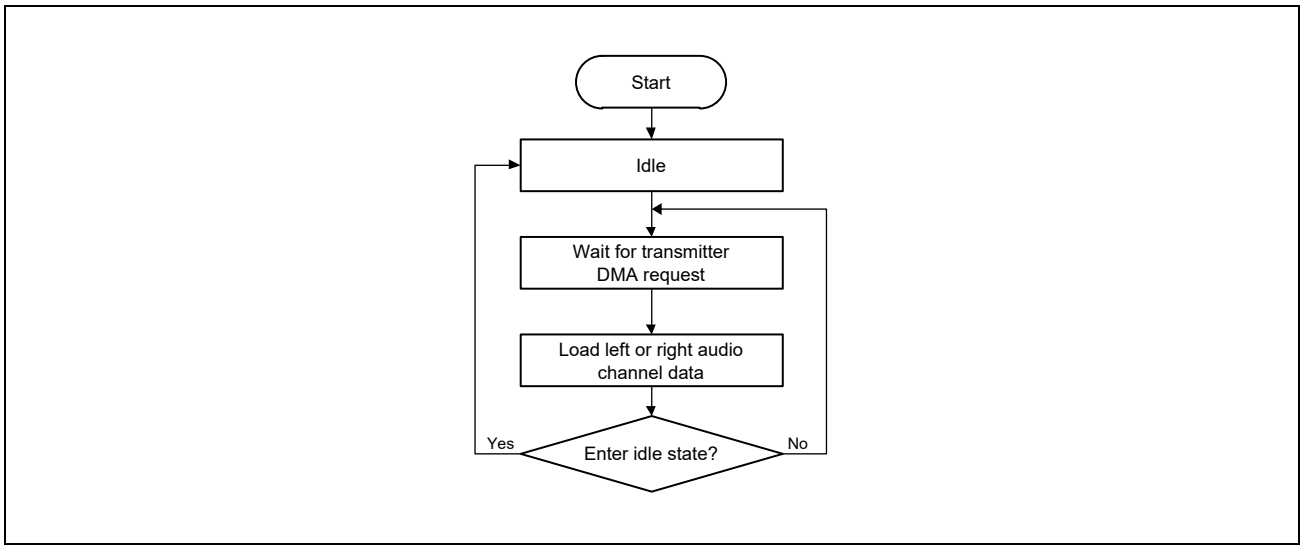

Figure 8.6-6 Transmitter Data Transfer Flow Diagram - DMA Request Driven

Channel status information is required to be updated when the information has changed. Because the updating needs to be done before the transmission of the next block, the channel status to be updated should be written after 30 frames have been sent; this is indicated either by an interrupt or by polling the status bit. If channel status is written before 30 frames have been sent (while current information is being sent) then an interrupt indicates that the channel status error bit (CSE) in the status register has been set.

NOTE

30 frames contains all the valid information in a single channel status block.

8.6.9 Functional Description — Receiver

8.6.9.1 Receiver Module

The receiver module demodulates data and clock signals from the input encoded according to the IEC60958 standard. The encoded data, shown in linear PCM format, is stored into the audio data register. The register also stores the channel status and user information being received simultaneously as auxiliary information.

The main clock for the receiver module is an oversampling clock supplied from the outside. The module operates at a frequency four times as large as the oversampling clock.

NOTE

The oversampling clock is the same for the transmitter and receiver.

Clock recovery is performed using a pulse width counter and averaging filters to produce a sampling pulse in the middle of each bit in the datastream. A clock error status bit indicates clock synchronization loss. Synchronization is achieved when a preamble occurs on the data stream for the first time. Continuous adjustment prevents jitter and/or clock drift from affecting clock recovery, provided that they fall within the clock recovery specifications.

Once the clock recovery is successful the biphase-mark decoder initiates its preamble detection. The decoder searches for the start of block preamble (see **Table 8.6-2**). A preamble error status bit indicates that following preambles have not appeared at the correct time, such failures are most likely caused by transmission loss or interference.

Even parity checking is performed on the decoded data. A discrepancy will result in the parity error status bit being set.

The SPDIF module acquires user data and channel status information in addition to audio data. The audio is stored in a double buffer arrangement. Either an interrupt request because of a full buffer or polling of the status bit will indicate when the data is ready to be read. DMA transfers receive channel 1 audio data on the first request and channel 2 data on the second.

Channel status is stored in a 30-bit register. Channel status information is received at 1-bit per subframe. Therefore, the registers will not be full until a total of 30 frames for each channel have been received. New channel status is compared with the current data to see if it has changed and is only read by the processor if it has. User data, which is also received at the same time, is stored into the register on a subframe basis, so that the reception is completed when 16 frames are reached.

NOTES

1. Channel status data requests do not support DMA.
2. When receiver user buffer overrun occurs, the current data in the buffer data of SPDIF is overwritten by the next incoming data from SPDIF interface.

8.6.9.2 Receiver Module Initialization

The device defaults to an idle state when it comes out of reset, or can be put into an idle state by writing 0 to bit RME in the CTRL register. Whilst idle the module has the following settings:

- The receiver idle status bit is set to 1, all other status bits are cleared to 0.
- Synchronization between channels 1 and 2 is set to 0 (0 for channel 1, 1 for channel 2).
- Both Word_count and frame_count are set to 0.

Channel status registers, user data registers and audio data registers will retain its value prior to putting the module into idle. To exit the idle state the user must write 1 to the bit RME in the CTRL register.

8.6.9.3 Receiver Module Data Transfer

Once the module has left the idle state it is ready for data transfer. Data transfer timing can be achieved in three ways. The transfer can be done by interrupts, or by polling the status register, or by DMA. There is a shared interrupt line (transmit and receive) and a single receiver DMA request line. Data transfer for the receiver can be interrupted by error signals caused by:

1. Clock recovery failure.
2. Transmission loss or interference – indicated by a preamble error.
3. Parity check failure.

Transmission loss or interference can cause the start of subframe or start of block preamble to be misplaced or not present.

Parity check failure occurs when the parity bit is incorrect, this can be caused by any of the above.

[Clock Recovery Deviation]

The receive margin for clock recovery is based on the following equation:

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\%$$

where M = receive margin
N = oversampling rate
L = frame length = 33
D = duty cycle = 0.6
F = oversampling clock deviation = Level II accuracy = 1000 in $10e^{-6}$

Figure 8.6-7 indicates what the receive margin M represents

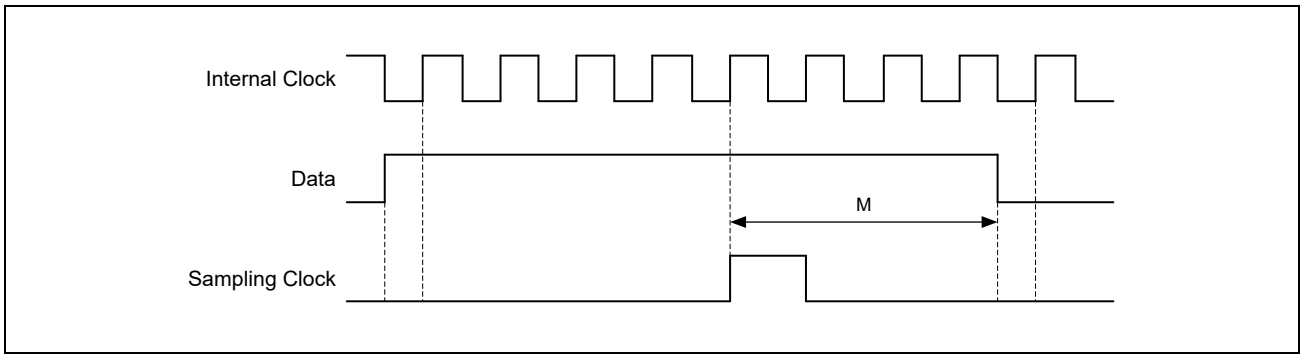

Figure 8.6-7 Receive Margin

Introducing jitter into the equation gives the following inequality.

$$J \leq \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\%$$

J = clock jitter

Eight times oversampling produces a receive margin = 39.25%
Four times oversampling produces a receive margin = 31.75%
Two times oversampling produces a receive margin = 16.75%

The fastest sample frequency is 48 kHz. This requires a clock speed of 128 × 48 kHz = 6.144 MHz. The worst case jitter in one cycle is specified at 40 ns = 24.5% of the period. This means that an oversampling rate of 4 or more will satisfy the inequality and therefore be sufficient for clock recovery.

Figure 8.6-8 illustrates the receiver data transfer using interrupts.

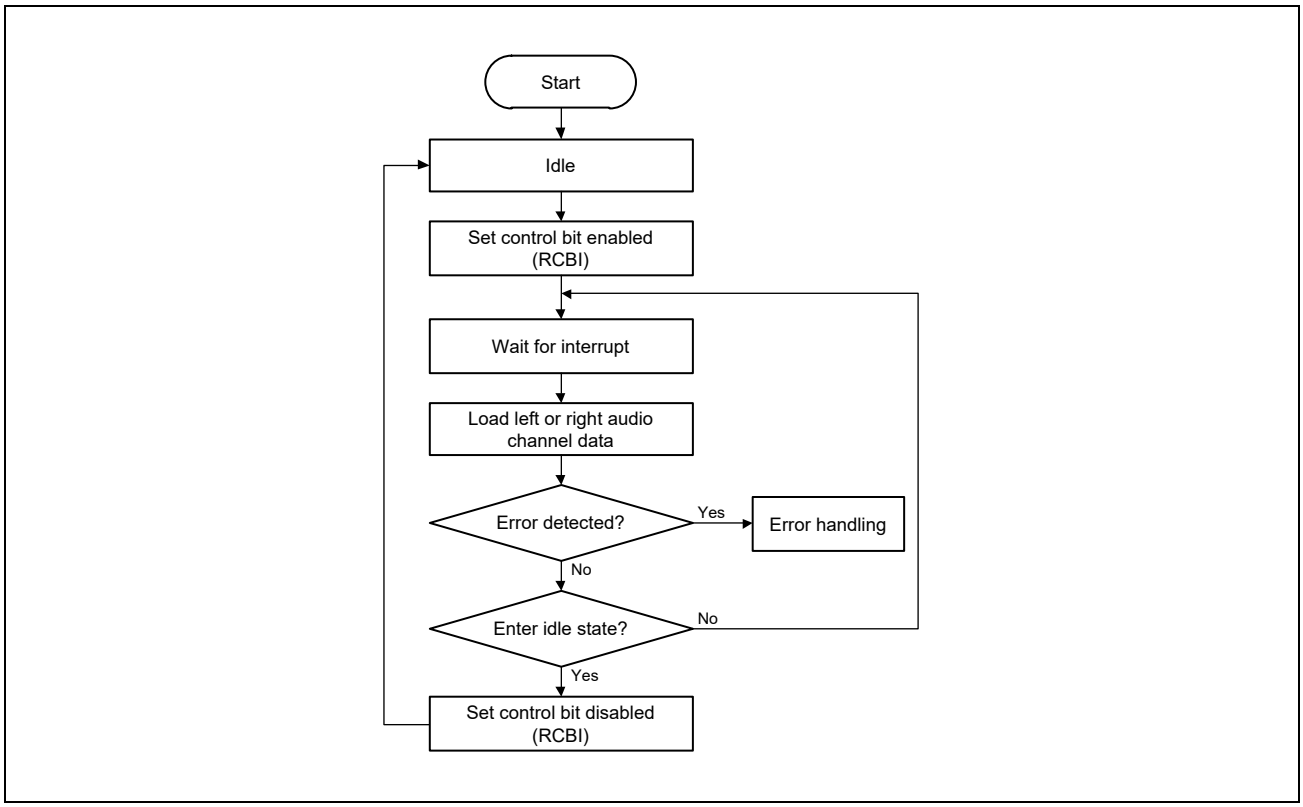

Figure 8.6-8 Receiver Data Transfer Flow Diagram - Interrupt Driven

Interrupts to indicate that the channel status information register is full occur after frame 30 has been received and only if the information has changed. When the first four bytes have been stored an interrupt occurs.

8.6.10 Disabling the Module

8.6.10.1 Transmitter and Receiver Idle

The transmitter or receiver modules can be disabled by writing 0 to the idle bit in the control register (TME for the transmitter and RME for the receiver). The idle state can be detected by polling the idle bit in the status register (TIS and RIS).

8.6.11 Compressed Mode Data

Compressed mode data is defined in the IEC 61937 specification. This module only detects compressed mode data. This is done by checking the parity flag (V flag) and bit 1 in the channel status data. If both are one then the data is in compressed mode. This is indicated by the setting of the CMD bit in the status register.

NOTE

Only the receiver detects compressed mode data since the information is not relevant to the transmitter.

8.6.12 References

- IEC60958 Digital Audio Interface
- IEC61937 Compressed Mode Digital Audio Interface

8.6.13 Usage Notes

8.6.13.1 Clearing TUIR

After TUI is written to, the TUIR bit is cleared only after transmission of a maximum of one frame is completed. When using a transmitter user information interrupt to write data to TUI, check that the TUIR bit is cleared before terminating the interrupt handling routine so that the interrupt is expectedly accepted again.

8.6.13.2 Frequency of Clock Input for Audio

The frequency of the clock input to the AUDIO_CLK1 or AUDIO_CLK2 must be lower than the P0ϕ frequency.

SECTION 8 AUDIO

8.7 PDM Interface (PDM)

This section describes the PDM interface.

8.7.1 Overview

This PDM interface is a unit for receiving voice data from an external PDM (pulse density modulation) device. For features and configuration, see the following sections.

8.7.1.1 Feature

Table 8.7-1 lists the features of this PDM interface.

Table 8.7-1 PDM Interface Specifications

Item	Description
Number of channels	3 channels
Functions	• Capable of filtering 1-bit digital input data PDM_DATn (n = 0, 1, 2) and converting them into 20-bit or 16-bit digital data. The bit order is little-endian. • This unit supports stereo microphone (L/R sampling by rising/falling clock edge). • This unit supports sound activity detector. • Each channel includes programmable filters: 4th order sinc filter, high-pass filter (for suppression of DC bias), correction filter (for sinc passband distortion), half-band decimation filter (for aliasing distortion). – This unit supports programmable and flexible decimation ratios. – The sinc filter is selectable as first-, second-, third-, and fourth-order. • This unit supports DMA operation through APB. • Each channel has an internal buffer. – 64 stages when designed – Capable of storing voice data during low power mode • Error detection functions can be used for debugging.
Interrupt sources	7 sources 1. Data reception interrupt per channel (Maximum 3 interrupts) 2. Sound detection interrupt (shared between channels) 3. Error detection interrupt per channel (Maximum 3 interrupts)
Low power consumption function	This unit supports microphone low power configuration (slower clock). This unit can switch to the higher clock speed after sound detection recognized.
Bus interface	This unit has an APB interface which is confirmed to APB4.

8.7.1.2 Block Diagram

The following is a block diagram of the PDM interface.

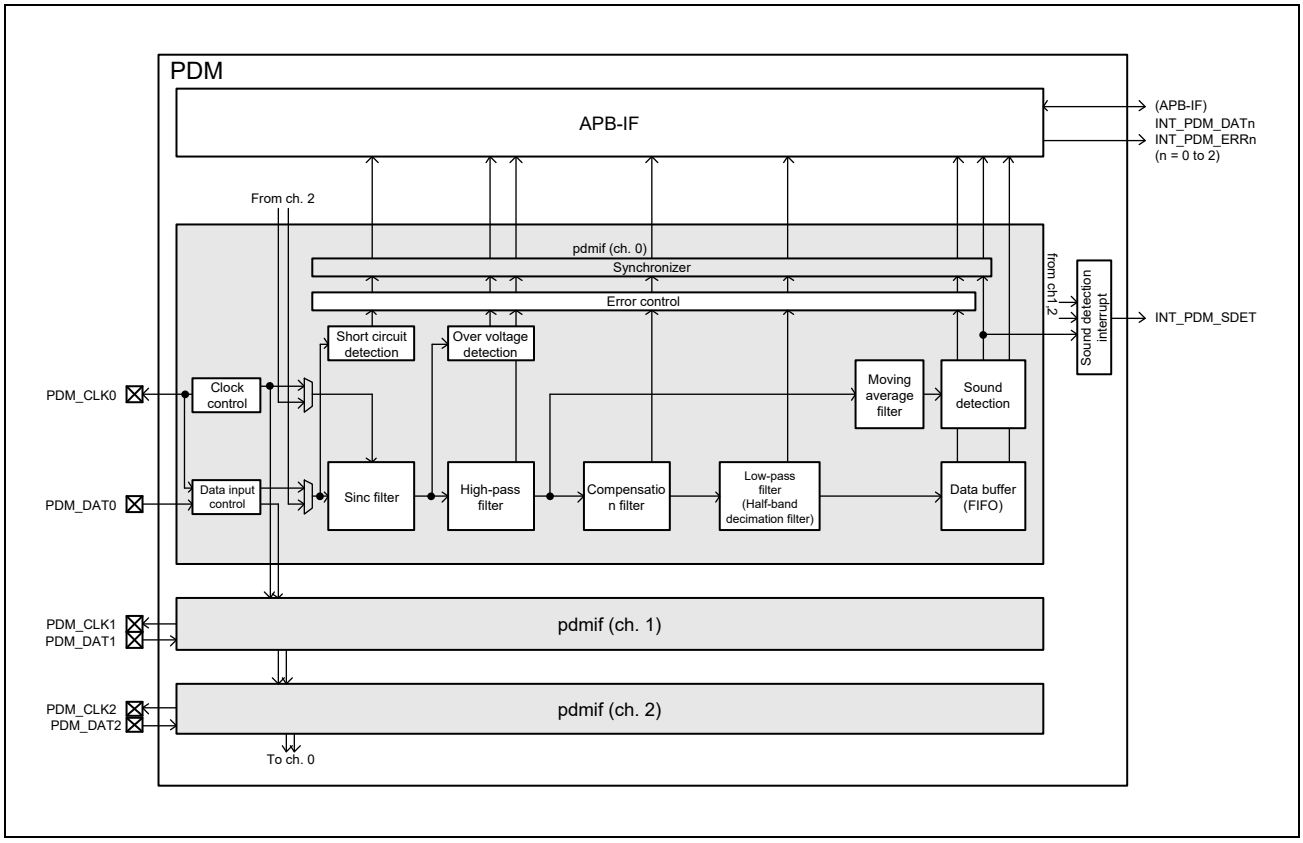

Figure 8.7-1 Three-Channel PDM-IF Block Diagram

Each channel of PDM-IF consists of following blocks:

- Clock control: Generates PDM_CLKn (n = 0, 1, 2) to the microphone, and internal timing signals to the sinc filter.
- Data input control: Receives PDM_DATn (n = 0, 1, 2) from the microphone.
- Sinc filter: Converts the 1-bit digital data stream input from PDM_DATn (n = 0, 1, 2) to 34-bit signed data. Then, the 34-bit signed data is clipped to 20-bit signed data.
- High-pass filter: A filter for suppression of DC bias
- Compensation filter: A filter for sinc passband distortion
- Low-pass (half-band decimation) filter: A filter for aliasing distortion
- Moving average filter: A simple filter for noise reduction before sound detection
- Sound detection: Generates the wakeup interrupt to recover from low power mode.
- Data buffer: Stores 20-bit or 16-bit data filtered by some filters.
- Short circuit detection: Detects the short circuit error which indicates consecutive 0's or 1's input from PDM_DATn (n = 0, 1, 2).
- Overvoltage detection: Detects the overvoltage error.

- Error control: Generates error flags from other blocks.

The 1-bit digital data stream input from PDM_DATn pin (n = 0, 1, 2) is converted to 34-bit signed data by the sinc filter and then the data is clipped to 20-bit signed data. The 20-bit singed data is used for sound detection and data storing in buffer.

The sound detection block receives 20-bit signed data through high-pass filter block and moving average filter block. The block compares received data to the programmed thresholds and generates a wakeup interrupt in case that the data is above the upper threshold or below the lower threshold.

The data buffer block receives 20-bit signed data through high-pass filter, compensation filter, and low-pass filter. The block stores the 20-bit signed data or the clipped 16-bit signed data. And then the block sends the 20-bit signed data or 16-bit signed data to APB-IF once APB read access occurs.

8.7.1.3 External Pins

Table 8.7-2 lists the PDM external pin specifications.

Table 8.7-2 Pin Configuration

Channel	Pin Name	Signal Name in This Section	Input/Output	Functional Description
0	PDM_CLK0	PDM_CLKn	Output	External PDM Ch0 clock output pin
	PDM_DAT0	PDM_DATn	Input	External PDM Ch0 data reception pin
1	PDM_CLK1	PDM_CLKn	Output	External PDM Ch1 clock output pin
	PDM_DAT1	PDM_DATn	Input	External PDM Ch1 data reception pin
2	PDM_CLK2	PDM_CLKn	Output	External PDM Ch2 clock output pin
	PDM_DAT2	PDM_DATn	Input	External PDM Ch2 data reception pin

Note: n = 0 to 2

8.7.1.4 Connected Unit

Table 8.7-3 lists the connected units.

Table 8.7-3 Connected Unit

Unit Name	Connected Unit Name	Function of Connected Unit
PDMm	CPG	Clock pulse generator (CPG)
	LSI Internal Bus	LSI Internal Bus
	Interrupt Controller	Interrupt control unit
	GPIO	Pin function controller

8.7.2 Registers

The register addresses of PDM are given as offsets from the individual base addresses <PDMm_base>. The register base addresses of each PDM are listed in the following table.

Table 8.7-4 Register Base Addresses

Base Address Name	Unit	Base Address
<PDM0_base>	PDM0	H'0_1005_A000 (H'5005_A000*1, H'4005_A000*2)

Note 1. Cortex-M33 address space (non-secure)

Note 2. Cortex-M33 address space (secure)

8.7.2.1 List of Registers

The list of PDM registers and the memory addresses are as follows.

For the actual addresses, the offset values indicated in the following table are added to the base addresses.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size (bits)
Channel Software Start Trigger Register	PDMm_PDCSTRTR	H'0000_0000	H'0000	32
Channel Software Stop Trigger Register	PDMm_PDCSTPTR	H'0000_0000	H'0004	32
Channel Software Change Trigger Register	PDMm_PDCCHGTR	H'0000_0000	H'0008	32
Channel Interrupt Control Register	PDMm_PDCICR	H'0000_0000	H'000C	32
Channel Status Register	PDMm_PDCSR	H'0000_0000	H'0010	32
Channel Status Clear Register	PDMm_PDCSCR	H'0000_0000	H'0014	32
Reserve	—	—	H'0018 to H'001F	—
Channel Sound Detection Control Register	PDMm_PDCSDCR	H'0000_0000	H'0020	32
Channel Data Read Control Register	PDMm_PDCDRCR	H'0000_0000	H'0024	32
Channel Data Clear Register	PDMm_PDCDCR	H'0000_0000	H'0028	32
Reserve	—	—	H'002C to H'007F	—

8.7.2.2 Register Description

The prefix (PDMm_) of the register names is omitted in this and subsequent sections.

8.7.2.2.1 Channel Software Start Trigger Register (PDMm_PDCSTRTR) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0000

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	STRTRG[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	STRTRG[2:0]	H'0	R0W	The read value is always 0b. Channel n start trigger 0b: Do nothing 1b: Start channel n

8.7.2.2.2 Channel Software Stop Trigger Register (PDMm_PDCSTPTR) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0004

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	STPTRG[2:0]	H'0	R0W	The read value is always 0b. Channel n stop trigger 0b: Do nothing 1b: Stop channel n

8.7.2.2.3 Channel Software Change Trigger Register (PDMm_PDCCHGTR) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0008

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	CHGTRG[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0W	R0W	R0W	R0	R0	R0	R0	R0	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	—	All 0	R0W	Reserved. This register is readable and the initial value can be written to it.
7 to 3	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	CHGTRG[2:0]	H'0	R0W	The read value is always 0b. Channel n change trigger 0b: Do nothing 1b: Change clock (PDM_CLKn) setting

8.7.2.2.4 Channel Interrupt Control Register (PDMm_PDCICR) (m = 0)

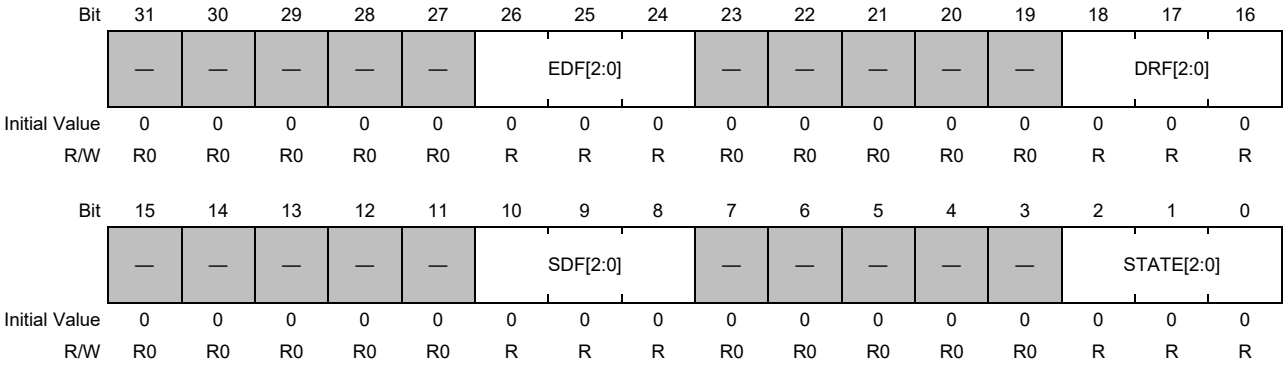
Access Size: 32 bits

Address(es): <PDMm_base> + H'000C

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	IEDE[2:0]			—	—	—	—	—	IDRE[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	RW	RW	RW	R0	R0	R0	R0	R0	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	ISDE[2:0]			—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	RW	RW	RW	R0	R0	R0	R0	R0	R0	R0	R0



Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26 to 24	IEDE[2:0]	H'0	RW	Channel n error detection interrupt enable bit 0b: Don't allow to issue INT_PDM_ERRn interrupt 1b: Allow to issue INT_PDM_ERRn interrupt
23 to 19	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18 to 16	IDRE[2:0]	H'0	RW	Channel n data reception interrupt enable bit 0b: Don't allow to issue INT_PDM_DATn interrupt 1b: Allow to issue INT_PDM_DATn interrupt
15 to 11	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	ISDE[2:0]	H'0	RW	Channel n sound detection interrupt enable bit 0b: Don not allow to issue INT_PDM_SDET interrupt when the sound for channel n is detected. 1b: Allow to issue INT_PDM_SDET interrupt when the sound for channel n is detected.
7 to 0	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.

8.7.2.2.5 Channel Status Register (PDMm_PDCSR) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0010

Initial Value: H'0000_0000

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26 to 24	EDF[2:0]	H'0	R	Channel n error detection flag 0b: Indicates that no data is detected. 1b: Indicates that an error is detected. Refer to the PDSRCHn register for details of errors.
23 to 19	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18 to 16	DRF[2:0]	H'0	R	Channel n data reception flag 0b: Indicates that the number of data stored in buffer does not exceed the threshold. 1b: Indicates that the number of data stored in buffer exceeded the threshold.
15 to 11	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	SDF[2:0]	H'0	R	Channel n sound detection flag 0b: Indicates that the sound which exceeded the threshold is not detected. 1b: Indicates that the sound which exceeded the threshold is detected.
7 to 3	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	STATE[2:0]	H'0	R	Channel n state 0b: Channel n stop 1b: Channel n in operation

EDFn

[Condition to become "1b"]

- When any error occurs. Refer to the PDSRCHn register for the kind of error.

[Condition to become "0b"]

- When all error flags are cleared by writing the PDSCRCHn, this flag is also cleared.

DRFn

Refer to **8.7.3.7 Data Buffer** for details.

[Condition to become “1b”]

- When PDCDRCR.DATREn = 1b and PDDSRCHn.DATNUM[7:0] is greater than or equal to a threshold which is configured by PDDBCRCHn.DATRITHR[2:0].

[Condition to become “0b”]

- When PDCDRCR.DATREn = 0b or PDDSRCHn.DATNUM[7:0] is less than a threshold.

SDFn

Refer to **8.7.3.6 Sound Detection** for details.

[Conditions to become “1b”]

- When PDCSDCR.SDEn = 1b and a moving average filter result is greater than or equal to PDSDUTRCHn.SDETU[19:0].
- When PDCSDCR.SDEn = 1b and a moving average filter result is less than or equal to PDSDLTRCHn.SDETL[19:0].

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDCSCR.SDFCn).

STATEn

Refer to **8.7.3.2 Channel Start and Channel Stop** for details.

[Condition to become “1b”]

- When “1b” is written to PDCSTRTR.STRTRGn.

[Condition to become “0b”]

- When “1b” is written to PDCSTPTR.STPTRGn.

8.7.2.2.6 Channel Status Clear Register (PDMm_PDCSCR) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0014

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	STPTRG	H'0	R0W	The read value is always 0b. Stop trigger 0b: Do nothing 1b: Stop the channel

8.7.2.2.13 Software Change Trigger Register Channel n (PDMm_PDCHGTRCHn) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0108

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHGTRG
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0W	R0	R0	R0	R0	R0	R0	R0	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	—	H'0	R0W	Reserved This register is readable and the initial value can be written to it.
7 to 1	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	CHGTRG	H'0	R0W	The read value is always 0b. Change trigger 0b: Do nothing 1b: Change settings of PDM_CLKn and sinc filter

8.7.2.2.14 Interrupt Control Register Channel n (PDMm_PDICRCHn) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'010C

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IEDE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	IDRE	ISDE	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	RW	RW	R0

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	IEDE	H'0	RW	Error detection interrupt enable bit 0b: Do not allow to issue INT_PDM_ERRn interrupt 1b: Allow to issue INT_PDM_ERRn interrupt
15 to 3	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	IDRE	H'0	RW	Data reception interrupt enable bit 0b: Do not allow to issue INT_PDM_DATn interrupt 1b: Allow to issue INT_PDM_DATn interrupt
1	ISDE	H'0	RW	Sound detection interrupt enable bit 0b: Do not allow to issue INT_PDM_SDET interrupt 1b: Allow to issue INT_PDM_SDET interrupt
0	—	H'0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.

8.7.2.2.15 Status Detection Control Register Channel n (PDMm_PDSDCRCHn) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0110

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	BFOWDE	—	—	—	—	—	—	—	—	OVUDE	OVLDE	SCDE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDE	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	RW	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27	BFOWDE	H'0	RW	Buffer overwriting detection enable bit 0b: Do not allow to detect buffer overwriting. 1b: Allow to detect buffer overwriting.
26 to 19	—	All 0	RW	Reserved This register is readable and the initial value can be written to it.
18	OVUDE	H'0	RW	Overvoltage upper limit exceeded detection enable bit 0b: Do not allow to detect data exceeding the upper limit. 1b: Allow to detect data exceeding the upper limit
17	OVLDE	H'0	RW	Overvoltage lower limit exceeded detection enable bit 0b: Do not allow to detect data falling below the lower limit. 1b: Allow to detect data falling below the lower limit
16	SCDE	H'0	RW	Short circuit detection enable bit 0b: Do not allow to detect the PDM_DATn pin short circuit 1b: Allow to detect the PDM_DATn pin short circuit
15 to 2	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	SDE	H'0	RW	Sound detection enable bit 0b: Do not allow to detect sound 1b: Allow to detect sound
0	—	H'0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.

8.7.2.2.16 Status Register Channel n (PDMm_PDSRCHn) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0114

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	BFOWDF	—	—	—	—	—	—	—	—	OVUDF	OVLDF	SCDF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	DRF	SDF	STATE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27	BFOWDF	H'0	R	Buffer overwriting detection flag 0b: Indicates that buffer overwriting does not occur. 1b: Indicates that buffer overwriting occurred.
26 to 19	—	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	OVUDF	H'0	R	Overvoltage upper limit exceeded detection flag 0b: Indicates that the data is not above the upper limit 1b: Indicates that the data has exceeded the upper limit
17	OVLDF	H'0	R	Overvoltage lower limit exceeded detection flag 0b: Indicates that the data is not below the lower limit 1b: Indicates that the data has falling below the lower limit
16	SCDF	H'0	R	Short circuit detection flag 0b: Indicates that the PDM_DATn pin short circuit is not detected 1b: Indicates that a short circuit on the PDM_DATn pin has been detected
15 to 3	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	DRF	H'0	R	Data reception flag 0b: Indicates that the number of data stored in buffer is less than a threshold 1b: Indicates that the number of data stored in buffer is greater than or equal to a threshold
1	SDF	H'0	R	Sound detection flag 0b: Indicates that the sound is not detected 1b: Indicates that the sound is detected
0	STATE	H'0	R	State 0b: Channel stop 1b: Channel in operation

BFOWDF

Refer to **8.7.3.7 Data Buffer** for details.

[Condition to become “1b”]

- When PDSDCRCHn.BFOWDE = 1b and data buffer is full and data is written to the buffer without reading.

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.BFOWDFC).

OVUDF

Refer to **8.7.3.9 Overvoltage Detection** for details.

[Condition to become “1b”]

- When PDSDCRCHn.OVUDE = 1b and a clipped sinc filter result is larger than an upper limit (PDOVUTRCHn.OVDU[19:0]).

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.OVUDFC).

OVLDF

Refer to **8.7.3.9 Overvoltage Detection** for details.

[Condition to become “1b”]

- When PDSDCRCHn.OVLDE = 1b and a clipped sinc filter result is smaller than a lower limit (PDOVLTRCHn.OVDL[19:0]).

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.OVLDFC).

SCDF

Refer to **8.7.3.8 Short-Circuit Detection** for details.

[Conditions to become “1b”]

- When PDSDCRCHn.SCDE = 1b and 1b is continuously input to the PDM_DATn pin, exceeding the number of times set in PDSCTSRCHn.SCDH[12:0].
- When PDSDCRCHn.SCDE = 1b and 0b is continuously input to the PDM_DATn pin, exceeding the number of times set in PDSCTSRCHn.SCDL[12:0].

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.SCDFC).

DRF

Refer to **8.7.3.7 Data Buffer** for details.

[Condition to become “1b”]

- When PDDRCRCHn.DATRE = 1b and PDDSRCHn.DATNUM[7:0] is greater than or equal to a threshold which is configured by PDDBCRCHn.DATRITHR[2:0].

[Condition to become “0b”]

- When PDDRCRCHn.DATRE = 0b or PDDSRCHn.DATNUM[7:0] is less than a threshold.

SDF

Refer to **8.7.3.6 Sound Detection** for details.

[Conditions to become “1b”]

- When PDSDCRCHn.SDE = 1b and a moving average filter result is PDSDUTRCHn.SDETU[19:0] or greater.
- When PDSDCRCHn.SDE = 1b and a moving average filter result is PDSDLTRCHn.SDETL[19:0] or less.

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.SDFC).

STATE

Refer to **8.7.3.2 Channel Start and Channel Stop** for details.

[Condition to become “1b”]

- When “1b” is written to PDSTRTRCHn.STRTRG.

[Condition to become “0b”]

- When “1b” is written to PDSTPTRCHn.STPTRG.

8.7.2.2.17 Status Clear Register Channel n (PDMm_PDSCRCHn) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'0118

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note: S: Signed bit.
When the overflow occurs, H'7FFFF is output. When the underflow occurs, H'80000 is output.

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	SINCDEC [7:0]	H'7C	RW	Sinc filter decimation ratio M indicates the decimation ratio. Decimation ratio M is set as follows. M = SINCDEC + 1 H'00: M = 1 (prohibited) H'01: M = 2 (prohibited) H'02: M = 3 (prohibited) H'03: M = 4 … H'7C: M = 125 (default) … H'FF: M = 256 Setting a value less than M = 4 is prohibited. If such a value is set, operation of the sinc filter is not guaranteed. The setting should satisfy D × M > 12. Otherwise, operation of other filters is not guaranteed. *Note*: D: PDM_CLKn's division ratio
15 to 4	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	CKDIV[3:0]	H'0	RW	PDM_CLKn's division ratio to core clock 0000b: 1/2 (default) 0001b: 1/4 0010b: 1/6 … 1101b: 1/28 1110b: 1/30 1111b: 1/32

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 20	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19 to 0	DAT[19:0]	All 0	R	Data 20-bit signed sound data or 16-bit signed sound data is read out. In case of 20-bit mode (PDMDSRCHn.DBIS[3:0] = 0xxxb), the signed bit is [19]. In case of 16-bit mode (PDMDSRCHn.DBIS[3:0] = 1xxxb), the signed bits are [19:15]. Writing is invalid.

8.7.2.2.35 Data Status Register Channel n (PDMm_PDDSRCHn) (m = 0)

Access Size: 32 bits

Address(es): <PDMm_base> + H'01EC

Initial Value: H'0000_0000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DATNUM[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7 to 0	DATNUM[7:0]	All 0	R	Number of data stored in buffer When PDDRCRCHn.DATRE = 0b, 0b is read out. When PDDRCRCHn.DATRE = 1b, the number of data stored in buffer is read out. In case that buffer size is 64 stages, the maximum value is 63.

8.7.2.3 Mirroring Register

The common registers except for the version register have mirroring registers in each channel. PDCSR.EDFn is a register which ORs all the error flags of the mirroring registers in each channel.

Use the common registers for synchronous control between channels.

Table 8.7-5 Mirroring Register

Common Register		Mirroring Register in Each Channel	
Register Name	Bit Name	Register Name	Bit Name
PDCSTRTR	STRTRGn	PDSTRTRCHn	STRTRG
PDCSTPTR	STPTRGn	PDSTPTRCHn	STPTRG
PDCCHGTR	CHGTRGn	PDCHGTRCHn	CHGTRG
PDCICR	ISDEn	PDICRCHn	ISDE
	IDREn		IDRE
	IEDEn		IEDE
PDCSR	STATEn	PDSRCHn	STATE
	SDFn		SDF
	DRFn		DRF
	EDFn		SCDF or OVLDF or OVUDF or BFOWDF
PDCSCR	SDFCn	PDSCRCHn	SDFC
PDCSDCR	SDEn	PDSDCRCHn	SDE
PDCDRCR	DATREn	PDDRCRCHn	DATRE
PDCDCR	DATCn	PDDCRCHn	DATC

8.7.3 Operation

This section describes the PDM basic control method. See **8.7.4.6 Setting PDM_CLKn (n = 0, 1, 2) Frequency and Sampling Frequency Generated by the Unit** for information on setting the PDM_CLKn (n = 0, 1, 2) frequency and the sampling frequency generated by the PDM unit, and see **8.7.4.7 DMA Transfer Method** for information on transferring data with the DMA master.

8.7.3.1 Clock Specifications

The frequency-divided core clock is generated and output to PDM_CLKn.

Table 8.7-6 lists the guaranteed clock frequency and clock mode in PDM-IF. Core clock (CCLK) and PCLK are asynchronous.

In this section, read “PCLK” as “PDM_PCLK”, “CCLK” as “PDM_CCLK”.

Table 8.7-6 Guaranteed Clock Frequency and Clock Mode

CCLK	PCLK PCLK_SFR	PDM_CLKn		
Frequency (MHz)	Frequency (MHz)	Frequency (MHz)	Supported Core Clock Division Ratio	Setting Value (PDSFCRCHn.CKDIV[3:0])
8	1 to 100	4	2	0000b
		2	4	0001b
		1.33	6	0010b
		1	8	0011b
		0.8	10	0100b
		0.67	12	0101b
		0.57	14	0110b
		0.5	16	0111b
		0.44	18	1000b
		0.4	20	1001b
		0.36	22	1010b
		0.33	24	1011b
		0.31	26	1100b
		0.29	28	1101b
		0.27	30	1110b
		0.25	32	1111b

8.7.3.2 Channel Start and Channel Stop

The channel start and the channel stop is controlled by the registers listed in **Table 8.7-7**.

Set the channels to be synchronized to 1 at the same time by using the common registers.

Set the channel start according to **8.7.4.1 Start Flow**.

Set the channel stop according to **8.7.4.2 Stop Flow**.

Table 8.7-7 Channel Start Trigger and Channel Stop Trigger

	Register Bit Name	
Category	Common Register	Channel Register
Channel start	PDCSTRTR.STRTRG0	PDSTRTRCH0.STRTRG
	PDCSTRTR.STRTRG1	PDSTRTRCH1.STRTRG
	PDCSTRTR.STRTRG2	PDSTRTRCH2.STRTRG
Channel stop	PDCSTPTR.STPTRG0	PDSTPTRCH0.STPTRG
	PDCSTPTR.STPTRG1	PDSTPTRCH1.STPTRG
	PDCSTPTR.STPTRG2	PDSTPTRCH2.STPTRG

8.7.3.3 PDM_CLKn's Frequency Change

The external microphone transitions the power mode according to the input clock frequency. PDM-IF enables the transition of microphone's power mode by changing PDM_CLKn's operating frequency which is output to the microphone when operating. The PDM_CLKn's operating frequency can be changed by using the PDSFCRCHn.CKDIV[3:0] bits. When the frequency is changed, the decimation ratio of the sinc filter also needs to be changed. Set PDSFCRCHn.SINCDEC[7:0] in accordance with the sampling frequency after the decimation. Furthermore, when the decimation ratio of the sinc filter is changed, its output range is changed. Set PDSFCRCHn.SINCRNG[4:0] together in accordance with the output range. Refer to **Table 8.7-8,** which lists example settings when the sampling frequency after the decimation is 30 kHz*[1].

For the method of calculating the set values of PDSFCRCHn.CKDIV[3:0], PDSFCRCHn.SINCDEC[7:0], and PDSFCRCHn.SINCRNG[4:0] for the expected sampling frequency of PDM_CLKn, refer to **8.7.4.6 Setting PDM_CLKn (n = 0, 1, 2) Frequency and Sampling Frequency Generated by the Unit**.

After changing the configuration of these registers, software needs to wait for the settling time of microphone and PDM-IF channel. Refer to **8.7.4.4 Low Power Mode Transition Flow** and **8.7.4.5 Normal Mode Transition Flow** for details.

Note 1. If the same filter coefficient has been set in filtering after the sinc filter, the characteristics of the filter changes with the change of the sampling frequency.

8.7.3.4 Filter

8.7.3.4.1 Data Clipping and Shifting between Filters

Voice sample data is clipped or shifted between filters. **Figure 8.7-2** shows this operation.

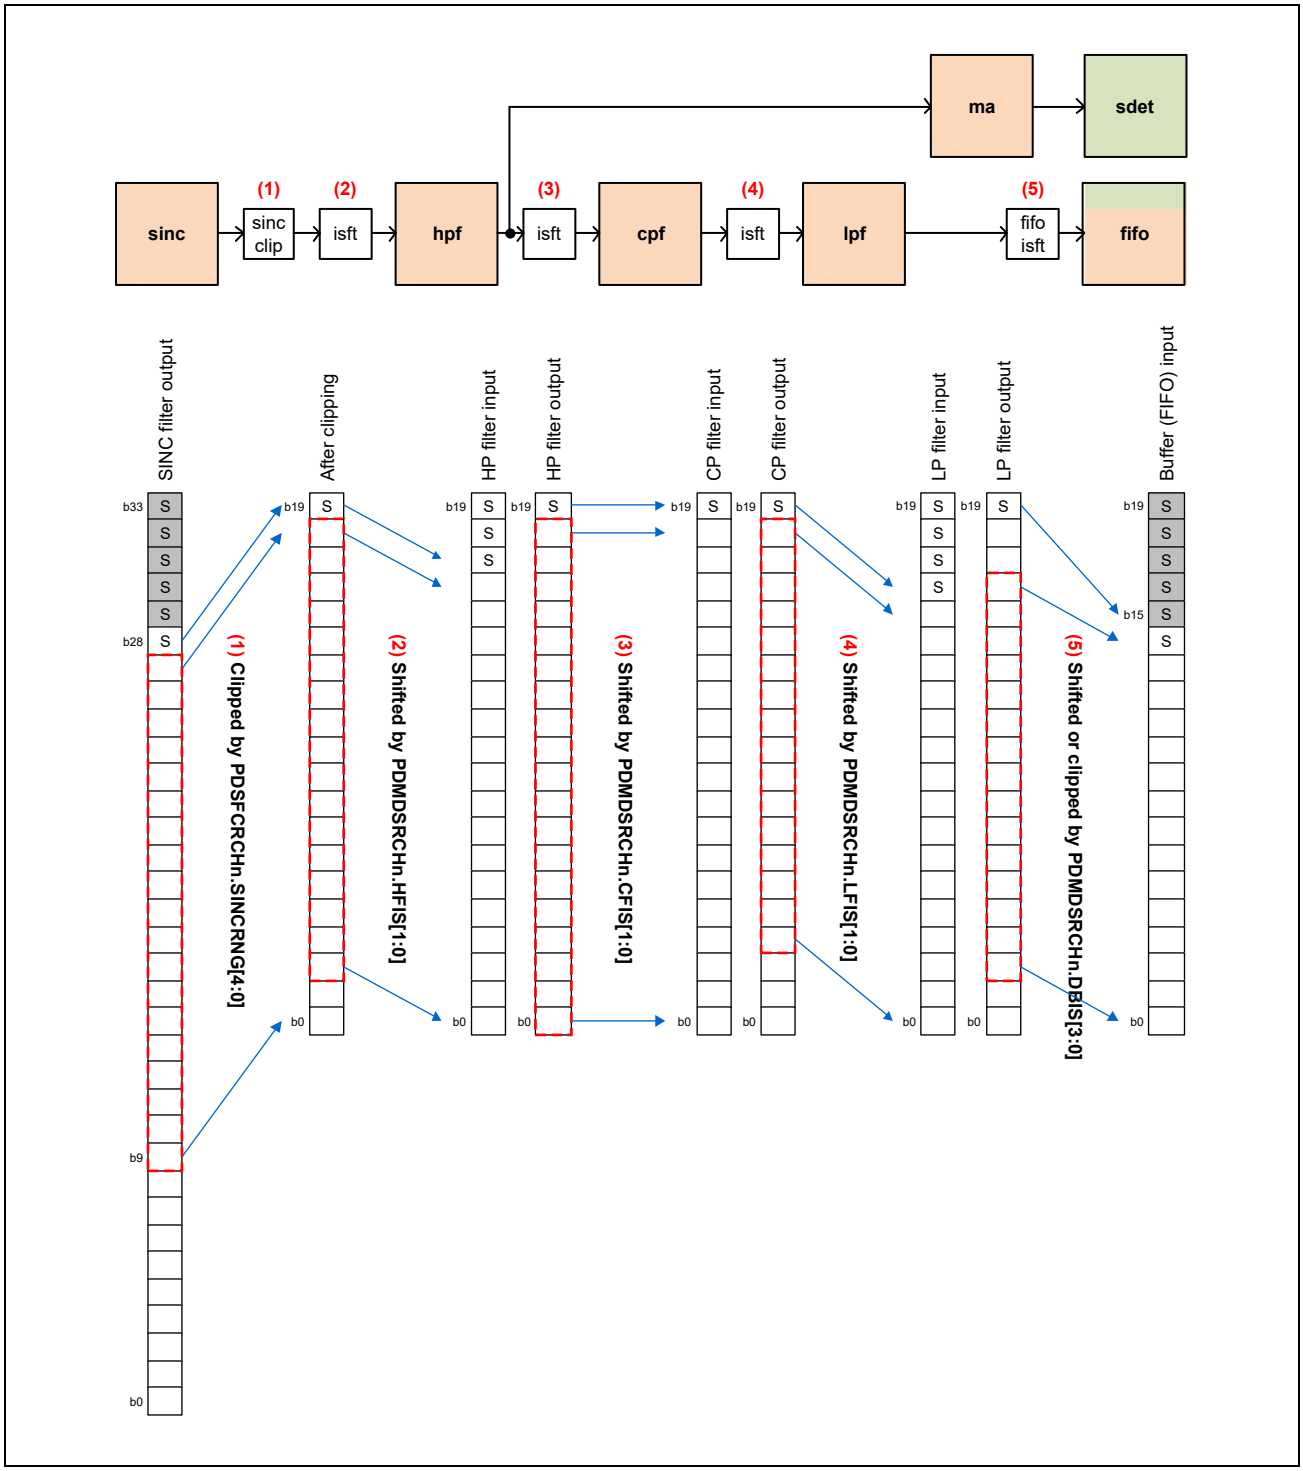

Figure 8.7-2 Data Clipping and Shifting between Filters

a) Sinc filter output clip

Table 8.7-8 lists the available settings of the sinc filter and data clipping.

It is controlled by PDSFCRCHn.SINCRNG[4:0].
It is prohibited to set other than those in **Table 8.7-8**.

Table 8.7-8 Sinc Filter Output Clip (1/2)

CCLK (MHz)	Sinc Filter Order	PDMDSRCHn. SFMD[2:0]	PDM_CLK's Division Ratio	PDSFCRCHn. CKDIV[3:0]	Sinc filter Decimation Ratio	PDSFCRCHn. An overflow or an underflow never occurs as long as the combinations which are shown in **Table 8.7-8** are set to PDMDSRCHn.SFMD[2:0], PDSFCRCHn.CKDIV[3:0], PDSFCRCHn.SINCDEC[7:0] and PDSFCRCHn.SINCRNG[4:0]. However, when other combinations are set to them, the overflow or the underflow might occur. When the overflow occurs, H'7FFFF is output. When the underflow occurs, H'80000 is output. Use the overvoltage detection function if you want to know if the overflow or the underflow occurs.

b) High-pass filter input shift

The clipped sinc filter output is right-shifted and input to the high-pass filter.

It is controlled by PDMDSRCHn.HFIS[1:0].

Table 8.7-9 High-pass Filter Input Shift

PDMDSRCHn.HFIS[1:0]	Function	Shifted Data*1
H'0	No shift	S, b18-b0
H'1	1-bit right-shift	S, S, b18-b1
H'2	2-bit right-shift	S, S, S, b18-b2
H'3	3-bit right-shift	S, S, S, S, b18-b3

Note 3. S: Signed bit (= bit 19)

c) Compensation filter input shift

The high-pass filter output is right-shifted and input to the compensation filter.

It is controlled by PDMDSRCHn.CFIS[1:0].

Table 8.7-10 Compensation Filter Input Shift

PDMDSRCHn.CFIS[1:0]	Function	Shifted Data*1
H'0	No shift	S, b18-b0
H'1	1-bit right-shift	S, S, b18-b1
H'2	2-bit right-shift	S, S, S, b18-b2
H'3	3-bit right-shift	S, S, S, S, b18-b3

Note 1. S: Signed bit (= bit 19)

d) Low-pass filter input shift

The compensation filter output is right-shifted and input to the low-pass (half-band decimation) filter.

It is controlled by PDMDSRCHn.LFIS[1:0].

Table 8.7-11 Low-pass Filter Input Shift

PDMDSRCHn.LFIS[1:0]	Function	Shifted Data*1
H'0	No shift	S, b18-b0
H'1	1-bit right-shift	S, S, b18-b1
H'2	2-bit right-shift	S, S, S, b18-b2
H'3	3-bit right-shift	S, S, S, S, b18-b3

Note 1. S: Signed bit (= bit 19)

e) Buffer input shift or clip

The compensation filter output is right-shifted, or 16-bit data is clipped from the compensation filter output. Then, the shifted or clipped data is input to buffer.

It is controlled by PDMDSRCHn.DBIS[3:0].

Table 8.7-12 Buffer Input Shift or Clip

PDMDSRCHn.DBIS[3:0]	Function	Valid Data Width	Shifted or Clipped Data*1
0000b	No shift	20-bit	S, b18-b0
0001b	1-bit right-shift	20-bit	S, S, b18-b1
0010b	2-bit right-shift	20-bit	S, S, S, b18-b2
0011b	3-bit right-shift	20-bit	S, S, S, S, b18-b3
1000b	Signed bit and b18-b4 is clipped	16-bit	S, b18-b4
1001b	Signed bit and b17-b3 is clipped*2	16-bit	S, b17-b3
1010b	Signed bit and b16-b2 is clipped*2	16-bit	S, b16-b2
1011b	Signed bit and b15-b1 is clipped*2	16-bit	S, b15-b1
1100b	Signed bit and b14-b0 is clipped*2	16-bit	S, b14-b0

Note 1. S: Signed bit (= bit 19)

Note 2. When an overflow occurs, H'7FFF is input to the buffer.
When an underflow occurs, H'8000 is input to the buffer.

8.7.3.4.2 Sinc Filter

The operating clock of the sinc filter is CCLK. Sinc filter is operated by using the 1-bit stream data latched with PDM_CLKn's rise-edge or fall-edge. Refer to **8.7.3.5 Data Input Control for Stereo Sound** for details.

Figure 8.7-3 shows a sinc filter block diagram.

The differentiation stage is operated by decimation clock (the frequency is 1/M of PDM_CLKn). M is the decimation ratio and is set in the PDSFCRCHn.SINCDEC[7:0] bits. The filter result is output in register every decimation clock.

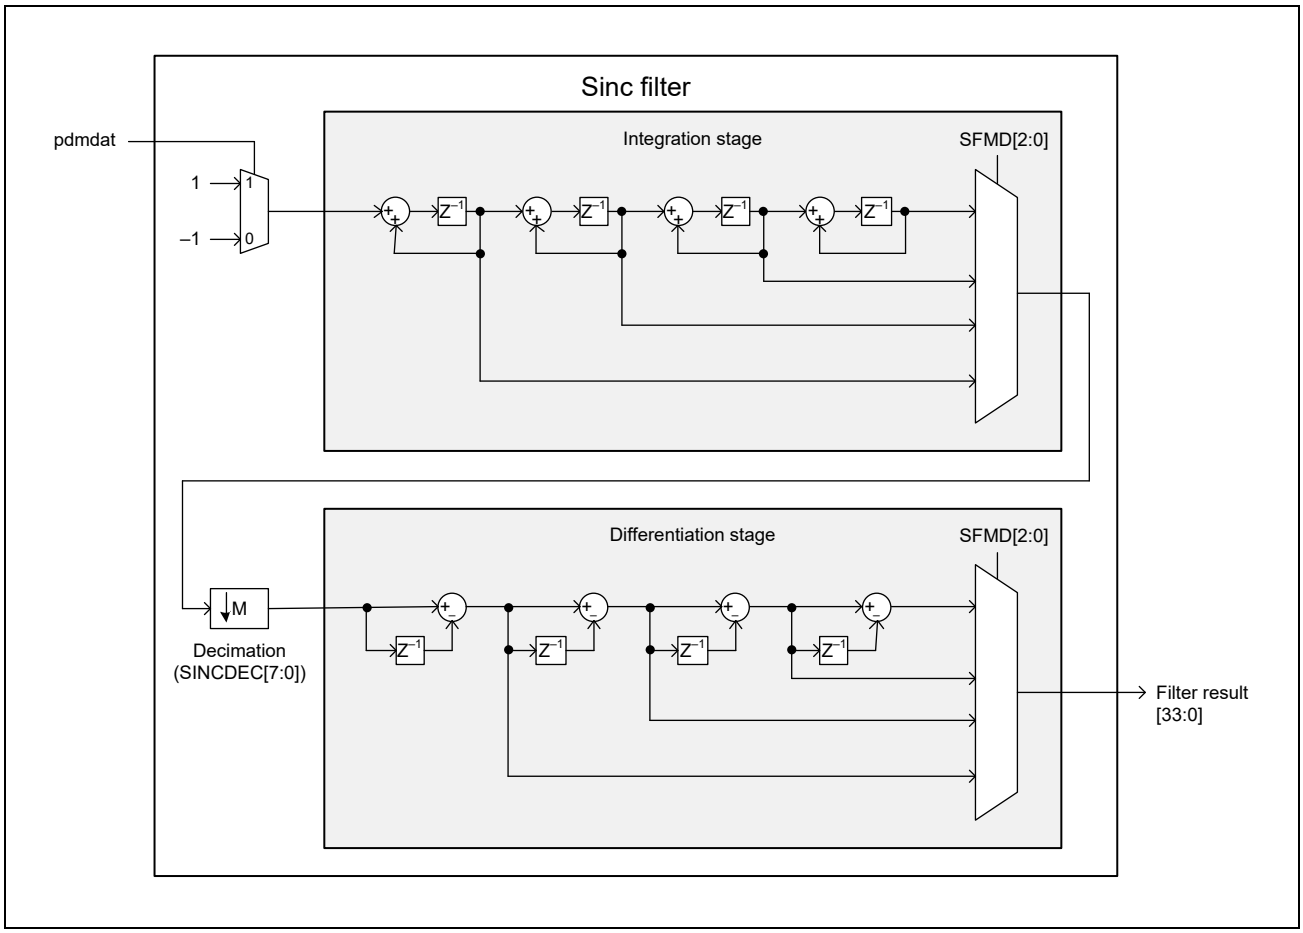

Figure 8.7-3 Sinc Filter Block Diagram

8.7.3.4.3 High-pass Filter

The operating clock of the high-pass filter is CCLK. The high-pass filter is operated by using the result of the sinc filter.

Figure 8.7-4 shows a high-pass filter block diagram.

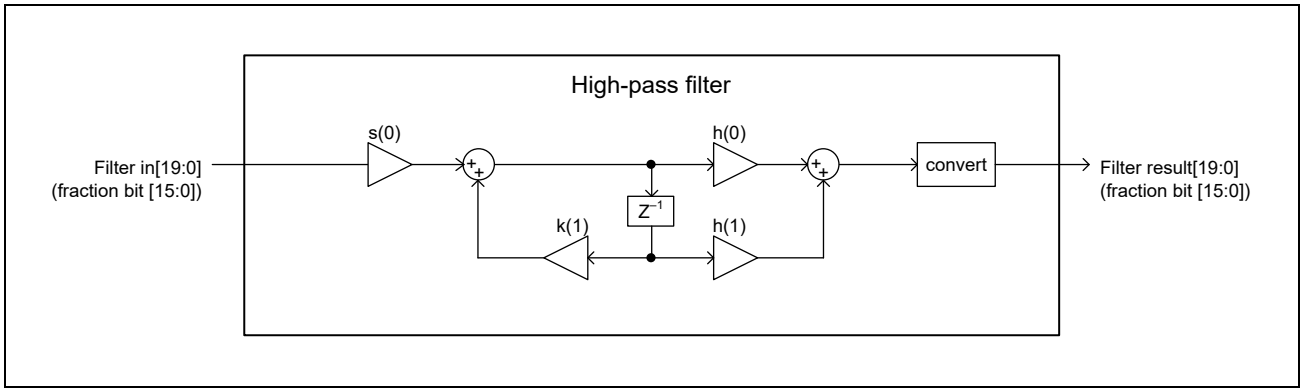

Figure 8.7-4 High-pass Filter Block Diagram

Table 8.7-13 lists the high-pass filter specification.

Table 8.7-13 High-pass Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Coefficient	Bit width	Signed 16-bit (fraction 14-bit) Refer to **8.7.2.2.20 High-Pass Filter Coefficient s(0) Register Channel n (PDMm_PDHFCS0RCHn) (m = 0)**, **8.7.2.2.21 High-Pass Filter Coefficient k(1) Register Channel n (PDMm_PDHFCK1RCHn) (m = 0)**, and **8.7.2.2.22 High-Pass Filter Coefficient h(p) Register Channel n (PDMm_PDHFCHpRCHn) (m = 0, p = 0, 1)** for details.
Delay Z	Bit width	Signed 32-bit (fraction 18-bit)
Multiplier	Input A bit width	Signed 32-bit (fraction 18-bit)
	Input B bit width	Signed 16-bit (fraction 14-bit)
	Output bit width	Signed 47-bit (fraction 32-bit)
Adder	Input A bit width	Signed 32-bit (fraction 18-bit)
	Input B bit width	Signed 32-bit (fraction 18-bit)
	Output bit width	Signed 33-bit (fraction 18-bit)
Output conversion	Input bit width	Signed 32-bit (fraction 18-bit)
	Output bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at functional unit input or final output.

8.7.3.4.4 Compensation Filter

The operating clock of the compensation filter is CCLK. The compensation filter is operated by using the result of the high-pass filter.

Figure 8.7-5 shows a compensation filter block diagram.

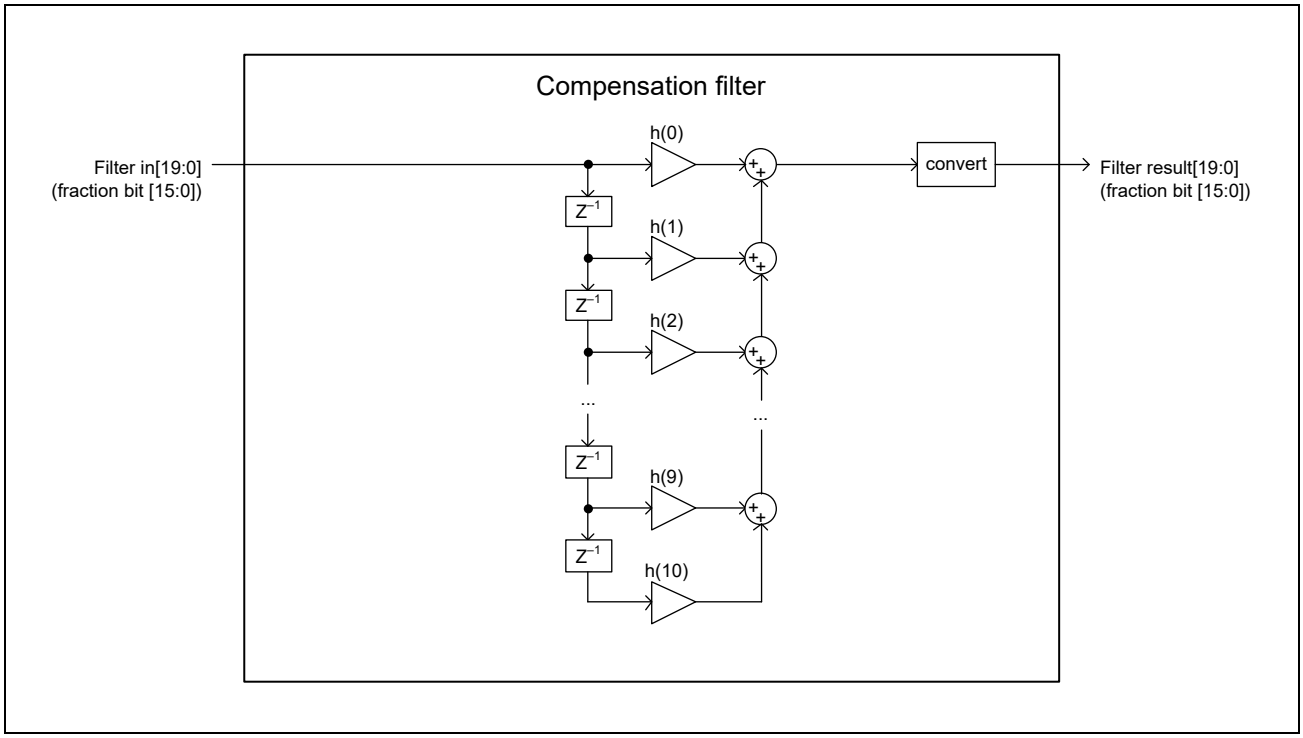

Figure 8.7-5 Compensation Filter Block Diagram

Table 8.7-14 shows a compensation filter specification.

Table 8.7-14 Compensation Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Coefficient	Bit width	Signed 13-bit (fraction 11-bit) Refer to **8.7.2.2.23 Compensation Filter Coefficient h(p) Register Channel n (PDMm_PDCFCHpRCHn) (m = 0, p = 00 to 10)** for details.
Delay Z	Bit width	Signed 20-bit (fraction 16-bit)
Multiplier	Input A bit width	Signed 20-bit (fraction 16-bit)
	Input B bit width	Signed 13-bit (fraction 11-bit)
	Output bit width	Signed 32-bit (fraction 27-bit)
Adder	Input A bit width	Signed 22-bit (fraction 18-bit)
	Input B bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 23-bit (fraction 18-bit)
Output conversion	Input bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at functional unit input or final output.

8.7.3.4.5 Low-Pass (Half-Band Decimation) Filter

The operating clock of the low-pass filter is CCLK. The low-pass filter is operated by using the result of the compensation filter. Output data is decimated to a half of input data.

Figure 8.7-6 shows a low-pass filter block diagram.

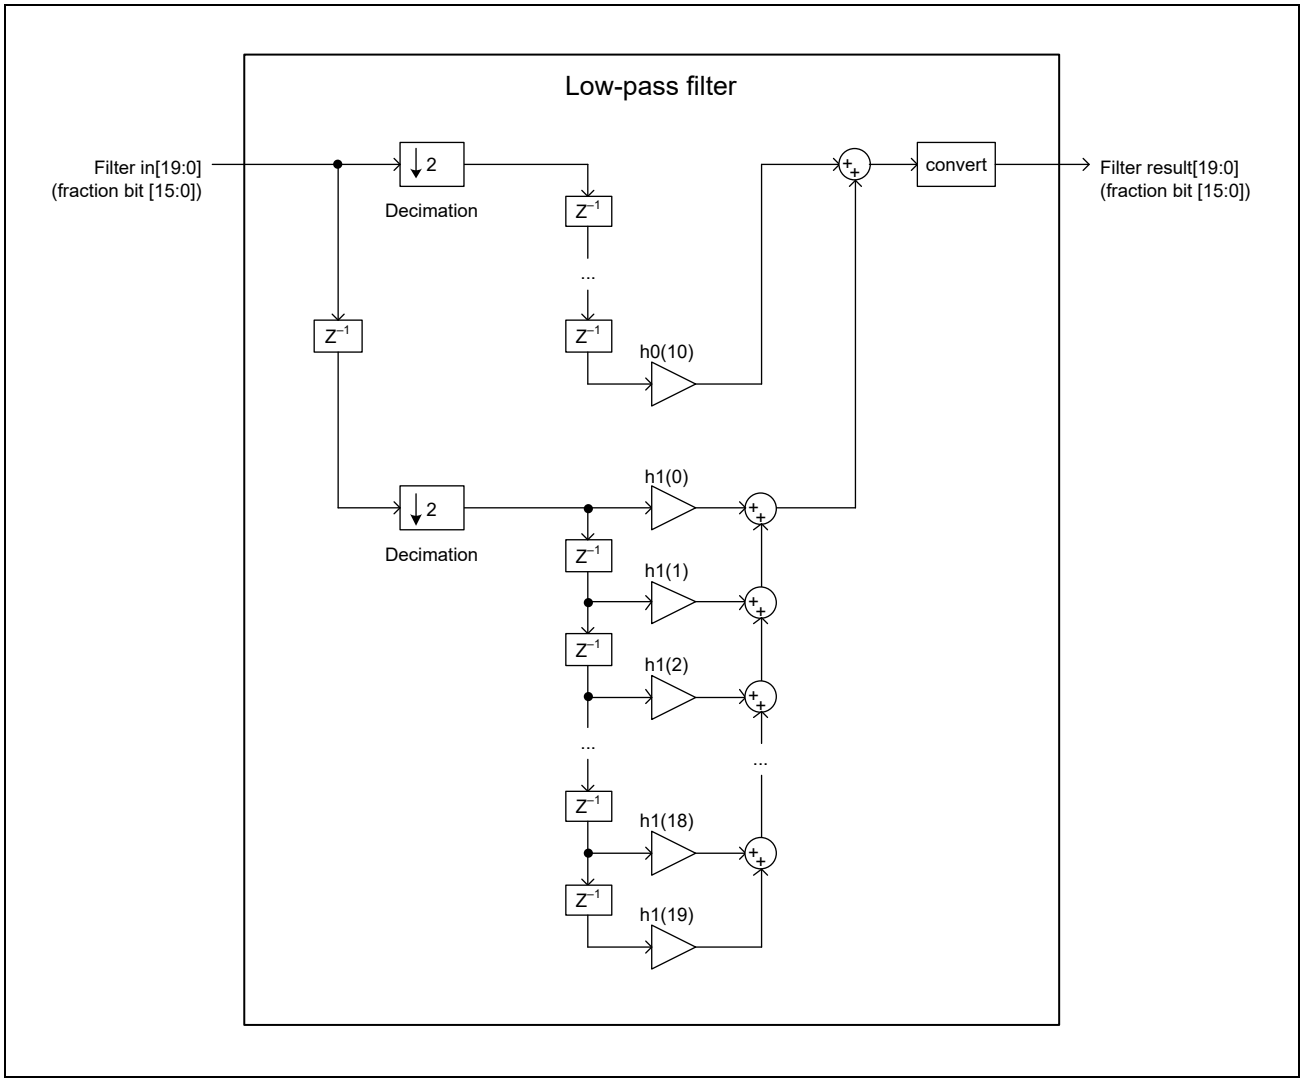

Figure 8.7-6 Low-Pass Filter Block Diagram

Table 8.7-15 lists a low-pass filter specification.

Table 8.7-15 Low-Pass Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Coefficient	Bit width	Signed 13-bit (fraction 11-bit) Refer to **8.7.2.2.33 Data Clear Register Channel n (PDMm_PDDCRCHn) (m = 0)** for detail.
Delay Z	Bit width	Signed 20-bit (fraction 16-bit)
Multiplier	Input A bit width	Signed 20-bit (fraction 16-bit)
	Input B bit width	Signed 13-bit (fraction 11-bit)
	Output bit width	Signed 32-bit (fraction 27-bit)
Adder	Input A bit width	Signed 22-bit (fraction 18-bit)
	Input B bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 23-bit (fraction 18-bit)
Output conversion	Input bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at functional unit input or final output.

8.7.3.4.6 Moving Average Filter

The operating clock of the moving average filter is CCLK. The moving average filter is operated by using the result of the high-pass filter. The order of the moving average filter can be changed by the setting of the PDMDSRCHn.SDMAMD[1:0] bits.

Figure 8.7-7 shows a moving average filter block diagram.

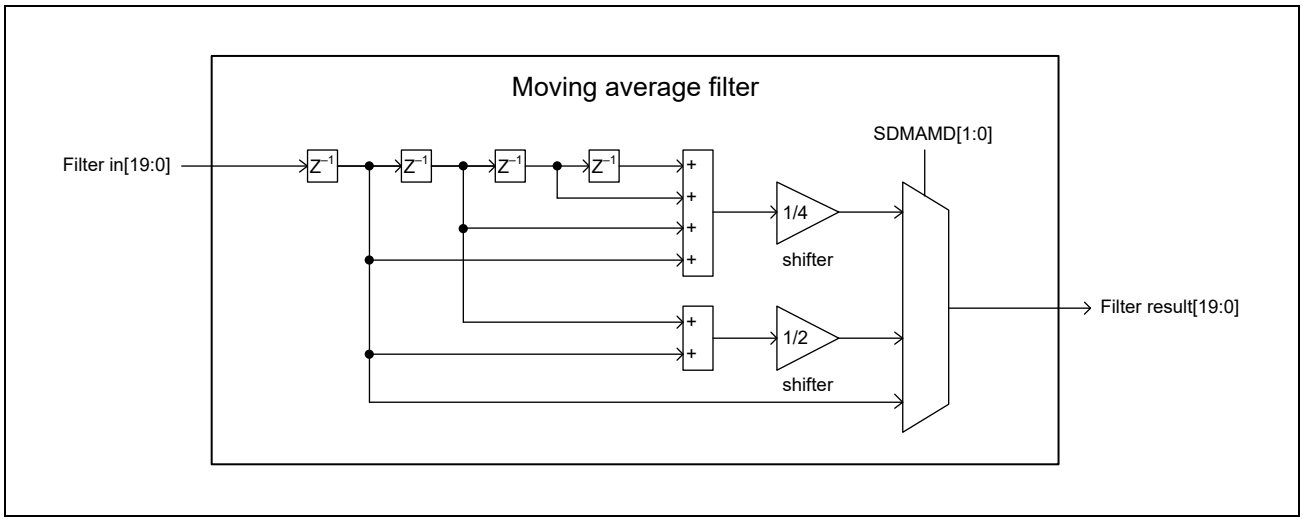

Figure 8.7-7 Moving Average Filter Block Diagram

Table 8.7-16 lists a moving average filter specification.

Table 8.7-16 Moving Average Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Delay Z	Bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at shifter.

8.7.3.4.7 Settling Time of Channel Activation / Setting Change

The settling time of channel activation is the time after a start trigger PDCSTRTR.STRTRGn (or PDSTRTRCHn.STRTRG) is set before the filter result is stable and output. The settling time of channel setting change is the time after a change trigger PDCCHGTR.CHGTRGn (or PDCHGTRCHn.CHGTRG) is set before the filter result is stable and output. **Figure 8.7-8** shows the settling time measurement point.

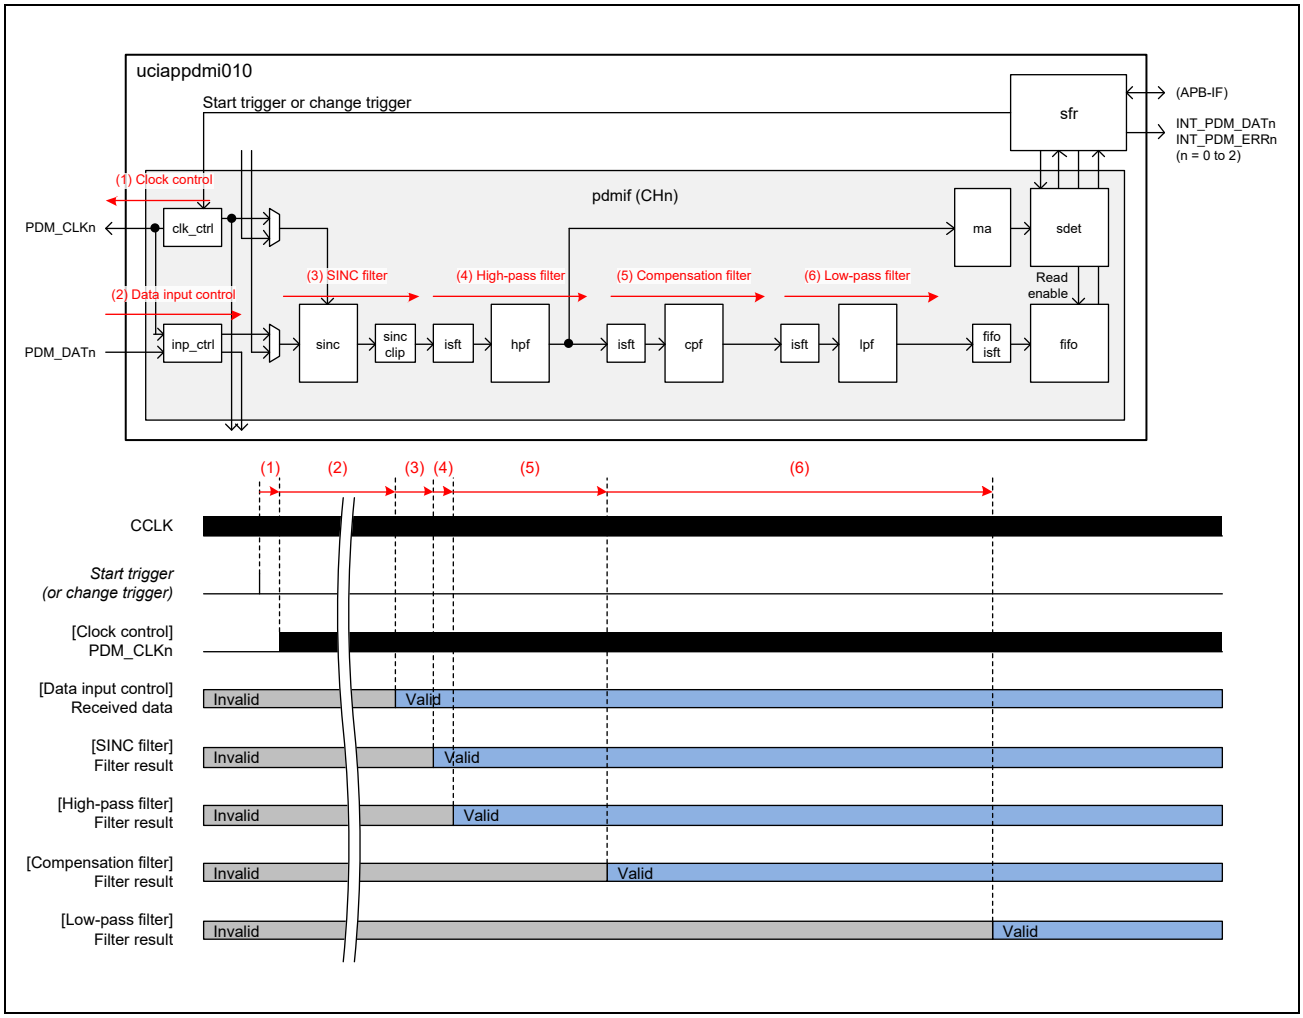

Figure 8.7-8 Settling Time of Channel Activation

The settling time is calculated as shown in **Table 8.7-17**.

Table 8.7-17 Settling Time of Channel Activation / Setting Change

No.	Function	Settling Time	
		Channel Activation	Channel Setting Change
(1)	Clock control	(4 + (D/2)) × Cp	(3 + Do + (D/2)) × Cp
(2)	Data input control	(D/2) × Cp + (Stable time for microphone*1)	
(3)	Sinc filter	(K × D × M) × Cp	
(4)	High-pass filter	(D × M + 5) × Cp	
(5)	Compensation filter	(10 × D × M + 12) × Cp	
(6)	Low-pass filter	(38 × D × M + 22) × Cp	

Note: Cp: CCLK period
D: PDM_CLKn's division ratio
Do: PDM_CLKn's division ratio (old setting)
K: Sinc filter order
M: Sinc filter decimation ratio

Note 1. Wakeup time from low power mode, Switching time, etc. Refer to the datasheet of microphone for details.

8.7.3.5 Data Input Control for Stereo Sound

The microphone which supports the stereo sound outputs the right sound synchronized with PDM_CLKn's rise-edge and the left sound synchronized with PDM_CLKn's fall-edge.

PDM-IF can process the right sound and the left sound using different channels.

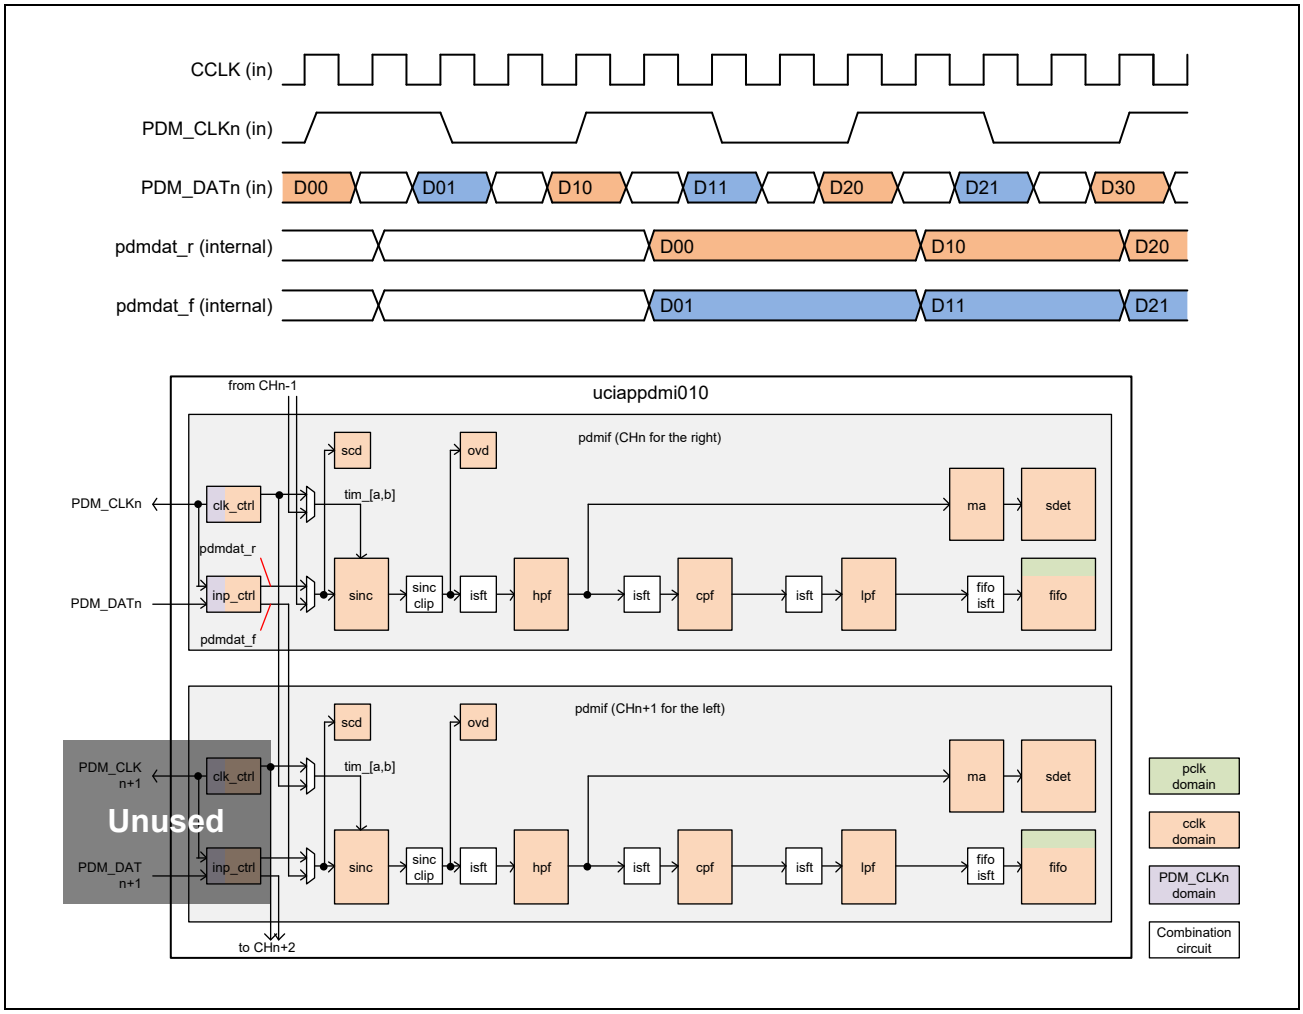

Figure 8.7-9 Data Input Control for Stereo Sound

Table 8.7-18 lists the channel combinations of stereo sound processing.

Table 8.7-18 Channel Combinations of Stereo Sound Processing

Input	Three Channels PDM-IF		Two Channels PDM-IF	
	Data Processing Latched at Rise-Edge (Right Sound)	Data Processing Latched at Fall-Edge (Left Sound)	Data Processing Latched at Rise-Edge (Right Sound)	Data Processing Latched at Fall-Edge (Left Sound)
PDM_CLK0 PDM_DAT0	Channel 0	Channel 1	Channel 0	Channel 1
PDM_CLK1 PDM_DAT1	Channel 1	Channel 2	Channel 1	Channel 0
PDM_CLK2 PDM_DAT2	Channel 2	Channel 0	Not implemented	

Table 8.7-19 lists an example of register settings for stereo sound processing using channel 0 and channel 1.

Table 8.7-19 Register Settings for Stereo Sound Processing

Register	Bit	Channel 0 Setting	Channel 1 Setting
PDICRCHn	All bits	Channel unique settings	Channel unique settings
PDSDCRCHn	All bits	Channel unique settings	Channel unique settings
PDMDSRCHn	INPSEL	0 (Use channel 0 data synchronized with rise-edge)	1 (Use channel 0 data synchronized with fall-edge)
	SFMD[2:0]	Same settings for channel 0 and channel 1 (Mandatory)	
	HFIS[1:0]	Channel unique settings	Channel unique settings
	HFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	CFIS[1:0]	Channel unique settings	Channel unique settings
	CFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	LFIS[1:0]	Channel unique settings	Channel unique settings
	LFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	SDHFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	SDMAMD[1:0]	Same settings for channel 0 and channel 1 (Mandatory)	
	DBIS[3:0]	Channel unique settings	Channel unique settings
PDSFCRCHn	CKDIV[3:0]	Setting of the clock which is supplied to the microphone connected to channel 0	Unuse
	SINCDEC[7:0]	Same settings for channel 0 and channel 1 (Mandatory)	
	SINCRNG[4:0]	Same settings for channel 0 and channel 1 (Mandatory)	
PDHFCS0RCHn	All bits	Channel unique settings	Channel unique settings
PDHFCK1RCHn	All bits	Channel unique settings	Channel unique settings
PDHFCH0RCHn	All bits	Channel unique settings	Channel unique settings
PDHFCH1RCHn	All bits	Channel unique settings	Channel unique settings
PDCFCHmRCHn	All bits	Channel unique settings	Channel unique settings
PDLFCH0mRCHn	All bits	Channel unique settings	Channel unique settings
PDLFCH1mRCHn	All bits	Channel unique settings	Channel unique settings
PDSDLTRCHn	All bits	Channel unique settings	Channel unique settings
PDSDUTRCHn	All bits	Channel unique settings	Channel unique settings
PDDBCRCHn	All bits	Same settings for channel 0 and channel 1 (Mandatory)	
PDSCTSRCHn	All bits	Channel unique settings	Channel unique settings
PDOVLTRCHn	All bits	Channel unique settings	Channel unique settings
PDOVUTRCHn	All bits	Channel unique settings	Channel unique settings

8.7.3.6 Sound Detection

The operating clock of the sound detection function is CCLK. When PDSDCRCHn.SDE = 1b, the function judges the sound detection using the moving average filter results.

A sound detection flag (PDSRCHn.SDF) is set to 1b when the result is above the upper limit PDSDUTRCHn.SDETU[19:0]. The sound detection flag is also set to 1b when the result is below the lower limit PDSDLTRCHn.SDETL[19:0]. The sound detection flag is cleared to 0b when 1b is written to PDSCRCHn.SDFC.

Figure 8.7-10 shows the sound detection function.

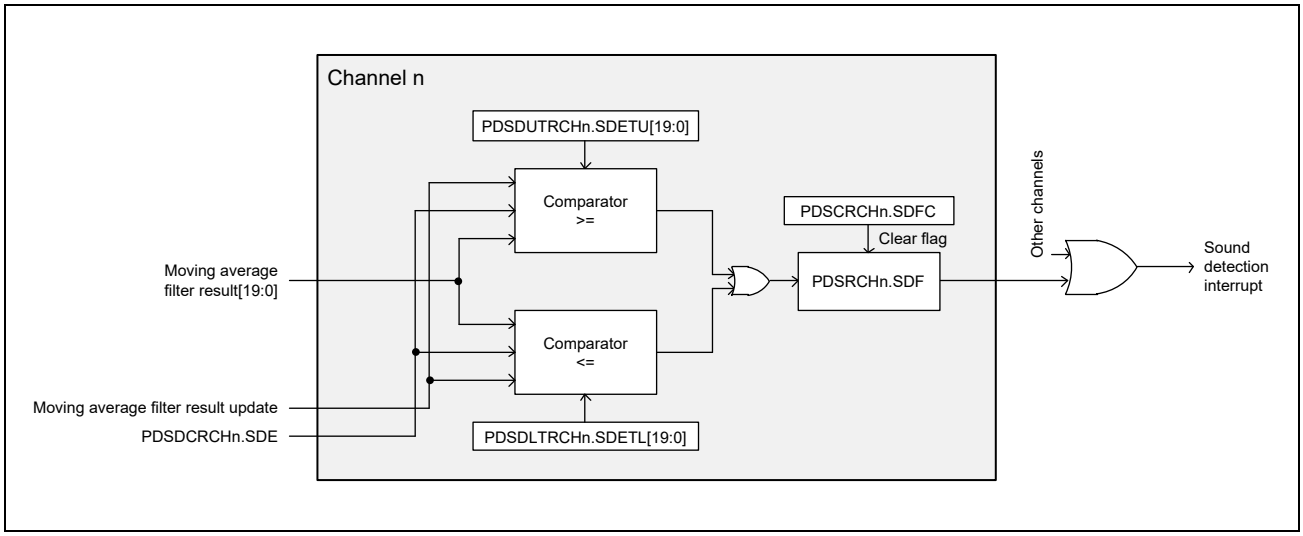

Figure 8.7-10 Sound Detection Function

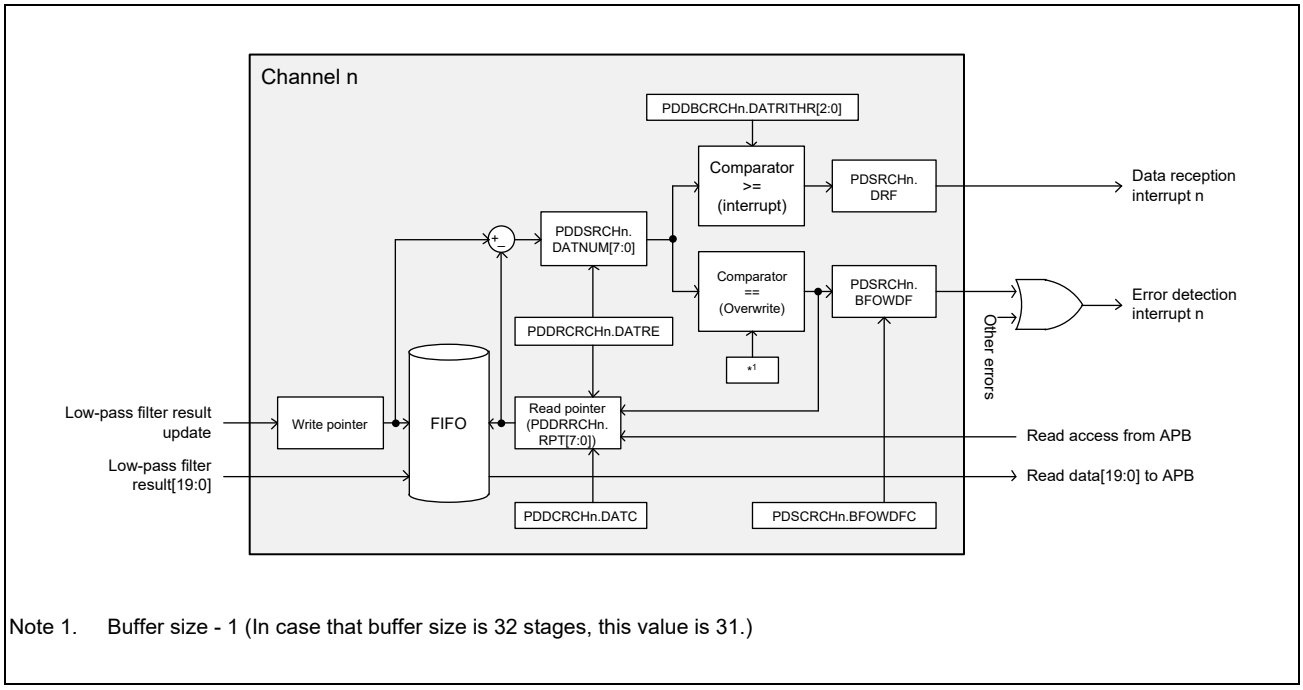
8.7.3.7 Data Buffer



Data buffer writes sound data to FIFO synchronizing with CCLK and reads sound data from FIFO synchronizing with PCLK. Data buffer stores sound data in FIFO until it is read out.

While PDDRCRCHn.DATRE = 0b (hereinafter, DATRE), PDDSRCHnDATNUM[7:0] (hereinafter, DATNUM[7:0]) shows 0 and PDM-IF does not allow to read sound data. After DATRE is changed from 0b to 1b, DATNUM[7:0] shows the buffer size minus 2 and PDM-IF allows to read sound data. While DATRE = 1b, data buffer increments DATNUM[7:0] when data is written and decrements DATNUM[7:0] when data is read.

When DATNUM[7:0] is greater than or equal to a threshold which is configured by PDDBCRCHn.DATRITHR[2:0], a data reception flag PDSRCHn.DRF (hereinafter, DRF) is set to 1b. When DATNUM[7:0] is less than the threshold by reading data or etc., a data reception flag DRF is cleared to 0b.

When DATNUM[7:0] is the buffer size minus 2 and data is written without reading, data buffer overwrites the oldest data with a new one and a buffer overwriting detection flag PDSRCHn.BFOWDF (hereinafter, BFOWDF) is set to 1b. And then DATNUM[7:0] is set to the buffer size minus 2 again after overwriting. However, data buffer overwrites but BFOWDF is not set after DATRE changes from 0b to 1b to before the first data is read.

Figure 8.7-11 shows the data buffer function.

Note 1. Buffer size - 1 (In case that buffer size is 32 stages, this value is 31.)

Figure 8.7-11 Data Buffer Function

8.7.3.8 Short-Circuit Detection

When Short-circuit detection enable (PDSDCRCHn.SCDE) is valid, the short-circuit detection can operate.

A dedicated 13-bit counter counts consecutive 0's or 1's input from pdm_dat which is outputs by data input control block of channel n or channel n+1.

When the number of consecutive 0's exceeds the value set in the PDSCTSRCHn.SCDL[12:0] register or the number of consecutive 1's exceeds the value set in the PDSCTSRCHn.SCDH[12:0] register, a short-circuit detection interrupt request is generated.

Figure 8.7-12 shows the configuration for the short-circuit detection function.

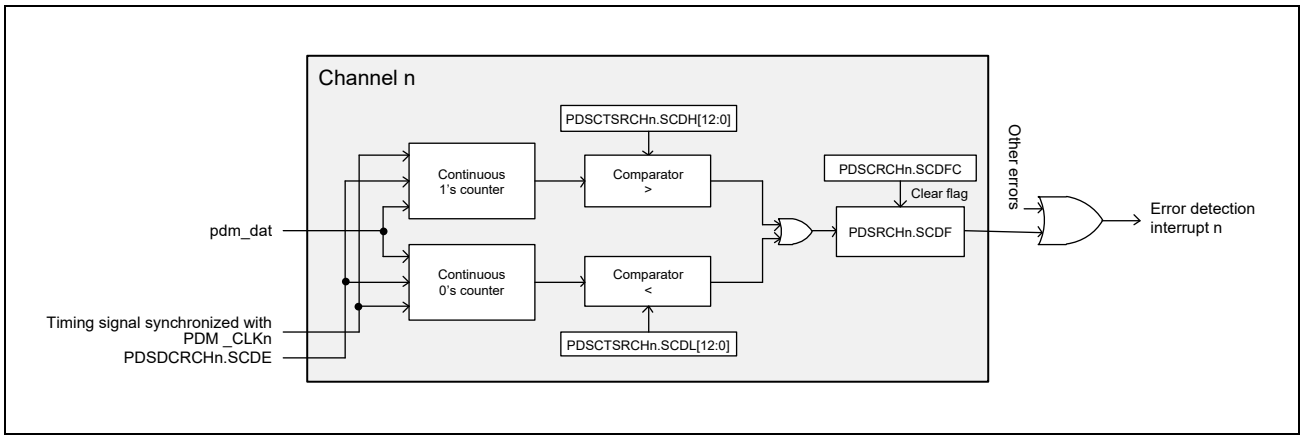


Figure 8.7-12 Short-Circuit Detection Function

8.7.3.9 Overvoltage Detection

When the overvoltage upper limit detection enable (PDSDCRCHn.OVUDE) is valid, the overvoltage upper limit detection can operate. When the overvoltage lower limit detection enable (PDSDCRCHn.OVLDE) is valid, the overvoltage lower limit detection can operate.

The sound data is clipped as a 20-bit data from 34-bit data output from sinc filter by the setting of the PDSFCRCHn.SINCRNG[4:0] bits. Refer to **Table 8.7-8** for details.

An overvoltage upper limit detection flag is set to 1b when the clipped sound data is greater than PDOVUTRCHn.OVDU[19:0].

An overvoltage lower limit detection flag is set to 1b when the clipped sound data is less than PDOVLTRCHn.OVDL[19:0].

Figure 8.7-13 shows the overvoltage detection function.

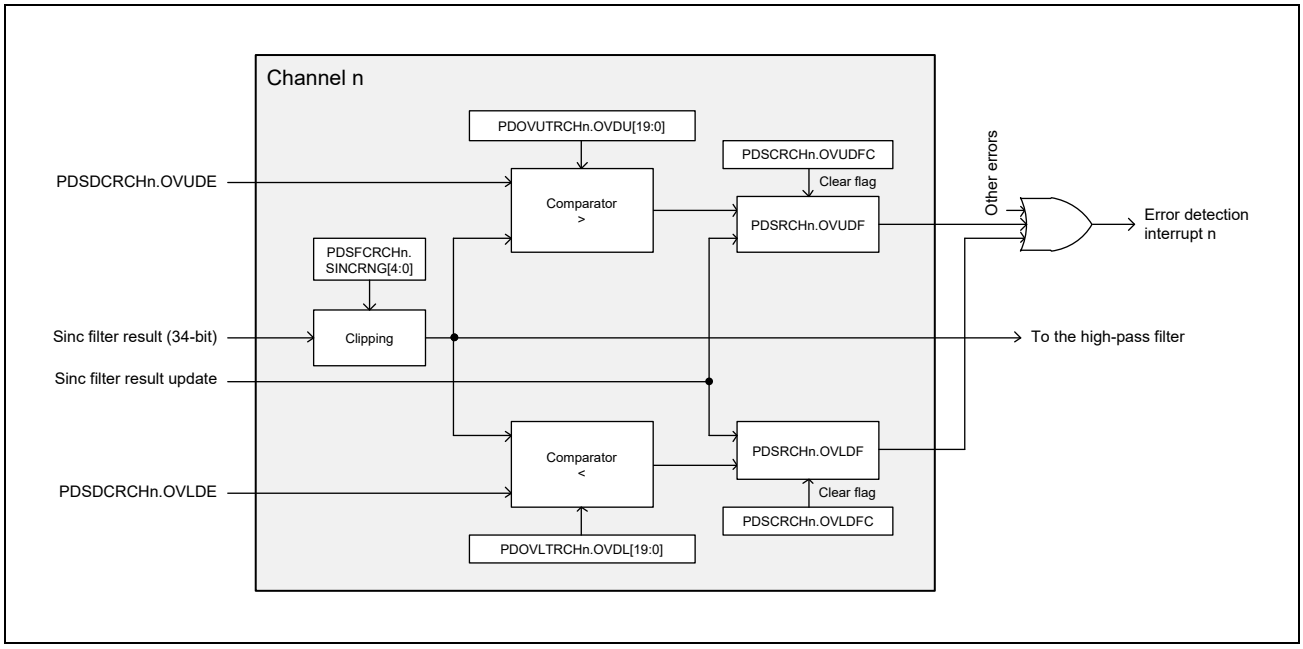

Figure 8.7-13 Overvoltage Detection Function

8.7.3.10 Error

Table 8.7-20 shows a PDM-IF error list.

Table 8.7-20 PDM-IF Error List

No.	Register Name	Description	Comment	Function (Related Section)
1	PDSRCHn.SCDF	Short circuit detection flag		**8.7.3.8 Short-Circuit Detection**
2	PDSRCHn.OVLDF	Overvoltage lower limit detection flag		**8.7.3.9 Overvoltage Detection**
3	PDSRCHn.OVUDF	Overvoltage upper limit detection flag		**8.7.3.9 Overvoltage Detection**
4	PDSRCHn.BFOWDF	Buffer overwriting detection flag	For debugging	**8.7.3.7 Data Buffer**

The errors in No.4 are for debugging. Software needs to set registers and operate PDM-IF so that these errors do not occur. If any of these error occur, stop PDM-IF following **8.7.4.2 Stop Flow** and change the settings.

8.7.3.11 Interrupt Function

PDM-IF has the following interrupt function.

Table 8.7-21 PDM-IF Interrupt List

No.	Signal Name	Interrupt Name	Number of Signals	Pulse or Level	Related Register Bit Name		Function (Related Section)
					Common Register	Channel Register	
1	INT_PDM_DATn (n = 0, 1, 2)	Data reception interrupt CHn	3	Level	PDCSR.DRFn	PDSRCHn.DRF	**8.7.3.7 Data Buffer**
2	INT_PDM_SDET	Sound detection interrupt (3-channel status flags are ORed.)	1	Level	PDCSR.SDFn	PDSRCHn.SDF	**8.7.3.6 Sound Detection**
3	INT_PDM_ERRn (n = 0, 1, 2)	Error detection interrupt CHn	3	Level	PDCSR.EDFn	PDSRCHn.SCDF	**8.7.3.8 Short-Circuit Detection**
						PDSRCHn.OVLDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn.OVUDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn.BFOWDF	**8.7.3.7 Data Buffer**

8.7.4 Setting Flow

Figure 8.7-14 and **Figure 8.7-15** show the example of the main procedure of PDM-IF.

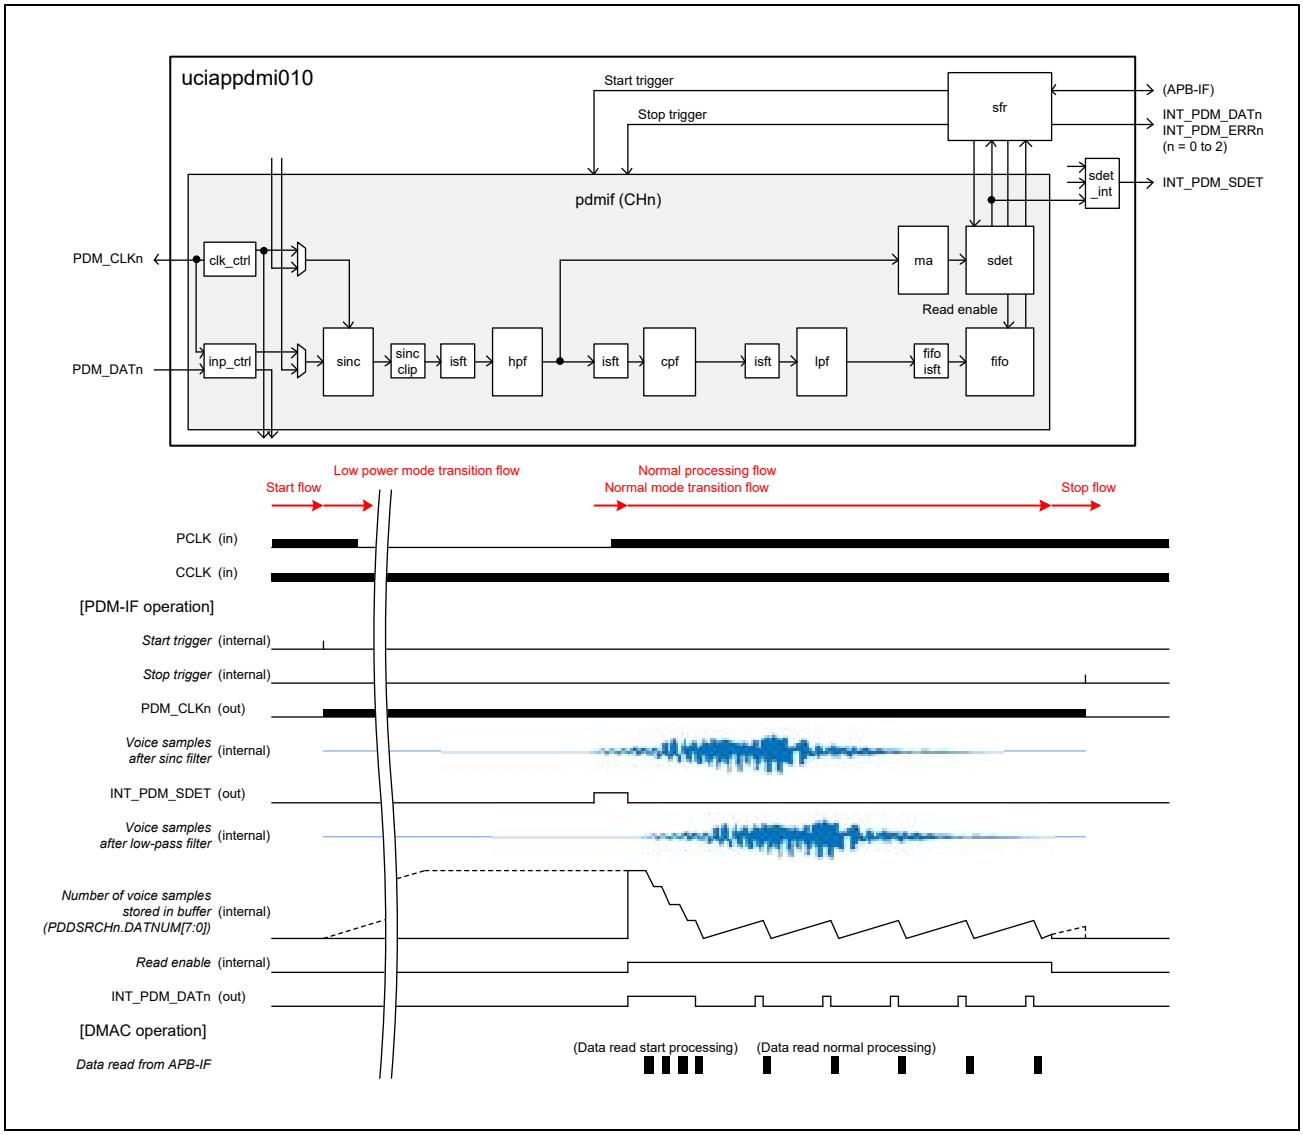

Figure 8.7-14 PDM-IF Operation Example

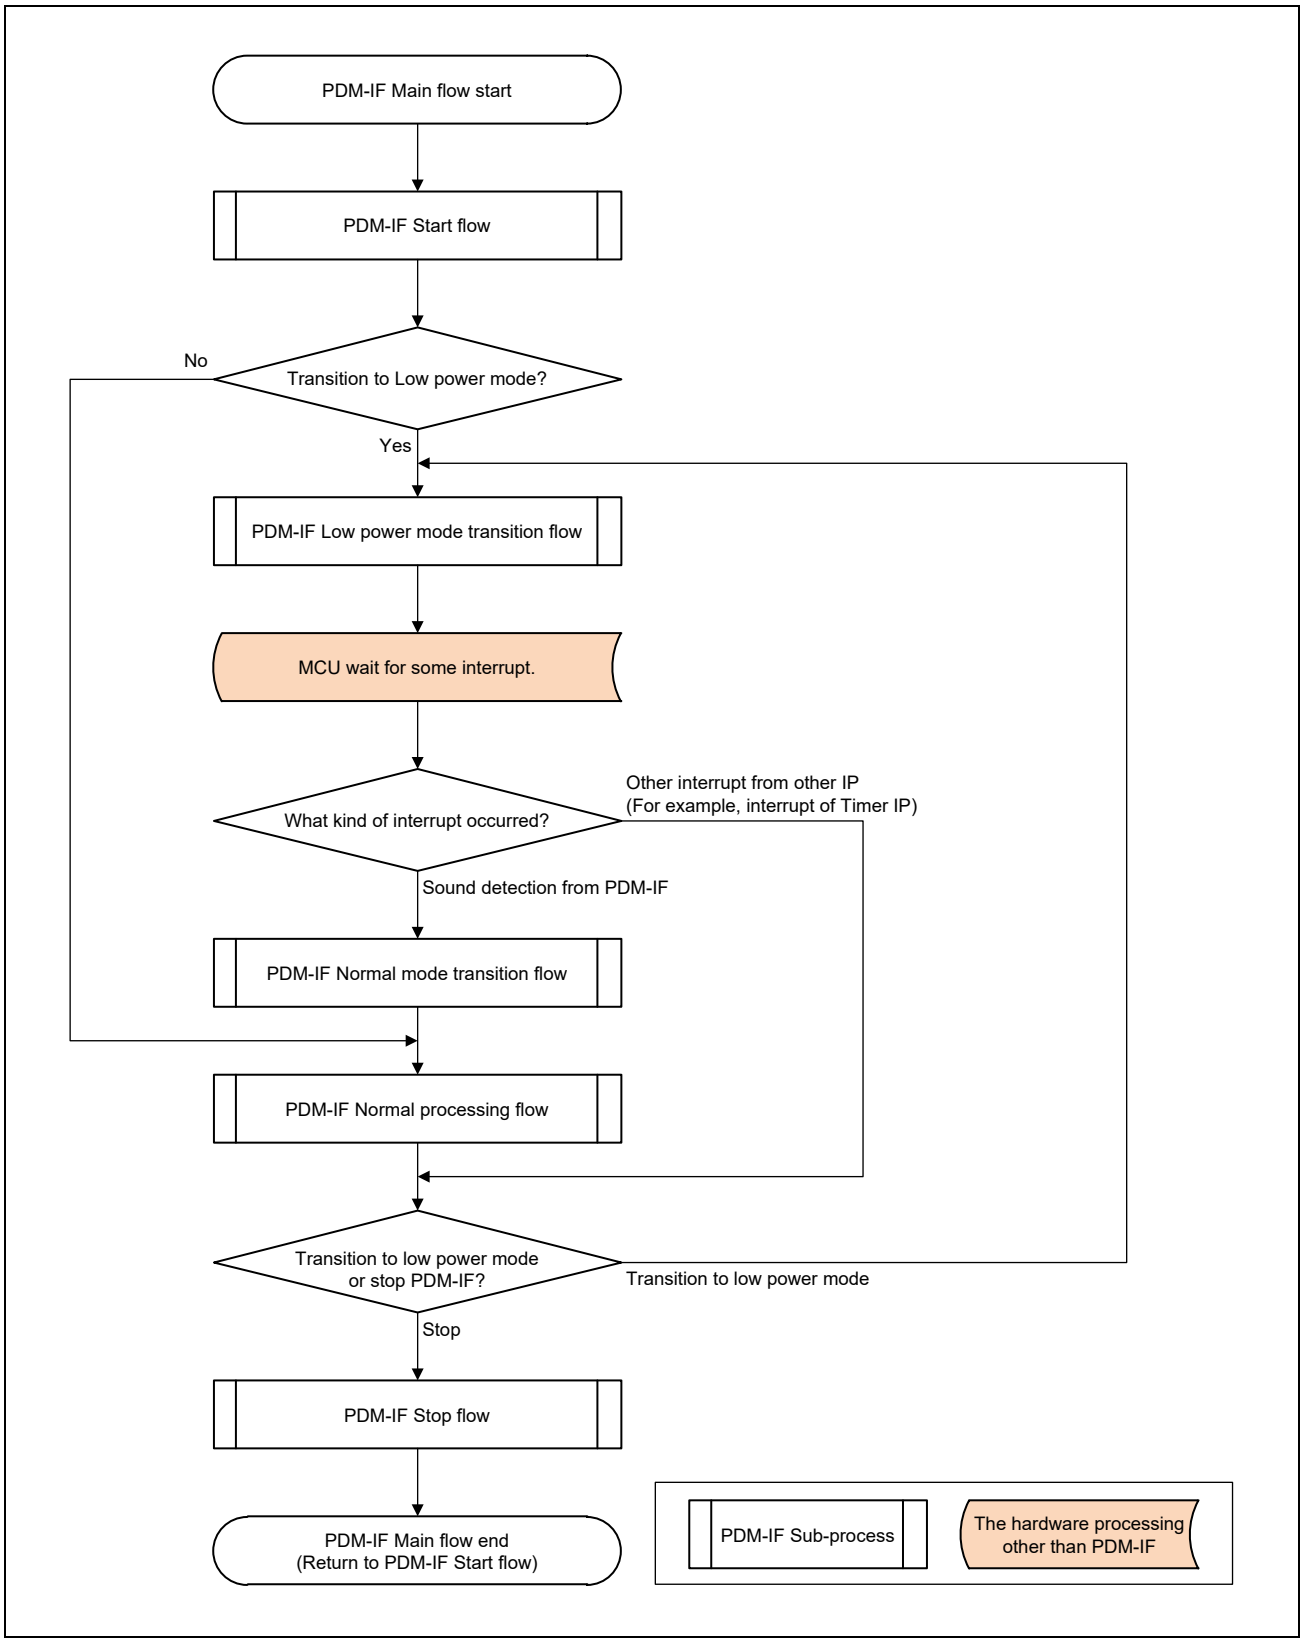

Figure 8.7-15 PDM-IF Setting Main Flow with Low Power Mode Transition

Figure 8.7-16 shows the example of the main procedure without low-power mode transition.

Note 1. If the channels are to be synchronized, complete the settings for respective channels before this step.

Figure 8.7-21 PDM-IF Normal Mode Transition Flow

8.7.4.6 Setting PDM_CLKn (n = 0, 1, 2) Frequency and Sampling Frequency Generated by the Unit

The frequency of PDM_CLKn (n = 0, 1, 2), which is the reference for receiving data from the external device, and the sampling frequency generated by the PDM unit for external input PDM data can be changed by setting the register. The PDM_CLKn (n = 0, 1, 2) frequency must match the clock input specifications of the external device. The sampling frequency generated by the unit should be set to the expected value.

In this LSI, the PDM reference clock CCLK is fixed at 8 MHz, so the PDM_CLK output frequency and the unit-generation sampling frequency follow the equation below when implementing the circuit.

- PDM_CLKn (n = 0, 1, 2) frequency

$$= \frac{\text{CCLK frequency}}{(\text{CKDIV} + 1) \times 2};$$

- Unit-generation sampling frequency

$$= \frac{\text{PDM_CLK frequency}}{(\text{SINCDEC} + 1) \times 2^{*1}} = \frac{\text{CCLK frequency}}{(\text{CKDIV} + 1) \times 2} \div (\text{SINCDEC} + 1) \times 2^{*1};$$

Remark: CKDIV: PDSFCRCHn.CKDIV[3:0] register set value (Set the PDM_CLKn division ratio to CCLK)
SINCDEC: PDSFCRCHn.SINCDEC[7:0] register set value (Set the decimation ratio of the Sinc filter)

Note 1. Reason for ×2: Low-pass filter decimation ratio

- PDMIF sampling rate:

$$\frac{\text{CCLK frequency}}{\big((\text{CKDIV} + 1) \times 2\big) \times (\text{SINCDEC} + 1) \times 2}$$

The output range of the sinc filter is changed by changing the decimation ratio of the sinc filter (SINCDEC) with the change of the sampling frequency above. Since the maximum number of effective bits for processing of audio data within the PDM following sinc filtering is 20 bits, PDSFCRCHn.SINCRNG[4:0] must also be changed according to the output range of the sinc filter. This allows avoiding the occurrence of overflow and underflow and maximizing the effective audio amplitude.

Recommended setting: Set PDSFCRCHn.SINCRNG[4:0] such that the higher-order 20 bits of valid data of the sinc filter output are effective in calculation processing following sinc filtering.

For details on clipping or sifting of the sinc filter output, see **8.7.3.4.1 Data Clipping and Shifting between Filters**.

- Output range of the sinc filter
  = ±decimation ratio (PDSFCRCHn.SINCDEC[7:0]) ^ order (PDMDSRCHn.SFMD[2:0]);

[Example]

When SINCDEC[7:0] = H'27 (decimation ratio: 40) and SFMD[2:0] = 0 (4-order), the output range of the sinc filter is ±2560000 (23 bits consisting of 22 bits of significant digits and a sign bit). The recommended setting of PDSFCRCHn.SINCRNG[4:0] in this case is 0_1011b (b22-b3).

8.7.4.7 DMA Transfer Method

This PDM unit can only receive voice data from external sources, and does not have a transmit function. The PDM unit does not have a dedicated REQ/ACK signal to the DMAC master, but only reads data from the PDM buffer read register via the APB I/F. Reading data via the CPU and reading data via the DMAC master are not different in terms of PDM functionality.

Figure 8.7-22 shows an overview of the PDM data read process.

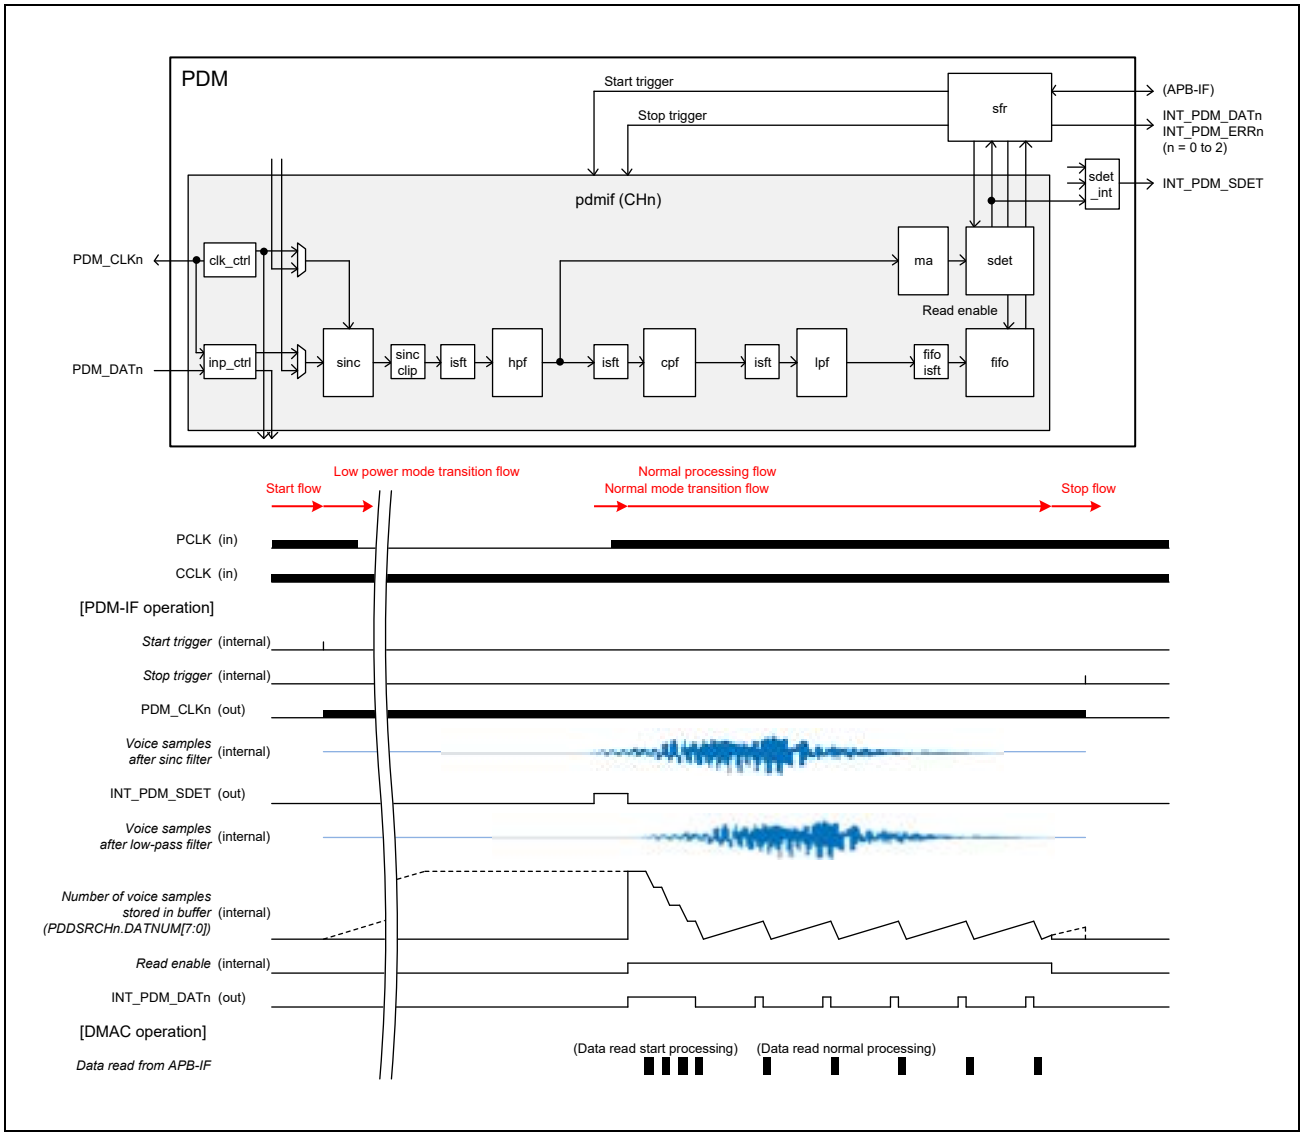

Figure 8.7-22 PDM-IF Operation Example

The DMA data transfer using the DMA master must follow the description in **8.7.4.3 Normal Processing Flow**. The following explains the connection configuration with the DMA master, initialization settings on the DMA master, and recommended settings for the INT_PDM_DAT0/1/2 signal at PDM initialization.

The connection configuration with the DMA master in this LSI is as follows, issuing a DMA request to the DMA master based on the INT_PDM_DAT0/1/2 signal of the PDM. The INT_PDM_DAT0/1/2 interrupt signal is active (high) depending on the amount of data stored in the receive buffer in the PDM (the amount of interrupt generation buffer can be changed by setting the register / PDDBCRCHn (n = 0, 1, 2).DATRITHR[2:0]).

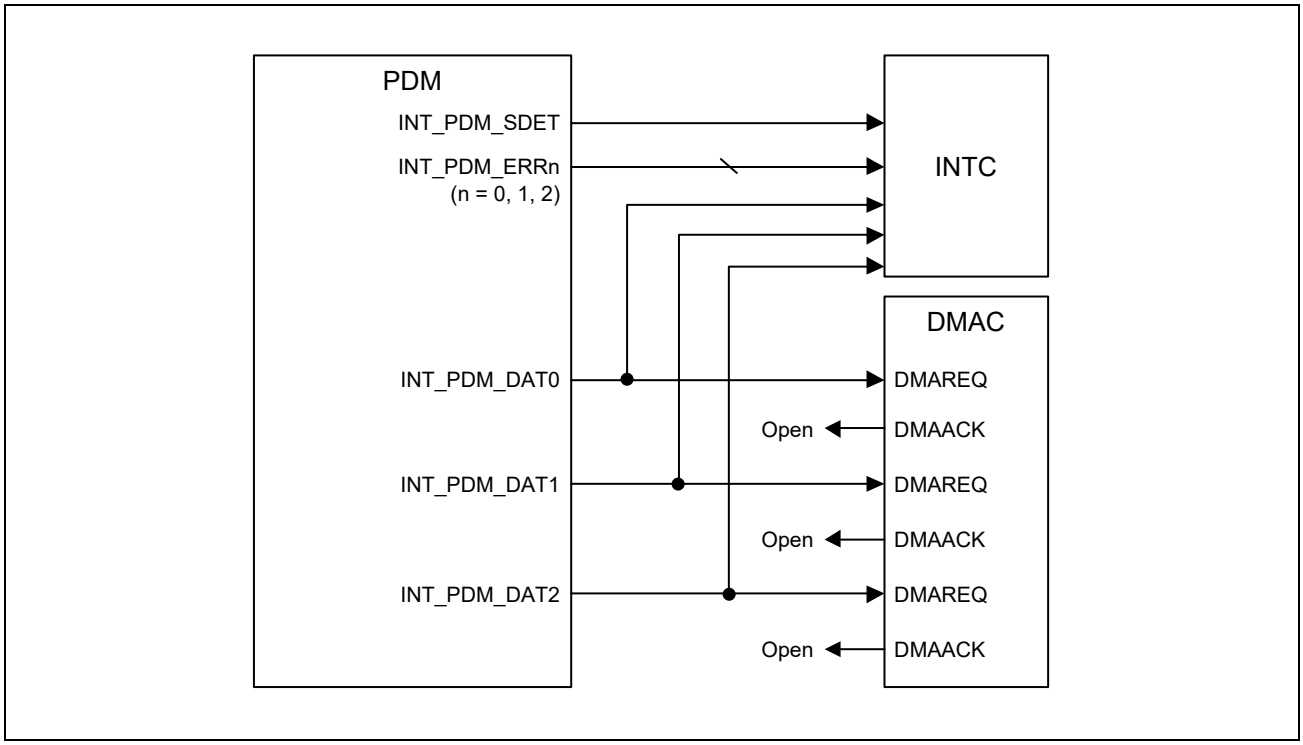

Figure 8.7-23 PDM Connection Configuration

This section describes the restrictions at DMA transfer and the active condition of the INT_PDM_DAT0/1/2 signal at PDM initialization.

1) Restrictions at DMA transfer:

The initialization setting on the DMA master is required in “Software configures DMAC/Software re-configures DMAC” in **Figure 8.7-19** of **8.7.4.3 Normal Processing Flow**. The restrictions on PDM DMA transfers are described below.

- DMA transfer mode (1): Single

  (One DMA transfer process is performed for one DMA request.)
  Reference value for the DMA master setting: TM register = 0b

- DMA transfer mode (2): Bus cycle mode

  (DMAREQ is masked in the bus cycle period (while DMAACK is active.))
  Reference value for the DMA master setting: AM[2:0] = H’010

- One DMA transfer: 32 bits

  Reference value for the DMA master: DDS or SDS register = 32 bits

- DMA REQ signal attribute: Level/High

  (The active polarity of the INT_PDM_DAT0/1/2 signal is high, so the DMA request signal must also be high.)
  Reference value for the DMA master: LVL = 1b, HIEN = 1b, LOEN = 0b

- DMA REQ signal active release timing: After the completion of data read from the PDM unit

  (DMA REQ is masked while DMA ACK is enabled.)
  Reference value for the DMA master: REQD = 0b

- DMA transfer data read register: PDDRRCHn (n = 0, 1, 2).DAT[19:0] register

2) Interrupt setting of the INT_PDM_DAT0/1/2 signal in the PDM receive initialization setting:

The interrupt setting for the INT_PDM_DAT0/1/2 signal is required in “Set Channel’s Data Buffer Control” in **Figure 8.7-17** of **8.7.4.1 Start Flow**.
As the receive buffer amount of PDM in this LSI is fixed at 64 stages, it is recommended to set PDDBCRCHn (n = 0, 1, 2).DATRITHR[2:0] = 4 (16 stages). Since a time difference may occur between the active timing of the INT_PDM_DAT0/1/2 signal and the request decision on the DMA master, the active timing of the INT_PDM_DAT0/1/2 signal must always be selected to be at least 2 stages.

8.7.4.8 Reset Clock Control

For the reset clock control, the following reset clock pins must be controlled.

Table 8.7-22 List of Reset Clocks

	Reset Signal	Clock Signal	Clock Source	Description
System 1	PRESETn	PCLK, PCLK_SFR	CPG unit (Divider clock for CPG PLL output)	For internal bus control circuit
System 2	CRESETn	CCLK	CPG unit (External system clock: 8 MHz fixed)	For external IF control circuit

The above reset clock pins are controlled by the CPG unit, and each reset clock can be controlled ON/OFF with the CPG register. When each reset is released, a feature is implemented on the CPG to stop the target clock before and after the reset is released.

For each system, reset and clock control should be performed according to the following procedure.

However, the reset and clock control between the two systems below are independent, and there are no restrictions on the order of settings between the systems.

Furthermore, when controlling the reset clock, the PDM unit should be stopped and accesses from related units should also be stopped.

1. Reset (PRESETn) and clock (PCLK, PCLK_SFR) for the internal bus control circuit:
   — PDM operation start condition (reset/clock supply): clock supply → reset release
   — PDM stop condition (reset/clock stop): reset enabled → clock stop
   — PDM reset (reset ON/OFF, clock supply continued): Reset can be enabled or disabled at any timing

2. Reset (CRESETn) and clock (CCLK) for the external IF control circuit:
   — PDM operation start condition (reset/clock supply): clock supply → reset release
   — PDM stop condition (reset/clock stop): reset enabled → clock stop
   — PDM reset (reset ON/OFF, clock supply continued): Reset can be enabled or disabled at any timing

As for PCLK/PCLK_SFR, the CPG unit can change the clock frequency variable (100 MHz, 50 MHz, 25 MHz, 12.5 MHz, 3.125 MHz). When lowering the PCLK/PCLK_SFR frequency, the performance of reading voice data from the PDM unit will be degraded. Use caution when lowering the frequency.

8.7.5 Interrupt

8.7.5.1 Interrupt List

Table 8.7-23 is a list of interrupt signals for this unit. For details on interrupts, refer to **4.6 Interrupt Controller**.

Table 8.7-23 PDM-IF Interrupt List

No.	Signal Name	Interrupt Name	Number of Signals	Pulse or Level	Related Register Bit Name		Function (Related Section)
					Common Register	Channel Register	
1	INT_PDM_DATn (n = 0, 1, 2)	Data reception interrupt CHn (n = 0, 1, 2)	3	Level	PDCSR.DRFn	PDSRCHn (n = 0, 1, 2).DRF	**8.7.3.7 Data Buffer**
2	INT_PDM_SDET	Sound detection interrupt (3-channel status flags are ORed.)	1	Level	PDCSR.SDFn	PDSRCHn (n = 0, 1, 2).SDF	**8.7.3.6 Sound Detection**
3	INT_PDM_ERRn (n = 0, 1, 2)	Error detection interrupt CHn (n = 0, 1, 2)	3	Level	PDCSR.EDFn	PDSRCHn (n = 0, 1, 2).SCDF	**8.7.3.8 Short-Circuit Detection**
						PDSRCHn (n = 0, 1 ,2).OVLDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn (n = 0, 1, 2).OVUDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn (n = 0, 1, 2) BFOWDF	**8.7.3.7 Data Buffer**

8.7.6 Usage Notes

8.7.6.1 Data Reception Interrupt Threshold Register Setting

A data reception interrupt INT_PDM_DATn is issued as a level output. Therefore, if the number of samples in buffer still exceeds the data reception interrupt threshold set in PDDBCRCHn.DATRITHR[2:0] when data reading of DMA finishes, the interrupt controller might not detect the edge of INT_PDM_DATn. The situation happens if data reading time exceeds sampling rate*1 x threshold. Set the appropriate threshold so that the interrupt controller can detect the interrupt.

In case the threshold cannot avoid the situation, read PDDBCRCHn.DATRITHR[2:0] and re-start DMA by software after reading the data.

Note 1. Sampling rate: Time to spend to store a sample in buffer.

8.7.6.2 Frequency Characteristics of Filters with Default Settings

The following figure and table show the frequency characteristics of the filters with the default settings for reference information.

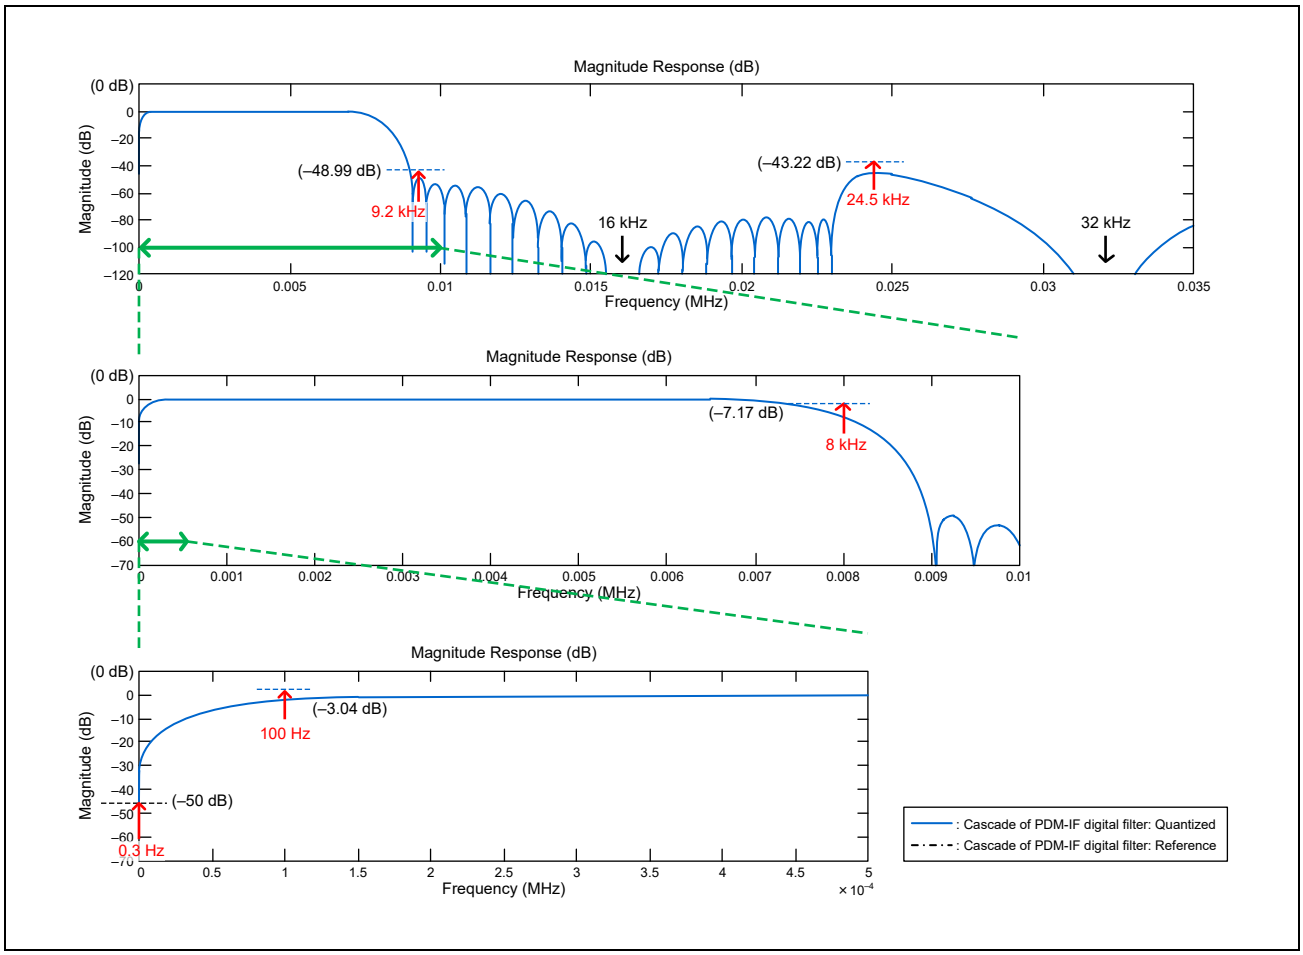

Figure 8.7-24 Frequency Characteristics of Filters with Default Settings

Table 8.7-24 Frequency Characteristics of Filters with Default Settings

Frequency (Hz)		Magnitude (dB)
Cut-off frequency of LPF	24.5 kHz	−43.22
	…	…
	9.2 kHz	−48.99
	8 kHz	−7.17
Passband	7 kHz	−0.39
	6 kHz	−0.07
	…	…
	150 Hz	−1.63
	100 Hz	−3.04
Cut-off frequency of HPF	50 Hz	−7.02
	0.3 Hz	−50.00

SECTION 9 IMAGE

9.1 Image Overview

This sections describes the Image unit of this LSI. For details, refer to the sections of each unit.

■ Camera Data Receive Unit (CRU) (See 9.2)

This LSI equips 1ch (1-lane or 2-lane) of MIPI® CSI-2 Interface (CRU).

■ Image Scaling Unit (ISU2) (See 9.3)

This LSI supports that reading out the image stored in the external DRAM, scales up or down image size, and outputs the reduced image into the DRAM. This LSI also supports a color format conversion and cropping image.

■ LCD Controller (LCDC) (See 9.4)

This LSI equips 1ch LCD Controller.

Selectable one display interface from MIPI DSI, LVDS and Parallel output interface.

■ MIPI DSI (See 9.5)

Conforms to the following standards.

- MIPI® Alliance Specification for Display Serial Interface Version 1.3.1
- MIPI® Alliance Specification for D-PHY Version 1.2

■ Low Voltage Didderential Signaling (LVDS) (See 9.6)

This LSI equips 1 LVDS interfaces.

■ Video Codec Processor (VCLP4) (See 9.7)

This LSI equips a H.264 codec.

■ Flame Compression Processor (FCPCS) (See 9.8)

■ 3D Graphics Engine (GE3D) (See 9.9)

This LSI includes the Arm® Mali™-G31 GPU as a 3D Graphics Engine (GE3D). This unit is an optional function.

SECTION 9 IMAGE

9.2 Camera Data Receiver Unit (CRU)

9.2.1 Overview

CRU has an MIPI CSI-2 input and then decodes the data type specified by the packet, handles conversion of the color space of pixels, LUT conversion, pixel format conversion, and image conversion such as demosaicing and obtaining statistics. After converting processed data to various pixel formats, it transfers the data to external memory.

CRU consists of the MIPI CSI2 block and an image converter. The main functions of these blocks are as follows.

MIPI CSI2

The MIPI CSI2 block receives signals compliant with the MIPI CSI-2 V2.1(DPHY V2.1) standard, extracts video signals from various packets, and sends data to the image converter, which is the next stage.

The details of its functions are described in **9.2.3 MIPI CSI2**.

Image Converter

The image converter receives video data from the MIPI CSI2 block, that is, from the previous stage, and handles image processing corresponding to the given data. Data to which image processing has been applied are initially stored in a FIFO buffer and then transferred to external memory.
The details of its functions are described in **9.2.4 Image Converter**.

9.2.2 Connected Units

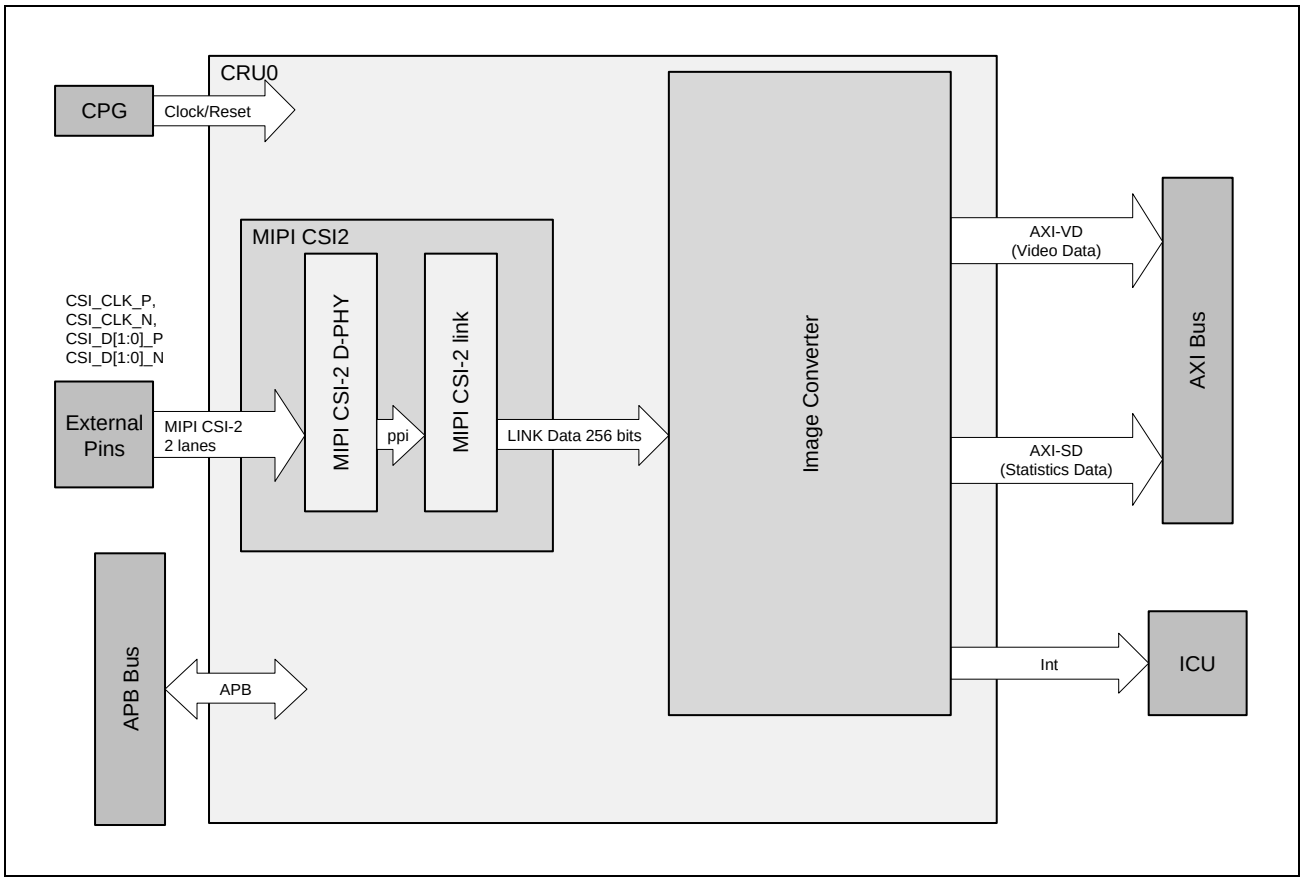

Figure 9.2-1 Block Diagram of CRU0

9.2.3 MIPI CSI2

9.2.3.1 Overview

MIPI CSI2 (camera serial interface 2) receives signals compliant with the DPHY standard from a camera module connected to external pins and decodes them as image data.

Data decoded by this module are sent to the image converter block as the next stage.

9.2.3.1.1 Features

This module has the following functions.

COMMON

1) Data input range

[Pixel size]

- Maximum number of pixels: 8.8 Mpixels; minimum number of pixels: QVGA (320 × 240) = 76.8 Kpixels
- Maximum number of effective pixels in the horizontal direction: 4096 pixels / 8192 pixels*1
- Maximum number of effective lines in the vertical direction: 4096 lines / 8192 lines*1

[Other than images]

- Data size range of input long packets: 1 to 24576 bytes

Note 1. 4096 pixels/lines when image processing and non-image processing are selected
8192 pixels/lines when full bypass is selected

2) Restrictions on the input bandwidth

Use the input bandwidth within the range which satisfies all conditions in **Table 9.2-1** and **Table 9.2-2**.

Table 9.2-1 Maximum Rate per Lane

	Transfer Rate per Lane (Mbps)		Transfer Rate for All Lanes (Mbps)	
Lane to be Used	MIN	MAX	MIN	MAX
1	80	1500	80	1500
2	80	1500	160	3000

Table 9.2-2 Maximum Transfer Rate per Format for Total of two Lanes (1/2)

CRUnCTRL.ATH	Data Path	Input Format	MIPI CSI-2 Transfer Rate (Mbps (max.))
0	Image Process	YUV422 8-bit	3000
0		YUV422 10-bit	3000
0		RGB444	3000
0		RGB555	3000
0		RGB565	3000
0		RGB666	3000
0		RGB888	3000

Table 9.2-2 Maximum Transfer Rate per Format for Total of two Lanes (2/2)

CRUnCTRL.ATH	Data Path	Input Format	MIPI CSI-2 Transfer Rate (Mbps (max.))
0	Image Process	RAW6	1584*1
0		RAW7	1840*1
0		RAW8	2128*1
0		RAW10	2619*1
0		RAW12	3000
0		RAW14	3000
0		RAW16	3000
0		RAW20	3000
0	Non Image Process	MIPI recommended memory storage format	3000
1 (full bypass)	Full Bypass	MIPI recommended memory storage format	3000

Note 1. If you turn on PLL SSCG for VCLK, the stated transfer rate will be reduced by 2.0%

3) Restrictions on blanking

At least the time given below is required during the period from the last valid data on a line to the first valid data on the next line.

- When demosaicing is in use: (300 + H-size) × 1/vclk (MHz) or more
  e.g. when vclk = 266 MHz, for VGA (640x480): (300 + 640) × 1/266 (MHz) = approx. 3.54 µs or more
- When demosaicing is not in use: 300 × 1/vclk (MHz) or more
  e.g. when vclk = 266 MHz: 300 × 1/266 (MHz) = approx. 1128 ns or more

4) Compliant with the specification for camera serial interface 2 (CSI-2)SM

5) Receiver error detection and reporting

- D-PHY level errors
- Packet level errors
- Protocol decoding level errors

D-PHY

1) Support MIPI D-PHY V2.1 (80 Mbps to 1500 Mbps/lane)

2) Support 1, and 2 lanes

3) D-PHY data lane type: CIL-SFEN (forward ULPS only).

LINK

1) Support MIPI CSI-2 V2.1

2) Support data de-scrambling

3) Support latency reduction and transport efficiency (LRTE)

4) ECC 1-bit error correction and 2-bit error detection in packet headers

5) CRC checking for payload data

6) Support 16 virtual channels

7) Number of stages of the FIFO for generic short packets: 16

8) Support data interleaving

- Data type interleaving
  - Packet-level interleaved data transmission
  - Frame-level interleaved data transmission
- Virtual channel identifier interleaving

9.2.3.1.2 Block Diagram

Figure 9.2-2 is a block diagram of MIPI CSI2.

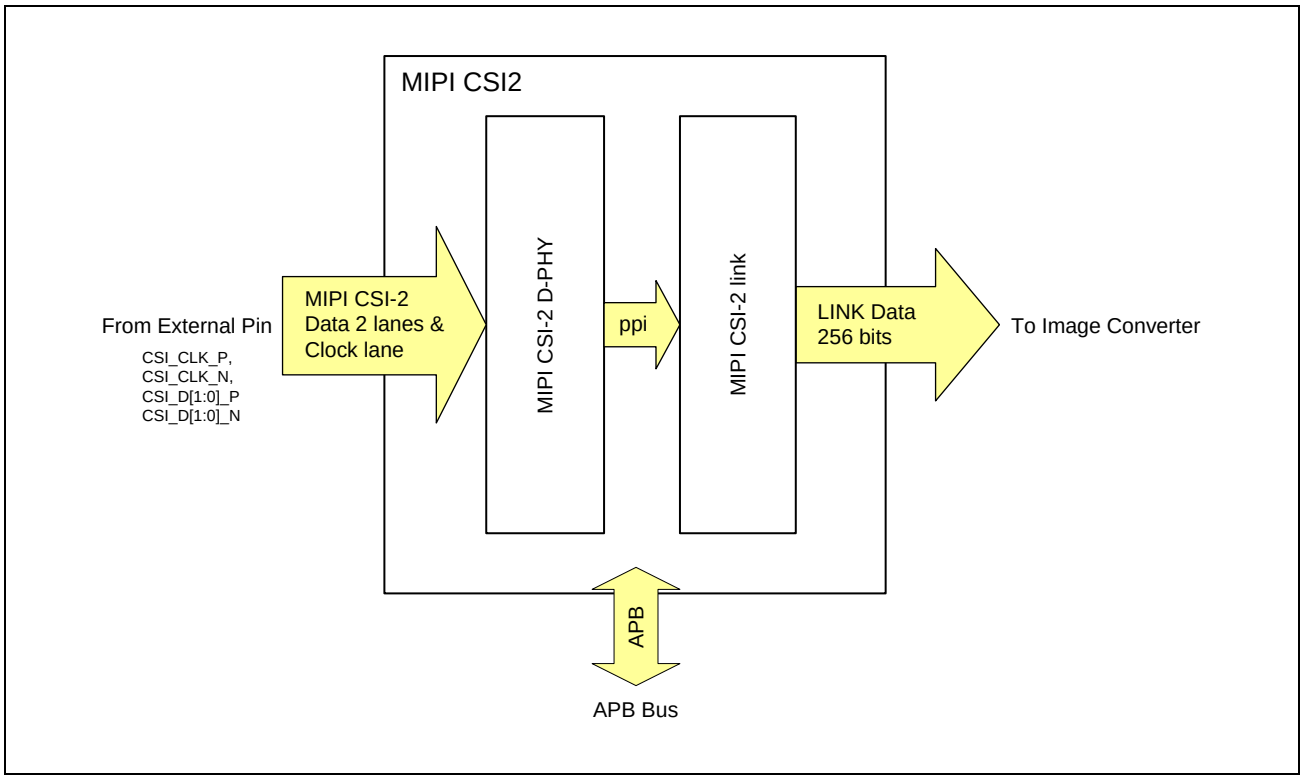

Figure 9.2-2 Block Diagram of MIPI-CSI2

9.2.3.1.3 External Pins

Table 9.2-3 lists the input/output pins of MIPI CSI2.

Table 9.2-3 MIPI CSI2 Input/Output Pins

Category	Pin Name	Input/Output	Functional description
DPHY Interface for MIPI CSI-2	CSI_CLK_P	Input	MIPI CSI-2 Rx clock input for CRU0 (positive)
	CSI_CLK_N	Input	MIPI CSI-2 Rx clock input for CRU0 (negative)
	CSI_D0_P	Input	MIPI CSI-2 Rx serial data input lane 0 for CRU0 (positive)
	CSI_D0_N	Input	MIPI CSI-2 Rx serial data input lane 0 for CRU0 (negative)
	CSI_D1_P	Input	MIPI CSI-2 Rx serial data input lane 1 for CRU0 (positive)
	CSI_D1_N	Input	MIPI CSI-2 Rx serial data input lane 1 for CRU0 (negative)

9.2.3.2 MIPI CSI2 Registers

The base addresses of the CRUm (m = 0) registers are shown below.

Base Address Name	Base Address
<CRU0_base>	0_1083_0000h (5083_0000h*1, 4083_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.2.3.2.1 List of Registers

(1) CRU LINK Registers [m = 0]

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Module Configuration Register	CRUm_CSI2nMCG	0010_0200h	0400h	32

Virtual Channel 1 Status Register	CRUm_CSI2nVCST1	0000_0000h	0510h	32
Virtual Channel 1 Status Clear Register	CRUm_CSI2nVCSC1	0000_0000h	0514h	32
Virtual Channel 1 Interrupt Enable Register	CRUm_CSI2nVCIE1	0000_0000h	0518h	32
Reserve	-	-	051Ch to 051Fh	-
Virtual Channel 2 Status Register	CRUm_CSI2nVCST2	0000_0000h	0520h	32
Virtual Channel 2 Status Clear Register	CRUm_CSI2nVCSC2	0000_0000h	0524h	32
Virtual Channel 2 Interrupt Enable Register	CRUm_CSI2nVCIE2	0000_0000h	0528h	32
Reserve	-	-	052Ch to 052Fh	-
Virtual Channel 3 Status Register	CRUm_CSI2nVCST3	0000_0000h	0530h	32
Virtual Channel 3 Status Clear Register	CRUm_CSI2nVCSC3	0000_0000h	0534h	32
Virtual Channel 3 Interrupt Enable Register	CRUm_CSI2nVCIE3	0000_0000h	0538h	32
Reserve	-	-	053Ch to 053Fh	-
Virtual Channel 4 Status Register	CRUm_CSI2nVCST4	0000_0000h	0540h	32
Virtual Channel 4 Status Clear Register	CRUm_CSI2nVCSC4	0000_0000h	0544h	32
Virtual Channel 4 Interrupt Enable Register	CRUm_CSI2nVCIE4	0000_0000h	0548h	32
Reserve	-	-	054Ch to 054Fh	-
Virtual Channel 5 Status Register	CRUm_CSI2nVCST5	0000_0000h	0550h	32
Virtual Channel 5 Status Clear Register	CRUm_CSI2nVCSC5	0000_0000h	0554h	32
Virtual Channel 5 Interrupt Enable Register	CRUm_CSI2nVCIE5	0000_0000h	0558h	32
Reserve	-	-	055Ch to 055Fh	-
Virtual Channel 6 Status Register	CRUm_CSI2nVCST6	0000_0000h	0560h	32
Virtual Channel 6 Status Clear Register	CRUm_CSI2nVCSC6	0000_0000h	0564h	32
Virtual Channel 6 Interrupt Enable Register	CRUm_CSI2nVCIE6	0000_0000h	0568h	32
Reserve	-	-	056Ch to 056Fh	-
Virtual Channel 7 Status Register	CRUm_CSI2nVCST7	0000_0000h	0570h	32
Virtual Channel 7 Status Clear Register	CRUm_CSI2nVCSC7	0000_0000h	0574h	32
Virtual Channel 7 Interrupt Enable Register	CRUm_CSI2nVCIE7	0000_0000h	0578h	32
Reserve	-	-	057Ch to 057Fh	-
Virtual Channel 8 Status Register	CRUm_CSI2nVCST8	0000_0000h	0580h	32
Virtual Channel 8 Status Clear Register	CRUm_CSI2nVCSC8	0000_0000h	0584h	32
Virtual Channel 8 Interrupt Enable Register	CRUm_CSI2nVCIE8	0000_0000h	0588h	32
Reserve	-	-	058Ch to 058Fh	-

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Virtual Channel 9 Status Register	CRUm_CSI2nVCST9	0000_0000h	0590h	32
Virtual Channel 9 Status Clear Register	CRUm_CSI2nVCSC9	0000_0000h	0594h	32
Virtual Channel 9 Interrupt Enable Register	CRUm_CSI2nVCIE9	0000_0000h	0598h	32
Reserve	-	-	059Ch to 059Fh	-
Virtual Channel 10 Status Register	CRUm_CSI2nVCST10	0000_0000h	05A0h	32
Virtual Channel 10 Status Clear Register	CRUm_CSI2nVCSC10	0000_0000h	05A4h	32
Virtual Channel 10 Interrupt Enable Register	CRUm_CSI2nVCIE10	0000_0000h	05A8h	32
Reserve	-	-	05ACh to 05AFh	-
Virtual Channel 11 Status Register	CRUm_CSI2nVCST11	0000_0000h	05B0h	32
Virtual Channel 11 Status Clear Register	CRUm_CSI2nVCSC11	0000_0000h	05B4h	32
Virtual Channel 11 Interrupt Enable Register	CRUm_CSI2nVCIE11	0000_0000h	05B8h	32
Reserve	-	-	05BCh to 05BFh	-
Virtual Channel 12 Status Register	CRUm_CSI2nVCST12	0000_0000h	05C0h	32
Virtual Channel 12 Status Clear Register	CRUm_CSI2nVCSC12	0000_0000h	05C4h	32
Virtual Channel 12 Interrupt Enable Register	CRUm_CSI2nVCIE12	0000_0000h	05C8h	32
Reserve	-	-	05CCh to 05CFh	-
Virtual Channel 13 Status Register	CRUm_CSI2nVCST13	0000_0000h	05D0h	32
Virtual Channel 13 Status Clear Register	CRUm_CSI2nVCSC13	0000_0000h	05D4h	32
Virtual Channel 13 Interrupt Enable Register	CRUm_CSI2nVCIE13	0000_0000h	05D8h	32
Reserve	-	-	05DCh to 05DFh	-
Virtual Channel 14 Status Register	CRUm_CSI2nVCST14	0000_0000h	05E0h	32
Virtual Channel 14 Status Clear Register	CRUm_CSI2nVCSC14	0000_0000h	05E4h	32
Virtual Channel 14 Interrupt Enable Register	CRUm_CSI2nVCIE14	0000_0000h	05E8h	32
Reserve	-	-	05ECh to 05EFh	-
Virtual Channel 15 Status Register	CRUm_CSI2nVCST15	0000_0000h	05F0h	32
Virtual Channel 15 Status Clear Register	CRUm_CSI2nVCSC15	0000_0000h	05F4h	32
Virtual Channel 15 Interrupt Enable Register	CRUm_CSI2nVCIE15	0000_0000h	05F8h	32
Reserve	-	-	05FCh to 05FFh	-
Power Management Status Register	CRUm_CSI2nPMST	000x_x00xh *1	0600h	32
Power Management Status Clear Register	CRUm_CSI2nPMSC	0000_0000h	0604h	32
Power Management Interrupt Enable Register	CRUm_CSI2nPMIE	0000_0000h	0608h	32
Reserve	-	-	060Ch to 067Fh	-
Generic Short Packet Control Register	CRUm_CSI2nGSCT	0001_0000h	0680h	32
Generic Short Packet Status Register	CRUm_CSI2nGSST	0000_0000h	0684h	32
Generic Short Packet Status Clear Register	CRUm_CSI2nGSSC	0000_0000h	0688h	32
Generic Short Packet Interrupt Enable Register	CRUm_CSI2nGSIE	0000_0000h	068Ch	32
Generic Short Packet Register	CRUm_CSI2nGSHT	0008_0000h	0690h	32
Generic Short Packet Information Update Register	CRUm_CSI2nGSIU	0000_0000h	0694h	32

Note 1. The initial value “x” changes depending on the DPHY state.

(2) CRU PHY Registers [m = 0]

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
D-PHY Control Register 0	CRUm_DPHYCTRL0	0000_0004h	0800h	32
D-PHY Timing Register 0	CRUm_DPHYTIM0	0000_0000h	0804h	32
D-PHY Timing Register 1	CRUm_DPHYTIM1	0000_0000h	0808h	32

9.2.3.2.2 Register Descriptions

(1) Module Configuration Register (CRUm_CSI2nMCG) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0400h
Initial Value : 0010_0200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	GSNM[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	SDLN[3:0]				-	-	-	-	VER[3:0]			
Initial Value	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 16	GSNM[7:0]	10h	R	Indicate the number of stages of the generic short packet FIFO (16 stages).
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 8	SDLN[3:0]	2h	R	Indicate the supported maximum number of data lanes. 2h: Operable with two lanes or one lane.
7 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	VER[3:0]	0h	R	Indicate the version of this core.

(2) Module Control Register 0 (CRUm_CSI2nMCT0) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0410h
Initial Value : 0200_0002h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	LFSREN	ECCV13	-	-	-	-	RVMD	-	EDMD	ZLMD
Initial Value	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	R	R	R0W	RW	R	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	VDLN[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25	LFSREN	1h	RW	Enables or disables de-scrambling. 0b: Disables de-scrambling. 1b: Enables de-scrambling.
24	ECCV13	0h	RW	CSI-2 specification-compliant mode for ECC checking 0b: 26 bits to be checked by ECC 1b: 24 bits to be checked by ECC It is prohibited to set this bit to 1b when receiving a packet whose virtual channel ID is from 4 to 15.
23 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	-	0h	R0W	The read value is always 0b. Do not change the value of this bit from 0h.
19	RVMD	0h	RW	For a packet whose data type is 38h to 3Fh (“Reserved” in "Table 10 Data Type Classes" of the CSI-2 specification), set the receive operation mode to 0. 0b: Discards the data (notifies an ErrID). 1b: Receives data as a long packet (outputs data to the image processing module when the corresponding bit in CSI2nDTEH is 1, or discards the data and notifies an ErrID when the corresponding bit in CSI2nDTEH is 0).
18	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	EDMD	0h	RW	Notifies ErrFrameData when an ECC 2-bit error or a packet of less than four bytes is received between FS and FE. 0b: Does not notify ErrFrameData. 1b: Notifies ErrFrameData.
16	ZLMD	0h	RW	Sets whether to output a long packet whose word count is 0 to the image processing module. Set this bit to 0. 0b: Output 1b: No output
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	VDLN[3:0]	2h	RW	Set the number of used data lanes. Change this field when CSI2nMCT3.RXEN = 0. A value equal to or less than the CSI2nMCG.SDLN value can be specified. 1h: Operation with one lane 2h: Operation with two lanes Others: Setting prohibited

(3) Module Control Register 2 (CRUm_CSI2nMCT2) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0418h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	FRRSKW[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	FRRCLK[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24 to 16	FRRSKW[8:0]	0h	RW	Internal setting parameter Set the following value by using the ROUNDDOWN function that rounds down the decimal places. (ROUNDDOWN((3 * vclk frequency/hsclk1 frequency), 0) + 1) where vclk = 266 MHz, hsclk1 = transfer rate/8 Example: Set 7h when the vclk frequency is 266 MHz and the transfer rate is 1 Gbps. ROUNDDOWN((3 * 266/(1000/8)), 0) + 1 = 7d
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8 to 0	FRRCLK[8:0]	0h	RW	Parameter for the IP to determine whether packets have been received if RxWordClkHS stops at the timing when the IP cannot recognize that RxValidHS is low. Set the following value by using the ROUNDDOWN function that rounds down the decimal places. (ROUNDDOWN((1.5 * vclk frequency/hsclk1 frequency), 0) + 1) where vclk = 266 MHz, hsclk1 = transfer rate/8 Example: Set 4h when the vclk frequency is 266 MHz and the transfer rate is 1 Gbps. ROUNDDOWN((1.5 * 266/(1000/8)), 0) + 1 = 4d

(4) Module Control Register 3 (CRUm_CSI2nMCT3) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 041Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RXEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	RXEN	0h	RW	Enables LINK data reception. 0b: Disables reception. 1b: Enables reception.

(5) Reset Control Register (CRUm_CSI2nRTCT) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0428h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	VSRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	VSRST	0h	R0W1	The read value is always 0b. Writing 1b to this bit resets the internal LINK signal by a software reset.

(6) Reset Status Register (CRUm_CSI2nRTST) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 042Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	VSRSTS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	VSRSTS	0h	R	Indicates the execution status of the software reset generated by CSI2nRTCT.VSRST. 0b: Not during a reset 1b: During a reset

(7) EPD Option Control Register (CRUm_CSI2nEPCT) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0440h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EPDEN	SSP[14:0]														
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

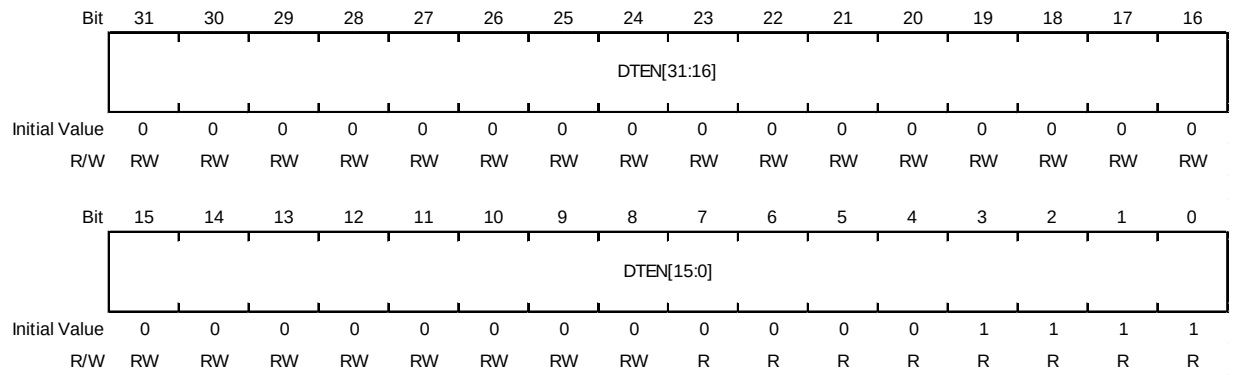
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EPDOP	SLP[14:0]														
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	EPDEN	0h	RW	Enables the EPD. 0b: Disables the EPD. 1b: Enables the EPD.
30 to 16	SSP[14:0]	0h	RW	Specify the number of spacers inserted after a short packet. This field is valid when EPDEN = 1. The following shows the specifiable minimum number of spacers when EPDEN = 1. Setting a value less than the minimum value is prohibited. When EPDOP=1b, the minimum spacer value is (1) The larger value of the following two values: • Minimum number of spacers due to the D-PHY setting • Minimum number of spacers due to the number of used lanes (2) Minimum number of spacers due to the D-PHY setting: The minimum value can be found by using the ROUNDUP function that rounds up the decimal places. ROUNDUP((105/UI[ns] + 20) / 8), 0) (3) Minimum number of spacers due to the number of used lanes: 1 lane: minimum spacer = 64 2 lanes: minimum spacer = 32
15	EPDOP	0h	RW	Selects an EPD option. Set this bit to 1b. 0b: D-PHY EPD Option 1 (0 cannot be set when EPDEN = 1) 1b: D-PHY EPD Option 2
14 to 0	SLP[14:0]	0h	RW	Specify the number of spacers inserted after a long packet. This field is valid when EPDEN = 1. When EPDEN = 1, the minimum number of spacers is the value described in the SSP field. Setting a value less than the minimum value is prohibited.

(8) Module Interrupt Status Register (CRUm_CSI2nMIST) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0450h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VC15S	VC14S	VC13S	VC12S	VC11S	VC10S	VC9S	VC8S	VC7S	VC6S	VC5S	VC4S	VC3S	VC2S	VC1S	VC0S
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



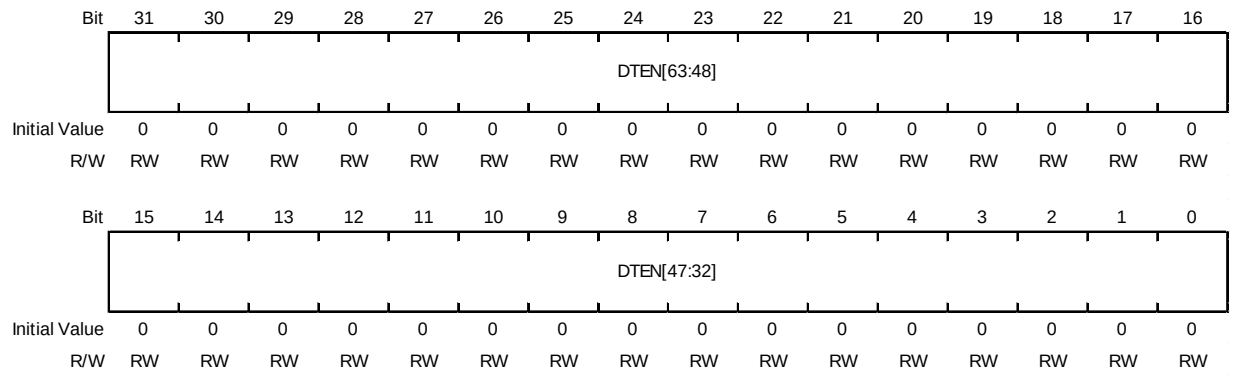
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	RXS	GSTS	PMS	-	-	-	-	-	-	DL1S	DL0S
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	VC15S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 15. Check the CSI2nVCST15 register for the details of the interrupt source.
30	VC14S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 14. Check the CSI2nVCST14 register for the details of the interrupt source.
29	VC13S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 13. Check the CSI2nVCST13 register for the details of the interrupt source.
28	VC12S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 12. Check the CSI2nVCST12 register for the details of the interrupt source.
27	VC11S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 11. Check the CSI2nVCST11 register for the details of the interrupt source.
26	VC10S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 10. Check the CSI2nVCST10 register for the details of the interrupt source.
25	VC9S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 9. Check the CSI2nVCST9 register for the details of the interrupt source.
24	VC8S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 8. Check the CSI2nVCST8 register for the details of the interrupt source.
23	VC7S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 7. Check the CSI2nVCST7 register for the details of the interrupt source.
22	VC6S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 6. Check the CSI2nVCST6 register for the details of the interrupt source.
21	VC5S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 5. Check the CSI2nVCST5 register for the details of the interrupt source.
20	VC4S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 4. Check the CSI2nVCST4 register for the details of the interrupt source.
19	VC3S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 3. Check the CSI2nVCST3 register for the details of the interrupt source.
18	VC2S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 2. Check the CSI2nVCST2 register for the details of the interrupt source.
17	VC1S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 1. Check the CSI2nVCST1 register for the details of the interrupt source.
16	VC0S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 0. Check the CSI2nVCST0 register for the details of the interrupt source.
15 to 11	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10	RXS	0h	R	When this bit is set to 1b, there is an interrupt source for the reception in general. Check the CSI2nRXST register for the details of the interrupt source.
9	GSTS	0h	R	When this bit is set to 1b, there is an interrupt source for reception of generic short packets. Check the CSI2nGSST register for the details of the interrupt source.
8	PMS	0h	R	When this bit is set to 1b, there is an interrupt source for the power management. Check the CSI2nPMST register for the details of the interrupt source.
7 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
1	DL1S	0h	R	When this bit is set to 1b, there is an interrupt source for data lane 1. Check the CSI2nDLST1 register for the details of the interrupt source.
0	DL0S	0h	R	When this bit is set to 1b, there is an interrupt source for data lane 0. Check the CSI2nDLST0 register for the details of the interrupt source.

(9) Receive Data Type Enable Low Register (CRUm_CSI2nDTEL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0460h
Initial Value : 0000_000Fh



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DTEN[31:0]	0000_000Fh	RW (R)	Receive data of a packet in which data type is one of the following. 0b: Does not receive data. 1b: Receives data. Note: After multiple data types are selected here, only one data type is selected by the INF[5:0] bits in the ICnIPMC_C0/1/2/3 register in the image processing module. See **Table 9.2-4** for details on setting this bit.

Table 9.2-4 Receive Data Type Enable Low Register (CSI2nDTEL)

Bit	Data Type	R/W	Description
31	YUV422 10-bit	RW	When this bit is set to 1b, data is output to the image processing module.
30	YUV422 8-bit	RW	
29	YUV420 10-bit	RW	
28	YUV420 8-bit	RW	
27	Reserved	RW	
26	Legacy YUV420 8-bit	RW	
25	YUV420 10-bit	RW	
24	YUV420 8-bit	RW	
23	Reserved	RW	
22	Generic long packet data type 4	RW	
21	Generic long packet data type 3	RW	
20	Generic long packet data type 2	RW	
19	Generic long packet data type 1	RW	
18	Embedded 8-bit non Image Data	RW	
17	Blanking Data	RW	
16	Null	RW	
15	Generic Short Packet Code 8	RW	Fixed to 1b for each bit.
14	Generic Short Packet Code 7	RW	When each bit is set to 1b and CSI2nGSCT.GFIF = 1, data is output to the generic short packet FIFO.
13	Generic Short Packet Code 6	RW	
12	Generic Short Packet Code 5	RW	
11	Generic Short Packet Code 4	RW	
10	Generic Short Packet Code 3	RW	
9	Generic Short Packet Code 2	RW	
8	Generic Short Packet Code 1	RW	
7 to 4	Reserved	R	Fixed to 0.
3 to 0	Reserved	R	Fixed to 1.

(10) Receive Data Type Enable High Register (CRUm_CSI2nDTEH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0464h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DTEN[63:32]	0000_0000h	RW	Receive data of a packet in which data type is one of the following. 0b: Does not receive data. 1b: Receives data. Note: See **Table 9.2-5** for details on setting this bit.

Table 9.2-5 Receive Data Type Enable High Register (CSI2nDTEH)

Bit	Data Type	R/W	Description
31	Reserved	RW	Changing the reserved bit from the initial value is prohibited.
30 to 24	Reserved	RW	When this bit is set to 1b and CSI2nMCT0.RVMD = 1, data is output to the image processing module.
23	User Defined 8-bit Data Type 8	RW	When this bit is set to 1b, data is output to the image processing module.
22	User Defined 8-bit Data Type 7	RW	
21	User Defined 8-bit Data Type 6	RW	
20	User Defined 8-bit Data Type 5	RW	
19	User Defined 8-bit Data Type 4	RW	
18	User Defined 8-bit Data Type 3	RW	
17	User Defined 8-bit Data Type 2	RW	
16	User Defined 8-bit Data Type 1	RW	
15	RAW20	RW	
14	RAW16	RW	
13	RAW14	RW	
12	RAW12	RW	
11	RAW10	RW	
10	RAW8	RW	
9	RAW7	RW	
8	RAW6	RW	
7 to 5	Reserved	RW	
4	RGB888	RW	
3	RGB666	RW	
2	RGB565	RW	
1	RGB555	RW	
0	RGB444	RW	

(11) Receive Status Register (CRUm_CSI2nRXST) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0470h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RACTDET	RACT
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FRM15	FRM14	FRM13	FRM12	FRM11	FRM10	FRM9	FRM8	FRM7	FRM6	FRM5	FRM4	FRM3	FRM2	FRM1	FRM0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RACTDET	0h	R	When this bit is set to 1b, CSI2nRXST.RACT = 1 has been detected. Write 1 to CSI2nRXSC.RACTDETC to clear this bit.
16	RACT	0h	R	Indicates that this IP is receiving packets.
15	FRM15	0h	R	Indicates that frames on virtual channel = 15 are being processed.
14	FRM14	0h	R	Indicates that frames on virtual channel = 14 are being processed.
13	FRM13	0h	R	Indicates that frames on virtual channel = 13 are being processed.
12	FRM12	0h	R	Indicates that frames on virtual channel = 12 are being processed.
11	FRM11	0h	R	Indicates that frames on virtual channel = 11 are being processed.
10	FRM10	0h	R	Indicates that frames on virtual channel = 10 are being processed.
9	FRM9	0h	R	Indicates that frames on virtual channel = 9 are being processed.
8	FRM8	0h	R	Indicates that frames on virtual channel = 8 are being processed.
7	FRM7	0h	R	Indicates that frames on virtual channel = 7 are being processed.
6	FRM6	0h	R	Indicates that frames on virtual channel = 6 are being processed.
5	FRM5	0h	R	Indicates that frames on virtual channel = 5 are being processed.
4	FRM4	0h	R	Indicates that frames on virtual channel = 4 are being processed.
3	FRM3	0h	R	Indicates that frames on virtual channel = 3 are being processed.
2	FRM2	0h	R	Indicates that frames on virtual channel = 2 are being processed.
1	FRM1	0h	R	Indicates that frames on virtual channel = 1 are being processed.
0	FRM0	0h	R	Indicates that frames on virtual channel = 0 are being processed.

(12) Receive Status Clear Register (CRUm_CSI2nRXSC) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0474h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RACTDETC	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RACTDETC	0h	R0W1	Write 1 to this bit to clear CSI2nRXST.RACTDET. Writing 0b to this bit has no effect.
16 to 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(13) Receive Interrupt Enable Register (CRUm_CSI2nRXIE) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0478h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RACTDETE	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RACTDETE	0h	RW	Enables interrupts generated by CSI2nRXST.RACTDET. 0b: Does not assert csi2_int_rx when CSI2nRXST.RACTDET = 1. 1b: Asserts csi2_int_rx when CSI2nRXST.RACTDET = 1.
16 to 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(14) Data Lane (N) Status Register (CRUm_CSI2nDLST(N)) (m = 0)

(N) indicates a logical data lane number.
(N) = 0 or 1

Access Size : 32 bits
Address : <CRUm_base> + 0480h + (N) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	ULP(N)	-	-	-	-	-	-	RUL(N)	EUL(N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	EES(N)	ECT(N)	ESS(N)	ESH(N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	ULP(N)	0h	R	Indicates the RxUlpsEsc status of logical data lane (N).
23 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RUL(N)	0h	R	When this bit is set to 1b, logical data lane (N) has transitioned to the ULPS receive mode (RxUlpsEsc). Write 1 to CSI2nDLSC(N).RULC(N) to clear this bit.
16	EUL(N)	0h	R	When this bit is set to 1b, logical data lane (N) has exited from the ULPS receive mode (RxUlpsEsc). Write 1 to CSI2nDLSC(N).EULC(N) to clear this bit.
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	EES(N)	0h	R	When this bit is set to 1b, an escape mode entry error (ErrESC) has occurred on logical data lane (N). Write 1 to CSI2nDLSC(N).EESC(N) to clear this bit.
2	ECT(N)	0h	R	When this bit is set to 1b, a control error (ErrControl) has occurred on logical data lane (N). Write 1 to CSI2nDLSC(N).ECTC(N) to clear this bit.
1	ESS(N)	0h	R	When this bit is set to 1, an SoT synchronization error (ErrSotSyncHS) has occurred on logical data lane (N). Write 1 to CSI2nDLSC(N).ESSC(N) to clear this bit.
0	ESH(N)	0h	R	When this bit is set to 1b, an SoT error (ErrSotHS) has occurred on logical data lane (N). Write 1 to CSI2nDLSC(N).ESHC(N) to clear this bit.

(15) Data Lane (N) Status Clear Register (CRUm_CSI2nDLSC(N)) (m = 0)

(N) indicates a logical data lane number.
(N) = 0 or 1

Access Size : 32 bits
Address : <CRUm_base> + 0484h+ (N) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RULC (N)	EULC (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1	R0W1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	EESC (N)	ECTC (N)	ESSC (N)	ESHC (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R0W1	R0W1	R0W1	R0W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RULC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).RUL(N). Writing 0b to this bit has no effect.
16	EULC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).EUL(N). Writing 0b to this bit has no effect.
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	EESC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).EES(N). Writing 0b to this bit has no effect.
2	ECTC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).ECT(N). Writing 0b to this bit has no effect.
1	ESSC(N)	0h	R0W1	Write 1 to this bit to clear CSI2nDLST(N).ESS(N). This bit cannot be modified to 0.
0	ESHC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).ESH(N). Writing 0b to this bit has no effect.

(16) Data Lane (N) Interrupt Enable Register (CRUm_CSI2nDLIE(N)) (m = 0)

(N) indicates a logical data lane number.
(N) = 0 or 1

Access Size : 32 bits
Address : <CRUm_base> + 0488h+ (N) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RULE (N)	EULE (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	EESE (N)	ECTE (N)	ESSE (N)	ESHE (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RULE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).RUL(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).RUL(N) = 1. 1b: Asserts csi2_int_dl when CSI2nDLST(N).RUL(N) = 1.
16	EULE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).EUL(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).EUL(N) = 1. 1b: Asserts csi2_int_dl when CSI2nDLST(N).EUL(N) = 1.
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	EESE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).EES(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).EES(N) = 1. 1b: Asserts csi2_int_dl when CSI2nDLST(N).EES(N) = 1.
2	ECTE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).ECT(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).ECT(N) = 1. 1b: Asserts csi2_int_dl when CSI2nDLST(N).ECT(N) = 1.
1	ESSE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).ESS(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).ESS(N) = 1. 1b: Asserts csi2_int_dl when CSI2nDLST(N).ESS(N) = 1.
0	ESHE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).ESH(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).ESH(N) = 1. 1b: Asserts csi2_int_dl when CSI2nDLST(N).ESH(N) = 1.

(17) Virtual Channel (M) Status Register (CRUm_CSI2nVCST(M)) (m = 0)

(M) indicates a virtual channel number.
(M) = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, or 15

Access Size : 32 bits
Address : <CRUm_base> + 0500h + (M) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	LER (M)	LSR (M)	FER (M)	FSR (M)	-	-	-	-	-	-	-	OVF (M)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	FRD (M)	FRS (M)	-	ECN (M)	ECC (M)	WCE (M)	IDE (M)	CRC (M)	ECD (M)	MLF (M)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27	LER(M)	0h	R	When this bit is set to 1b, a packet whose data type is "Line End Code" has been received. Write 1 to CSI2nVCSC(M).LERC(M) to clear this bit.
26	LSR(M)	0h	R	When this bit is set to 1b, a packet whose data type is "Line Start Code" has been received. Write 1 to CSI2nVCSC(M).LSRC(M) to clear this bit.
25	FER(M)	0h	R	When this bit is set to 1b, a packet whose data type is "Frame End Code" has been received. Write 1 to CSI2nVCSC(M).FERC(M) to clear this bit.
24	FSR(M)	0h	R	When this bit is set to 1b, a packet whose data type is "Frame Start Code" has been received. Write 1 to CSI2nVCSC(M).FSRC(M) to clear this bit.
23 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	OVF(M)	0h	R	When this bit is set to 1b, the generic short packets on virtual channel M have been discarded due to an overflow of the generic short packet FIFO. Write 1 to CSI2nVCSC(M).OVFC(M) to clear this bit.
15 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
9	FRD(M)	0h	R	When this bit is set to 1b, ErrFrameData has been detected. This bit is set to 1 if any of the following errors occurs during the period between FS and FE: • ErrCRC • ErrWC • ECC 2-bit error (when CSI2nMCT0.EDMD = 1) • Reception of a packet of less than four bytes (when CSI2nMCT0.EDMD = 1) Note that this bit is set to 1 if virtual channel = 0 between FS and FE because the virtual channel for the packet with an ECC 2-bit error or the virtual channel which has received a packet of less than four bytes cannot be determined. Write 1 to CSI2nVCSC(M).FRDC(M) to clear this bit.
8	FRS(M)	0h	R	When this bit is set to 1b, ErrFrameSync has been detected. This bit is set to 1 if any of the following conditions occurs: • After an FS was received, another FS has been received on the same virtual channel without receiving an FE. • Although an FE was received, an FS has not been received on the same virtual channel. Write 1 to CSI2nVCSC(M).FRSC(M) to clear this bit.
7	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6	ECN(M)	0h	R	When this bit is set to 1b, no error was found in ECC checking on the received packets. Write 1 to CSI2nVCSC(M).ECNC(M) to clear this bit.
5	ECC(M)	0h	R	When this bit is set to 1b, a 1-bit error was found in ECC checking on the received packets and the error was corrected. Write 1 to CSI2nVCSC(M).ECCC(M) to clear this bit.

Bit	Bit Name	Initial Value	R/W	Description
4	WCE(M)	0h	R	When this bit is set to 1b, the data payload length of the packet being shorter than the value indicated by WC has been detected. Write 1 to CSI2nVCSC(M).WCEC(M) to clear this bit.
3	IDE(M)	0h	R	When this bit is set to 1b, an ErrID was detected and the packet was discarded. This bit is set to 1 if any of the following conditions occurs: • A packet which is defined as "Reserved" in "Chapter 9 Low Level Protocol" of the CSI-2 specification has been received. - A packet whose data type is 04h to 07h has been received. - A packet whose data type is 38h to 3Fh has been received when CSI2nMCT0.RVMD = 0. • A generic short packet (data type = 08h to 0Fh) for which the corresponding bit in CSI2nDTEL.DTEN is 0 has been received. • A long packet (data type = 10h to 3Fh) for which the corresponding bit in CSI2nDTEL(H).DTEN is 0 has been received. Write 1 to CSI2nVCSC(M).IDEC(M) to clear this bit. Note that this bit may also be set to 1 if more spacers than the count specified in CSI2nEPCT.SSP/SLP are received when EPD option 2 is in use.
2	CRC(M)	0h	R	When this bit is set to 1b, a CRC error was detected in the received packet. Write 1 to CSI2nVCSC(M).CRCC(M) to clear this bit.
1	ECD(M)	0h	R	When this bit is set to 1b, a 2-bit error was found in ECC checking on the received packets. Because the virtual channel for the packet with an error cannot be determined, the ECD0 field is set to 1 for all virtual channels. To clear the ECD0 field for all virtual channels, write 1 to CSI2nVCSC(M).AECDC(M) for any virtual channel. To clear the ECD0 field of virtual channel M, write 1 to CSI2nVCSC(M).ECDC(M).
0	MLF(M)	0h	R	When this bit is set to 1b, a packet of less than 4 bytes has been received. Because the virtual channel for the packet with an error cannot be determined, the MLF0 field is set to 1 for all virtual channels. To clear the MLF0 field for all virtual channels, write 1 to CSI2nVCSC(M).AMLFC(M) for any virtual channel. To clear the MLF0 field of virtual channel 0, write 1 to CSI2nVCSC(M).MLFC(M).

(18) Virtual Channel (M) Status Clear Register (CRUm_CSI2nVCSC(M)) (m = 0)

(M) indicates a virtual channel number.

Initial Value	0	x	0	0	0	0	0	0	0	0	0	0	x	0	x	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25. 24	DLUL[1:0]	0h	R	Indicate the RxUlpsEsc status of a logical data lane. Bit 0: RxUlpsEsc of logical lane 0 Bit 1: RxUlpsEsc of logical lane 1
23 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17, 16	DLSS[1:0]	xh *1	R	Indicate the stop state of a logical data lane. Bit 0: Stop state of logical lane 0 Bit 1: Stop state of logical lane 1
15	CLUL	0h	R	Indicates the inverted state of RxUlpsClkNot of the PPI clock lane. 0b: Not in ULPS 1b: In ULPS
14	CLSS	xh *1	R	Indicates the stop state of the PPI clock lane. 0b: Not in the stop state 1b: In the stop state
13 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7	CUN	0h	R	When this bit is set to 1b, the clock lane has transitioned to ULPS mode (inverse of RxUlpsClkNot). Write 1 to CSI2nPMSC.CUNC to clear this bit.
6	CUX	0h	R	When this bit is set to 1b, the clock lane has transitioned from ULPS mode (inverse of RxUlpsClkNot) to non-ULPS mode. Write 1 to CSI2nPMSC.CUXC to clear this bit.
5	DUN	0h	R	When this bit is set to 1b, all valid data lanes have transitioned to ULPS mode. Write 1 to CSI2nPMSC.DUNC to clear this bit.
4	DUX	0h	R	When this bit is set to 1b, all valid data lanes have transitioned from ULPS mode to any other state. Write 1 to CSI2nPMSC.DUXC to clear this bit.
3	CSN	xh *1	R	When this bit is set to 1b, the clock lane has transitioned to the stop state. Write 1 to CSI2nPMSC.CSNC to clear this bit.
2	CSX	0h	R	When this bit is set to 1b, the clock lane has transitioned from the stop state to a non-stop state. Write 1 to CSI2nPMSC.CSXC to clear this bit.
1	DSN	xh *1	R	When this bit is set to 1b, all valid data lanes have transitioned to the stop state. Write 1 to CSI2nPMSC.DSNC to clear this bit.
0	DSX	0h	R	When this bit is set to 1b, all valid data lanes have transitioned from the stop state to any other state. Write 1 to CSI2nPMSC.DSXC to clear this bit.

Note 1. The initial value “x” changes depending on the DPHY state.

R/W	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	-	0h	R0W	The read value is always 0b. Do not change the value of this bit from 0h.
16	GFIF	1h	RW	When this bit is set to 1b, the received generic short packet is stored in the generic short packet FIFO (GS FIFO).
15 to 7	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6 to 0	SHTH[6:0]	0h	RW	Asserts CSI2nGSST.GTH while the number of packets stored in the generic short packet FIFO equals or exceeds the value of this field + 1. Set this field to 15 or less when using CSI2nGSST.GTH. Set the default value when not using CSI2nGSST.GTH.

(24) Generic Short Packet Status Register (CRUm_CSI2nGSST) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0684h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	STRDS	GCD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PNUM[7:0]								-	-	-	GOV	-	-	GTH	GNE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	STRDS	0h	R	Indicates whether the received generic short packets can be stored in the generic short packet FIFO. 0b: Can be stored in the generic short packet FIFO. 1b: Cannot be stored in the generic short packet FIFO. This field indicates an inverted value of the store_en signal described in **9.2.3.3.1 Data Reception** with a delay for an internal latency. The previous value may be read depending on the signal change timing.
16	GCD	0h	R	When this bit is set to 1b, the GS FIFO is being cleared by CSI2nGSCT.GFCLR.
15 to 8	PNUM[7:0]	0h	R	Indicate the number of packets stored in the generic short packet FIFO.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GOV	0h	R	When this bit is set to 1b, the generic short packet FIFO has overflowed. Write 1 to CSI2nGSSC.GOVC to clear this bit.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	GTH	0h	R	When this bit is set to 1b, the number of packets stored in the generic short packet FIFO equals or exceeds "CSI2nGSCT.SHTH + 1".
0	GNE	0h	R	When this bit is set to 1b, the generic short packet FIFO is not empty.

(25) Generic Short Packet Status Clear Register (CRUm_CSI2nGSSC) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0688h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	GOVC	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R0W1	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GOVC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nGSST.GOV. Writing 0b to this bit has no effect.
3 to 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(26) Generic Short Packet Interrupt Enable Register (CRUm_CSI2nGSIE) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 068Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	GOVE	-	-	GTHE	GNEE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GOVE	0h	RW	Enables interrupts generated by CSI2nGSST.GOV. 0b: Does not assert csi2_int_gst when CSI2nGSST.GOV = 1. 1b: Asserts csi2_int_gst when CSI2nGSST.GOV = 1.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	GTHE	0h	RW	Enables interrupts generated by CSI2nGSST.GTH. 0b: Does not assert csi2_int_gst when CSI2nGSST.GTH = 1. 1b: Asserts csi2_int_gst when CSI2nGSST.GTH = 1.
0	GNEE	0h	RW	Enables interrupts generated by CSI2nGSST.GNE. 0b: Does not assert csi2_int_gst when CSI2nGSST.GNE = 1. 1b: Asserts csi2_int_gst when CSI2nGSST.GNE = 1.

(27) Generic Short Packet Register (CRUm_CSI2nGSHT) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0690h
Initial Value : 0008_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 24	SPVC[3:0]	0h	R	Indicate the virtual channel.
23, 22	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
21 to 16	DTYP[5:0]	8h	R	Indicate the data type. 08h-0Fh
15 to 0	SPDT[15:0]	0h	R	Indicate 16-bit user-defined data.

(28) Generic Short Packet Information Update Register (CRUm_CSI2nGSIU) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0694h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	GFEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	GFCLR	-	-	-	-	-	-	-	FINC
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	R	R	R0W1

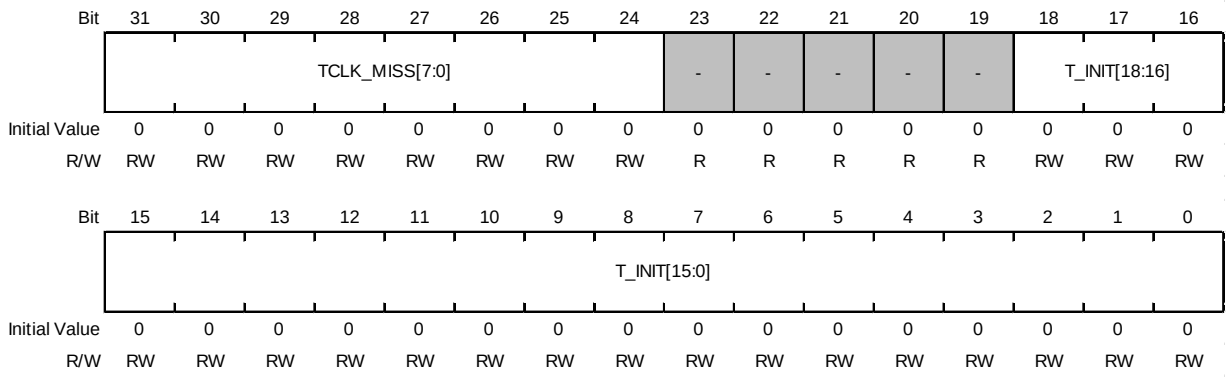
Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	GFEN	0h	R0W1	The read value is always 0b. When the GS FIFO has overflowed, write 1b to this bit to enable storing of generic short packets in the GS FIFO which has been disabled.
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	GFCLR	0h	RW	Clears the GS FIFO. Writing 1 to this bit requests clearing of the FIFO. Writing 0 to this bit requests clearing of the FIFO to be released.
7 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	FINC	0h	R0W1	The read value is always 0b. Write 1b to this bit to update data of the packet indicated in the CSI2nGSHT register for the next packet. Writing 0b to this bit has no effect. Writing 1b to this bit while CSI2nGSST.PNUM = 0b is prohibited.

(29) D-PHY Control Register 0 (CRUm_DPHYCTRL0) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0800h

Initial Value : 0000_0004h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
16	-	0h	RW	Reserved Do not change the value of this bit from 0h.
15 to 9	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
8	-	0h	RW	Reserved Do not change the value of this bit from 0h.
7 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2	-	1h	RW	Reserved Do not change the value of this bit from 1h.
1	EN_COM_LDO	0h	RW	D-PHY power control 1 Enable 1'b1: Enable 1'b0: Disable
0	EN_BGR	0h	RW	D-PHY power control 0 Enable 1'b1: Enable 1'b0: Disable

(30) D-PHY Timing Register 0 (CRUm_DPHYTIM0) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0804h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TCLK_MISS [7:0]	0h	RW	Timing parameter*[1]
23 to 19	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
18 to 0	T_INIT [18:0]	0h	RW	Timing parameter*[1]

Note 1. **Table 9.2-6** lists the recommended setting values

Table 9.2-6 Recommended Setting Values of the D-PHY Timing Register

Timing Paramter	Transmission Rate								Note
	80 Mbps to 100 Mbps	100 Mbps to 130 Mbps	130 Mbps to 200 Mbps	200M bps to 300 Mbps	300 Mbps to 400 Mbps	400 Mbps to 700 Mbps	700 Mbps to 1000 Mbps	1000 Mbps to 1500 Mbps

23 to 16	TCLK_PREPARE[7:0]	0h	RW	Timing parameter*1
15 to 8	THS_SETTLE[7:0]	0h	RW	Timing parameter*1
7 to 0	TCLK_SETTLE[7:0]	0h	RW	Timing parameter*1

Note 1. **Table 9.2-6** lists the recommended setting values.

9.2.3.3 Operation (Short Packet Reception)

The prefix “CRUm” of the register names is omitted in the following subsections.

9.2.3.3.1 Data Reception

(1) Common between short packets and long packets

Figure 9.2-3 shows the flow when receiving a packet whose data type is A and virtual channel is M (0, 1, 2, to 15).

This flow is common between short packets and long packets.

Upon receiving a packet, the LINK checks the length of the received packet.

If the length of the received packet is less than the packet header length (4 bytes), a virtual channel cannot be determined, resulting in setting CSI2nVCST(M).MLF(M) to 1b for all virtual channels. In addition, this packet is discarded because it is invalid.

When the length of the received packet is 4 bytes or more, ECC checking is performed. The check results are indicated in the CSI2nVCST(M) register.

- 2-bit error: Because the virtual channel of the packet with an error cannot be determined, CSI2nVCST(M).ECD(M) is set to 1b for all virtual channels.
  In addition, the packet is discarded because error correction cannot be performed.
- 1-bit error: CSI2nVCST(M).ECC(M) is set to 1b for the relevant virtual channel.
  Error correction proceeds because it is possible.
  No error: CSI2nVCST(M).ECN(M) is set to 1b for the relevant virtual channel.

If the ECC check results are “1-bit error” or “no error”, the data type field of the packet header is analyzed.

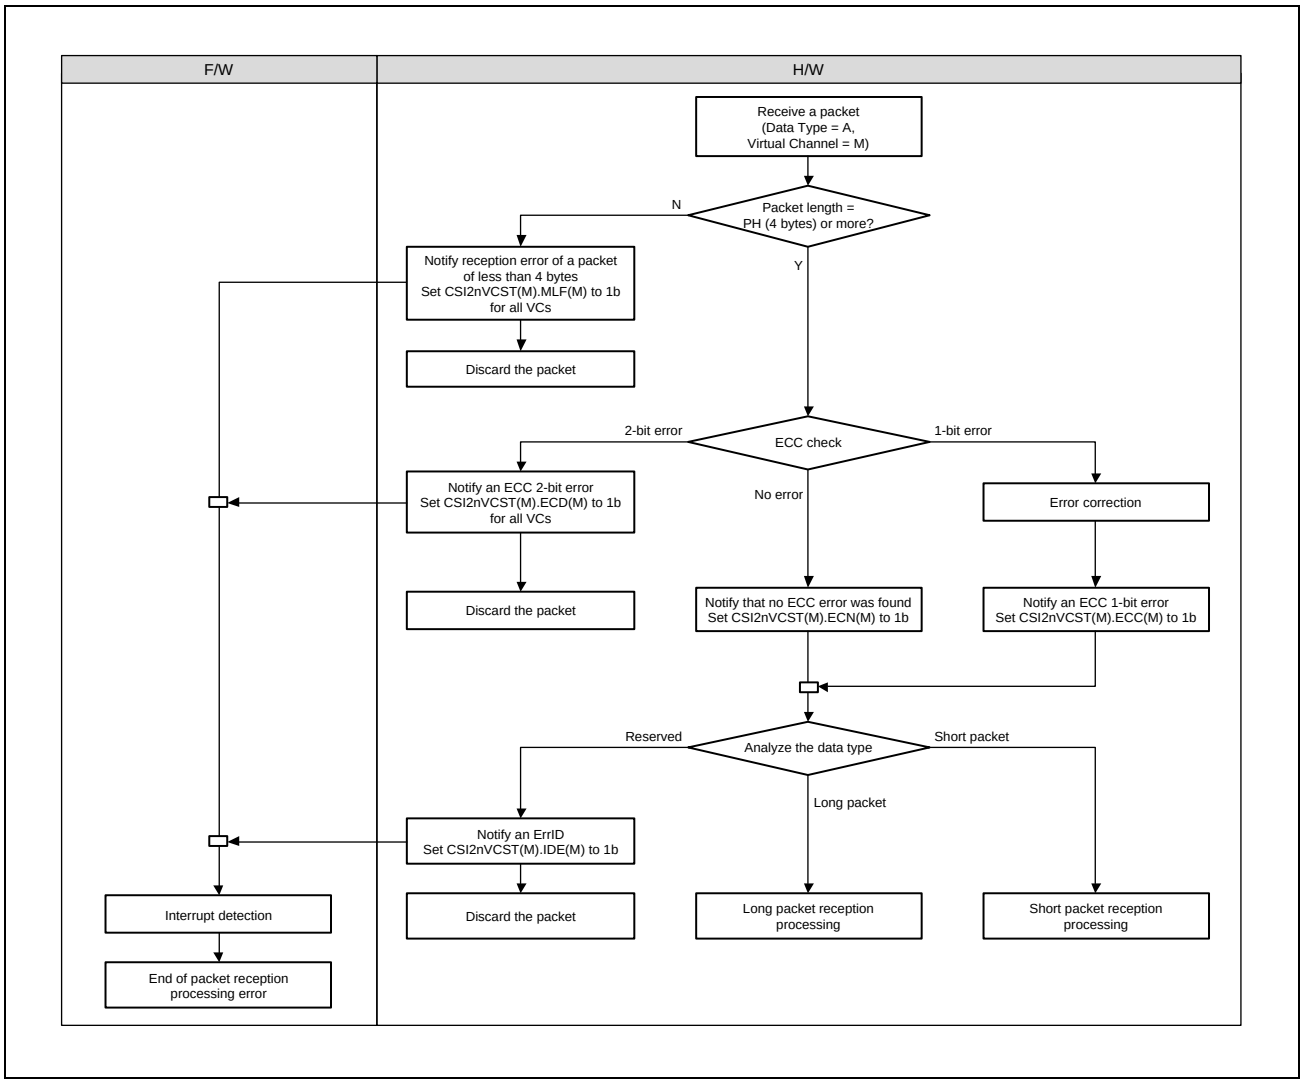

Figure 9.2-3 Packet Reception Processing

(2) Generic short packet data type code

Figure 9.2-4 shows the flow when receiving a packet whose data type is generic short packet code 1 to 8 and virtual channel is M.

When the corresponding bit in CSI2nDTEL.DTEN is set to 0b, CSI2nVCST(M).IDE(M)) is asserted and the packet is discarded.

When the corresponding bit in CSI2nDTEL.DTEN is set to 1b and CSI2nGSCT.GFIF is set to 1b, the generic short packet is output to the generic short packet FIFO. For details on the operation when using the generic short packet FIFO, see the flow in **Figure 9.2-4**.

The initial value of internal signal store_en which is described in the flow is 1. When store_en is set to 1, packets can be stored in the generic short packet FIFO. When it is set to 0, packets cannot be stored in the generic short packet FIFO.

- store_en is set to 0 when the generic short packet FIFO has overflowed.
- store_en is set to 1 when 1b is written to CSI2nGSIU.GFEN.

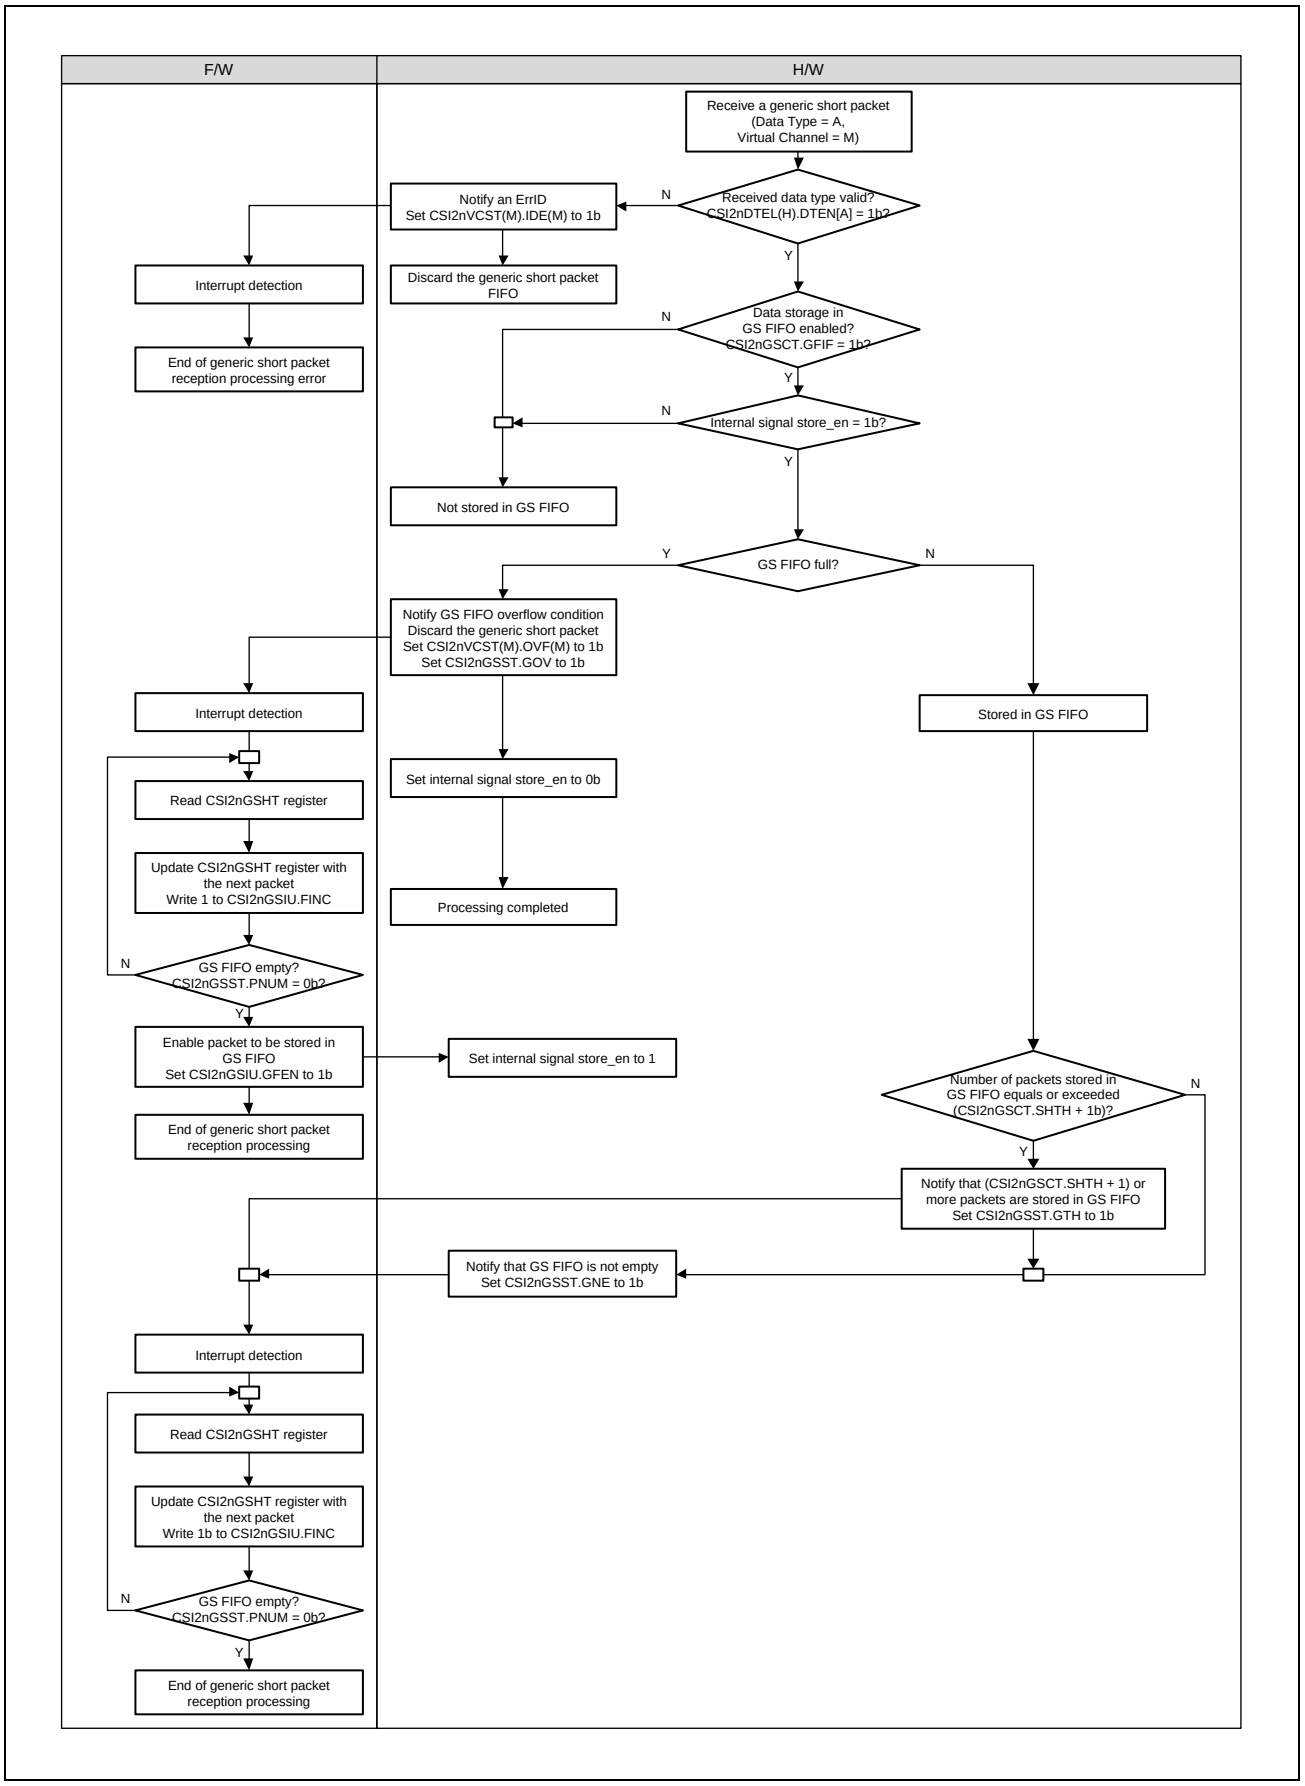

Figure 9.2-4 Generic Short Packet Reception Processing

(3) Clearing the generic short packet FIFO

Figure 9.2-5 shows how the generic short packet FIFO is cleared.

Writing 1b to CSI2nGSIU.GFCLR starts clearing the generic short packet FIFO.

After requesting to clear the generic short packet FIFO, check if CSI2nGSST.GCD is set to 1b to make sure that the FIFO is cleared. Then, writing 0b to CSI2nGSIU.GFCLR cancels the request for clearing the generic short packet FIFO. Check if CSI2nGSST.GCD is set to 0b to make sure that the request for clearing the generic short packet FIFO is canceled.

When CSI2nMCG.GSNM is set to 0b, it is prohibited to clear the generic short packet FIFO.

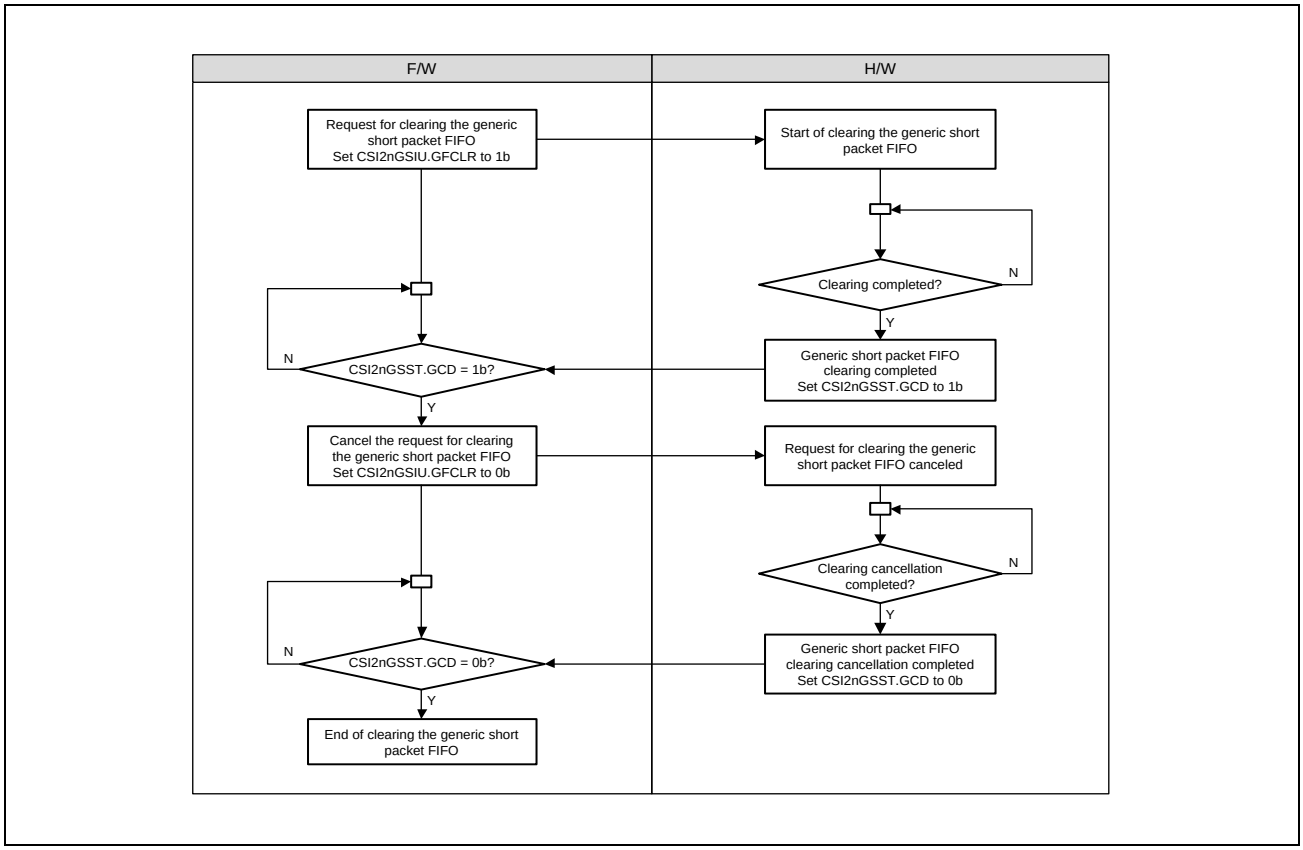

Figure 9.2-5 Clearing the Generic Short Packet FIFO

9.2.3.4 Interrupts

Figure 9.2-6 shows the structure of interrupt signals of MIPI CSI2. CRU0 has an interrupt. The conditions for interrupt generation, interrupt source registers, and interrupt enable registers are listed in **Table 9.2-7**, **Table 9.2-8**, and **Table 9.2-9**. The CSI2nMIST register indicates the interrupt output state. When an interrupt is generated, read the CSI2nMIST register to identify the interrupt source.

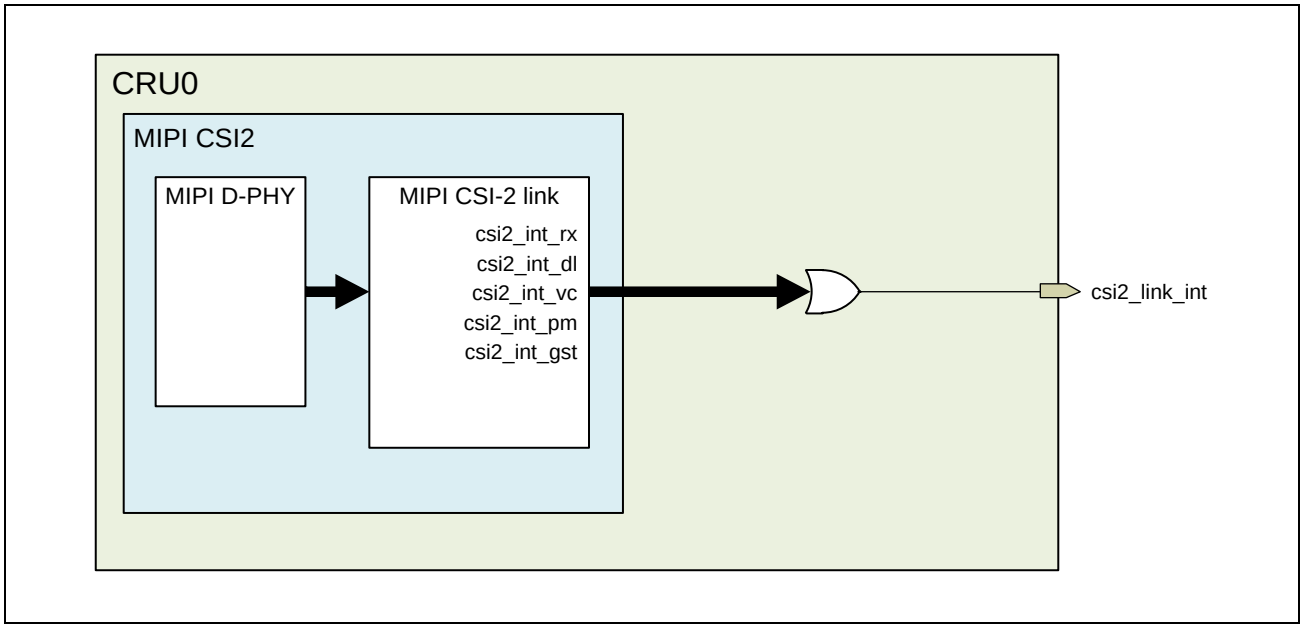

Figure 9.2-6 Interrupt Structure

Table 9.2-7 Interrupt States and Generation Conditions (1)

Interrupt State	Interrupt Source Register Field	Interrupt Enable Register Field	Generation Condition
CSI2nMIST.RXS	CSI2nRXST.RACTDET	CSI2nRXIE.RACTDETE	This IP received a packet.
CSI2nMIST.DLS0	CSI2nDLST0.ESH0	CSI2nDLIE0.ESHE0	ErrSotHS occurred on DL0.
	CSI2nDLST0.ESS0	CSI2nDLIE0.ESSE0	EnSotSyncHS occurred on DL0.
	CSI2nDLST0.ECT0	CSI2nDLIE0.ECTE0	ErrControl occurred on DL0.
	CSI2nDLST0.EES0	CSI2nDLIE0. EESE0	ErrESC occurred on DL0.
	CSI2nDLST0.EUL0	CSI2nDLIE0.EULE0	DL0 exited from the ULPS.
	CSI2nDLST0.RUL0	CSI2nDLIE0.RULE0	DL0 transitioned to the ULPS.
CSI2nMIST.DLS1	CSI2nDLST1.ESH1	CSI2nDLIE1.ESHE1	ErrSotHS occurred on DL1.
	CSI2nDLST1.ESS1	CSI2nDLIE1.ESSE1	EnSotSyncHS occurred on DL1.
	CSI2nDLST1.ECT1	CSI2nDLIE1.ECTE1	ErrControl occurred on DL1.
	CSI2nDLST0.EES1	CSI2nDLIE0. EESE1	ErrESC occurred on DL1.
	CSI2nDLST1.EUL1	CSI2nDLIE1.EULE1	DL1 exited from the ULPS.
	CSI2nDLST1.RUL1	CSI2nDLIE1.RULE1	DL1 transitioned to the ULPS.

Table 9.2-8 Interrupt States and Generation Conditions (2)

Interrupt State	Interrupt Source Register Field	Interrupt Enable Register Field	Generation Condition
CSI2nMIST.VCS0	CSI2nVCST0.MLF0	CSI2nVCIE0.MLFE0	Malformed packet was received on VC0.
	CSI2nVCST0.ECD0	CSI2nVCIE0.ECDE0	ErrEccDouble occurred on VC0.
	CSI2nVCST0.CRC0	CSI2nVCIE0.CRCE0	ErrCrc occurred on VC0.
	CSI2nVCST0.IDE0	CSI2nVCIE0.IDEE0	ErrID occurred on VC0.
	CSI2nVCST0.WCE0	CSI2nVCIE0.WCEE0	ErrWC occurred on VC0.
	CSI2nVCST0.ECC0	CSI2nVCIE0.ECCE0	ErrEccCorrected occurred on VC0.
	CSI2nVCST0.ECN0	CSI2nVCIE0.ECNE0	ErrEccNoError occurred on VC0.
	CSI2nVCST0.FRS0	CSI2nVCIE0.FRSE0	ErrFrameSync occurred on VC0.
	CSI2nVCST0.FRD0	CSI2nVCIE0.FRDE0	ErrFrameData occurred on VC0.
	CSI2nVCST0.OVF0	CSI2nVCIE0.OVFE0	Generic short packets on VC0 were discarded because GS FIFO overflowed.
	CSI2nVCST0.FSR0	CSI2nVCIE0.FSRE0	Frame start was received on VC0.
	CSI2nVCST0.FER0	CSI2nVCIE0.FERE0	Frame end was received on VC0.
	CSI2nVCST0.LSR0	CSI2nVCIE0.LSRE0	Line start was received on VC0.
	CSI2nVCST0.LER0	CSI2nVCIE0.LERE0	Line end was received on VC0.
CSI2nMIST.VCS1	CSI2nVCST1.MLF1	CSI2nVCIE1.MLFE1	Malformed packet was received on VC1.
	CSI2nVCST1.ECD1	CSI2nVCIE1.ECDE1	ErrEccDouble occurred on VC1.
	CSI2nVCST1.CRC1	CSI2nVCIE1.CRCE1	ErrCrc occurred on VC1.

CSI2nMIST.PMS	CSI2nPMST.DSX	CSI2nPMIE.DSXE	All data lanes exited from the stop state.
	CSI2nPMST.DSN	CSI2nPMIE.DSNE	All data lanes transitioned to the stop state.
	CSI2nPMST.CSX	CSI2nPMIE.CSXE	The clock lane exited from the stop state.
	CSI2nPMST.CSN	CSI2nPMIE.CSNE	The clock lane transitioned to the stop state.
	CSI2nPMST.DUX	CSI2nPMIE.DUXE	All data lanes exited from the ULPS.
	CSI2nPMST.DUN	CSI2nPMIE.DUNE	All data lanes transitioned to the ULPS.
	CSI2nPMST.CUX	CSI2nPMIE.CUXE	The clock lane exited from the ULPS.
	CSI2nPMST.CUN	CSI2nPMIE.CUNE	The clock lane transitioned to the ULPS.
CSI2nMIST.GSTS	CSI2nGSST.GNE	CSI2nGSIE.GNEE	GS FIFO is not empty.
	CSI2nGSST.GTH	CSI2nGSIE.GTHE	Data stored in GS FIFO equals or exceeds the threshold.
	CSI2nGSST.GOV	CSI2nGSIE.GOVE	GS FIFO overflowed.

9.2.4 Image Converter

9.2.4.1 Overview

The image converter module is a data conversion module which handles image clipping, frame subsampling, demosaicing (only selectable for SVC0, and only for RAW input), linear matrix, statistics (only selectable for SVC0, and only for RAW input), color space conversion, LUT conversion, pixel format conversion, and so on. It has an MIPI CSI2 (**9.2.3 MIPI CSI2**) input as an image sensor interface and its processing is roughly divided into two.

- Video system (Image Process, Non Image Process, All Bypass): Data are initially stored in FIFO-VD and transferred to external memory through the internal AXI-VD bus.
- Statistics system: Data are initially stored in FIFO-SD and transferred to external memory through the internal AXI-SD bus.

The video system further has image processing, non-image processing and full bypass systems. Full bypass is used when images are not to be processed by the image converter. Image processing and non-image processing can be used simultaneously (however, the data type cannot be set simultaneously within a single VC). The image processing system handles image processing and the non-image processing system does not handle image processing. Therefore, the data type for image processing, such as RGB, YUV, or RAW, can be selected for image processing, while several data types which are not for image processing, such as embedded 8-bit non-image data and a user-defined 8-bit data type, can be selected for non-image processing. In full bypass (CRUnCTRL.ATH = 1b), image processing within the CRU is not used and data from the MIPI CSI-2 link (in the recommended memory storage format for MIPI CSI-2) are directly transferred to external memory (image processing and non-image processing data cannot be used with full bypass).

The statistics system only handles data processing to produce statistics.

For MIPI CSI-2 input, up to four channels (SVC0 to 3) can be selected from among 16 virtual channels (VC0 to 15) and only one data type for image processing is processed per channel and several data types can be selected for non-image processing.

Additionally, when only SVC0 is used, some parameters are adjustable from frame to frame, and when demosaicing processing for multiple virtual channels (the image sizes, etc. are the same) is to proceed, control is applied with switching on frame-by-frame demarking by changing a register setting. However, this function cannot be used for sensors that have different VC for each line.

9.2.4.1.1 Features

The operating range of the image converter is as follows.

Image processing

- Range of effective pixels: QVGA (320 × 240) to 8.8 Mpixels
- Range of effective pixels in the horizontal direction: 320 to 4096 pixels
- Range of effective pixels in the vertical direction: 240 to 4096 lines
- Non-image processing and full bypass:
  The size range of application-specific payloads within input packets is from 1 to 24576 bytes.

Common

The maximum transfer rate at the time of MIPI CSI-2 input differs with the input format. For details, see **9.2.3.1.1 Features**.

- Input data format (type): See **9.2.4.3.1 Input Formats and Image Processing**.
  - Image processing:
    Only one data type from among YUV, RGB, RAW, etc. is selectable for each SVC.
  - Non-image processing:
    Several data types such as embedded 8-bit non-image data and user-defined 8-bit data are selectable for each SVC.

- Video output data format (type): Little endian is only supported.
  - 8-bit multiplexing of YCbCr422/YCbCr420 (with support for switching the order of Y and U/V)
  - YC separation of YCbCr422 and YCbCr420 (separation into Y and CbCr components)
  - Extraction of the Y component of YCbCr422
  - U and V in YUV422/YCbCr420 outputs are expressed in offset binary or as two’s complements.
  - RGB-888 (24 bits/pixel)
  - RGB-888 (32 bits/pixel)
  - ARGB-8888 (32 bits/pixel)
  - RAW6, 7, 8, 10, 12, 14, 16, 20
  - MIPI CSI-2 recommended memory storage format

- Demosaicing
  - RAW6, 7, 8, 10, 12, 14, 16, 20 to RGB888

- Color correction by linear matrix operations
  - Offset calculation included

- Color space conversion
  - YCbCr422 to RGB888
  - RGB888 to YCbCr422

- Image format conversion
  - YCbCr422 → YC separation (separation into Y and CbCr components)
  - YCbCr422 → Y component extraction
  - YCbCr422 → YCbCr420
  - RGB-888 → RGB-888 (32 bits/pixel)
  - RGB-888 → ARGB-8888 (32 bits/pixel) B first and A last format
  - RGB-888 → ARGB-8888 (32 bits/pixel) A first and B last format
  - RGB-565 → RGB-888 conversion (intermediate processing)
  - RGB-666 → RGB-888 conversion (intermediate processing)
  - RGB-555 → RGB-888 conversion (intermediate processing)
  - RGB-444 → RGB-888 conversion (intermediate processing)
  - RAW6, 7 → RAW8 conversion (intermediate processing)
  - RAW20: 16 higher-order bits are used for processing (demosaic, statis_cal) (intermediate processing)

- 4 channels (SVC0 to 3) from among virtual channels 0 to 15 can be selected for input (Please note that there are some features that are only available in SVC0. See **Table 9.2-10** for details.)
- Conversion by a lookup table (LUT): 10-bit to 8-bit conversion
- Data clipping: Suppressing the level of YCbCr data. For details see **9.2.4.3.10 Data Clipping**.
- Image clipping
- Frame subsampling
- Bypassing of each function (not performing the function): Several data types selectable

- Pattern generator (for debugging)
  - Y, U, and V register values are output.

- Statistics (statistical processing operations: horizontal detection area: 320 to 4096 pixels; vertical detection area: 240 to 4096)
  - Accumulation in the (16×16, 32×32, 64×64, and 128×128) areas for each of R, G, and B from RAW6, 7, 8, 10, 12, 14, 16, and 20 data
  - Summation of absolute values for differences from adjacent pixel values of G from RAW6, 7, 8, 10, 12, 14, 16, and 20 data

- FIFO
  - Video system: 16 Kbytes
  - Statistics system: 2 Kbytes

- AXI master: 2 channels (video system, statistics system)

- Memory bank address settings
  - Support for 8 bank memory bank addresses (video system)
    - SVC offset address
    - Non-image processing offset address
    - Offset address when separation into Y and UV is selected
  - Support for 8 memory bank addresses (statistics system: SVC0)

- Memory addressing
  - Video: Stored with image striding
  - Statistics: Stored with consecutive writing line

- Appending of a header (data type, VC, word count) to the start of a line: turning this off or on is possible.
- Appending of a footer (256’d1/256’d0)

  A footer value (256’d1/256’d0) is inverted when writing to the same bank so that the CPU can judge how far data have been written.
  - Appending of a footer to the end of each line (video system)
  - Appending of a footer to the end of each frame (statistics system)

- APB slave: Only 32-bit access supported

- Interrupt sources
  - Scan line interrupt: 4 sources
  - Start-of-frame/end-of-frame interrupt: 8 sources
  - FIFO overflow interrupt (video system, statistics system): 2 sources
  - AXI SLVERR and DECERR error interrupts (video system, statistics system): 4 sources
  - AXI specified address transfer completed interrupt (video system: 5 addresses; statistics system: 2 addresses): 7 sources

9.2.4.1.2 Block Diagram

Figure 9.2-7 is a block diagram of the image converter.

Note 1. This block only supports SVC0.

Note 2. When using this function, only SVC0 is supported.
When bypassing this function, it is possible to pass through the SVCs set by CRUm_ICnSVCNUM out of SVC0 to SVC3.

Figure 9.2-7 Block Diagram of Image Converter

Pattern Generator

This function is used for debugging and generates image data for testing. The data types are limited to YCbCr422.

Input Selector (1 of 2)

A register setting selects data for input to the image converter from among the following three sources.

- Image data for testing
- Link data from this CRU

Video

- Image Processing
  - SVC/Data Type Selector
    A register setting selects one channel from among 16 VCs (MIPI CSI-2 virtual channels) for use by the image converter. Four channels are selectable and these are treated as SVC0 to 3.
    A register setting selects one data type for use in image processing. Four data types are selectable.

- 8-bit Expansion
  Input data less than 8 bits ((RGB444/RGB555/RGB565/RGB666, RAW6/7) are expanded to 8 bits (RGB888, RAW8).
- Image Clipping
  Input images are cropped to the size selected by register settings for the output of small images.
- Frame Subsampling
  Subsamples input image frames to lower the frame rate. This is used to reduce the bandwidth on the bus.
- Data Arrangers 1 and 2
  Converts the negative expression of the UV component of YUV (YCbC) data.
- Data Clipping
  Limits data values of YUV (YCbCr) to upper and lower limits. This is used when standards having upper and lower limits such as ITU-R BT.601 and 702 are applicable.
- Demosaicing
  Interpolates converted RGB data from RAW (Bayer-array) data.
- Linear Matrix
  Applies matrix operations to correct the colors of RGB data converted by demosaicing.
- Color Space Conversion
  Converts the color space from YCbCr to RGB and vice versa.
- LUT (Lookup Table)
  Converts 10-bit data after color space conversion (YCbCr to RGB or RGB to YCbCr) to a table of 8-bit entries. A basic bit rounding function is set, but the table can also be used for non-linear image correction such as gamma correction.
- YC Post Processing
  - YCbCr422 to 420
    Subsamples YCbCr422 data to convert it into YCbCr422.
  - Y/C Separation
    Sorts and separates YCbCr data into Y and C components.
  - Only Y
    Deletes the C components of YCbCr data so that only Y data remain.
- 256-bit Packing
  Packs data into 256-bit units to suit the bus width for transmission through the AXI.

- Non-Image Processing
  - SVC/Data Type Selector
    The same channels as those set as SVC0 to 3 described under “Image Processing” are used.
    A register setting selects several data types for use in non-image processing.
  - Header Appending
    Since non-image processing and full bypass involve the selection of several data types and storage of the data in a mixed state in the same SVC memory, a header is appended to the start of a line of non-image processing or full bypass data so that the data types and data lengths can be identified when read.
- Full Bypass
  - VC/Data Type Selector
    The same channels as those set as SVC0 to 3 described under “Image Processing” are used.
    A register setting selects several data types for use in full bypass.

- Footer Appending
  Appends 256’d0/d1 as a footer, which is inverted every time the memory bank is overwritten, so that the CPU can recognize the bank number to which the memory data have been written.
- AXI MASTER (AXI-VD)
  Video data are initially stored in a FIFO buffer and then written to the DRAM by the AXI master.

Statistics

- Statistics
  Acquires statistics for each block which is divided from a display for 3A (AE/AWB/AF).
- Footer Appending
  Appends 512 bits as a footer, which is inverted every time the memory bank is overwritten, so that the CPU can recognize the bank number to which the memory data have been written.
  The footer value is written alternately: (1) higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h1 and (2) higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h0.
- AXI MASTER (AXI-SD)
  Statistics data are initially stored in a FIFO buffer and then written to the DRAM by the AXI master.

APB Registers

Only 32-bit access is supported.

9.2.4.2 IMC Registers

See **9.2.3.2 MIPI CSI2 Registers** for the CRUm base addresses.

9.2.4.2.1 List of Registers [m = 0]

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
CRU Control Register	CRUm_CRUnCTRL	0000_0000h	0000h	32
CRU Interrupt Enable Register1	CRUm_CRUnIE1	0000_0000h	0004h	32
CRU Interrupt Enable Register2	CRUm_CRUnIE2	0000_0000h	0008h	32
CRU Interrupt Status Register1	CRUm_CRUnINTS1	0000_0000h	000Ch	32

9.2.4.2.2 Register Descriptions

(1) Bypass Setting for Each Function

Figure 9.2-8 shows where the bypass settings by the ICnIPMC_C0/1/2/3.*THR and CRUnCTRL.ATH registers work.

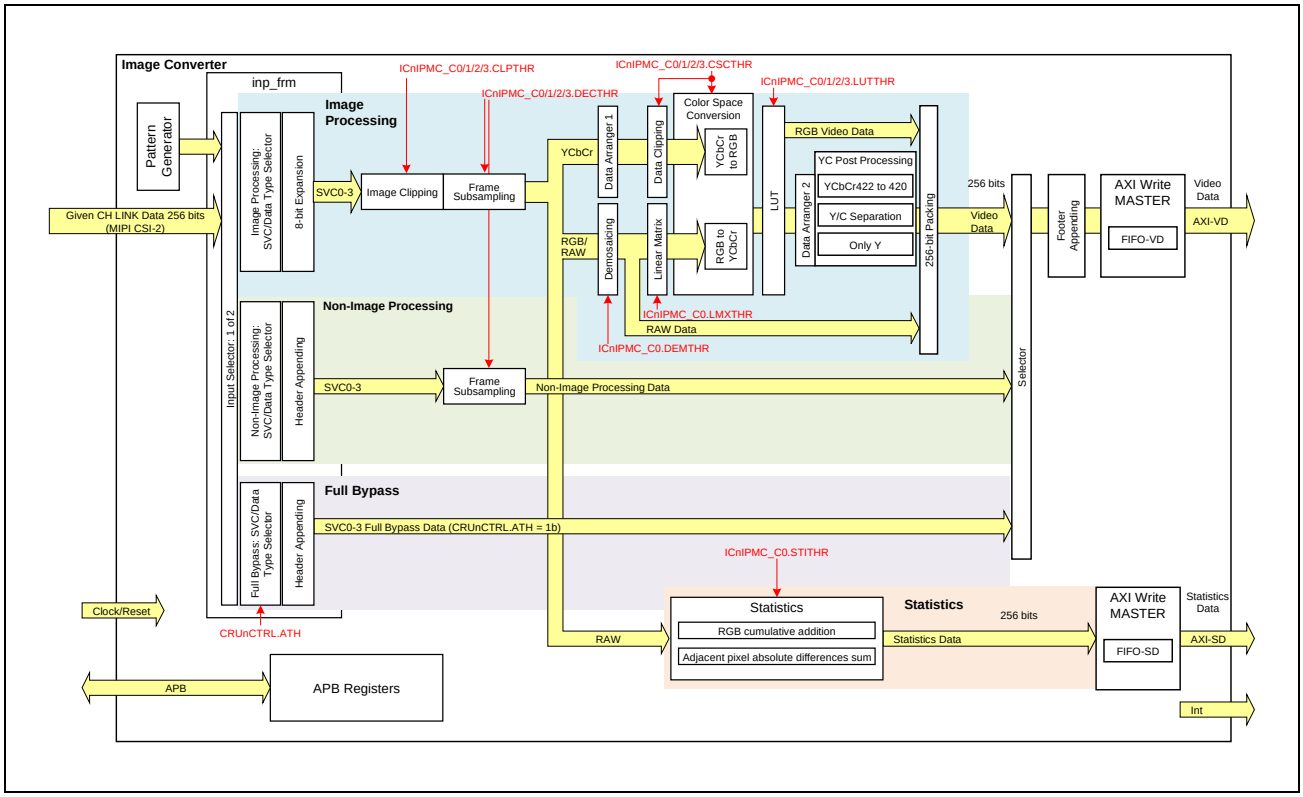

Figure 9.2-8 Bypass Setting for Each Function

(2) CRU Control Register (CRUm_CRUnCTRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ATH	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
1	ATH	0h	RW	Full bypass setting for the image converter 0b: Normal 1b: Full bypass is performed and the data from the LINK is output as is to the AXI-VD (the virtual channels and data types set by registers ICnSVC and ICnNIPDT_C0~3L/H are bypassed). Note: See **Figure 9.2-8**.
0	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.

(3) CRU Interrupt Enable Register1 (CRUm_CRUnIE1) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SDDECEE	SDSLVEE	SDFOE	-	-	-	-	-	DECEE	SLVEE	FOE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
30 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
10	SDDECEE	0h	RW	AXI-SD DECERR (statistics data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct.
9	SDSLVEE	0h	RW	AXI-SD SLVERR (statistics data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings.
8	SDFOE	0h	RW	FIFO-SD overflow (statistics data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
7 to 4	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
3	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
2	DECEE	0h	RW	AXI-VD DECERR (video data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct.
1	SLVEE	0h	RW	AXI-VD SLVERR (video data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings.
0	FOE	0h	RW	FIFO-VD overflow (video data-related) interrupt enable control (for debugging) 0b: No interrupts are generated. 1b: Interrupts are generated.

(4) CRU Interrupt Enable Register2 (CRUm_CRUnIE2) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	SDADR1WE	SDADR0WE	-	-	-	VDADR4WE	VDADR3WE	VDADR2WE	VDADR1WE	VDADR0WE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	R	R	R	R	RW	RW	R	R	R	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	SL3E	FE3E	FS3E	SL2E	FE2E	FS2E	SL1E	FE1E	FS1E	SL0E	FE0E	FS0E
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
30	-	0h	RW	Do not change the value of this bit from 0.
29 to 26	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
25	SDADR1WE	0h	RW	AXI-SD bus write completion interrupt enable control (video data-related) for designated address 1 (35-bit memory address set by AMnSDIVT1ADDRL and AMnSDIVT1ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
24	SDADR0WE	0h	RW	AXI-SD bus write completion interrupt enable control(statistics data-related) for designated address 0 (35-bit memory address set by AMnSDIVT0ADDRL and AMnSDIVT0ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
23 to 21	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
20	VDADR4WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 4 (35-bit memory address set by AMnIVT4ADDRL and AMnIVT4ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
19	VDADR3WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 3 (35-bit memory address set by AMnIVT3ADDRL and AMnIVT3ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
18	VDADR2WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 2 (35-bit memory address set by AMnIVT2ADDRL and AMnIVT2ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
17	VDADR1WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 1 (35-bit memory address set by AMnIVT1ADDRL and AMnIVT1ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
16	VDADR0WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 0 (35-bit memory address set by AMnIVT0ADDRL and AMnIVT0ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
15 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11	SL3E	0h	RW	SVC3 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
10	FE3E	0h	RW	SVC3 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.

Bit	Bit Name	Initial Value	R/W	Description
9	FS3E	0h	RW	SVC3 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
8	SL2E	0h	RW	SVC2 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
7	FE2E	0h	RW	SVC2 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
6	FS2E	0h	RW	SVC2 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
5	SL1E	0h	RW	SVC1 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
4	FE1E	0h	RW	SVC1 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
3	FS1E	0h	RW	SVC1 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
2	SL0E	0h	RW	SVC0 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
1	FE0E	0h	RW	SVC0 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
0	FS0E	0h	RW	SVC0 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.

(5) CRU Interrupt Status Register1 (CRUm_CRUnINTS1) (m = 0)

See **Figure 9.2-7** for where each bit of the interrupt is detected.

Access Size : 32 bits
Address : <CRUm_base> + 000Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW1	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SDDECES	SDSLVES	SDFOS	-	-	-	-	-	DECES	SLVES	FOS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW1	RW1	RW1	RW1	R	R	R	R	RW1	RW1	RW1	RW1

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	RW1	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
30 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11	-	0h	RW1	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
10	SDDECES	0h	RW1	AXI-SD DECERR (statistics data-related) interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE1.SDDECEE = 1. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct. Note: This status is detected in the AXI Master of Statistics Data.
9	SDSLVES	0h	RW1	AXI-SD SLVERR (statistics data-related) interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE1.SDSLVEE = 1. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings. Note: This status is detected in the AXI Master of Statistics Data.
8	SDFOS	0h	RW1	FIFO-SD overflow (statistics data-related) interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE1.SDFOE = 1. Note: This status is detected in the AXI Master of Statistics Data.
7 to 4	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
3	-	0h	RW1	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
2	DECES	0h	RW1	AXI-VD DECERR (video data-related) interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE1.DECEE = 1. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct. Note: This status is detected in the AXI Master of Video Data.

Bit	Bit Name	Initial Value	R/W	Description
1	SLVES	0h	RW1	AXI-VD SLVERR (video data-related) interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit only is valid when CRUnIE1.SLVEE = 1. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings. Note: This status is detected in the AXI Master of Video Data.
0	FOS	0h	RW1	FIFO-VD overflow (video data-related) interrupt status (for debugging) Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE1.FOE = 1. Note: This status is detected in the AXI Master of Video Data.

(6) CRU Interrupt Status Register2 (CRUm_CRUnINTS2) (m = 0)

See **Figure 9.2-7** for where each bit of the interrupt is detected.

Access Size : 32 bits
Address : <CRUm_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	0h	RW1	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
29 to 26	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
25	SDADR1WS	0h	RW1	AXI-SD bus write completion interrupt status (statistics data-related) for designated address 1 (35 bits) Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.SDADR1WE = 1. Note: This status is detected in the AXI Master of Statistics Data.
24 to 21	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
20	VDADR4WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 4 (35 bits) Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR4WE = 1. Note: This status is detected in the AXI Master of Video Data.
19	VDADR3WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 3 (35 bits) Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR3WE = 1. Note: This status is detected in the AXI Master of Video Data.
18	VDADR2WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 2 (35 bits) Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR2WE = 1. Note: This status is detected in the AXI Master of Video Data.
17	VDADR1WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 1 (35 bits) Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR1WE = 1. Note: This status is detected in the AXI Master of Video Data.
16 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.

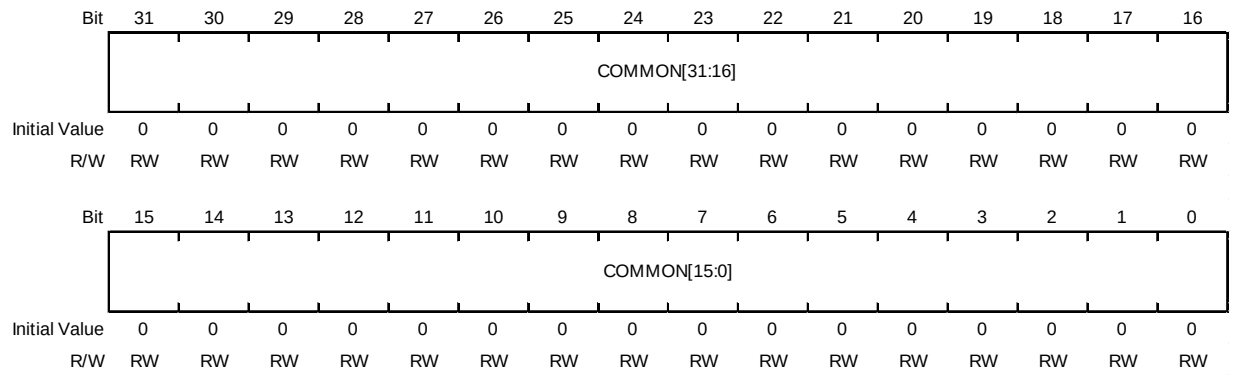
Bit	Bit Name	Initial Value	R/W	Description
11	SL3S	0h	RW1	SVC3 Scan line interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.SL3E = 1. Note: This status is detected in SVC3 Image Clipping.
10	FE3S	0h	RW1	SVC3 Frame end interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FE3E = 1. Note: This status is detected in SVC3 Image Clipping.
9	FS3S	0h	RW1	SVC3 Frame start interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FS3E = 1. Note: This status is detected in SVC3 Image Clipping.
8	SL2S	0h	RW1	SVC2 Scan line interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.SL2E = 1. Note: This status is detected in SVC2 Image Clipping.
7	FE2S	0h	RW1	SVC2 Frame end interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FE2E = 1. Note: This status is detected in SVC2 Image Clipping.
6	FS2S	0h	RW1	SVC2 Frame start interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FS2E = 1. Note: This status is detected in SVC2 Image Clipping.
5	SL1S	0h	RW1	SVC1 Scan line interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.SL1E = 1. Note: This status is detected in SVC1 Image Clipping.
4	FE1S	0h	RW1	SVC1 Frame end interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FE1E = 1. Note: This status is detected in SVC1 Image Clipping.
3	FS1S	0h	RW1	SVC1 Frame start interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FS1E = 1. Note: This status is detected in SVC1 Image Clipping.
2	SL0S	0h	RW1	SVC0 Scan line interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.SL0E = 1. Note: This status is detected in SVC0 Image Clipping.
1	FE0S	0h	RW1	SVC0 Frame end interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FE0E = 1. Note: This status is detected in SVC0 Image Clipping.
0	FS0S	0h	RW1	SVC0 Frame start interrupt status Write 0: Invalid, 1: Clears the interrupt & status Read 0: No interrupts generated, 1: Interrupts generated Note: This bit is only valid when CRUnIE2.FS0E = 1. Note: This status is detected in SVC0 Image Clipping.

(7) CRU Reset Register (CRUm_CRUnRST) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0018h

Initial Value : 0000_0000h

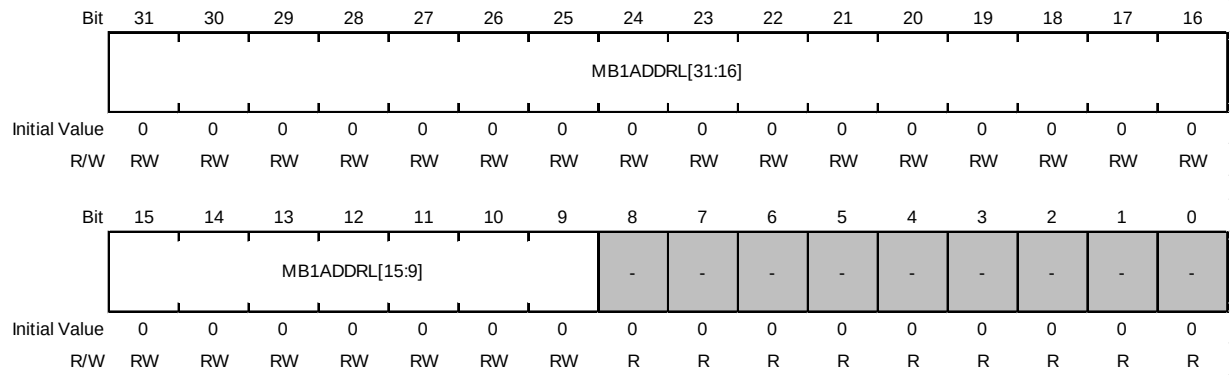


Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	VRESETN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	VRESETN	0h	RW	0b: Resets the Image Converter module. 1b: Releases the Image Converter module from the reset state.

(8) CRU General Read/Write Register (CRUm_CRUnCOM) (m = 0)



Access Size : 32 bits
Address : <CRUm_base> + 002Ch
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	COMMON[31:0]	0h	RW	General register The value written to this register can be read.

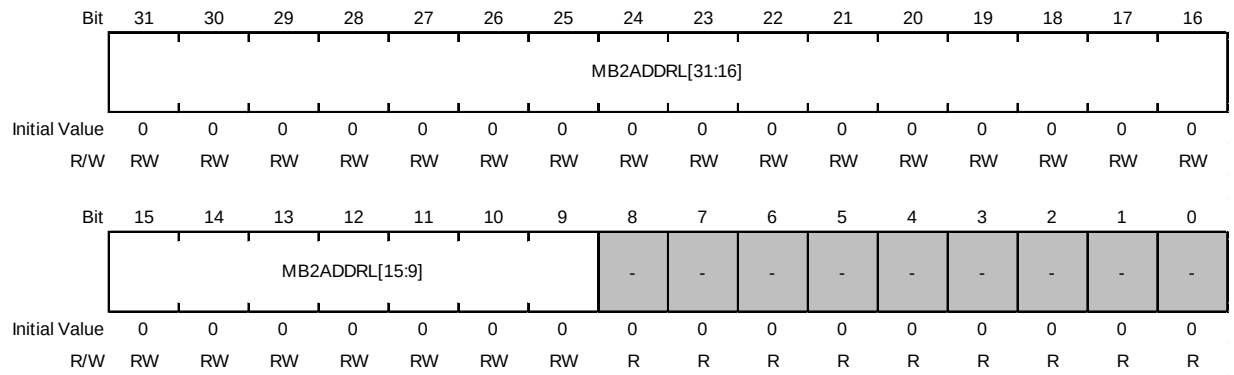
(9) Memory Bank 1 Base Address Lower Register for Video Data (CRUm_AMnMB1ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0040h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB1ADDRL [31:9]	0h	RW	Video data transfer destination base address 1 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(10) Memory Bank 1 Base Address Higher Register for Video Data (CRUm_AMnMB1ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0044h
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB1ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB1ADDRH [34:32]	0h	RW	Video data transfer destination base address 1 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

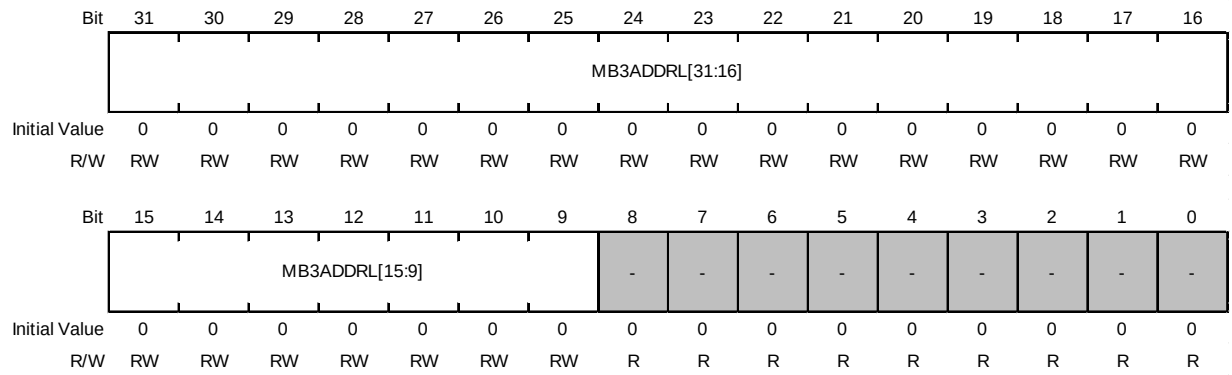
(11) Memory Bank 2 Base Address Lower Register for Video Data (CRUm_AMnMB2ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0048h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB2ADDRL [31:9]	0h	RW	Video data transfer destination base address 2 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(12) Memory Bank 2 Base Address Higher Register for Video Data (CRUm_AMnMB2ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 004Ch
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB2ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB2ADDRH [34:32]	0h	RW	Video data transfer destination base address 2 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(13) Memory Bank 3 Base Address Lower Register for Video Data (CRUm_AMnMB3ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0050h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB3ADDRL [31:9]	0h	RW	Video data transfer destination base address 3 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(14) Memory Bank 3 Base Address Higher Register for Video Data (CRUm_AMnMB3ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0054h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB3ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB3ADDRH [34:32]	0h	RW	Video data transfer destination base address 3 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(15) Memory Bank 4 Base Address Lower Register for Video Data (CRUm_AMnMB4ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0058h
Initial Value : 0000_0000h

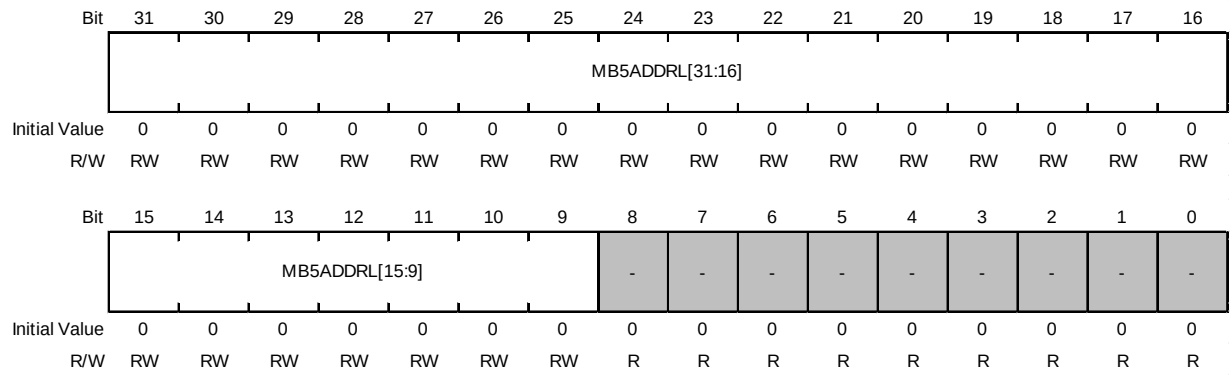
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MB4ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MB4ADDRL[15:9]							-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB4ADDRL [31:9]	0h	RW	Video data transfer destination base address 4 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(16) Memory Bank 4 Base Address Higher Register for Video Data (CRUm_AMnMB4ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 005Ch
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB4ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB4ADDRH [34:32]	0h	RW	Video data transfer destination base address 4 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

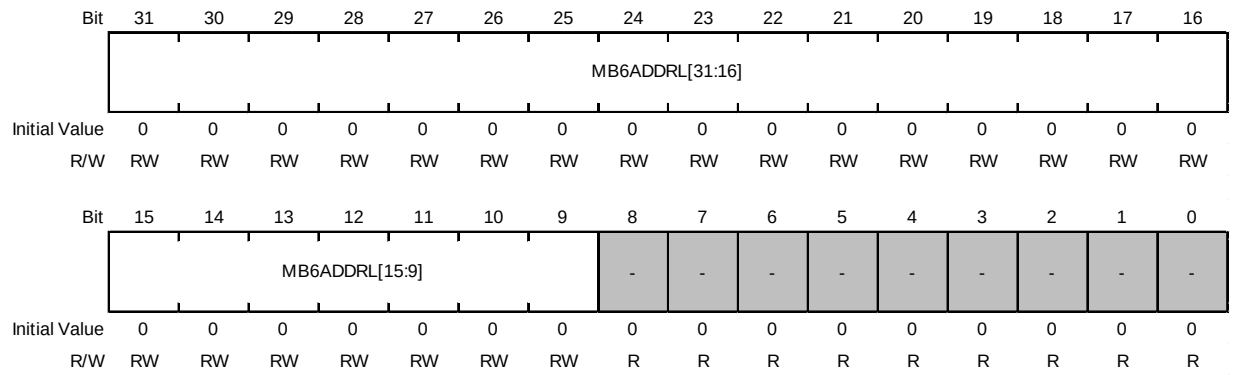
(17) Memory Bank 5 Base Address Lower Register for Video Data (CRUm_AMnMB5ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0060h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB5ADDRL [31:9]	0h	RW	Video data transfer destination base address 5 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(18) Memory Bank 5 Base Address Higher Register for Video Data (CRUm_AMnMB5ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0064h
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB5ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB5ADDRH [34:32]	0h	RW	Video data transfer destination base address 5 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

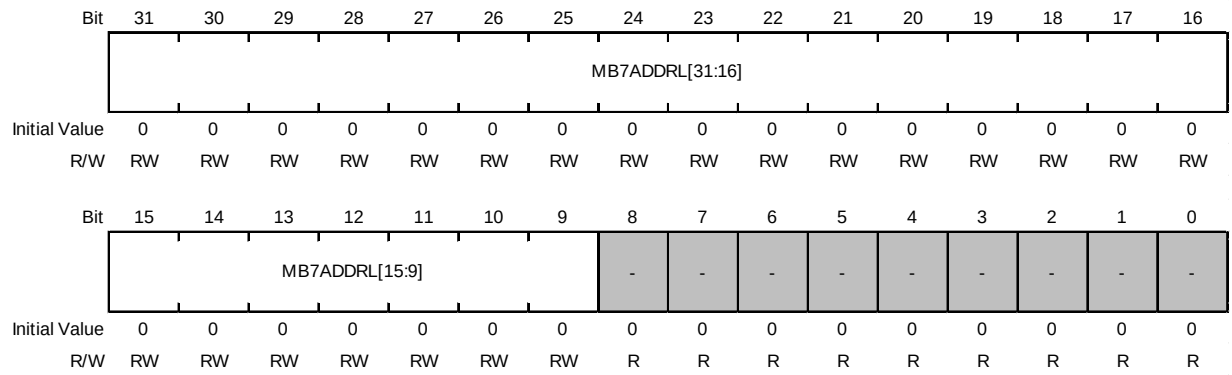
(19) Memory Bank 6 Base Address Lower Register for Video Data (CRUm_AMnMB6ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0068h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB6ADDRL [31:9]	0h	RW	Video data transfer destination base address 6 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(20) Memory Bank 6 Base Address Higher Register for Video Data (CRUm_AMnMB6ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 006Ch
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB6ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB6ADDRH [34:32]	0h	RW	Video data transfer destination base address 6 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

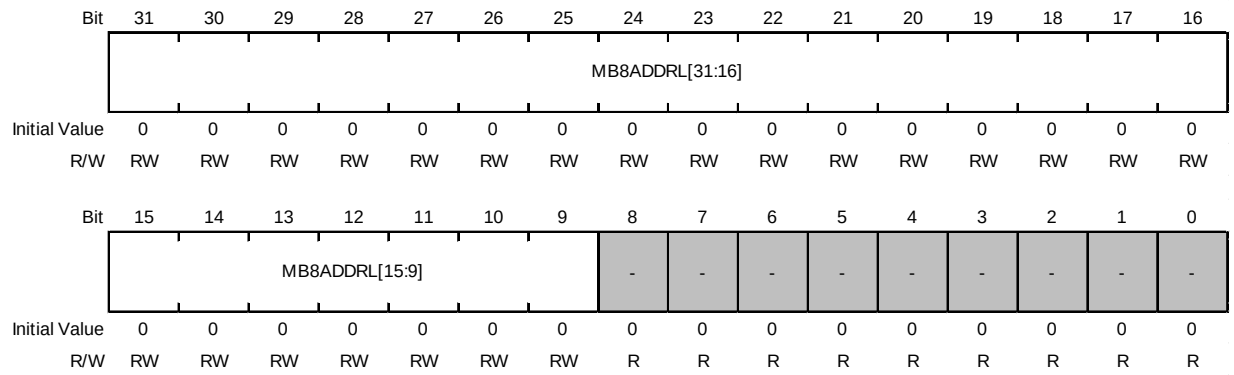
(21) Memory Bank 7 Base Address Lower Register for Video Data (CRUm_AMnMB7ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0070h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB7ADDRL [31:9]	0h	RW	Video data transfer destination base address 7 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(22) Memory Bank 7 Base Address Higher Register for Video Data (CRUm_AMnMB7ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0074h
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB7ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB7ADDRH [34:32]	0h	RW	Video data transfer destination base address 7 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(23) Memory Bank 8 Base Address Lower Register for Video Data (CRUm_AMnMB8ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0078h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	MB8ADDRL [31:9]	0h	RW	Video data transfer destination base address 8 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(24) Memory Bank 8 Base Address Higher Register for Video Data (CRUm_AMnMB8ADDRH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 007Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MB8ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MB8ADDRH [34:32]	0h	RW	Video data transfer destination base address 8 (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(25) UV Data Address Offset Lower Register for Video Data (CRUm_AMnUVAOFL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	UVAOFL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	UVAOFL[15:9]							-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	UVAOFL [31:9]	0h	RW	UV data address offset for image processing data YUV output (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(26) UV Data Address Offset Higher Register for Video Data (CRUm_AMnUVAOFH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0084h
Initial Value : 0000_0000h

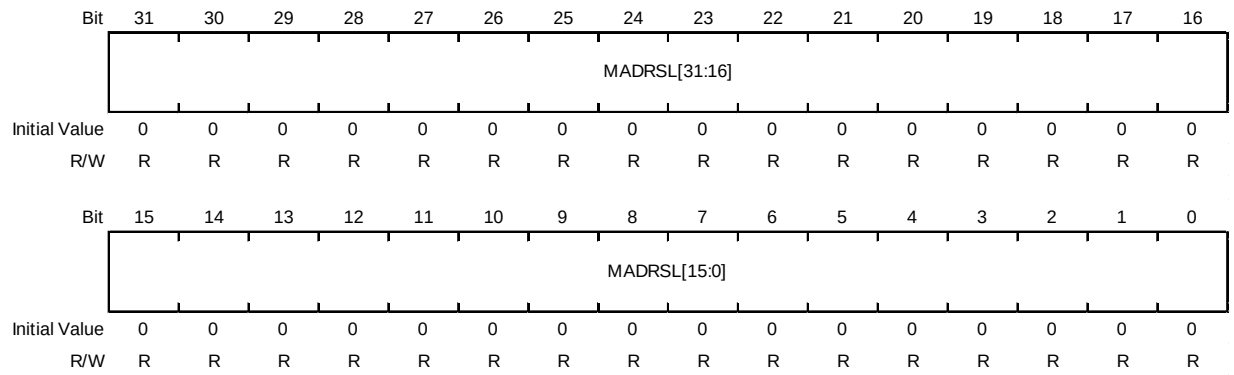
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	UVAOFH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	UVAOFH [34:32]	0h	RW	UV data address offset for image processing data YUV output (valid bits: [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(27) Memory Bank Enable Register for Video Data (CRUm_AMnMBVALID) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0088h
Initial Value : 0000_0001h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	MBVALID[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
7 to 0	MBVALID[7:0]	1h	RW	Video data transfer destination valid address (the details are described in **9.2.4.3.3 Transfer to DRAM**.) [0]: 0: MB1 invalid, 1: MB1 valid [1]: 0: MB2 invalid, 1: MB2 valid [2]: 0: MB3 invalid, 1: MB3 valid [3]: 0: MB4 invalid, 1: MB4 valid [4]: 0: MB5 invalid, 1: MB5 valid [5]: 0: MB6 invalid, 1: MB6 valid [6]: 0: MB7 invalid, 1: MB7 valid [7]: 0: MB8 invalid, 1: MB8 valid Note: Set the valid destination address from the LSB continuously. Data transferred from the LSB are written sequentially only to valid memory banks, and the processing is repeated from the start (LSB) when the last address is reached. (These bits cannot be modified while the AXI-VD is operating.)

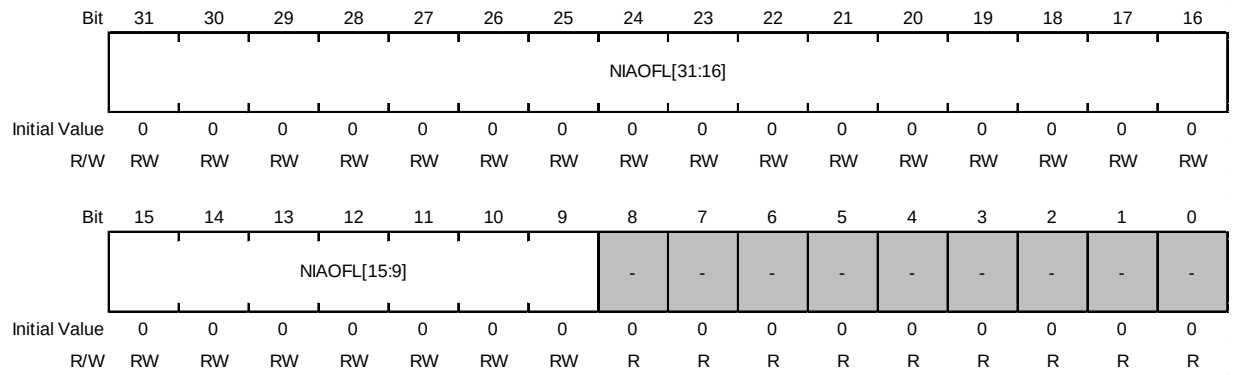
(28) Memory Address Lower Status Register for Video Data (CRUm_AMnMADRSL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 008Ch
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MADRSL[31:0]	0h	R	Memory address for video data (lower) Reads the memory address (lower) to which the current video data was written. Note: When this register is read, AMnMADRSH of the higher-order address also latches the address. Note: Be sure to read AMnMADRSH after AMnMADRSL has been read.

(29) Memory Address Higher Status Register for Video Data (CRUm_AMnMADRSH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0090h
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	MADRSH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	MADRSH [34:32]	0h	R	Memory address for video data (higher) Read the memory address (higher) to which the current video data was written. Note: When the AMnMADRSL register is read, the higher address AMnMADRSH also latches the address. Note: Be sure to lead AMnMADRSH after AMnMADRSL lead.

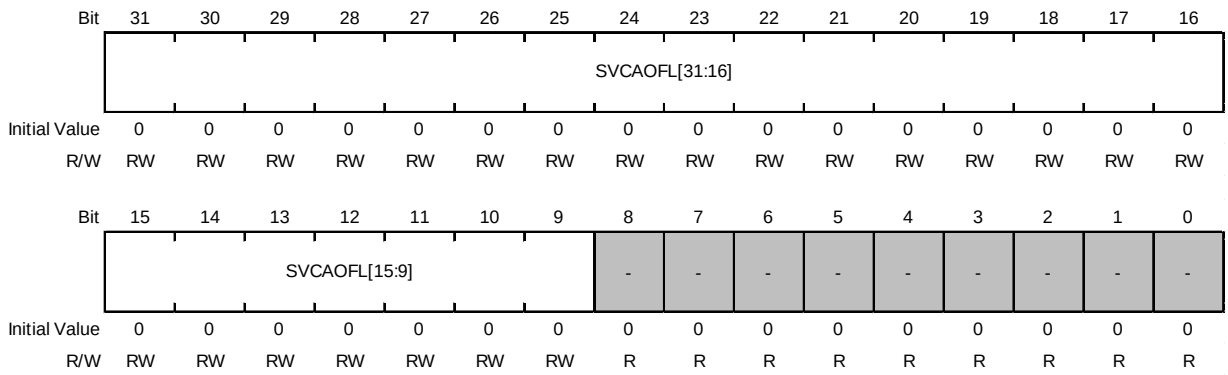
(30) Non Image Process Address Offset Lower Register (CRUm_AMnNIAOFL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0094h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	NIAOFL[31:9]	0h	RW	Non-image processing address offset (lower) for image processing for video data (significant bits [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(31) Non Image Process Address Offset Higher Register (CRUm_AMnNIAOFH) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0098h
Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	NIAOFH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	NIAOFH [34:32]	0h	RW	Non-image processing address offset (higher) for image processing for video data (valid bits [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(32) SVC Data Address Offset Lower Register for Video Data (CRUm_AMnSVCAOFL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 009Ch
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	SVCAOFL [31:9]	0h	RW	SVC data address offset (lower) for video data (valid bits [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(33) SVC Data Address Offset Higher Register for Video Data (CRUm_AMnSVCAOFH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00A0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SVCAOFH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	SVCAOFH [34:32]	0h	RW	SVC data address offset (higher) for video data (valid bits [34:32]) (These bits cannot be modified while the AXI-VD is operating.)

(34) AXI-VD Bus Transfer Completion Event Address 0 Lower Register (CRUm_AMnIVT0ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 00B4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IVT0ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IVT0ADDRL[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IVT0ADDRL [31:0]	0h	RW	AXI-VD bus transfer completion event address 0 for video data (lower) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(35) AXI-VD Bus Transfer Completion Event Address 0 Higher Register (CRUm_AMnIVT0ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00B8h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	IVT0ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	IVT0ADDRH [34:32]	0h	RW	AXI-VD bus transfer completion event address 0 for video data (higher) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(36) AXI-VD Bus Transfer Completion Event Address 1 Lower Register (CRUm_AMnIVT1ADDRL) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00BCh

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IVT1ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IVT1ADDRL[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IVT1ADDRL [31:0]	0h	RW	AXI-VD bus transfer completion event address 1 for video data (lower) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(37) AXI-VD Bus Transfer Completion Event Address 1 Higher Register (CRUm_AMnIVT1ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00C0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	IVT1ADDRH [34:32]	0h	RW	AXI-VD bus transfer completion event address 1 for video data (higher) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(38) AXI-VD Bus Transfer Completion Event Address 2 Lower Register (CRUm_AMnIVT2ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 00C4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IVT2ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IVT2ADDRL[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IVT2ADDRL [31:0]	0h	RW	AXI-VD bus transfer completion event address 2 for video data (lower) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(39) AXI-VD Bus Transfer Completion Event Address 2 Higher Register (CRUm_AMnIVT2ADDRH) (m = 0)

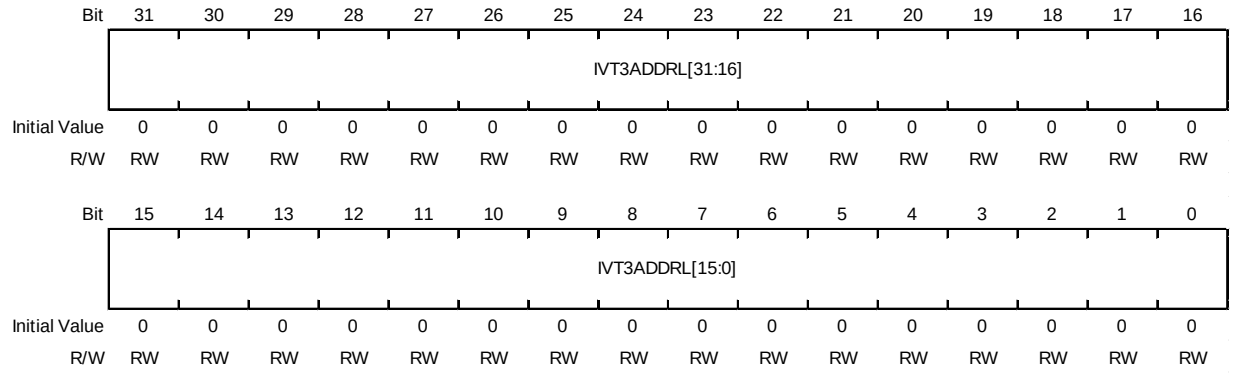
Access Size : 32 bits

Address : <CRUm_base> + 00C8h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	IVT2ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW



Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	IVT2ADDRH [34:32]	0h	RW	AXI-VD bus transfer completion event address 2 for video data (higher) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(40) AXI-VD Bus Transfer Completion Event Address 3 Lower Register (CRUm_AMnIVT3ADDRL) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00CCh

Initial Value : 0000_0000h

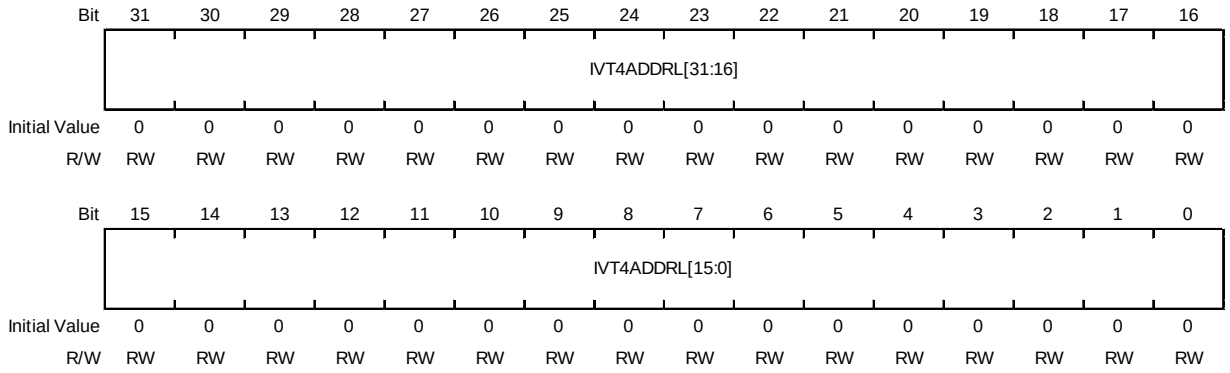
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IVT3ADDRL [31:0]	0h	RW	AXI-VD bus transfer completion event address 3 for video data (lower) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(41) AXI-VD Bus Transfer Completion Event Address 3 Higher Register (CRUm_AMnIVT3ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00D0h

Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	IVT3ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	IVT3ADDRH [34:32]	0h	RW	AXI-VD bus transfer completion event address 3 for video data (higher) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(42) AXI-VD Bus Transfer Completion Event Address 4 Lower Register (CRUm_AMnIVT4ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 00D4h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IVT4ADDRL [31:0]	0h	RW	AXI-VD bus transfer completion event address 4 for video data (lower) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(43) AXI-VD Bus Transfer Completion Event Address 4 Higher Register (CRUm_AMnIVT4ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 00D8h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	IVT4ADDRH [34:32]	0h	RW	AXI-VD bus transfer completion event address 4 for video data (higher) Note: The completion of transfer of video data to the address set in this register is notified by an interrupt.

(44) AXI-VD Bus Master Transfer Setting Register (CRUm_AMnAXIATTR) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 00ECh
Initial Value : 0020_0150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	R	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	AXILEN[3:0]			
Initial Value	0	0	0	0	0	0	0	1	0	1	0	1	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
27 to 24	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
23	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
22 to 16	-	20h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
15 to 10	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
9, 8	-	1h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
7	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
6 to 4	-	5h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
3 to 0	AXILEN[3:0]	0h	RW	Maximum value setting of AXI-VD burst length for video data (changing the value during AXI-VD operation is prohibited) Note: If the transfer speed is given priority, set AXILEN[3:0] = Fh. When YUV is not separated (ICnDMR.YCMODE[2:0]≠010b or 110b): 0h: Up to 1 burst (initial value) 1h: Up to 2 bursts 2h: Up to 3 bursts 3h: Up to 4 bursts 4h: Up to 5 bursts 5h: Up to 6 bursts ⋮ Fh: Up to 16 bursts (recommended value) When YUV is separated (ICnDMR.YCMODE[2:0] = 010b or 110b): 0h: Up to 1 burst 1h: Up to 1 burst 2h: Up to 2 bursts 3h: Up to 2 bursts 4h: Up to 3 bursts 5h: Up to 3 bursts ⋮ Eh: Up to 8 bursts Fh : Up to 8 bursts (recommended value)

(45) AXI-VD Bus Master FIFO Pointer Register (CRUm_AMnFIFOPNTR) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 00F8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FIFORPNTR_B1[7:0]								FIFORPNTR_B0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FIFOWPNTR_B1[7:0]								FIFOWPNTR_B0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	FIFORPNTR_B1[7:0]	0h	R	FIFO-VD read pointer (bank 1) The read pointer and write pointer comparison allows checking if there are data in the FIFO. Bank 1 FIFO-VD read pointer [7:0] Real RAM address for FIFO-VD (Max.: FFh) Note : When (AMnFIFOPNTR.FIFOWPNTR_B0[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B0[7:0])‖(AMnFIFOPNTR.FIFOWPNTR_B1[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B1[7:0], data are present in the FIFO-VD.
23 to 16	FIFORPNTR_B0[7:0]	0h	R	FIFO-VD read pointer (bank 0) The read pointer and write pointer comparison allows checking if there are data in the FIFO. Bank 0 FIFO-VD read pointer [7:0] Real RAM address for FIFO-VD (Max.: FFh) Note: When (AMnFIFOPNTR.FIFOWPNTR_B0[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B0[7:0])‖(AMnFIFOPNTR.FIFOWPNTR_B1[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B1[7:0], data are present in the FIFO-VD.
15 to 8	FIFOWPNTR_B1[7:0]	0h	R	FIFO-VD write pointer (bank 1) The read pointer and write pointer comparison allows checking if there are data in the FIFO. Bank 1 FIFO-VD write pointer [7:0] Real RAM address for FIFO-VD (Max.: FFh) Note: When (AMnFIFOPNTR.FIFOWPNTR_B0[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B0[7:0])‖(AMnFIFOPNTR.FIFOWPNTR_B1[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B1[7:0], data are present in the FIFO-VD.
7 to 0	FIFOWPNTR_B0[7:0]	0h	R	FIFO-VD write pointer (bank 0) The read pointer and write pointer comparison allows checking if there are data in the FIFO. Bank 0 FIFO-VD write pointer [7:0] Real RAM address for FIFO-VD (Max.: FFh) Note: When (AMnFIFOPNTR.FIFOWPNTR_B0[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B0[7:0])‖(AMnFIFOPNTR.FIFOWPNTR_B1[7:0]≠ AMnFIFOPNTR.FIFORPNTR_B1[7:0], data are present in the FIFO-VD.

(46) AXI-VD Bus Master FIFO Setting Register (CRUm_AMnFIFO)

Access Size : 32 bits

Address : <CRUm_base> + 00F0h

Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	RETSVC[2:0]			-	-	-	FIFOOVFREC
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	RW	RW	RW	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
6 to 4	RETSVC[2:0]	0h	RW	SVC number setting to resume when FIFO-VD overflow 000b : Resume from the beginning of SVC0 frame (initial value) 001b : Resume from the beginning of the SVC1 frame 010b : Resume from the beginning of the SVC2 frame 011b: Resume from the beginning of the SVC3 frame 1xxb : Resume from the VC first frame that came, without SVC designation
3 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	FIFOOVFREC	1h	RW	Mode setting when image data FIFO-VD overflows When a FIFO-VD overflows, the FIFO-VD is cleared and the AXI-VD master stops transferring to memory. There are two methods as shown below. 0b: Recovery mode: The AXI-VD Master performs the following operations after stopped. - Resume import from SVC selected by AMnFIFO.RETSVC[2:0] - Resume writing from the beginning of the overflow MB 1b: Stop mode (default): The FIFO remains stopped after the overflow occurs. [How to resume] When the AXI-VD master stops, it updates the FOS bit in the CRUnINTS1 register and reg_axi_mst_err_int Interrupts are generated. Set the AXI_TRANS_START bit of the AMnFIFOTRST register to 1 after detection. After this, the operation resumes with the same behavior as in recovery mode. Note 1: The image data being processed will be corrupted during FIFO overflow. FIFO overflow may be caused by bus congestion. Please take measures to alleviate bus congestion. Note 2: The data for the first horizontal line after FIFO-VD overflow return is not guaranteed. Note 3: If set Footer appending ON (ICnDTVP.FTON=1), only if no FIFO-VD overflow occurs. Set to Footer appending OFF (ICnDTVP.FTON=0), when FIFO-VD will overflow occurs.

(47) AXI-VD Bus Master Transfer Resume Register (CRUm_AMnFIFOTRST)

Access Size : 32 bits

Address : <CRUm_base> + 00F4h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	AXI_TRANS_START
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW1

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	AXI_TRANS_START	0h	RW1	AXI-VD transfer control for image data (valid when AMnFIFO.FIFOOVFREC = 1). 0b: Writing prohibited. Write 1 to this bit to recover the image-related AXI-VD (transfer resume) (This bit returns to 0 when transfer is resumed.)

(48) AXI-VD Bus Master Transfer Stop Register (CRUm_AMnAXISTP) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0110h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	AXI_STOP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	AXI_STOP	0h	RW	AXI-VD bus transfer stop (used to stop the CRU receiving data. Follow the procedure for stopping reception described in **9.2.5.2 Stopping Reception for the MIPI CSI-2 Input.**) 0b: Does not stop the AXI-VD master transferring data. 1b: Stops the AXI-VD master transferring data.

(49) AXI-VD Bus Master Transfer Stop Status Register (CRUm_AMnAXISTPACK) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0114h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	AXI_STOP_ACK
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	AXI_STOP_ACK	0h	R	AXI-VD bus transfer stop response (used to stop the CRU receiving data. Follow the procedure for stopping reception described in **9.2.5.2 Stopping Reception for the MIPI CSI-2 Input.**) 0b: The AXI-VD master is transferring data. 1b: The AXI-VD master has finished transferring data (valid when AXI_STOP = 1)

(50) Image Stride Setting Register (CRUm_AMnIS) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0128h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	IS[7:0]								-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
14 to 7	IS[7:0]	0h	RW	Line start address offset setting for image stride You can set 128 to 32640 bytes (with a 128-byte step) by setting IS[7:0]. IS[7:0] = 00h: Setting prohibited IS[7:0] = 01h: 128 bytes IS[7:0] = 02h: 256 bytes IS[7:0] = 03h: 384 bytes IS[7:0] = 04h: 512 bytes ⋮ IS[7:0] = 80h: 16384 bytes ⋮ IS[7:0] = FFh: 32640 bytes Note: For output format RGB888 (24 bits), the setting must be in units of 384 bytes (multiples of 3 for IS [7:0]). Note: If the output format is other than RGB888 (24 bits), the setting must be in units of 128 bytes. Note: The setting must be at least the number of bytes per line. Note: When adding a header and footer, set the value including a header and footer. Note: Only data output from the video data bus are supported. Statistics data output is not supported.
6 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(51) Memory Bank 1 Base Address Lower Register for CRU Statistics Data (CRUm_AMnSDMB1ADDRL) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 013Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SDMB1ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SDMB1ADDRL[15:9]							-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	SDMB1ADDRL [31:9]	0h	RW	Statistics data transfer destination base address 1 (valid bits: [31:9]) Set it as the base address in units of 512 bytes. Note: The 9 lower-order bits cannot be written. (These bits cannot be modified while the AXI-VD is operating.)
8 to 0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(52) Memory Bank 1 Base Address Higher Register for CRU Statistics Data (CRUm_AMnSDMB1ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0140h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	SDMB8ADDRH [34:32]	0h	RW	Statistics data transfer destination base address 8 (valid bits: [34:32]) (These bits cannot be modified while the AXI-SD is operating.)

(67) Memory Bank Enable Register for CRU Statistics Data (CRUm_AMnSDMBVALID) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 018Ch
Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	SDMBVALID[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
7 to 0	SDMBVALID [7:0]	1h	RW	Statistics data transfer destination valid address (the details are described in **9.2.4.3.3 Transfer to DRAM**.) [0]: 0: SDMB1 invalid, 1: SDMB1 valid [1]: 0: SDMB2 invalid, 1: SDMB2 valid [2]: 0: SDMB3 invalid, 1: SDMB3 valid [3]: 0: SDMB4 invalid, 1: SDMB4 valid [4]: 0: SDMB5 invalid, 1: SDMB5 valid [5]: 0: SDMB6 invalid, 1: SDMB6 valid [6]: 0: SDMB7 invalid, 1: SDMB7 valid [7]: 0: SDMB8 invalid, 1: SDMB8 valid Note: Set the valid destination address from the LSB continuously. Data transferred from the LSB are written sequentially only to valid memory banks, and the processing is repeated from the start (LSB) when the last address is reached. (These bits cannot be modified while the AXI-SD is operating.)

(68) Memory Bank Status Register for CRU Statistics Data (CRUm_AMnSDMBS) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0190h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SDMBSTS[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	SDMBSTS[2:0]	0h	R	Indicates which memory bank from SDMB1 to SDMB8 the statistics data are being transferred to. (0h: SDMB1, 1h: SDMB2 … 6h: SDMB7, 7h: SDMB8)

(69) AXI-SD Bus Transfer Completion Event Address 0 Lower Register (CRUm_AMnSDIVT0ADDRL) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0194h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SDIVT0ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SDIVT0ADDRL[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SDIVT0ADDRL [31:0]	0h	RW	AXI-SD bus transfer completion event address 0 for statistics data (lower) Note: The completion of transfer of statistics data to the address set in this register is notified by an interrupt.

(70) AXI-SD Bus Transfer Completion Event Address 0 Higher Register (CRUm_AMnSDIVT0ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0198h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SDIVT0ADDRH[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	SDIVT0ADDRH [34:32]	0h	RW	AXI-SD bus transfer completion event address 0 for statistics data (higher) Note: The completion of transfer of statistics data to the address set in this register is notified by an interrupt.

(71) AXI-SD Bus Transfer Completion Event Address 1 Lower Register (CRUm_AMnSDIVT1ADDRL) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 019Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SDIVT1ADDRL[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SDIVT1ADDRL[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SDIVT1ADDRL [31:0]	0h	RW	AXI-SD bus transfer completion event address 1 for statistics data (lower) Note: The completion of transfer of statistics data to the address set in this register is notified by an interrupt.

(72) AXI-SD Bus Transfer Completion Event Address 1 Higher Register (CRUm_AMnSDIVT1ADDRH) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 01A0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
2 to 0	SDIVT1ADDRH [34:32]	0h	RW	AXI-SD bus transfer completion event address 1 for statistics data (higher) Note: The completion of transfer of statistics data to the address set in this register is notified by an interrupt.

(73) AXI-SD Bus Master FIFO Pointer Register (CRUm_AMnSDFIFOPNTR) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 01C0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	SDFIFORPNTR[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	SDFIFOWPNTR[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
21 to 16	SDFIFORPNTR [5:0]	0h	R	FIFO-SD read pointer for statistics data The read pointer and write pointer comparison allows checking if there are data in the FIFO. FIFO-SD read pointer [5:0] Real RAM address for FIFO-SD (Max.: 3Fh) Note: When (AMnSDFIFOPNTR.SDFIFOWPNTR[5:0]≠AMnSDFIFOPNTR.SDFIFORPNTR[5:0]), data are present in the FIFO-SD.
15 to 6	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
5 to 0	SDFIFOWPNTR [5:0]	0h	R	FIFO-SD write pointer for statistics data The read pointer and write pointer comparison allows checking if there are data in the FIFO. Bank 1 FIFO-SD write pointer [5:0] Real RAM address for FIFO-SD (Max.: 3Fh) Note: When (AMnSDFIFOPNTR.SDFIFOWPNTR[5:0]≠AMnSDFIFOPNTR.SDFIFORPNTR[5:0]), data are present in the FIFO-SD.

(74) AXI-SD Bus Master Transfer Stop Register (CRUm_AMnSDAXISTP) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 01D8h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SD_AXI_STOP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	SD_AXI_STOP	0h	RW	Statistics data AXI-SD transfer stop (used to stop the CRU receiving data. Follow the procedure for stopping reception described in **9.2.5.2 Stopping Reception for the MIPI CSI-2 Input**.) 0b: Does not stop the AXI-SD master transferring data. 1b: Stops the AXI-SD master transferring data.

(75) AXI-SD Bus Master Transfer Stop Status Register (CRUm_AMnSDAXISTPACK) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 01DCh

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SD_AXI_STOP_ACK
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	SD_AXI_STOP_ACK	0h	R	Statistics data AXI-SD transfer stop response (used to stop the CRU receiving data. Follow the procedure for stopping reception described in **9.2.5.2 Stopping Reception for the MIPI CSI-2 Input**.) 0b: The AXI-SD master is transferring data. 1b: The AXI-SD master has finished transferring data (valid when AXI_STOP = 1)

(76) CRU Image Converter Enable Register (CRUm_ICnEN) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 01F0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ICEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	ICEN	0h	RW	Enables the operation of the Image Converter module. (Enable or disable the operation according to **9.2.5 Operation**.) 0b: Disables the Image Converter module. 1b: Enables the Image Converter module. Note: If this bit is set to 0, a frame start is not detected. If this bit is changed from 1 to 0 while a frame is being processed, the data at that time is processed as the frame end and then the next frames are not processed.

(77) CRU Data Value Processing (CRUm_ICnDTVP) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 01F4h

Initial Value : 0000_0003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	420UVIS	-	-	FTON	HDON	-	IBINSEL	CLP[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R	RW	R	R	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
8	420UVIS	0h	RW	When set to YUV420 Y/UV separation (ICnDMR.YCMODE[2:0] = 110b), the Image Stride setting on the U/V side. 0 : U/V side Image Stride=AMnIS.IS×2 (default) 1 : U/V side Image Stride=AMnIS.IS×1 (NV12)
7, 6	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
5	FTON	0h	RW	Footer appending ON/OFF 0: Do not append a footer 1: Append a footer Note: The footer of both Video Data and Statistics Data are turned ON/OFF. Note: Video Data footers write a 256-bit (256'd1/256'd0) footer at the end of each line unit. Initially, 1h is written as a footer. When the memory banks are full and overwriting starts with the next round of writing, 0h is written as the footer. After that, 1h and 0h are written alternately every time the memory bank is overwritten. Note: The footer of Statistics Data writes a 512-bit Footer ({upper 256bit: Reserve (indefinite value), lower 256bit: 256'd1}/512bit {upper 256bit: Reserve (indefinite value), lower 256bit: 256'd0}) at the end of each frame unit). The upper 256 bits of 512 bits are Reserve (indefinite value), so please skip reading it. Initially, 512 bits {upper 256bit: reserve (indefinite value), lower 256bit: 256'd1} are written as footer. Next, when the memory bank goes around one lap and overwrites, 512 bits {upper 256bit: reserve (irdefinite value), lower 256bit: 256'd0} are written as footer. After that, 512 bits {upper 256bit: reserve (indefinite value), lower 256bit: 256'd1} and 512bit {upper 256bit: reserve (irdefinite value), lower 256bit: 256'd0} are written alternately each time it is overwritten.
4	HDON	0h	RW	Header appending ON/OFF ON/OFF selection for whether to append a header to the start of a line for transfer data from the AXI-VD bus to DRAM 0: Do not append a header 1: Append a header Note: The data type, byte number, and virtual channel number are added to the header (256 bits). Note: See **9.2.4.3.3 (5) Frame Structure**.
3	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
2	IBINSEL	0h	RW	Data Arranger 1 UV(CbCr) binary type selection for YUV422(YCbCr) data 0b: Offset binary (straight binary) 1b: Two's complement binary Note: Valid when the input is YUV422/420.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	CLP[1:0]	3h	RW	Data clipping setting for the YCbCr422 (YUV422) format To make the input data compliant with the ITU-R BT.601 standard, specify whether to clip the values below 16 and above 240 (when YCbCr is 8 bits). When CRUm_ICnIPMC_C0/X.CSCTHR is set to 1, CLP[1:0] are set to 00b. 00b: No clipping for Y When CbCr is 8 bits: Values below 16 and above 240 are clipped for CbCr When CbCr is 10 bits: Values below 64 and above 960 are clipped for CbCr 01b: When YCbCr is 8 bits: Values below 16 and above 240 are clipped for Y : Values below 16 and above 240 are clipped for CbCr When YCbCr is 10 bits: Values below 64 and above 960 are clipped for Y : Values below 64 and above 960 are clipped for CbCr 10b: No clipping for Y When CbCr is 8 bits: Values below 16 are increased to 128 and values above 240 are clipped to 128 for CbCr When CbCr is 10 bits: Values below 64 are increased to 512 and values above 960 are clipped to 512 for CbCr 11b: No clipping for Y and CbCr (initial value) Note: See **9.2.4.3.10 Data Clipping** .

(78) CRU SVC Number Register (CRUm_ICnSVCNUM) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 01F8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SVCNUM[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
1, 0	SVCNUM[1:0]	0h	RW	Set how many channels are used from among SVC0 to 3. 00b: Only SVC0 enabled; SVC1 to 3 disabled (initial value) 01b: SVC0 and 1 enabled; SVC2 and 3 disabled 10b: SVC0 to 2 enabled; SVC3 disabled 11b: SVC0 to 3 enabled Note: When changing the frame synchronization register, only the setting of ICnSVCNUM.SVCNUM [1:0] = 00 can be used. Note: Select virtual channels for SVC0 to 3 by the ICnSVC register setting. Note: When using demosaicing, linear matrix, or statistics, the setting of this must be 00b.

(79) CRU VC Select Register (CRUm_ICnSVC) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 01FCh
Initial Value : 0000_3210h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SVC3[3:0]				SVC2[3:0]				SVC1[3:0]				SVC0[3:0]			
Initial Value	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
15 to 12	SVC3[3:0]	3h	RW	Selected Virtual Channel 3 (SVC3) The maximum number of channels that can be used by the image converter is 4 (SVC0~3). Assign one of VC0~15 to SVC3. 0h: Virtual channel 0 selected 1h: Virtual channel 1 selected 2h: Virtual channel 2 selected : Eh: Virtual channel 14 selected Fh: Virtual channel 15 selected Note: Do not set the same value as other SVC0/1/2[3:0].
11 to 8	SVC2[3:0]	2h	RW	Selected Virtual Channel 2 (SVC2) The maximum number of channels that can be used by the image converter is 4 (SVC0~3). Assign one of VC0~15 to SVC2. 0h: Virtual channel 0 selected 1h: Virtual channel 1 selected 2h: Virtual channel 2 selected : Eh: Virtual channel 14 selected Fh: Virtual channel 15 selected Note: Do not set the same value as other SVC0/1/3[3:0].
7 to 4	SVC1[3:0]	1h	RW	Selected Virtual Channel 1 (SVC1) The maximum number of channels that can be used by the image converter is 4 (SVC0~3). Assign one of VC0~15 to SVC1. 0h: Virtual channel 0 selected 1h: Virtual channel 1 selected 2h: Virtual channel 2 selected : Eh: Virtual channel 14 selected Fh: Virtual channel 15 selected Note: Do not set the same value as other SVC0/2/3[3:0].
3 to 0	SVC0[3:0]	0h	RW	Selected Virtual Channel 0 (SVC0) The maximum number of channels that can be used by the image converter is 4 (SVC0~3). Assign one of VC0~15 to SVC0. 0h: Virtual channel 0 selected 1h: Virtual channel 1 selected 2h: Virtual channel 2 selected : Eh: Virtual channel 14 selected Fh: Virtual channel 15 selected Note: Do not set the same value as other SVC1/2/3[3:0].

(80) CRU Image Converter Main Control Register (SVC0) (CRUm_ICnIPMC_C0) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0200h
Initial Value : 001E_00FEh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	RAWSTTYP [1:0]		-	-	INF[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W	R	R	R	R	R	R	RW	RW	R	R	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	STITHR	LUTTHR	CSCTHR	LMXTHR	DEMTHR	CLPTHR	DECTHR	-
Initial Value	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
25, 24	RAWSTTYP [1:0]	0h	RW	Specify the color component of the first pixel of the first line of RAW data for SVC0 00b: R (RGrRGr...) 01b: Gr (GrRGrR...) 10b: Gb (GbBGbB...) 11b: B (BGbBGb...)
23, 22	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
21 to 16	INF[5:0]	1Eh	RW	Specify the MIPI input image formats for SVC0 to be processed by the image converter module. For details about the formats, see Data Type Codes in the MIPI CSI-2 V2.1 specification. Of the formats specified here, only one format is processed. Note 1. Initial value: YUV422 8-bit Note 2. The following values can be set. Other settings are prohibited. 13h to 16h: Generic Long Packet Data Type 18h to 1Ah, 1Ch to 1Fh: YUV Data 20h to 24h: RGB Data 28h to 2Fh: RAW Data 30h to 37h: User-Defined Byte-based Data The data types specified here must be set in CSI2nDTEL.DTEN and CSI2nDTEH.DTEN of MIPI CSI2.
15 to 8	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
7	STITHR	1h	RW	Bypassing statistics processing for SVC0 (the details are described in **9.2.4.3.18 Statistics**.) 0b: Statistics processing is performed. 1b: Statistics processing is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
6	LUTTHR	1h	RW	Bypassing LUT-based image color conversion for SVC0 (the details are described in **9.2.4.3.14 LUT (Lookup Table)**.) Regardless of whether the setting of this bit is 0b or 1b, the output of the LUT is 8 bits for 10-bit input. 0b: Image color conversion is performed. 1b: Image color conversion is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
5	CSCTHR	1h	RW	Bypassing color space conversion and Data clipping for SVC0 (YCbCr(YUV) → RGB, RGB → YCbCr(YUV)) (the details are described in **9.2.4.3.13 Color Space Conversion**.) 0b: Color space conversion and Data clipping are performed. 1b: Color space conversion and Data clipping are not performed (bypassed). Note 1. The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**. Note 2. Even when this bit is 1, the data is expanded from 8 bits to 10 bits.

Bit	Bit Name	Initial Value	R/W	Description
4	LMXTHR	1h	RW	Bypassing liner matrix processing for SVC0 (the details are described in **9.2.4.3.12 Liner Matrix**.) 0b: Liner matrix processing is performed. 1b: Liner matrix processing is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
3	DEMTHR	1h	RW	Bypassing demosaicing of RAW data for SVC0 (the details are described in **9.2.4.3.11 Demosaicing**.) 0b: Demosaicing is performed. 1b: Demosaicing is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
2	CLPTHR	1h	RW	Bypassing image clipping for SVC0 (the details are described in **9.2.4.3.7 Image Clipping**.) 0b: Image clipping is performed. 1b: Image clipping is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
1	DECTHR	1h	RW	Bypassing frame subsampling for SVC0 (the details are described in **9.2.4.3.8 Frame Subsampling**.) 0b: Subsampling is performed. 1b: Subsampling is not performed (bypassed). Note: Image processing, non-image processing, and statistics data are supported. Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(81) CRU Image Converter Main Control Register (SVCx) (CRUm_ICnIPMC_Cx) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0258h (x = 1)
<CRUm_base> + 025Ch (x = 2)
<CRUm_base> + 0260h (x = 3)

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
25. 24	-	0h	RW	Reserved These bits are read as 0b. The written value will be always be 0b.
23, 22	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
21 to 16	INF[5:0]	1Eh	RW	Specify the MIPI input image formats for SVCx to be processed by the image converter module. For details about the formats, see Data Type Codes in the MIPI CSI-2 V2.1 specification. Of the formats specified here, only one format is processed. Note 1. Initial value: YUV422 8-bit Note 2. The following values can be set. Other settings are prohibited. 13h to 16h: Generic Long Packet Data Type 18h to 1Ah, 1Ch to 1Fh: YUV Data 20h to 24h: RGB Data 28h to 2Fh: RAW Data 30h to 37h: User-Defined Byte-based Data The data types specified here must be set in CSI2nDTEL.DTEN and CSI2nDTEH.DTEN of MIPI CSI2.
15 to 7	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
6	LUTTHR	1h	RW	Bypassing LUT-based image color conversion for SVCx (the details are described in **9.2.4.3.14 LUT (Lookup Table)**.) Regardless of whether the setting of this bit is 0b or 1b, the output of the LUT is 8 bits for 10-bit input. 0b: Image color conversion is performed. 1b: Image color conversion is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
5	CSCTHR	1h	RW	Bypassing color space conversion and Data clipping for SVCx (YCbCr(YUV) → RGB, RGB → YCbCr(YUV)) (the details are described in **9.2.4.3.13 Color Space Conversion**.) 0b: Color space conversion and Data clipping are performed. 1b: Color space conversion and Data clipping are not performed (bypassed). Note 1. The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**. Note 2. Even when this bit is 1, the data is expanded from 8 bits to 10 bits.
4, 3	-	0h	RW	Reserved These bits are read as 0b. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
2	CLPTHR	1h	RW	Bypassing image clipping for SVCx (the details are described in **9.2.4.3.7 Image Clipping**.) 0b: Image clipping is performed. 1b: Image clipping is not performed (bypassed). Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
1	DECTHR	1h	RW	Bypassing frame subsampling for SVCx (the details are described in **9.2.4.3.8 Frame Subsampling**.) 0b: Subsampling is performed. 1b: Subsampling is not performed (bypassed). Note: Image processing, non-image processing, and statistics data are supported. Note: The setting 0b only applies for the corresponding formats shown in **9.2.4.3.1 Input Formats and Image Processing**.
0	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.

(82) CRU Non Image Process Data Type Code Select Lower Register (SVCx) (CRUm_ICnNIPDT_CxL) (m = 0)

Access Size : 32 bits

	-	-	-	-	-	-	-	-	-	-	-	-	-	-	STUNIT[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
19 to 16	STSADPOS [3:0]	0h	RW	Input data bit position selection (0-8) for the sum of absolute differences for adjacent pixels for statistics processing of SVC0 Use the 8 lower-order bits from the MSB-"n" bit for each type of RAW. Example: For RAW 16, use input data [15-n:8-n]. Note: Comply with the restrictions described in ICnSTIC1.STUNIT. Note: Only image processing data are supported.
15 to 2	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
1, 0	STUNIT[1:0]	0h	RW	Selecting an arithmetic processing unit for SVC0 statistics processing 0: 16x16 pixels 1: 32x32 pixels 2: 64x64 pixels 3: 128x128 pixels Note: Only image processing data are supported.

(97) CRU Image Converter Register Setting Change Control Register (CRUm_ICnREGC) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0244h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	REFEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW1

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	REFEN	0h	RW1	Allows register setting changes to be reflected. By using this register for an MIPI CSI-2 input, the registers at offset addresses 01FCh to 023Ch can be changed through frame synchronization during operation. (Allow or disallow this according to **9.2.5.3 Frame Synchronization Settings**.) 0b: Does not allow register setting changes to be reflected. 1b: Allows register setting changes to be reflected. Note: If this bit is set to 1 while the Image Converter module is operating (ICnEN.ICEN = 1), the register setting values (at offset addresses 01FCh to 023Ch) are reflected at a frame start, and then the bit is cleared to 0 automatically. Note: If the Image Converter module is stopped (ICnEN.ICEN = 0), the register setting values can be reflected irrespective of this register. Note that registers other than the above cannot be changed during operation. Note: Only image processing data are supported.

(98) CRU Module Status Register (CRUm_ICnMS) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 02D8h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	IA3	AV3	CA3	-	IA2	AV2	CA2	-	IA1	AV1	CA1	-	IA0	AV0	CA0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
14	IA3	0h	R	Indicates whether the Image Converter block (the module converting the video data input up to the pre-FIFO-VD/SD stage) is processing data. (for SVC3) 0b: Video/statistics data have not been received. 1b: Video/statistics data are being converted.
13	AV3	0h	R	Indicates whether processing is performed within the image-clipped area. (for SVC3) (For details, see **9.2.4.3.7 Image Clipping**.) 0b: Processing is performed outside the image-clipped area. 1b: Processing is performed within the image-clipped area. Note: Only image processing data are supported.
12	CA3	0h	R	Indicates whether the frame is subsampled. (for SVC3) (For details, see **9.2.4.3.8 Frame Subsampling**.) 0b: A subsampled frame is being processed. 1b: A frame which is not subsampled is being processed. Note: This bit is 0 when CRUnRST.VRESETN is 0. This bit is set to 1 two cycles of PCLK after CRUnRST.VRESETN has been changed from 0 to 1. Note: Only image processing data are supported.
11	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
10	IA2	0h	R	Indicates whether the Image Converter block (the module converting the video data input up to the pre-FIFO-VD/SD stage) is processing data. (for SVC2) 0b: Video/statistics data have not been received. 1b: Video/statistics data are being converted.
9	AV2	0h	R	Indicates whether processing is performed within the image-clipped area. (for SVC2) (For details, see **9.2.4.3.7 Image Clipping**.) 0b: Processing is performed outside the image-clipped area. 1b: Processing is performed within the image-clipped area. Note: Only image processing data are supported.
8	CA2	0h	R	Indicates whether the frame is subsampled. (for SVC2) (For details, see **9.2.4.3.8 Frame Subsampling**.) 0b: A subsampled frame is being processed. 1b: A frame which is not subsampled is being processed. Note: This bit is 0 when CRUnRST.VRESETN is 0. This bit is set to 1 two cycles of PCLK after CRUnRST.VRESETN has been changed from 0 to 1.
7	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
6	IA1	0h	R	Indicates whether the Image Converter block (the module converting the video data input up to the pre-FIFO-VD/SD stage) is processing data. (for SVC1) 0b: Video/statistics data have not been received. 1b: Video/statistics data are being converted. Note: Only image processing data are supported.

Bit	Bit Name	Initial Value	R/W	Description
5	AV1	0h	R	Indicates whether processing is performed within the image-clipped area. (for SVC1) (For details, see **9.2.4.3.7 Image Clipping**.) 0b: Processing is performed outside the image-clipped area. 1b: Processing is performed within the image-clipped area.
4	CA1	0h	R	Indicates whether the frame is subsampled. (for SVC1) (For details, see **9.2.4.3.8 Frame Subsampling**.) 0b: A subsampled frame is being processed. 1b: A frame which is not subsampled is being processed. Note: This bit is 0 when CRUnRST.VRESETN is 0. This bit is set to 1 two cycles of PCLK after CRUnRST.VRESETN has been changed from 0 to 1.
3	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
2	IA0	0h	R	Indicates whether the Image Converter block (the module converting the video data input up to the pre-FIFO-VD/SD stage) is processing data. (for SVC0) 0b: Video/statistics data have not been received. 1b: Video/statistics data are being converted.
1	AV0	0h	R	Indicates whether processing is performed within the image-clipped area. (for SVC0) (For details, see **9.2.4.3.7 Image Clipping**.) 0b: Processing is performed outside the image-clipped area. 1b: Processing is performed within the image-clipped area. Note: Only image processing data are supported.
0	CA0	0h	R	Indicates whether the frame is subsampled. (for SVC0) (For details, see **9.2.4.3.8 Frame Subsampling**.) 0b: A subsampled frame is being processed. 1b: A frame which is not subsampled is being processed. Note: This bit is 0 when CRUnRST.VRESETN is 0. This bit is set to 1 two cycles of PCLK after CRUnRST.VRESETN has been changed from 0 to 1.

(99) CRU Frame Subsampling Control Register (CRUm_ICnDEC) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 02DCh

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	FRMDEC[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
3 to 0	FRMDEC[3:0]	0h	RW	Subsampling interval in frame subsampling (For details, see **9.2.4.3.8 Frame Subsampling**.) 0h: All images are passed. 1h: One pass every two frames 2h: One pass every three frames Omitted 14h: One pass every 15 frames 15h: One pass every 16 frames Note: Image processing and non-image processing and statistics data are supported.

(100) CRU Line Count Register (SVCx) (CRUm_ICnLC_Cx) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 02E0h (x = 0)
<CRUm_base> + 02E4h (x = 1)
<CRUm_base> + 02E8h (x = 2)
<CRUm_base> + 02ECh (x = 3)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	LC[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
12 to 0	LC[12:0]	0h	R	Indicate the line counter value before image clipping and subsampling by the Image Converter module. (for SVCx) Note: Only image processing data are supported. Note: The maximum line value is 1000h.

(101) CRU Frame Subsampling Interrupt Control Register (CRUm_ICnINTCTRL) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0300h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DECINTE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	DECINTE	0h	RW	Specifies whether an interrupt (CRUnINTS2.FS0/1/2/3S, CRUnINTS2.FE0/1/2/3S, or CRUnINTS2.SL0/1/2/3S) is generated for a subsampled frame. 0b: No interrupt is generated for a subsampled frame. (Initial value) 1b: An interrupt is generated for a subsampled frame. Note: Image processing and non-image processing and statistics data are supported.

(102) CRU Output Image Format Register (CRUm_ICnDMR) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0304h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A8BIT[7:0]								-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	OBINSEL	-	YCMODE[2:0]			-	-	RGBMODE[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	RW	RW	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	A8BIT[7:0]	0h	RW	Alpha bit for AXI-VD bus Alpha value in the ARGB8888 format output Note: The default value is 0h, so it is transparent. Note: This bit is valid when ICnDMR.RGBMODE[1:0]=10b,11b.
23 to 9	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
8	OBINSEL	0h	RW	Data Arranger 2 UV(CbCr) binary type selection for YUV422(YCbCr) data 0b: Offset binary (straight binary) 1b: Two's complement binary Note: Valid when the output is YUV422/420.
7	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
6 to 4	YCMODE[2:0]	0h	RW	YC output data format selection for AXI-VD bus 000b: YCbCr422, 8-bit multiplexed (YUYV format (Y 1st)) 001b: YCbCr422, 8-bit multiplexed (UYVY format (Cb 1st)) 010b: YC separation from YCbCr422 011b: Y component extraction from YCbCr422 100b: YCbCr420, 8-bit multiplexed (YUYV format (Y 1st)) 101b: YCbCr420, 8-bit multiplexed (UYVY format (Cb 1st)) 110b : YC Separation of YCbCr420 *The CbCr (UV) side Image Stride changes in the register setting of ICnDTVP.420UVIS. 111b : Y component extraction of YCbCr420 (equivalent to YUV422)
3, 2	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
1, 0	RGBMODE[1:0]	0h	RW	RGB output data format selection for AXI-VD bus 00b: RGB888 (24-bit) 01b: RGB888 (32-bit) (The eight higher-order bits are padded with 00h.) 10b: ARGB888 (32-bit, B First A Last) 11b: ARGB888 (32-bit, A First B Last)

(103) CRU YCbCr → RGB Color Space Conversion Coefficient 1 Register (CRUm_ICnCSCC1) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0308h
Initial Value : 0000_129Fh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	YMUL[13:0]													
Initial Value	0	0	0	1	0	0	1	0	1	0	0	1	1	1	1	1
R/W	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
13 to 0	YMUL[13:0]	129Fh	RW	Y data multiplication coefficient These bits specify a Y data multiplication coefficient in YCbCr → RGB color space conversion. (Initial value: 1.164) Specify an unsigned 14-bit integer which is the desired coefficient value multiplied by 4096.

(104) CRU YCbCr → RGB Color Space Conversion Coefficient 2 Register (CRUm_ICnCSCC2) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 030Ch

Initial Value : 0100_0800h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
27 to 16	YSUB[11:0]	100h	RW	Y data subtraction coefficient These bits specify a Y data subtraction coefficient in YCbCr → RGB color space conversion. Specify an unsigned 12-bit integer. Calculate on 12 bits extended from YCbCr422 8-/10-bit.
15 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11 to 0	CSUB[11:0]	800h	RW	CbCr data subtraction coefficient These bits specify a Cb and Cr data subtraction coefficient in YCbCr → RGB color space conversion. Specify an unsigned 12-bit integer. Calculate on 12 bits extended from YCbCr422 8-/10-bit.

(105) CRU YCbCr → RGB Color Space Conversion Coefficient 3 Register (CRUm_ICnCSCC3) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0310h
Initial Value : 1989_0D02h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16	CRCLCEN	0h	RW	Cr Calculation Data Clip Enable (Data Clipping Process Control for Cr Data Calculation in RGB → YCbCr Color Space Conversion) 0: Data clipping is not performed 1: Data clipping is performed
15 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11 to 0	CRCLAP[11:0]	800h	RW	Value added for normalization of Cr calculation data (specification of Cr data addition constant in RGB → YCbCr color space conversion)

(116) CRU Lookup Table Control Register (CRUm_ICnLUT) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 034Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	LUTWR	LUTSEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
1	LUTWR	0h	RW	Enables APB read/write access to the lookup table (LUT). 0b: Disables APB access (set this bit to 0 in operation with the normal path). 1b: Enables APB access (normal access is unavailable in this case). Note: See **Figure 9.2-57** for the LUT setting procedure.
0	LUTSEL	0h	RW	Specifies the access path of the lookup table (LUT). 0b: Normal path (image conversion by using the LUT) 1b: APB I/F (read/write from registers) Used to write (and confirm) data to the LUT in initial setting. Set this bit to 0 after finishing writing and reading data. Note that the LUT data is retained even after a reset. Note: See **Figure 9.2-57** for the LUT setting procedure.

(117) CRU Lookup Table Status Register (CRUm_ICnLUTS) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0350h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	LUTREGSEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
0	LUTREGSEL	0h	R	Indicates that the lookup table (LUT)is writable and readable from the APB. The LUTWR register value is reflected in this register after a while. Access the lookup table after confirming this bit. 0b: Neither writable nor readable. 1b: Writable and readable. Note: See **Figure 9.2-57** for the LUT setting procedure.

(118) CRU Lookup Table Pointer Register (CRUm_ICnLUTP) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0354h
Initial Value : 0000_0000h

R/W	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LTCBPR[5:0]						LTYPR[9:0]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
29 to 20	LTCRPR[9:0]	0h	RW	Lookup table (LUT) Cr/B pointer Specify the current pointer (access point) to the lookup table Cr/B in APB access. The pointer is incremented automatically when ICnLUTD.LTCRDT[7:0] are written. It returns to 0 upon an overflow. It is not incremented when reading these bits. Note: See **Figure 9.2-57** for the LUT setting procedure.
19 to 10	LTCBPR[9:0]	0h	RW	Lookup table (LUT) Cb/G pointer Specify the current pointer (access point) to lookup table Cb/G in APB access. The pointer is incremented automatically when ICnLUTD.LTCBDT[7:0] are written. It returns to 0 upon an overflow. It is not incremented when reading these bits. Note: See **Figure 9.2-57** for the LUT setting procedure.
9 to 0	LTYPR[9:0]	0h	RW	Lookup table (LUT) Y/R pointer Specify the current pointer (access point) to lookup table Y/R in APB access. The pointer is incremented automatically when ICnLUTD.LTYDT[7:0] are written. It returns to 0 upon an overflow. It is not incremented when reading these bits. Note: See **Figure 9.2-57** for the LUT setting procedure.

(119) CRU Lookup Table Data Register (CRUm_ICnLUTD) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0358h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
23 to 16	LTCRDT[7:0]	0h	RW	Lookup table (LUT) Cr/B data Read and write data to the location indicated by the ICnLUTP.LTCRPR[9:0] pointer in lookup table Cr/B through the APB interface.
15 to 8	LTCBDT[7:0]	0h	RW	Lookup table (LUT) Cb/G data Read and write data to the location indicated by the ICnLUTP.LTCBPR[9:0] pointer in lookup table Cb/G through the APB interface.
7 to 0	LTYDT[7:0]	0h	RW	Lookup table (LUT) Y/R data Read and write data to the location indicated by the ICnLUTP.LTYPR[9:0] pointer in lookup table Y/R through the APB interface.

(120) CRU Test Image Generation Control 1 Register (CRUm_ICnTICTRL1) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 035Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	TIRATE[4:0]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIPTNV1[3:0]				TIPTNU1[3:0]				TIPTNY1[3:0]				-	TIROTSEL	TIMODE	TIEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
20 to 16	TIRATE[4:0]	0h	RW	Specify the test image generation rate. 16 pixels / (18 + TIRATE) cycles It can be used in the following ranges. 1) When ICnDMR.YCMODE=010b or 110b or ICnDMR.RGBMODE=00b 1.390 Gbps (ICnTICTRL1.TTIRATE[4:0]=Fh) to 3.584 Gbps (ICnTICTRL1.TTIRATE[4:0]=1h) 2) When ICnDMR.YCMODE≠010b, ICnDMR.YCMODE≠110b and ICnDMR.RGBMODE≠00b 1.390 Gbps (ICnTICTRL1.TTIRATE[4:0]=Fh) to 3.783 Gbps (ICnTICTRL1.TTIRATE[4:0]=0h)
15 to 12	TIPTNV1[3:0]	0h	RW	Specify the pixel (V) counter bits for the test image pattern. 0000b: Selects bits [3:0]. 0001b: Selects bits [4:1]. 0010b: Selects bits [5:2]. Omitted 1100b: Selects bits [15:12]. 1101b to 1111b: Setting prohibited
11 to 8	TIPTNU1[3:0]	0h	RW	Specify the pixel (U) counter bits for the test image pattern. 0000b: Selects bits [3:0]. 0001b: Selects bits [4:1]. 0010b: Selects bits [5:2]. Omitted 1100b: Selects bits [15:12]. 1101b to 1111b: Setting prohibited
7 to 4	TIPTNY1[3:0]	0h	RW	Specify the pixel (Y) counter bits for the test image pattern. 0000b: Selects bits [3:0]. 0001b: Selects bits [4:1]. 0010b: Selects bits [5:2]. Omitted 1100b: Selects bits [15:12]. 1101b to 1111b: Setting prohibited
3	-	0h	R	Reserved These bits are read as 0b. The written value will be ignored.
2	TIROTSEL	0h	RW	Image processing/non-image processing route selection for test image output 0b: Input for image processing 1b: Input for non-image processing
1	TIMODE	0h	RW	Specifies a test image generation pattern. 0b: Selects a counter value for YUV output. 1b: Same-color YUV output for the entire screen
0	TIEN	0h	RW	Enables generation of a test image pattern. This test image works with VC0 only. 0b: Does not generate a test image pattern (processes the data type from the LINK). 1b: Generates a test image pattern (process test image pattern data). Note: When this bit is set to 1b, test data is forcibly selected regardless of CRUnCTRL.VINSEL.

(121) CRU Test Image Generation Control 2 Register (CRUm_ICnTICTRL2) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0360h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	TIPTNV2[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIPTNU2[7:0]								TIPTNY2[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
23 to 16	TIPTNV2[7:0]	0h	RW	Specify V for the entire-screen same-color test image pattern. Note: This bit is valid when ICnTICTRL1.TIMODE=1b.
15 to 8	TIPTNU2[7:0]	0h	RW	Specify U for the entire-screen same-color test image pattern. Note: This bit is valid when ICnTICTRL1.TIMODE=1b.
7 to 0	TIPTNY2[7:0]	0h	RW	Specify Y for the entire-screen same-color test image pattern. Note: This bit is valid when ICnTICTRL1.TIMODE=1b.

(122) CRU Test Image Size Setting 1 Register (CRUm_ICnTISIZE1) (m = 0)

Access Size : 32 bits

Address : <CRUm_base> + 0364h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	TIPPL[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11 to 0	TIPPL[11:0]	0h	RW	Number of valid pixels per line in the test image pattern Note 1. If a value from 0 to 15 is specified, operation is for the setting of 16. Note 2. The four lower-order bits are invalid.

(123) CRU Test Image Size Setting 2 Register (CRUm_ICnTISIZE2) (m = 0)

Access Size : 32 bits
Address : <CRUm_base> + 0368h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	TIM[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	TIN[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
27 to 16	TIM[11:0]	0h	RW	Invalid period (number of lines) per frame in the test image pattern Note: If 0 is specified, operation is for the setting of 1.
15 to 12	-	All 0	R	Reserved These bits are read as 0b. The written value will be ignored.
11 to 0	TIN[11:0]	0h	RW	Valid period (number of lines) per frame in the test image pattern Note: If 0 is specified, operation is for the setting of 1.

9.2.4.3 Function Description

The prefix “CRUm (m = 0)” of the register names is omitted in the following subsections.

9.2.4.3.1 Input Formats and Image Processing

Table 9.2-10, **Table 9.2-11**, and **Table 9.2-12** list the input formats in which images can be processed by this module and the corresponding available forms of image processing.

Table 9.2-10 Input Formats and Corresponding Forms of Image Processing (for Image Processing) (1/3)

| Input Format | | | Processing Indicator | | | | | | | | | | | | | | | | | Interrupt | | | Output Format | | | | | | | | | | | | | | | | |

Table 9.2-10 Input Formats and Corresponding Forms of Image Processing (for Image Processing) (2/3)

Note 1. The CbCr(U/V) side is Image Stride(AMnIS) × 2. See **Image Stride** in **9.2.4.3.3(5)(a) Video data frame** for details.

Note 2. When transferring data to memory, there are cases where Cb and Cr data are transferred to one area as Y, or when data is divided into two independent areas. The types in this column represent the following.
Not-use: Cb and Cr data are transferred to the same area as Y when transferred to memory.

Use: When Cb and Cr data are transferred to memory, they are transferred to an area separate from Y. This separate area is transferred to the area specified in the AMnUVAOFH/L register for the Y data storage destination.

9.2.4.3.3 Transfer to DRAM

In data transfer from the CRU to the DRAM, data are transferred frame by frame separately based on the concept of memory banks. The memory banks can be set to operate with from 1 to 8 planes. As the transfer destination address for each memory bank, the transfer destination start address of the memory bank must be set such that it does not overlap with memory for the previous frames of data. Operation takes a cyclic form whereby the frame data returns to 1 when it reaches the last plane (see **Figure 9.2-9**). Accordingly, data on the DRAM must have been taken for next processing before overwriting. Set the number of memory banks so that this can be done before overwriting.

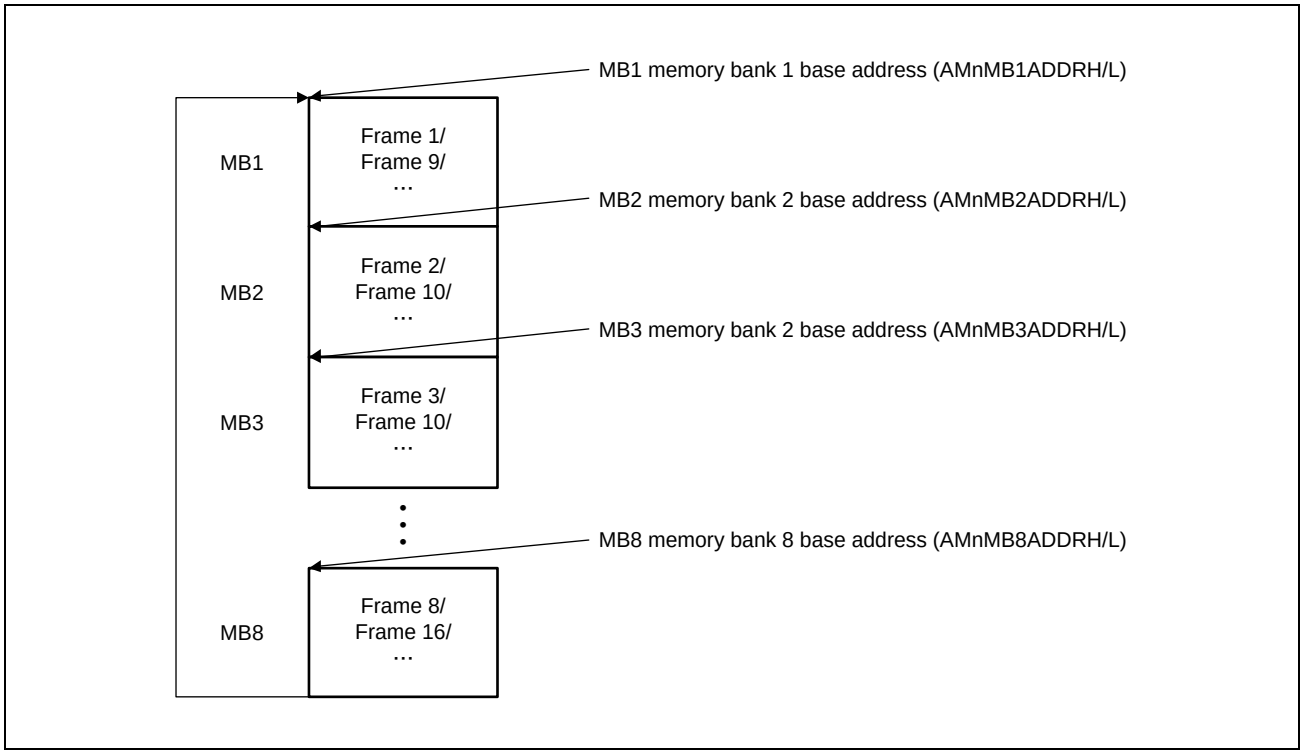

Figure 9.2-9 Image of Data Transfer to DRAM (Example: Eight Destinations in DRAM for the Transfer of Image-Processing Data)

Table 9.2-16 lists the memory bank setting addresses required for the DRAM. In this module, the transfer destination start addresses for the transfer of image data can be specified by setting the offsets listed below to proceed with transfer of up to four planes for SVC, transfer of the UV plane at the time of Y/UV separation, and transfer of non-image processing data or full-bypass data.

Furthermore, the transfer destination start addresses can be specified independently of those for statistics data that are transferred through the statistics bus.

Table 9.2-16 Memory Bank Setting Addresses

x = 0 to 7 (number of memory banks); y = 0 to 3 (number of SVC channels)

Transfer Bus	Processing	Transfer Destination Start Address	Description	Related Section
Video data bus	Image processing data	AMnMBxADDRH/L + AMnSVCAOFH/Lxy	Image data transfer destination. Transfer is possible for SVC0 to 3.	**(1) Video Data Transfer Destination Address (Video Data Storage Destination)**
		AMnMBxADDRH/L + AMnSVCAOFH/Lxy + AMnUVAOFH/L	Transfer destination of the CbCr (UV) plane at the time of YCbCb separation in image data. Transfer is possible for SVC0 to 3.	**(2) Video Data Transfer Destination Address (Storage in Y/UV Separation)**
	Non-Image processing data/ full bypass	AMnMBxADDRH/L + AMnSVCAOFH/Lxy + MnNIAOFH/L	Non-image data/full-bypass transfer destination. Transfer is possible for SVC0 to 3.	**(3) Video Data Transfer Destination Address (Image Processing/Non-Image Processing, 4-ch. SVC, Y/UV Separated Data)**
Statistics data bus	Statistics processing	AMnSDMBxADDRH/L	Statistics data transfer destination. Transfer is only possible for SVC0.	**(4) Statistics Data Transfer Destination Address (Statistics Data Storage Destination)**

Note: x represents the number of planes of each memory bank and it can be set from one to eight planes by the AMnMBVALID and AMnSDMBVALID registers (the number differs between video and statistics).
y represents the channel number of SVC and it can be set from SVC0 to SVC3 by the ICnSVCNUM register.

Data are transferred to the address obtained by adding the given offset to AMnMBxADDRH/L, the image processing data transfer destination start address for SVC0.

1) SVC OFFSET

SVCs from SVC0 to 3 are supported. Data are transferred to the address obtained by adding the offset of SVC1 to 3 to the image data transfer destination start address for SVC0.

SVC1: AMnMBxADDRH/L + AMnSVCAOFH/L
SVC2: AMnMBxADDRH/L + AMnSVCAOFH/L × 2
SVC3: AMnMBxADDRH/L + AMnSVCAOFH/L × 3

2) UV OFFSET

In the separate transfer of Y and CbCr (UV), the CbCr (UV) plane is transferred to the address obtained by adding AMnUVAOFH/L to AMnMBxADDRH/L, the image data transfer destination start address for SVC0.

UV plane for SVC0: AMnMBxADDRH/L + AMnUVAOFH/L
UV plane for SVC1: AMnMBxADDRH/L + AMnSVCAOFH/L + AMnUVAOFH/L
UV plane for SVC2: AMnMBxADDRH/L + AMnSVCAOFH/L × 2 + AMnUVAOFH/L
UV plane for SVC3: AMnMBxADDRH/L + AMnSVCAOFH/L × 3 + AMnUVAOFH/L

3) Non-Image Processing Data

Data are transferred to the address obtained by adding AMnNIAOFH/L to AMnMBxADDRH/L, the image data transfer destination start address for SVC0.

Non-image data plane for SVC0: AMnMBxADDRH/L + AMnNIAOFH/L
Non-image data plane for SVC1: AMnMBxADDRH/L + AMnSVCAOFH/L + AMnNIAOFH/L
Non-image data plane for SVC2: AMnMBxADDRH/L + AMnSVCAOFH/L × 2 + AMnNIAOFH/L
Non-image data plane for SVC3: AMnMBxADDRH/L + AMnSVCAOFH/L × 3 + AMnNIAOFH/L

4) Statistics Data

Statistics data are transferred through the static data (SD) bus, which is independent of the video data bus. Therefore, the destination addresses for these data are defined in the following form, regardless of the address settings for image data. In addition, such data are only transferred to the following set locations, since they are only supported for SVC0.

AMnSDMBxADDRH/L

(1) Video Data Transfer Destination Address (Video Data Storage Destination)

- The start address of each memory bank as the video data transfer destination is determined by the AMnMB1 to 8ADDRL and AMnMB1 to 8ADDRH registers. Valid AMnMB1ADDRH/L, AMnMB2ADDRH/L, … registers are switched by AMnMBVALID. 1 to 8 can be set for one step of memory-bank transfer (examples for settings of 8, 4, and 1 are shown in **(a) AMnMBVALID[7:0] = 1111_1111b (eight transfer destinations)**, **(b) AMnMBVALID[7:0] = 0000_1111b (four transfer destinations)**, and **(c) AMnMBVALID[7:0] = 0000_0001b (one transfer destination)**, respectively).

Set the following offset addresses as required based on the above. Set the following offset addresses as required based on the above description.

- Set the SVC offset addresses, AMnSVCAOFL and AMnSVCAOFH, when SVC1 to 3 are used.
- Set the non-image processing offset addresses, AMnNIAOFL and AMnNIAOFH, when non-image processing/full bypass is selected.
- Set the YC offset addresses, AMnUVAOFL and AMnUVAOFH, when YC separation (ICnDMR.YCMODE[2:0] = 010b/110b) is selected.

(a) AMnMBVALID[7:0] = 1111_1111b (eight transfer destinations)

Order of transfer destinations: MB1 → MB2 → …. → MB8 → MB1 → MB2 → …

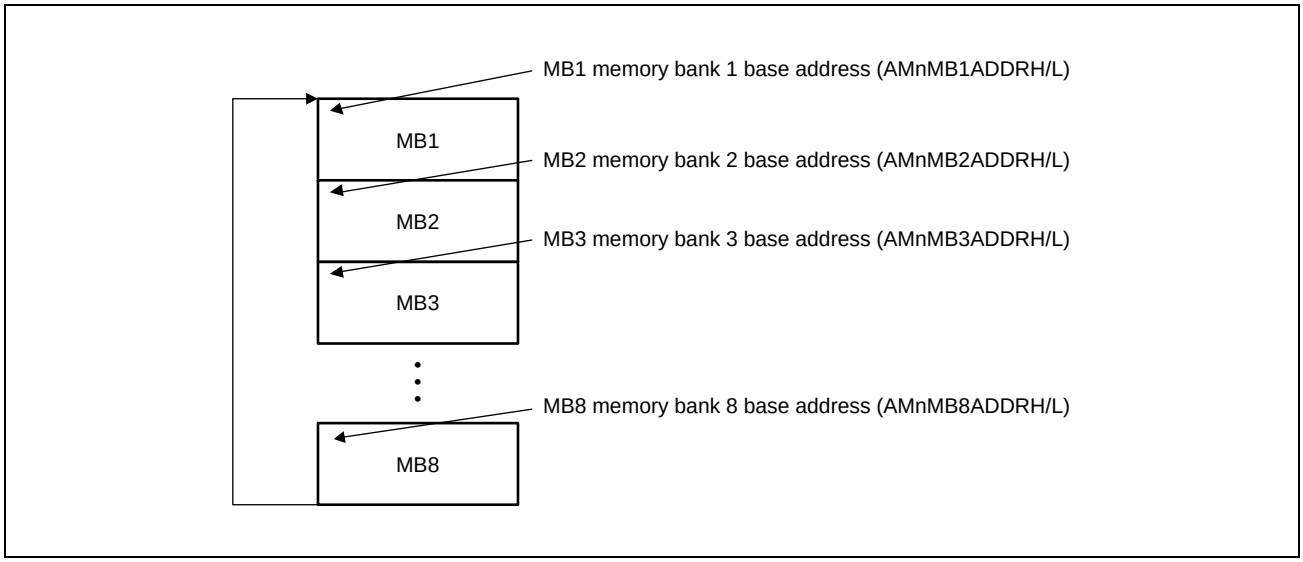

Figure 9.2-10 Image of Memory Bank (Eight Transfer Destinations)

(b) AMnMBVALID[7:0] = 0000_1111b (four transfer destinations)

Order of transfer destinations: MB1 → MB2 → MB3 → MB4 → MB1 → MB2 → …

Figure 9.2-18 Image of Data Storage (Example of Division by MB)

(4) Statistics Data Transfer Destination Address (Statistics Data Storage Destination)

The results of statistics processing are transferred from the statistics data bus to external memory. Since this statistics function is limited to SVC0, the external transfer destination start address is determined by AMnSDMB1 to 8ADDRL and AMnSDMB1 to 8ADDRH.

The number of planes of the memory bank is determined by AMnSDMBVALID. The transfer start address (statistics data storage destination) is determined by the MnSDMB1 to 8ADDRL and AMnSDMB1 to 8ADDRH registers.

The valid AMnSDMB1ADDR, AMnSDMB2ADDR, …registers are switched by AMnSDMBVALID.

(a) AMnSDMBVALID[7:0] = 1111_1111b (eight transfer destinations)

- Order of transfer destinations: SDMB1 → SDMB2 → … → SDMB8 → SDMB1 → SDMB2 → …

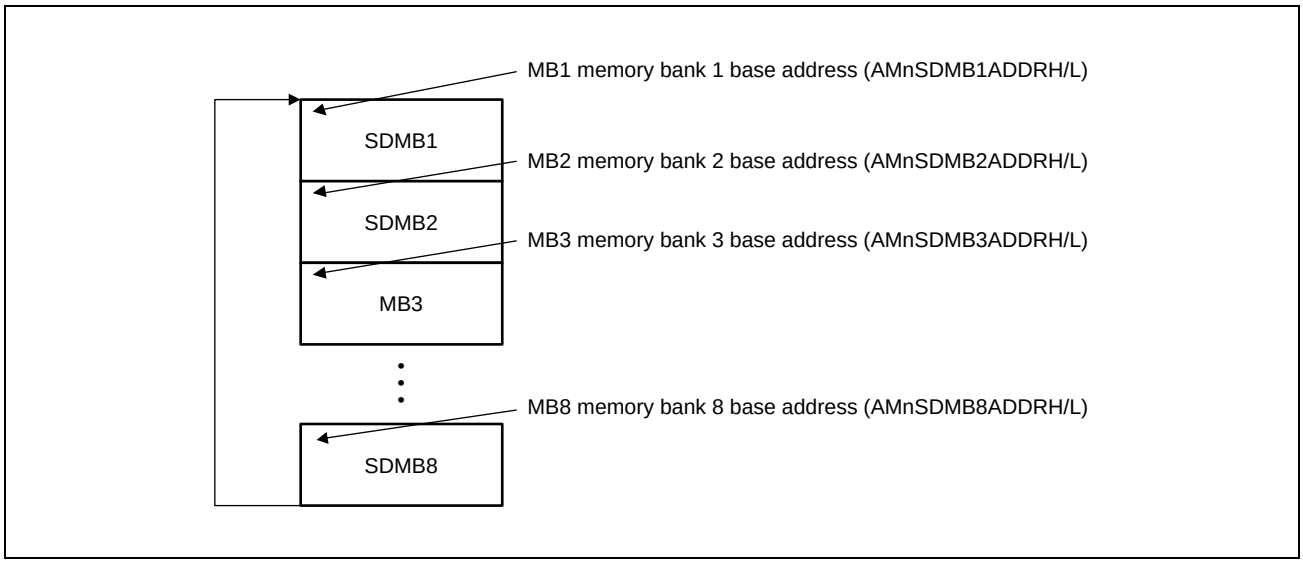

Figure 9.2-19 Image of Memory Bank (Eight Transfer Destinations)

(5) Frame Structure

(a) Video data frame

Image Stride

The image stride function is always handled for image processing and non-image processing from the video data system.

Figure 9.2-20 through **Figure 9.2-22** show the image of the storage of data with the image stride function. The image stride function involves writing from the memory write start address of each line in memory in units of address with the value set by the AMnIS (128-byte Step) register. The end of the line for writing is determined in multiples of 256 bits (32 bytes), so take this into account when setting the address. Furthermore, if a header and footer are to be appended, make the setting in consideration of that amount of data.

The following are the descriptions of storage in memory for each output format.

TYPE1: When the output format is YUV without separation (ICnDMR.YCMODE[2:0] = 000b to 001b, 011b to 101b,111b), RGB, RAW or MIPI Recommended Memory Storage Format.

As shown in **Figure 9.2-20**, the first address of memory write for each horizontal line is written to memory in address units.

TYPE2: When the output format is YUV422 (ICnDMR.YCMODE[2:0] = 010b)

As shown in **Figure 9.2-21**, the first address of memory write for each horizontal line is written to memory in address units.

TYPE3: When the output format is YUV420 (ICnDMR.YCMODE[2:0] = 110b) & U/V side Image Stride=AMnIS.IS×2 (ICnDTVP.420UVIS=0)

As shown in **Figure 9.2-22**, Y writes the first address of memory write for each line to memory in address units of the value set in the AMnIS register.

Note that UV writes the first address of each line to memory in units of twice the value set in the AMnIS register.

TYPE4: When the output format is YUV420 (ICnDMR.YCMODE[2:0] = 110b) & U/V side Image Stride=AMnIS.IS×1 (NV12) (ICnDTVP.420UVIS=1)

As shown in **Figure 9.2-21**, both Y and UV writes the first address of memory write for each line to memory in address units of the value set in the AMnIS register.

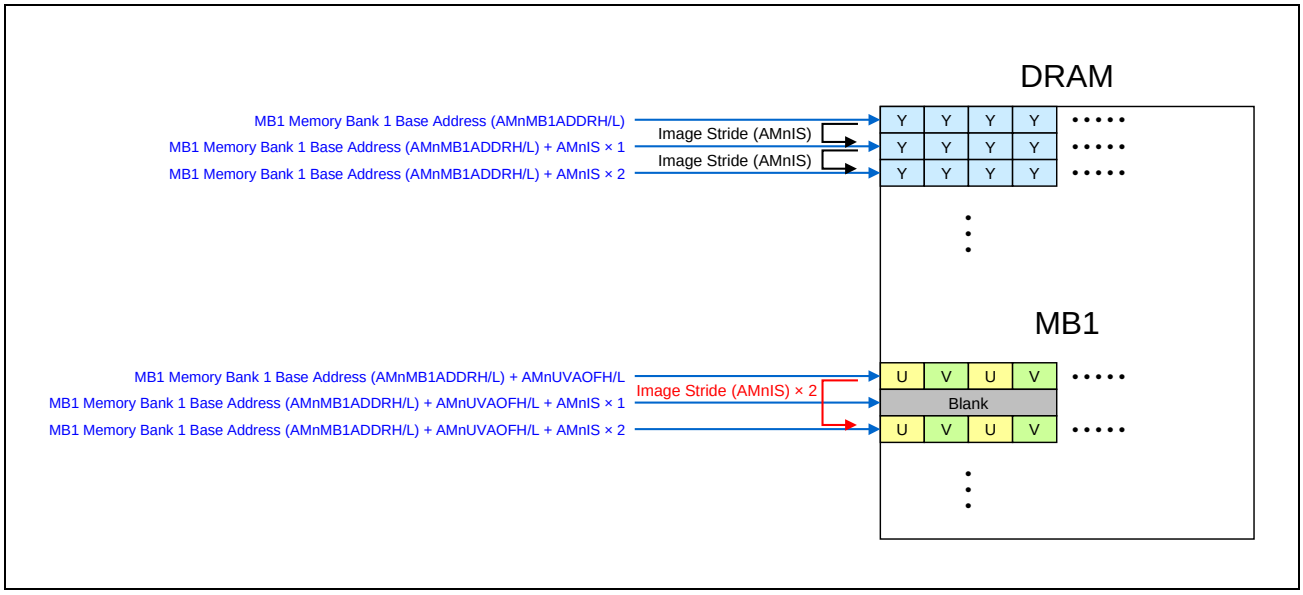

Figure 9.2-22 Image of Data Storage with Image Stride Function (TYPE3)

Image Processing Data Frame

Figure 9.2-23 shows the structure of the image processing data frame.

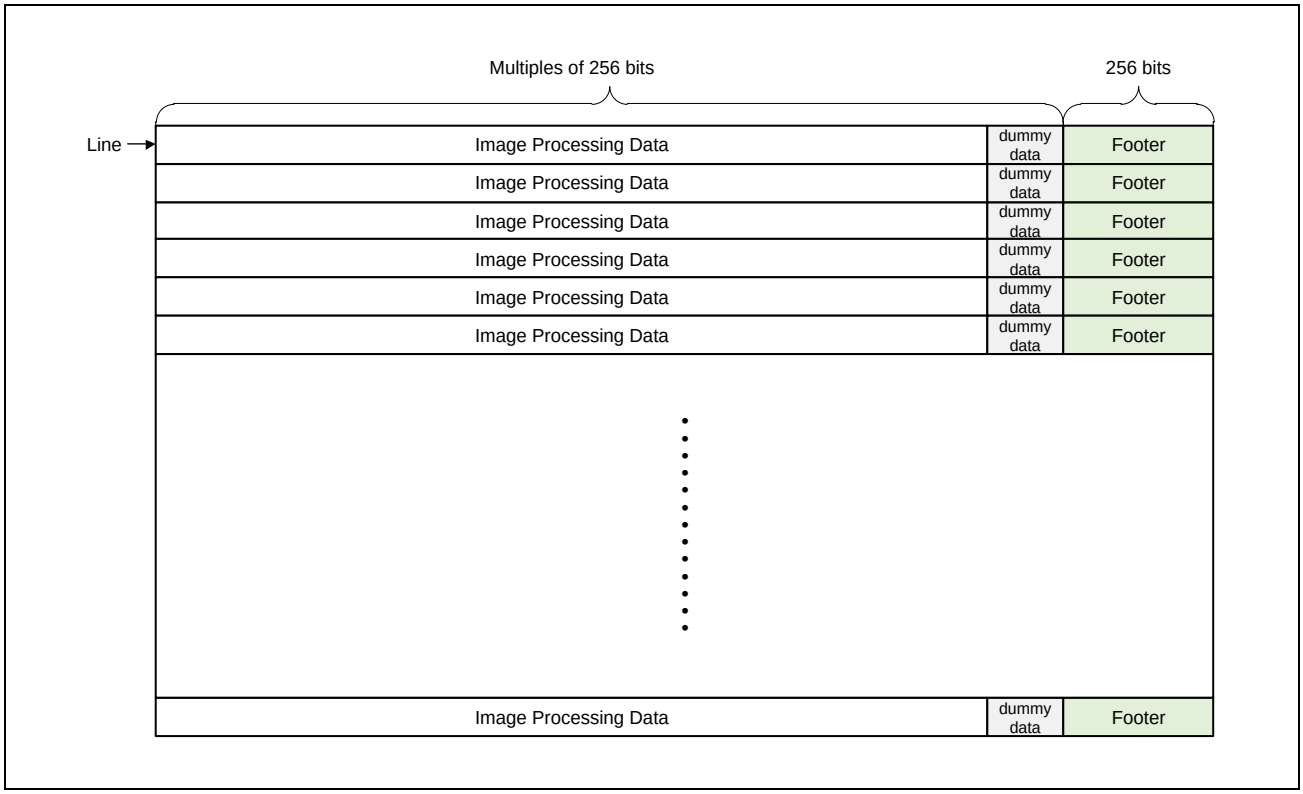

Figure 9.2-23 Image Processing Data Frame Structure

1) Dummy data

Transfer from this module to external memory proceeds in units of 256 bits (32 bytes). Therefore, only the amount of dummy data which is required to reach a 32-byte boundary is transferred. When processing images, ignore the dummy data.

2) Footer

Whether or not to insert footer with the image data can be selected by using the ICnDTVP.FTON register. For the data format of 256 bits of footer data, see **Footer Appending Function**. The value of this footer is updated alternately every time data at the target address are updated. The state of progress can be checked by monitoring which horizontal line has been updated.

This module has functionality for checking the address for transfer from the AXI bus via a register or using an interrupt to indicate the transfer of data to the specified address. Actually, whether or not data have been written to the DRAM can be checked by inspecting the footer to confirm the updating of data.

Non-Image Processing Data/Full-Bypass Data Frame

Figure 9.2-24 shows the structure of the non-image processing data/full-bypass data frame.

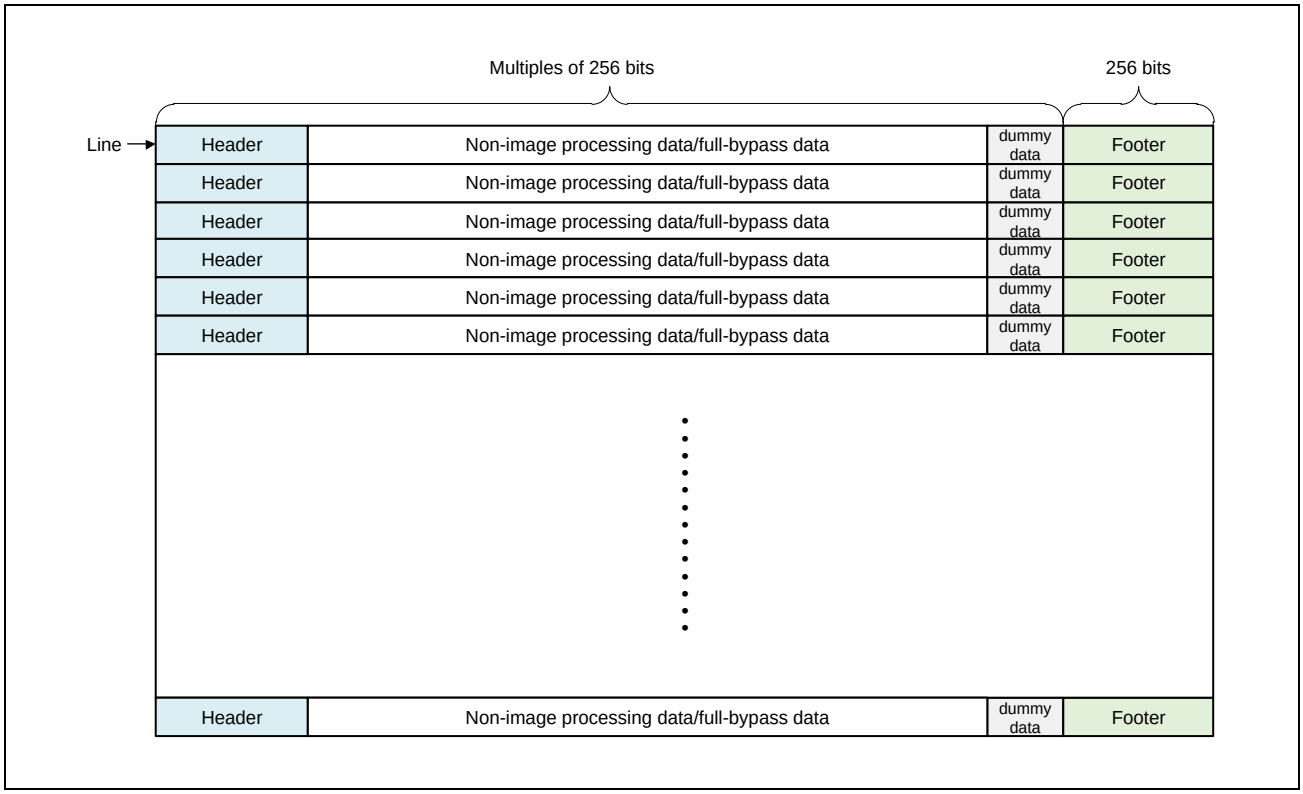

Figure 9.2-24 Non-Image Processing Data/Full-Bypass Data Frame Structure

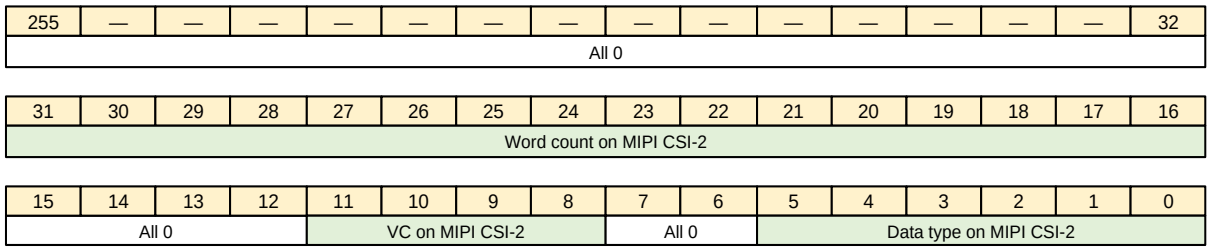
A difference from an image processing frame is that a header can be inserted for these frame types.

Insertion of the header can be set by using the ICnDTVP.HDON register. For the format of the header, see **Header Appending Function (for Non-Image Processing Data/Full-Bypass Data)**.



Since there are several data types for non-image processing and full-bypass data whereas image processing data are of one data type, the purpose of the header is to allow the CRU to identify the data type in line units. If the CRU has recognized the data type beforehand or a single data type is selected, headers need not be inserted.

Header Appending Function (for Non-Image Processing Data/Full-Bypass Data)

The data types for non-image processing and full-bypass are selectable from among several data types and the data are stored in a state such that they are mixed in the same SVC memory area, so a header can be appended at the start of each line for non-image processing or full-bypass data so that the data type and data length can be identified when read. Since this header appending function is not required for a sensor that can identify the data types by their order, etc., it can be switched on or off.

However, when the pattern generator is selected for output, a header will not be appended regardless of whether the setting for header appending is on or off.

Figure 9.2-25 shows the contents of the header.

Note: Since “Word count” is the word count value based on MIPI CSI-2, it does not include data such as headers and footers which have been appended by the CRU.

Figure 9.2-25 Header Contents

Footer Appending Function

This function writes footer data to memory so that the user can see up to which horizontal line data has been written in the memory bank set by AMnMB1-8ADDRH/L (for video data).

This function can be switched on or off with ICnDTVP.FTON.

For the video data footer, 256 bits (256’h1/256’h0) are written at the end of each line unit.

At first, 256’h1 is written as a footer. The next time the memory bank is overwritten after round of writing, 256’h0 is written as a footer. Subsequently, 256’h1 and 256’h0 are written alternately each time the memory bank is overwritten.

Accordingly, by checking the value of the footer, it is possible to prevent erroneous use of data before it is overwritten.

A 256-bit footer (256’d1/256’d0) is appended to the end of each line unit from the image system (image processing, non-image processing, or full bypass) and to the end of each frame unit from the statistics system.

(b) Statistics data frame

Figure 9.2-26 shows the structure of the image processing data frame.

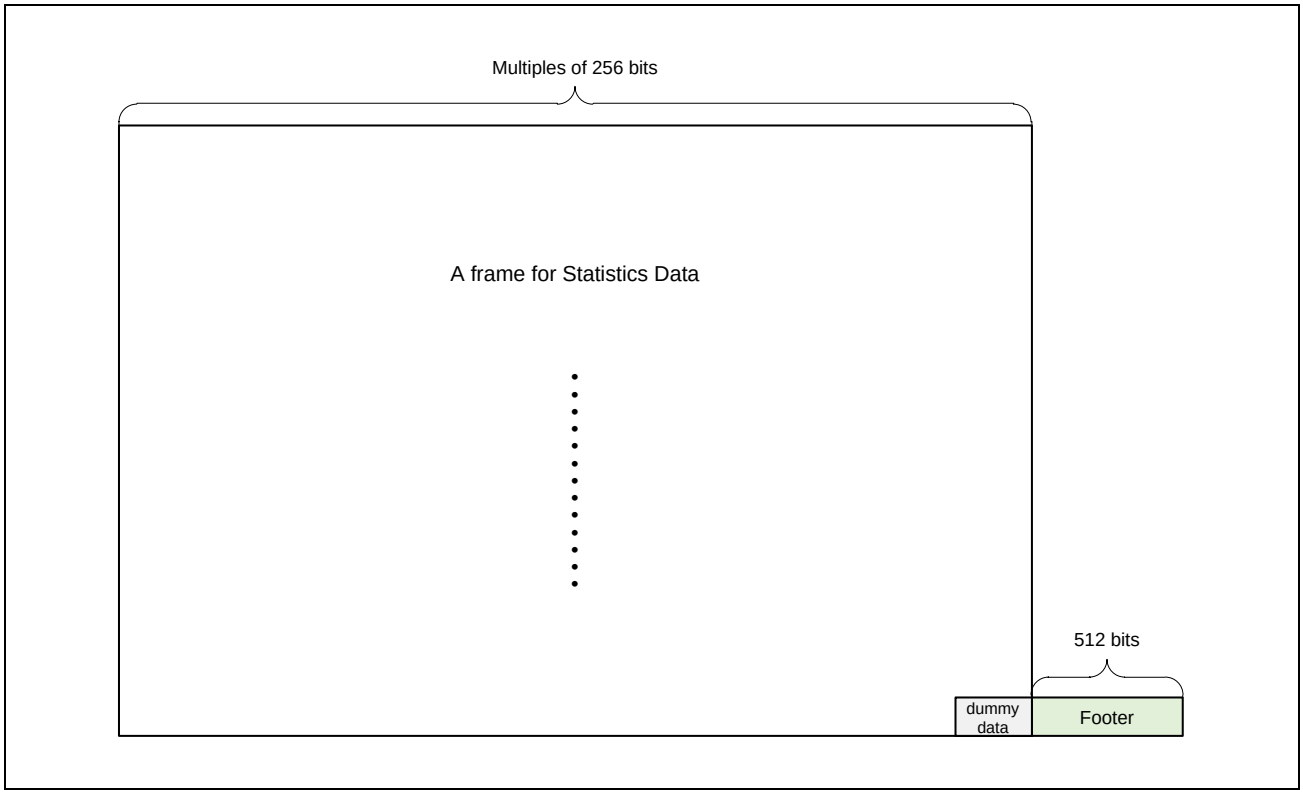


Figure 9.2-26 Statistics Data Frame Structure

Two differences between statistics frames and frames from image processing and non-image processing are that statistics frames have no concept of image striding and that footers are added in frame units. This is because statistics are processed in block units so that line-by-line processing is not possible.

Processing of the Last Line in a Frame (for Statistics Data)

Figure 9.2-27 shows an image of storing frames of statistics data. Statistics data are written to memory with no intervals in the data to reflect line transitions. The end of the frame for writing is determined in multiples of 256 bits (32 bytes), so take this into account when setting the address.

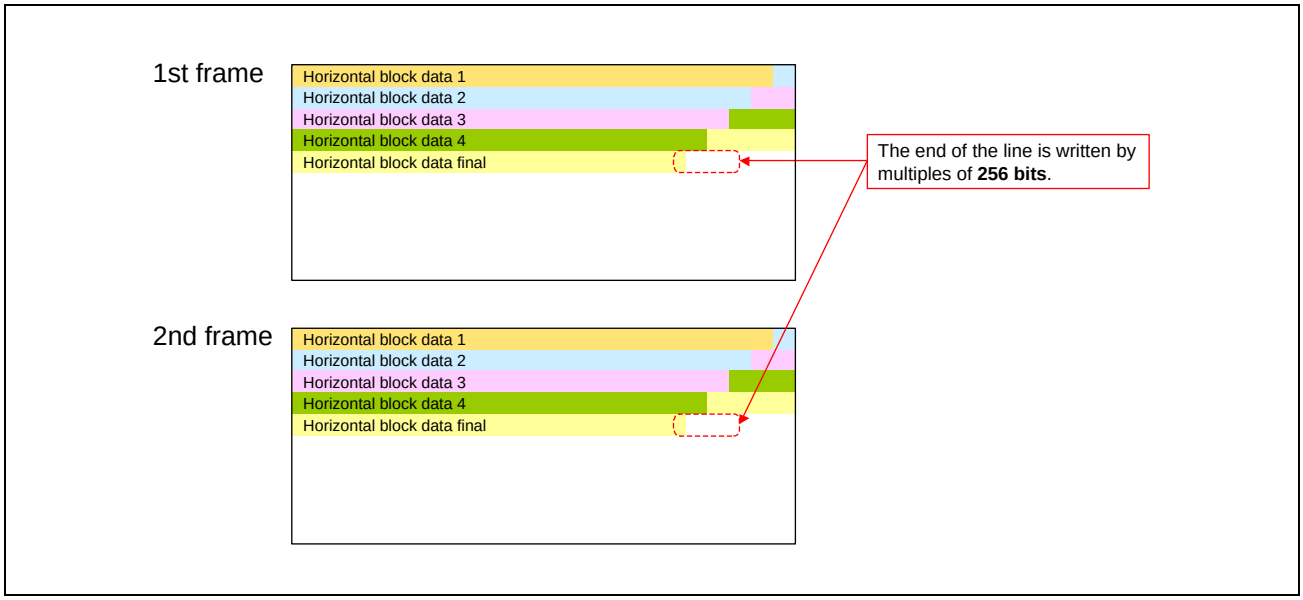

Figure 9.2-27 Image of Storing Frames of Statistics Data

Footer Appending Function

This function writes a footer to the end of each memory so that the user can see which bank number of the memory bank set by MnSDMB1-8ADDRH/L (for statistics data) has been written to the memory.

This function can be switched on or off with ICnDTVP.FTON.

A 512-bit ({higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h1} or 512-bit {higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h0}) footer of statistics data is written at the end of each frame unit.

Ignore the higher-order 256 bits of 512 bits because they are reserved (indefinite value).

At first, 512 bits {higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h1} are written as a footer.

The next time the memory bank is overwritten after one round of writing, 512 bits {higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h0} are written as a footer.

After that, 512 bits {higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h1} and 512 bits {higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256’h0} are alternately written each time overwriting is done.

Therefore, by checking the footer value as the video data footer, it is possible to prevent the data from being inadvertently used before overwriting.

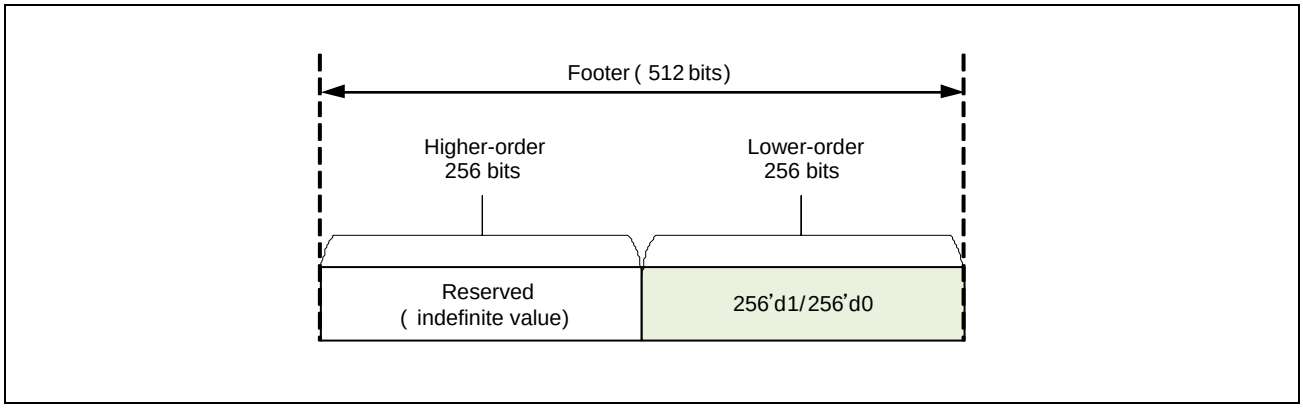

Figure 9.2-28 Statistics Data Footer Structure

9.2.4.3.4 Pattern Generator (for Debugging)

A test image (YUV422 only) can be generated for use as an image converter input by setting the following registers. This function is used for debugging to identify where the problem is originated (in the sensor or in the internal settings). Two modes are implemented for this pattern (monochrome or pattern). This pattern generator operates as VC0. You can select the route of image processing/non-image processing. See **9.2.5 Operation** for the setting procedure.

TIEN = ICnTICTRL1.TIEN: Enables generation of a test image pattern.
TIMODE = ICnTICTRL1.TIMODE: Selects a test image generation pattern (monochrome or pattern).

TIROTSEL = ICnTICTRL1.TIROTSEL: Selects the route of image processing/non-image processing.

TIPTNY1[3:0] = ICnTICTRL1.TIPTNY1[3:0]: Bit settings for the pixel (Y) counter
TIPTNU1[3:0] =ICnTICTRL1.TIPTNU1[3:0]: Bit settings for the pixel (U) counter
TIPTNV1[3:0] = ICnTICTRL1.TIPTNV1[3:0]: Bit settings for the pixel (V) counter

TIRATE[4:0] = ICnTICTRL1.TIRATE[4:0]: Specify a test image generation rate.

TIPTNY2[7:0] = ICnTICTRL2.TIPTNY2[7:0]: Specify Y for the entire-screen same-color test image pattern.
TIPTNU2[7:0] = ICnTICTRL2.TIPTNU2[7:0]: Specify U for the entire-screen same-color test image pattern.
TIPTNV2[7:0] = ICnTICTRL2.TIPTNV2[7:0]: Specify V for the entire-screen same-color test image pattern.

TIPPL[11:0] = ICnTISIZE1.TIPPL[11:0]: Number of valid pixels per line in the test image pattern
TIN[11:0] = ICnTISIZE2.TIN[11:0]: Valid period (number of lines) per frame in the test image pattern
TIM[11:0] = ICnTISIZE2.TIM[11:0]: Invalid period (number of lines) per frame in the test image pattern

(1) Image and Settings (Common to Monochrome and Pattern Generation)

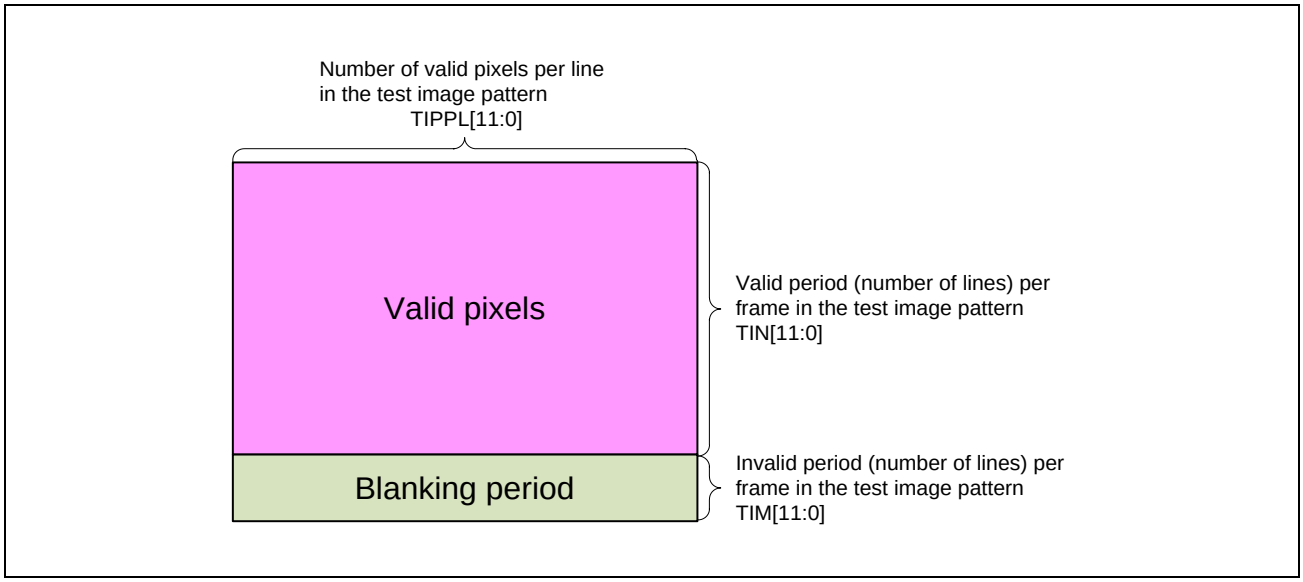

Figure 9.2-29 Image and Settings

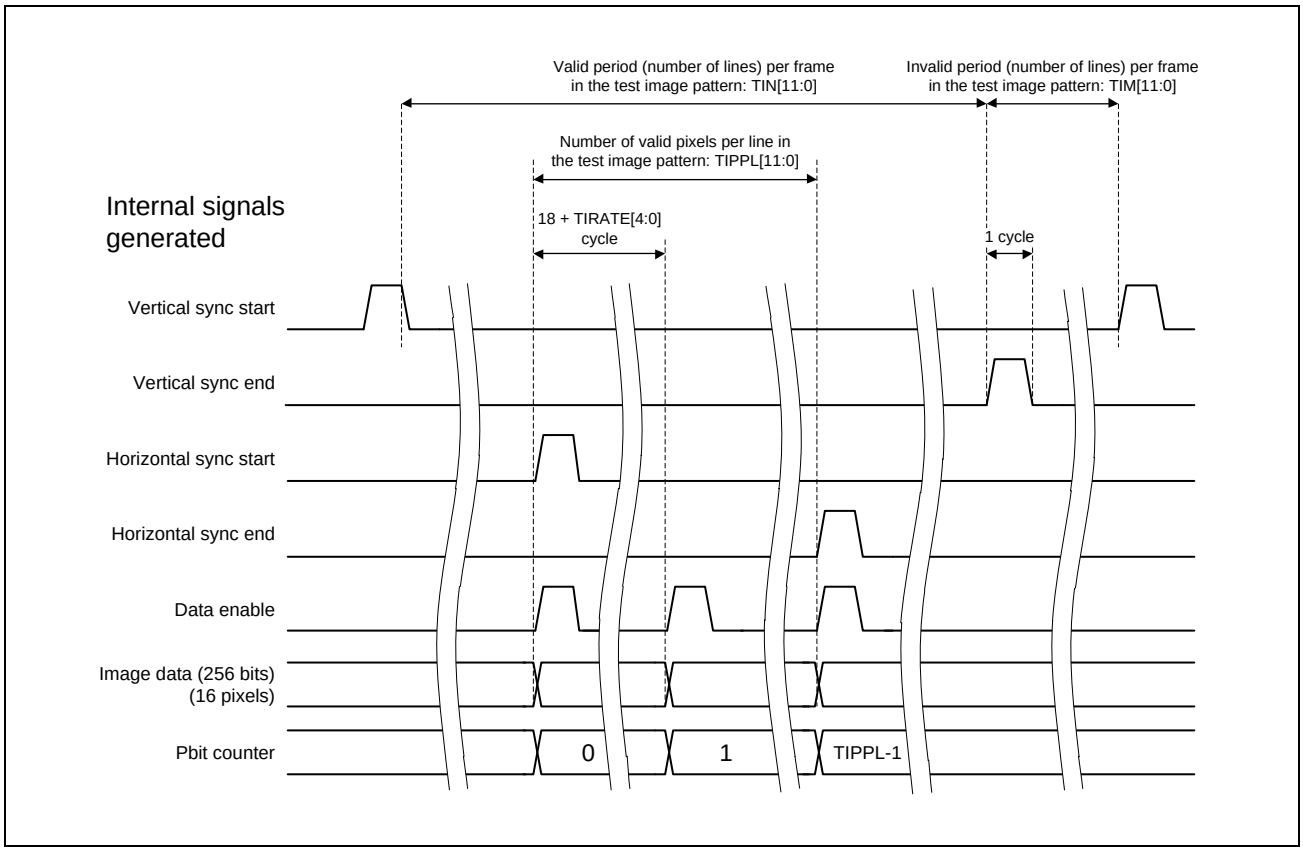
(2) Timing Generation and Settings (Common to Monochrome and Pattern Generation)

(Bits TIRATE[4:0] allow the test image generation rate to be set in the range between 1.390 Gbps and 3.783 Gbps with VCLK at 266 MHz.)



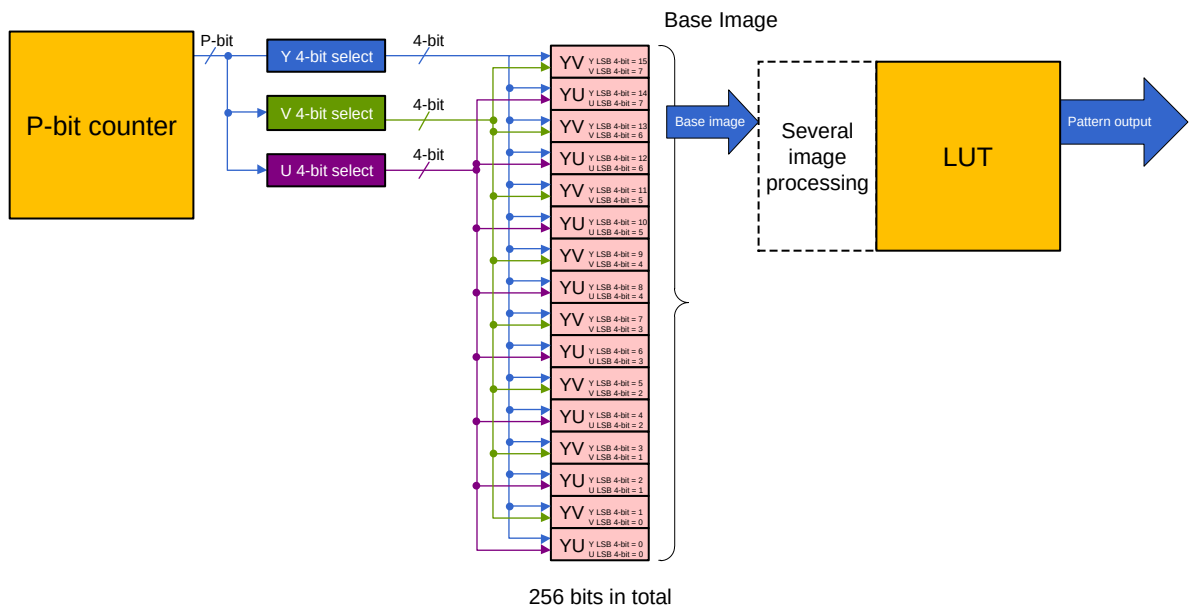


Figure 9.2-30 Timing Generation and Settings

(3) Data Generation Circuit (in the Case of Pattern Generation)

Image YUV422 8-bit data of 256 bits (16 pixels) is generated as follows (other formats cannot be generated). The 16-bit Pbit counter is incremented in 18 + TIRATE[4:0] (cycles at 266 MHz). The bits of this Pbit counter are selected by the TIPTNV1[3:0], TIPTNU1[3:0], and TIPTNY1[3:0] bits, and then they are packed and sent as follows:

Note: The counter is 16 bits wide.

Figure 9.2-31 Data Generation Circuit (in the Case of Pattern Generation)

(4) Data Generation Circuit (in the Case of Monochrome Generation)

Image YUV422 8-bit data of 256 bits (16 pixels) is generated in monochrome as follows (other formats cannot be generated). The values set by the TIPTNV2[7:0], TIPTNU2[7:0], and TIPTNY2[7:0] bits are packed and sent as follows:

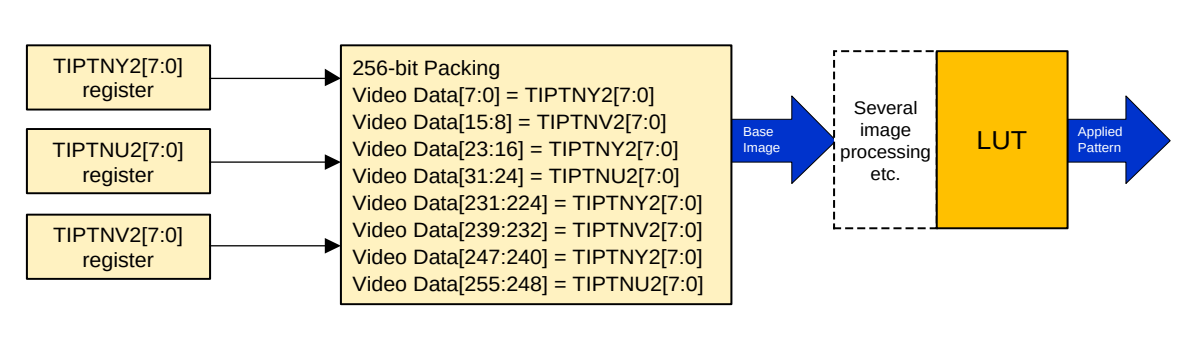

Figure 9.2-32 Data Generation Circuit (in the Case of Monochrome Generation)

(5) Generated Image Data Example (in the Case of Pattern Generation)

VGA (640 × 480): TIEN = 1b, TIMODE = 0b, TIPTNY1[3:0] = 0000b, TIPTNU1[3:0] = 0100b, TIPTNV1[3:0] = 1000b (Offset binary: ICnIPMC_C0/1/2/3.IBINSEL = 0b, ICnDMR.OBINSEL = 0b)

9.2.4.3.5 VC/Data Type Selector (for Image Processing)

Virtual channels from VC0 to VC15 are supported for video input data input from the MIPI CSI2 block. On the other hand, the number of channels which can be handed in image processing is up to four. This block handles assignment of the selected virtual channels (SVCs).

Only one data type can be handled by each SVC and the data types are selected in the ICnIPMC_C0 to 3.INF[5:0] registers.

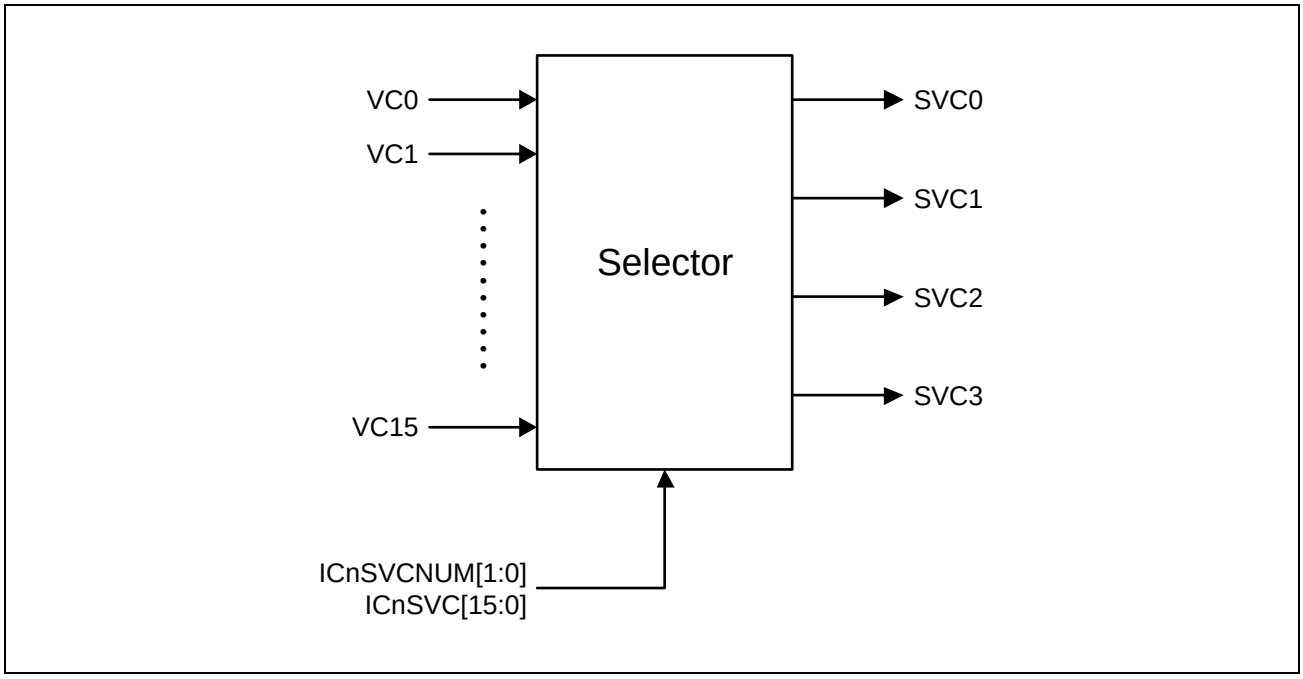

Figure 9.2-35 VC Selector Image

9.2.4.3.6 8-bit Expansion

(1) RGB444/RGB555/RGB565/RGB666 to RGB888

This block handles internal processing of RGB with 8 bits for each color. Inputs with fewer color bits are expanded to 8 bits. The conversion of inputs in the RGB444 and RGB555 and in the RGB565 and RGB666 formats to RGB888 is shown in **Table 9.2-19** and **Table 9.2-20**, respectively.

Table 9.2-19 RGB444/RGB555 to RGB888 Conversion

RGB444	RGB888
R[3:0]	{R[3:0],R[3:0]}

(2) RAW6/7 to RAW8

This block handles internal processing of RAW with 8 bits for each color. Inputs with fewer color bits are expanded to 8 bits. The conversion of inputs in the RAW6 and RAW7 formats to RGB888 is shown in **Table 9.2-21**.

Table 9.2-21 RAW6/7 to RAW8 Conversion

RAW6	RAW8
RAW[5:0]	{RAW[5:0],RAW[5:4]}

RAW7	RAW8
RAW[6:0]	{RAW[6:0],RAW[6]}

9.2.4.3.7 Image Clipping

Ranges for the clipping of input images are controlled by register settings. Specifically, the ranges of clipping for each SVC are set through the following register settings.

(Horizontal direction)

- Image clipping start pixel registers: ICnSPPrC_C0~3.SPPrC[12:0]
- Image clipping end pixel registers: ICnEPPrC_C0~3.EPPrC[12:0]

(Vertical direction)

- Image clipping start line registers: ICnSLPrC_C0~3.SLPrC[12:0]
- Image clipping end line registers: ICnELPrC_C0~3.ELPrC[12:0]

While the part of the image with the size after clipping (the gray part below) is being processed, the value of register ICnMS.AV0/1/2/3 = 1b. For the rest of the image, ICnMS.AV0/1/2/3 = 0b. When subsampling is done, operation proceeds in the same way for the subsampled images.

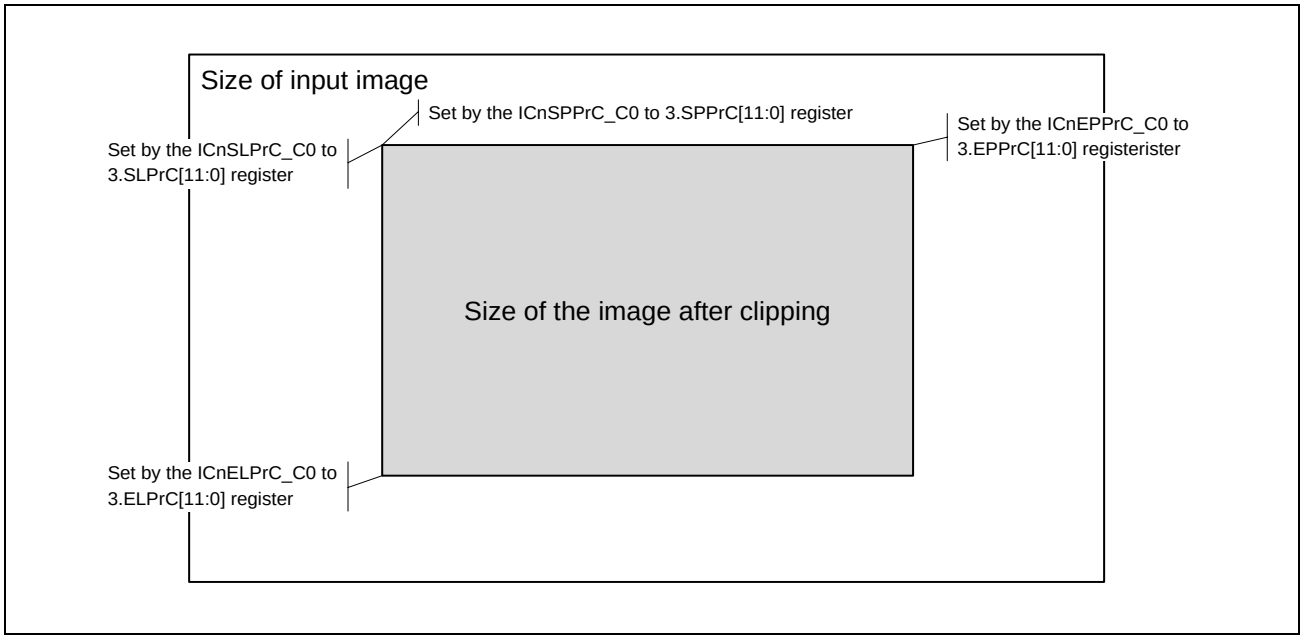

Figure 9.2-36 Image of Image Clipping

9.2.4.3.8 Frame Subsampling

Image frames are subsampled with the use of the registers which set input images. The settings of the following bit fields select the number of frames to be transferred in each round of transfer.

- Frame subsampling control register: ICnDEC.FRMDEC[3:0] (common to all SVCs)

Operation when the setting of ICnDEC.FRMDEC[3:0] = 2h is as follows:

Images are transferred in units of (the above register value + 1) frames. The state of ICnMS.CA0/1/2/3 is 1b when an image which is not to be eliminated by subsampling is being processed, as shown below.

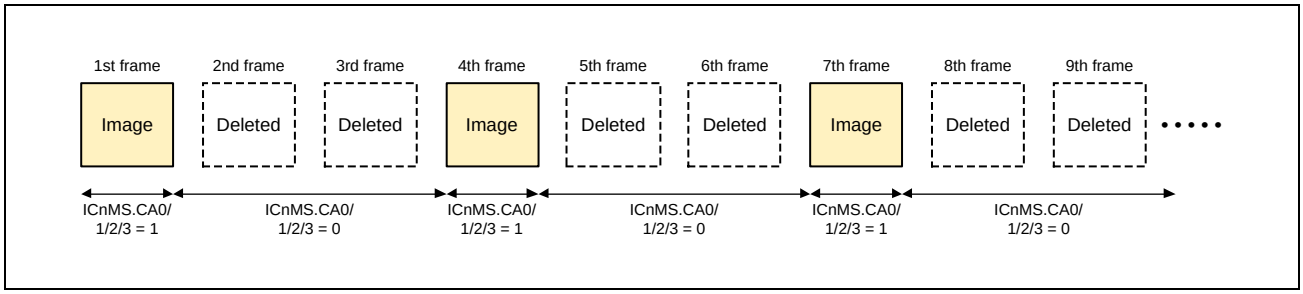

Figure 9.2-37 Frame Subsampling when ICnDEC.FRMDEC[3:0] = 2h

9.2.4.3.9 Data Arrangers 1 and 2

When image data are input and output, UV values expressed in negative form in YUV (YCbCr) data are converted. The data arranger 1 input side and data arranger 2 output side settings can be made by using the ICnDTVP.IBINSEL and ICnDMR.OBINSEL registers, respectively.

Settings for data arranger 1 must suit the specifications of the sensor. Data arranger 1 supports 8 or 10 bits depending on the number of bits of input data. Settings for data arranger 2 must suit the specifications of the destination for output. Data arranger 2 supports 8 bits depending on the output data. YUV of MIPI CSI-2 is usually used in offset binary. However, this depends on the sensor, and it may be output as two's complements. **Table 9.2-22** shows an example of processing when the input is 8 bits. Data arranger 1 also has 10-bit input, and when 10-bit input is used, it can be converted to 10-bit offset binary/2's complement as well as 8-bit.

Table 9.2-22 Input Formats and Corresponding Forms of Image Processing (at 8-bit input)

UV Value (Hex)	Offset Binary (Dec) Register Settings: Data Arranger 1: ICnDTVP.IBINSEL = 0b Data Arranger 2: ICnDMR. OBINSEL =0b	Two's Complements (Dec) Register Settings: Data Arranger 1: ICnDTVP.IBINSEL = 1b Data Arranger 2: ICnDMR. OBINSEL = 1b
FFh	127	−1
FEh	126	−2
…	…	…
81h	1	−127
80h	0	−128
7Fh	−1	127
…	…	…
01h	−127	1
00h	−128	0

9.2.4.3.10 Data Clipping

Data clipping is performed on the YUV (YCbCr) format. To make input data for RGB conversion compliant with the ITU-R BT.601 standard, whether or not to clip values less than or equal to 16 and greater than or equal to 240 in 8-bit encoding (or less than or equal to 64 and greater than or equal to 960 in 10-bit encoding) is specified. This setting is made by using the ICnDTVP.CLP[1:0] register.

9.2.4.3.11 Demosaicing

This function is only valid on input data of the RAW type. Its operation is on the assumption that the RAW data are Bayer data and generates pixel data that are interpolated from the RAW data.

The demosaicing function uses a bilinear method. Of the peripheral 3 × 3 pixels at the position to be calculated, 2 or 4 pixels are used for interpolation processing. The interpolation formula is given below.

The following describes the method of calculating the RGB components (R22, Gb22/Gr22, B22) of the pixels at the center position.

In the case of RAW10/12/14/16/20, the eight higher-order bits are used for the calculation.

(1) RAW20 to RAW16

For a RAW20 input, the higher-order bits of RAW20 are extracted and the lower-order bits are truncated in preprocessing for demosaicing and statistics.

RAW20 → RAW8 (RAW[19:4])

(2) Calculating the Gb22 data portion

Figure 9.2-38 shows the method of interpolation calculation for pixel data (R/G/B) of Gb22.

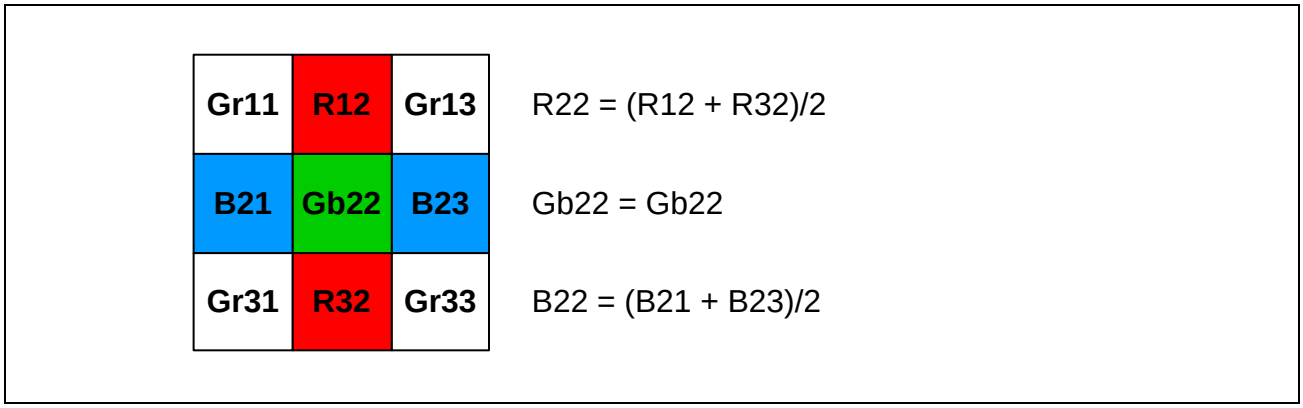

Figure 9.2-38 Calculation of the Gb22 Data Portion

(3) Calculating the B22 data portion

Figure 9.2-39 shows the method of interpolation calculation for pixel data (R/G/B) of B22.

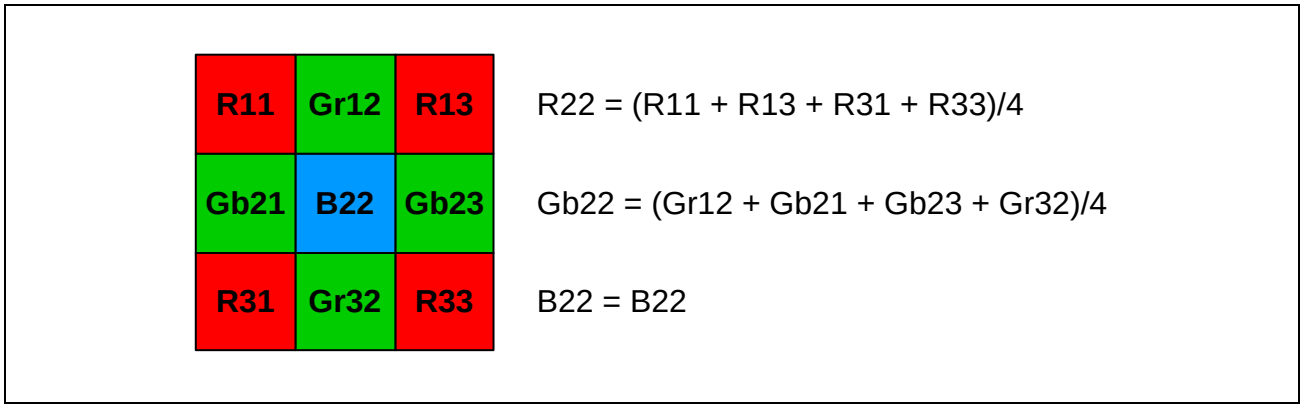

Figure 9.2-39 Calculation of the B22 Data Portion

(4) Calculating the R22 data portion

Figure 9.2-40 shows the method of interpolation calculation for pixel data (R/G/B) of R22.

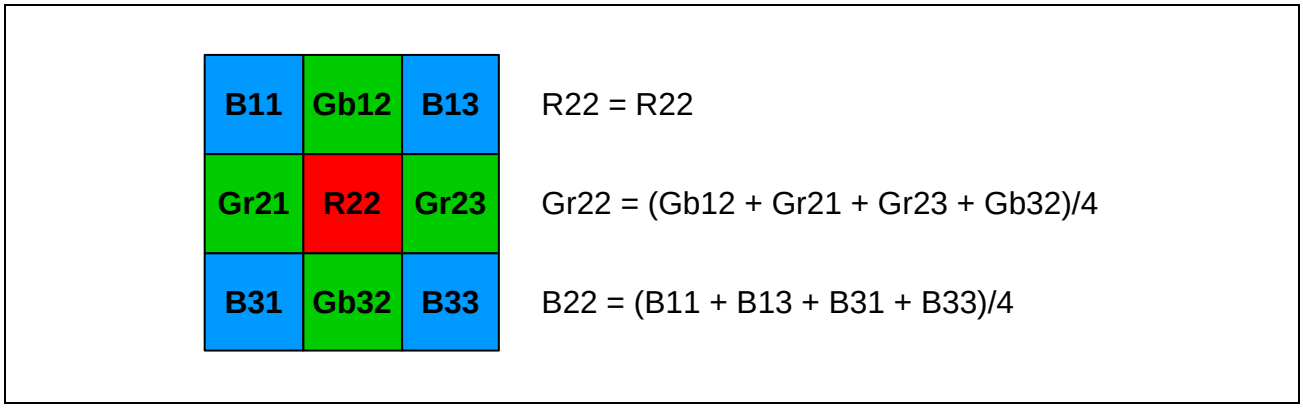

Figure 9.2-40 Calculation of the R22 Data Portion

(5) Calculating the Gr22 data portion

Figure 9.2-41 shows the method of interpolation calculation for pixel data (R/G/B) of G22.

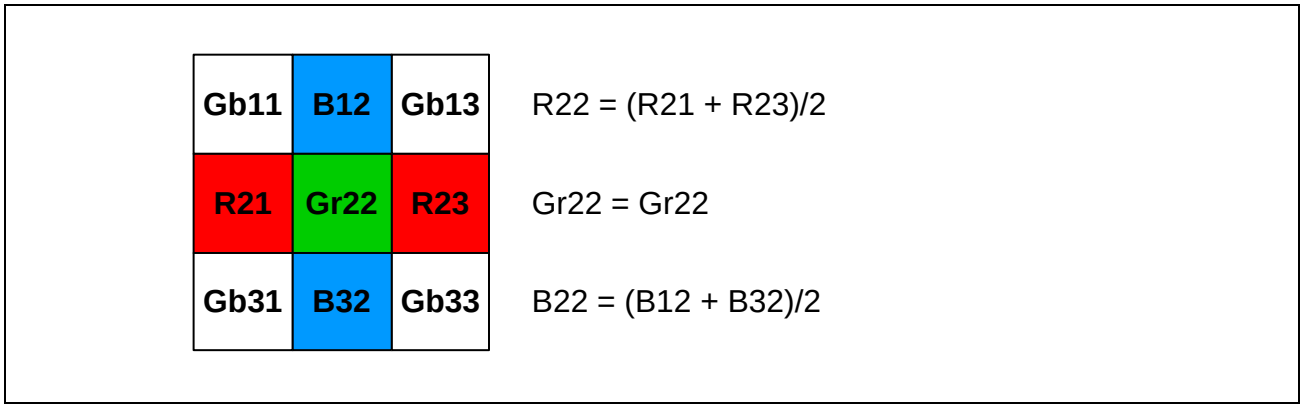

Figure 9.2-41 Calculation of the Gr22 Data Portion

9.2.4.3.12 Linear Matrix

Linear matrix processing involves calculation of the matrix of R', G', and B' (8 bits per color) by using the registers listed below to set the following coefficients for R, G, and B (8 bits per color) after demosaicing as the previous stage.

Gof = Register ICnLMXOF.GOF[7:0]
Rof = Register ICnLMXOF.ROF[7:0]
Bof= Register ICnLMXOF.BOF[7:0]

Rr = Register ICnLMXRC1.RR[12:0]
Rb = Register ICnLMXRC2.RB[12:0]
Rg = Register ICnLMXRC2.RG[12:0]

Gr = Register ICnLMXGC1.GR[12:0]
Gb = Register ICnLMXGC2.GB[12:0]
Gg = Register ICnLMXGC2.GG[12:0]

Br = Register ICnLMXBC1.BR[12:0]
Bb = Register ICnLMXBC2.BB[12:0]
Bg = Register ICnLMXBC2.BG[12:0]

$$R' = \frac{Rr \cdot (R + Rof)^{*1} + Rg \cdot (G + Gof)^{*1} + Rb \cdot (B + Bof)^{*1}}{1024}$$

$$G' = \frac{Gr \cdot (R + Rof)^{*1} + Gg \cdot (G + Gof)^{*1} + Gb \cdot (B + Bof)^{*1}}{1024}$$

$$B' = \frac{Br \cdot (R + Rof)^{*1} + Bg \cdot (G + Gof)^{*1} + Bb \cdot (B + Bof)^{*1}}{1024}$$

Note 1. When the result of addition is a negative value, it is converted to 0.

9.2.4.3.13 Color Space Conversion

(1) RGB to YCbCr

RGB (8/10 bits) data to which image clipping, frame subsampling, or demosaicing has been applied are expanded to 12 bits and then converted to 10-bit YCbCr. Calculations equivalent to those specified in ITU-R BT.601 or ITU-R BT.709 are performed by setting coefficients through registers.

The calculations proceed according to the coefficients and expressions set in the following registers.

YCLRP = Register ICnYCCR1.YCLRP[12:0]
YCLBP = Register ICnYCCR2.YCLBP[12:0]
YCLGP = Register ICnYCCR2.YCLGP[12:0]
YCLSFT = Register ICnYCCR3.YCLSFT[4:0]
YCLAP = Register ICnYCCR3.YCLAP[11:0]

CBCLRP = Register ICnCBCCR1.CBCLRP[12:0]
CBCLBP = Register ICnCBCCR2.CBCLBP[12:0]
CBCLGP = Register ICnCBCCR2.CBCLGP[12:0]
CBCLSFT = Register ICnCBCCR3.CBCLSFT[4:0]
CBCLAP = Register ICnCBCCR3.CBCLAP[11:0]

CRCLRP = Register ICnCRCCR1.CRCLRP[12:0]
CRCLBP = Register ICnCRCCR2.CRCLBP[12:0]
CRCLGP = Register ICnCRCCR2.CRCLGP[12:0]
CRCLSFT = Register ICnCRCCR3.CRCLSFT[4:0]
CRCLAP = Register ICnCRCCR3.CRCLAP[11:0]

$$Y = \left(\frac{YCLRP \times R + YCLGP \times G + YCLBP \times B}{2^{YCLSFT}}\right) + YCLAP$$

$$Cb = \left(\frac{CBCLRP \times R + CBCLGP \times G + CBCLBP \times B}{2^{CBCLSFT}}\right) + CBCLAP$$

$$Cr = \left(\frac{CRCLRP \times R + CRCLGP \times G + CRCLBP \times B}{2^{CRCLSFT}}\right) + CRCLAP$$

For ITU-R BT.601 (8 bits): (Same as the default values)

$Y = 0.257 \times R + 0.504 \times G + 0.098 \times B + 16$
$Cb = -0.148 \times R - 0.291 \times G + 0.439 \times B + 128$
$Cr = 0.439 \times R - 0.368 \times G - 0.071 \times B + 128$

[Register settings]

YCLRP = 0107h
YCLBP = 0064h
YCLGP = 0204h
YCLSFT = 0Ah
YCLAP = 100h

CBCLRP = 1F68h
CBCLBP = 01C2h
CBCLGP = 1ED6h

CBCLSFT = 0Ah
CBCLAP = 800h

CRCLRP = 01C2h
CRCLBP = 1FB7h
CRCLGP = 1E87h
CRCLSFT = 0Ah
CRCLAP = 800h

(2) YCbCr to RGB

YCbCr (8/10 bits) data which have been arranged and clipped are expanded to 12 bits (by appending zeros as the lower-order bits) and then converted to 10-bit RGB. Calculations equivalent to those specified in ITU-R BT.601 or ITU-R BT.709 are performed by setting coefficients through registers.

The calculations proceed according to the coefficients and expressions set in the following registers.

YMUL = Register ICnCSCC1.YMUL[13:0]
YSUB = RegisterICnCSCC2.YSUB[11:0]
RCRMUL = Register ICnCSCC2.CSUB[11:0]
GCRMUL = Register ICnCSCC3.RCRMUL[13:0]
GCBMUL = Register ICnCSCC3.GCRMUL[13:0]
BCBMUL = Register ICnCSCC4.GCBMUL[13:0]
CSUB = Register ICnCSCC4.BCBMUL[13:0]

$$R = \frac{(YMUL \times (Y - YSUB)^{*1} + RCRMUL \times (Cr - CSUB)}{4096}$$

$$G = \frac{YMUL \times (Y - YSUB)^{*1} - GCRMUL \times (Cr - CSUB) - GCBMUL \times (Cb - CSUB)}{4096}$$

$$B = \frac{YMUL \times (Y - YSUB)^{*1} + BCBMUL \times (Cb - CSUB)}{4096}$$

Note 1. A negative value is rounded up to 0.

For ITU-R BT.601 (8 bits): (Same as the default values)

R = 1.164 × (Y − 16) + 1.596 × (Cr − 128)
G = 1.164 × (Y − 16) − 0.813 × (Cr − 128) − 0.392 × (Cb − 128)
B = 1.164 × (Y − 16) + 2.017 × (Cb − 128)

[Register settings]

YMUL = 129Fh
YSUB = 100h
RCRMUL = 1989h
GCRMUL = 0D02h
GCBMUL = 0645h
BCBMUL = 2045h
CSUB = 800h

9.2.4.3.14 LUT (Lookup Table)

This is used to convert 10-bit data after color space conversion (YCbCr to RGB or RGB to YCbCr) into 8-bit data.

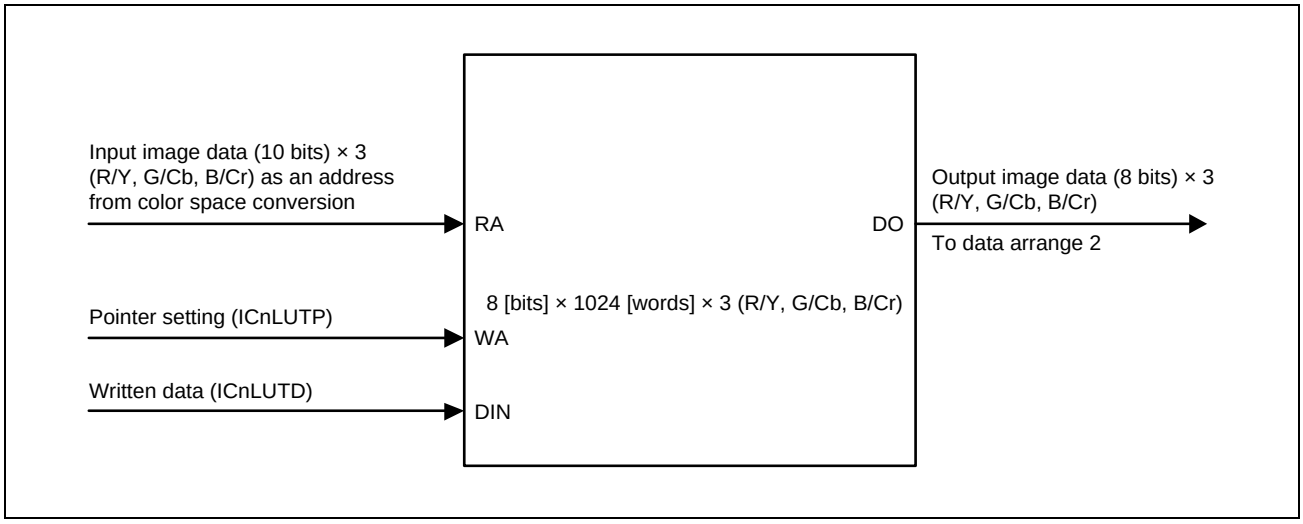

Figure 9.2-42 Lookup Table (LUT)

(1) Pointer Access

The pointer is incremented every time the ICnLUTD register is written.

The incremented value can be read from the ICnLUTP register. When the ICnLUTD register is read, the pointer is not incremented. The pointer must be set immediately before the register is read.

Follow the procedure below to access the lookup table. See **9.2.5.1 Starting Reception for the MIPI CSI-2 Input**.

The lookup table cannot be accessed from the CPU in normal mode.

(2) Usage Notes on LUT

1. Set the lookup table only after the CRU has stopped its operation.
2. Rewrite the entire lookup table before use because the initial values are not guaranteed after the power is turned on.
3. Data to be set in the lookup table must be restricted to the range that is compatible with the input bit width.

9.2.4.3.15 YC Post Processing

(1) YCbCr422 to 420

This function thins out the even-line CbCr data for the image processed in the previous stage and outputs only Y. Averaging or any other calculations are not performed. This conversion can be set by ICnDMR.YCMODE[2:0]=100b/101b/110b.

(2) Y/C Separation

This function separates the Y and C (CbCr) components for storage in two separate memory banks of the DRAM. For details, see **9.2.4.3.3 Transfer to DRAM**.

(3) Y Only

This function changes the method of storage in the DRAM. For details, see **9.2.4.3.3 Transfer to DRAM**.

9.2.4.3.16 VC/Data Type Selector (for Non-Image Processing)

When non-image processing is selected, set the target SVC and data types. When selecting the number of channels of SVC to be used, use the ICnSVCNUM.SVCNUM[1:0] register to set how many channels are used from among SVC0 to 3. Selection of SVCs with the ICnSVC.SVC0~3[3:0] registers determines the allocation of which channels are to be selected from among VC0 to VC15 for SVC0 to 3.

In data type selection, the required type can be selected with the ICnNIPDT_C0~3H/L registers and selection of several types is also possible (see **Figure 9.2-43**).

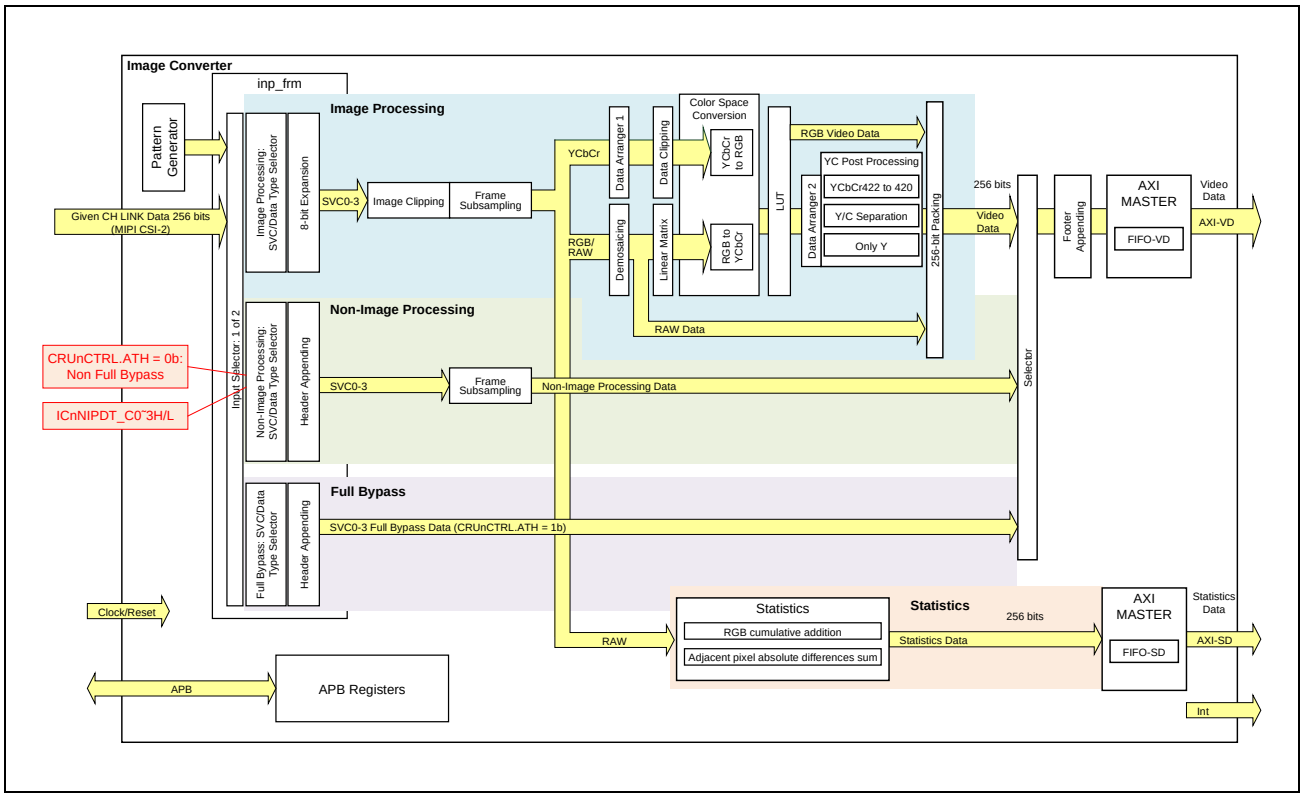

Figure 9.2-43 Example of VC Specification and Selection of Several Data Types for Non-Image Processing

9.2.4.3.17 Full Bypass function

Figure 9.2-44 shows an example of the settings for full bypass. These settings are used when you want to store images in memory without processing them within the CRU (for example, when you want to process images with the unit).

The full bypass function handles the transfer of data of the data type selected for the specified single VC from the video data bus to memory. Data are not corrected at all and are transferred in the recommended memory storage format for MIPI CSI-2.

The data types are not limited to one and several types can be selected by the settings of ICnNIPDT_C0~3H/L.

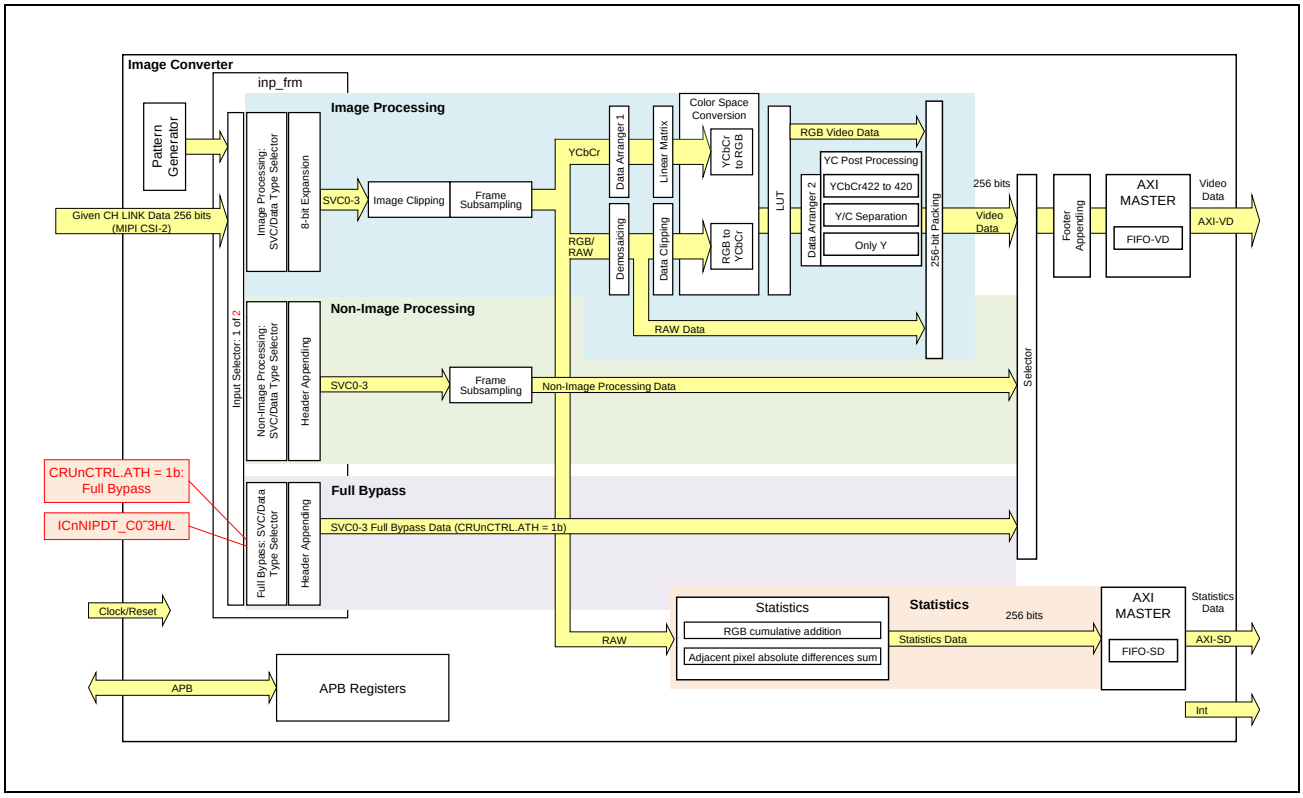

Figure 9.2-44 Example of Settings for Full Bypass

9.2.4.3.18 Statistics

This function is limited to a RAW data input through SVC0. This module divides one image vertically and horizontally into blocks (see **Figure 9.2-45**). The statistical information within this block is transferred to memory and the image is adjusted by weighting the information of every block by the CPU and providing feedback to the external video state.

The number of block divisions can be determined by the setting of register ICnSTIC1.STUNIT[1:0].

The statistical information of each block has two types and their respective purposes are as follows.

1) In-block accumulation

Accumulation of each color component, R, G, and B, is performed within each block.

On the CPU side, the weighting is applied per block based on the information from each block, and the obtained evaluation values can be used for exposure control, etc. from the next frame.

The weighting could in general be center-weighted allocation, weighted allocation according to the subject, and so on. If the subject is judged to be dark, exposure control is applied to widen the aperture, and if the subject is judged to be bright, the aperture is made narrower.

Additionally, each color component among the R, G, and B components is adjusted and the latter stage performs operations in such a way that the B component is reduced, for example, in video which appears bluish in white regions.

This adjustment of each color includes changing the coefficients of the sensor or the linear matrix as the latter stage.

2) In-block sum of absolute difference values

Focusing on the G component within the block, the overall value for the differences from the adjacent parts of the image is extracted and accumulation is performed within the block.

On the CPU side, the weighting is applied per block based on the information from each block, and the obtained evaluation values can be used for focus adjustment, etc. from the next frame.

The weighing could in general be center-weighted allocation, weighted allocation according to the subject, and so on. If the obtained evaluation value is compared with the previous frame and if the amount continues to be reduced, the evaluation value is increased to adjust the focus, for example, by adjusting the distance between the lens and the sensor toward the opposite direction.

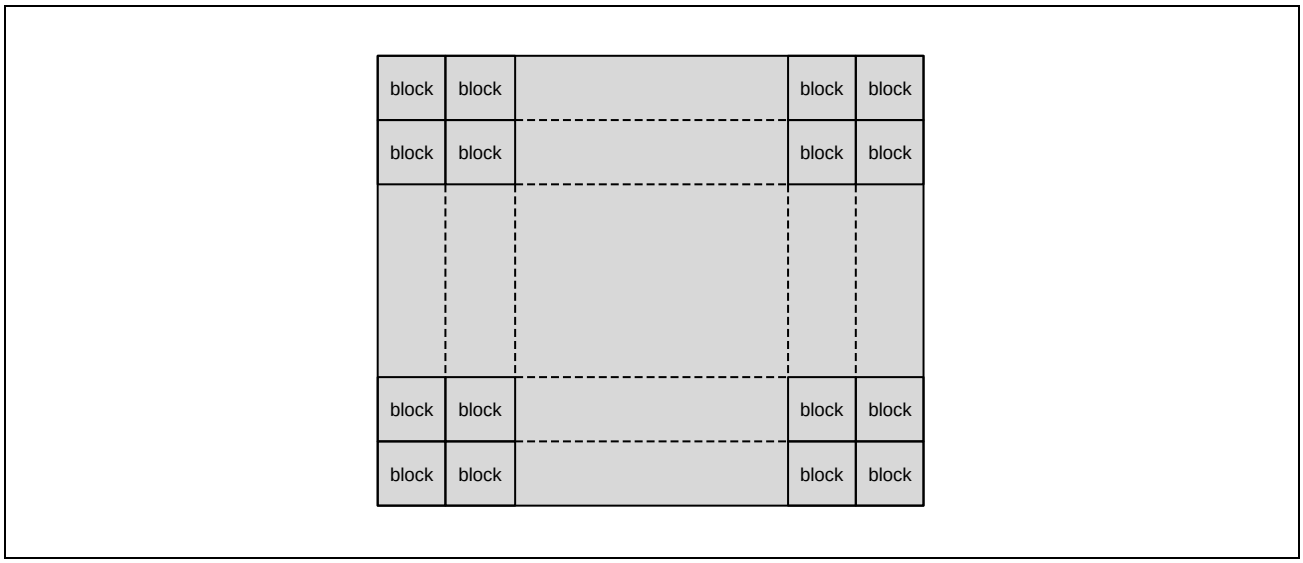

Figure 9.2-45 Image of Dividing an Image into Blocks Vertically and Horizontally

Figure 9.2-46 is a block diagram of statistics. The result of AE/AWB statistical calculations for per block is 8 bits × 3 = 3 bytes, respectively, and that of the AF statistical calculations is 1 byte for G only, so a total of 4 bytes of data are output.

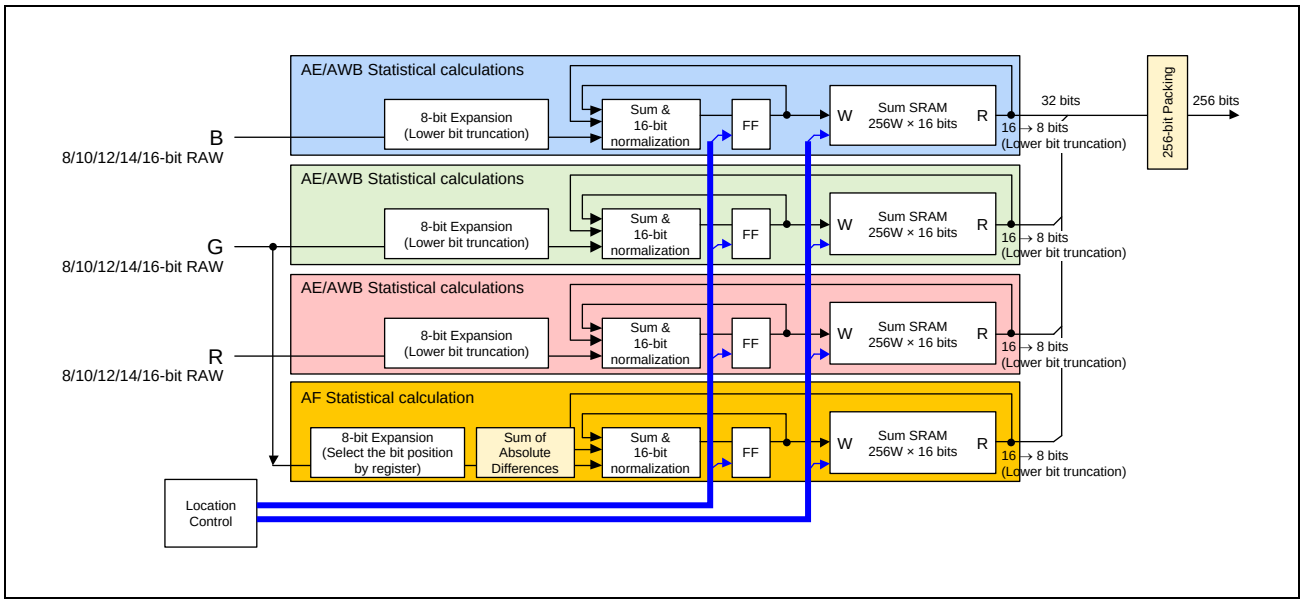

Figure 9.2-46 Statistics Block Diagram

(1) RGB cumulative addition

The STUNIT[1:0] bit fields in each of the ICnSTIC1 registers are used to select the pixel (block) sizes for statistical calculations from among four values, 16×16, 32×32, 64×64, and 128×128. The target pixels when the setting is 16×16 are described in **(a) Target pixels when the block size is selected as 16×16 (ICnSTIC1.STUNIT[1:0] = 0b)** and the methods of calculation for each block-size setting are described in **(b) Methods of calculation for each block-size setting**.

(a) Target pixels when the block size is selected as 16×16 (ICnSTIC1.STUNIT[1:0] = 0b)

G component: 128 pixels are present in the area of 16×16
R and B components: 64 pixels are present in the area of 16×16

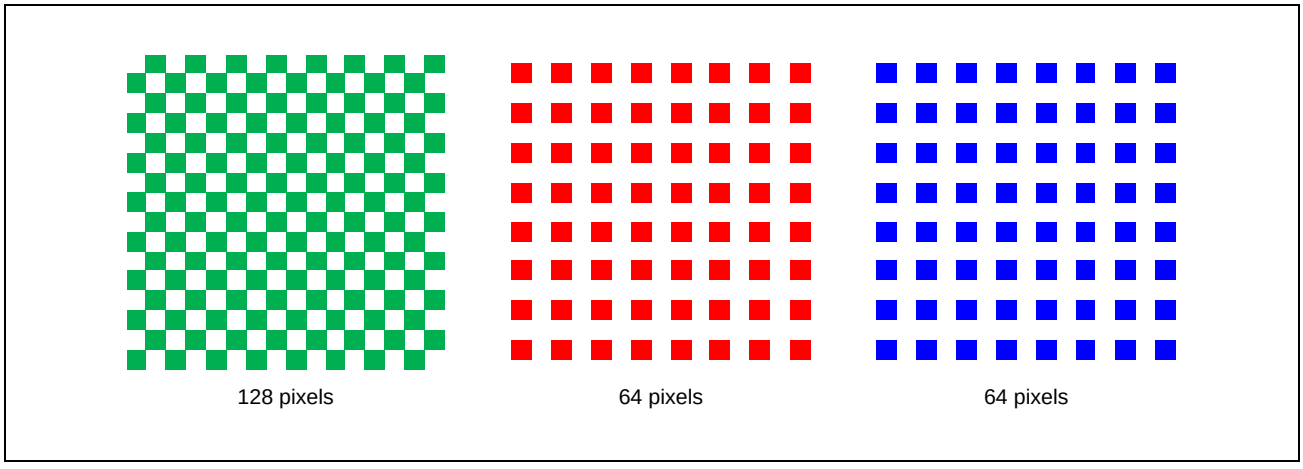

Figure 9.2-47 Target Pixels when the Block Size is Selected as 16×16

(b) Methods of calculation for each block-size setting

[G component]

- When the block size is 16×16: 8 bits × 128 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
- When the block size is 32×32: 8 bits × 512 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
- When the block size is 64×64: 8 bits × 2048 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
- When the block size is 128×128: 8 bits × 8192 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.

[R and B components]

- When the block size is 16×16: 8 bits × 64 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
- When the block size is 32×32: 8 bits × 256 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
- When the block size is 64×64: 8 bits × 1024 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
- When the block size is 128×128: 8 bits × 4096 pixels are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.

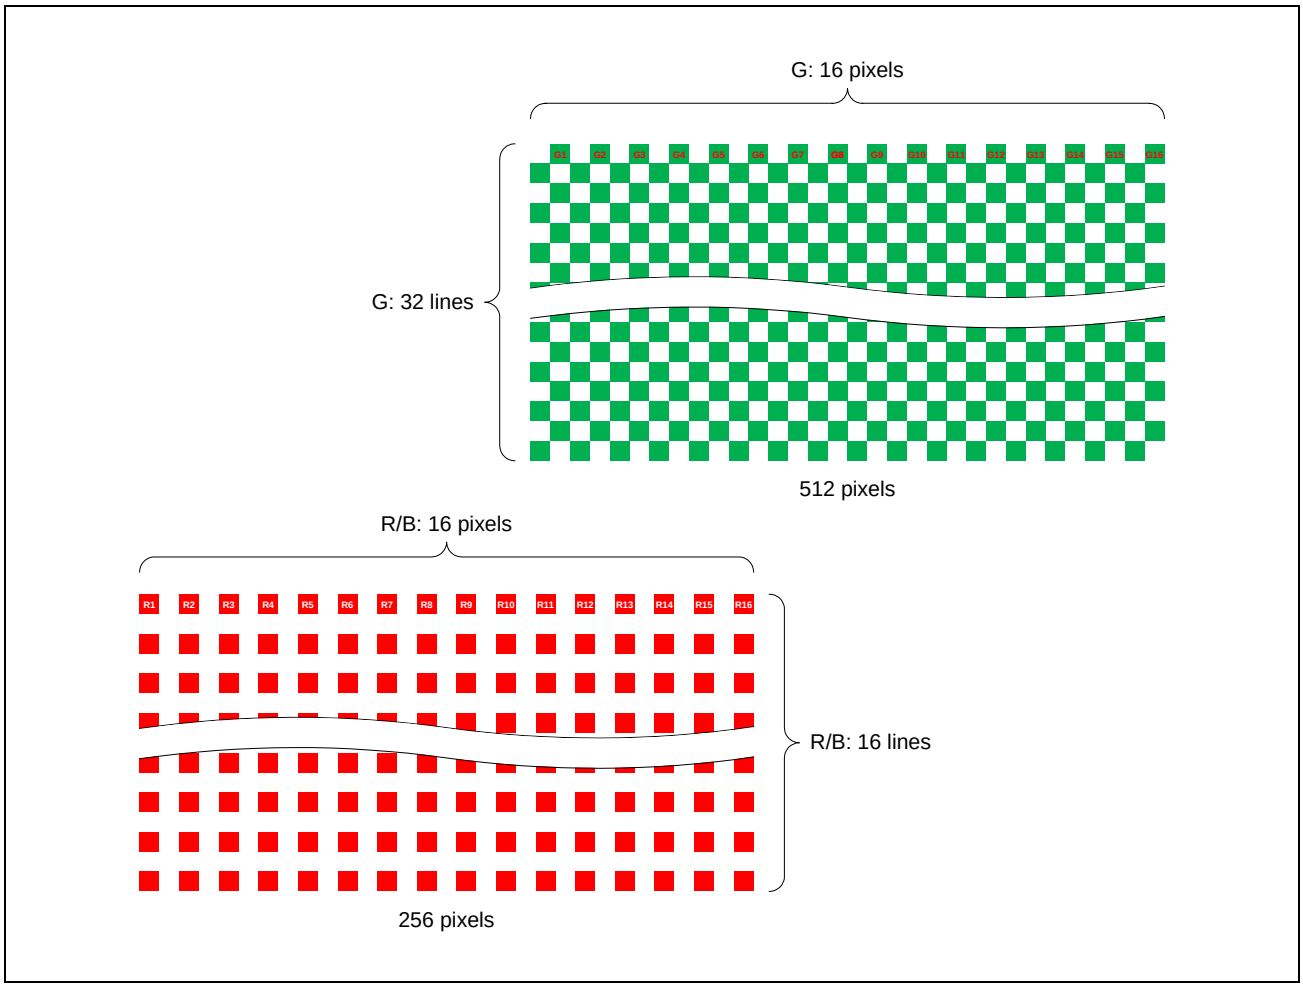

Figure 9.2-48 Illustration Diagram of Accumulation within the Block when the Block Size is 32×32

(2) Sum of absolute differencs for adjacent pixels

Set the area for which the sum of absolute differences for adjacent pixels is taken with the use of register ICnSTIC1.STUNIT[1:0] to make the calculations in the following ways.

- **In the case of 16×16 pixel unit operations (ICnSTIC1.STUNIT[1:0] = 0b):**
  - For 8-bit data: Up to 16 bits
  - For 10- to 16-bit data: A sum-of-absolute-differences (SAD) operation is performed with the eight higher-order bits (default).
  - Addition can also be performed with the eight lower-order bits by shifting the bits by setting register ICnSTIC1.STSADPOS[3:0].

- **Methods of calculation for the setting area:**

[G component calculation]

  - When the block size is 16×16: Adjacent differences × 128 are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
  - When the block size is 32×32: Adjacent differences × 512 are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
  - When the block size is 64×64: Adjacent differences × 2048 are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.
  - When the block size is 128×128: Adjacent differences × 8192 are accumulated: The eight higher-order bits are output after accumulation and normalization with a 16-bit precision.

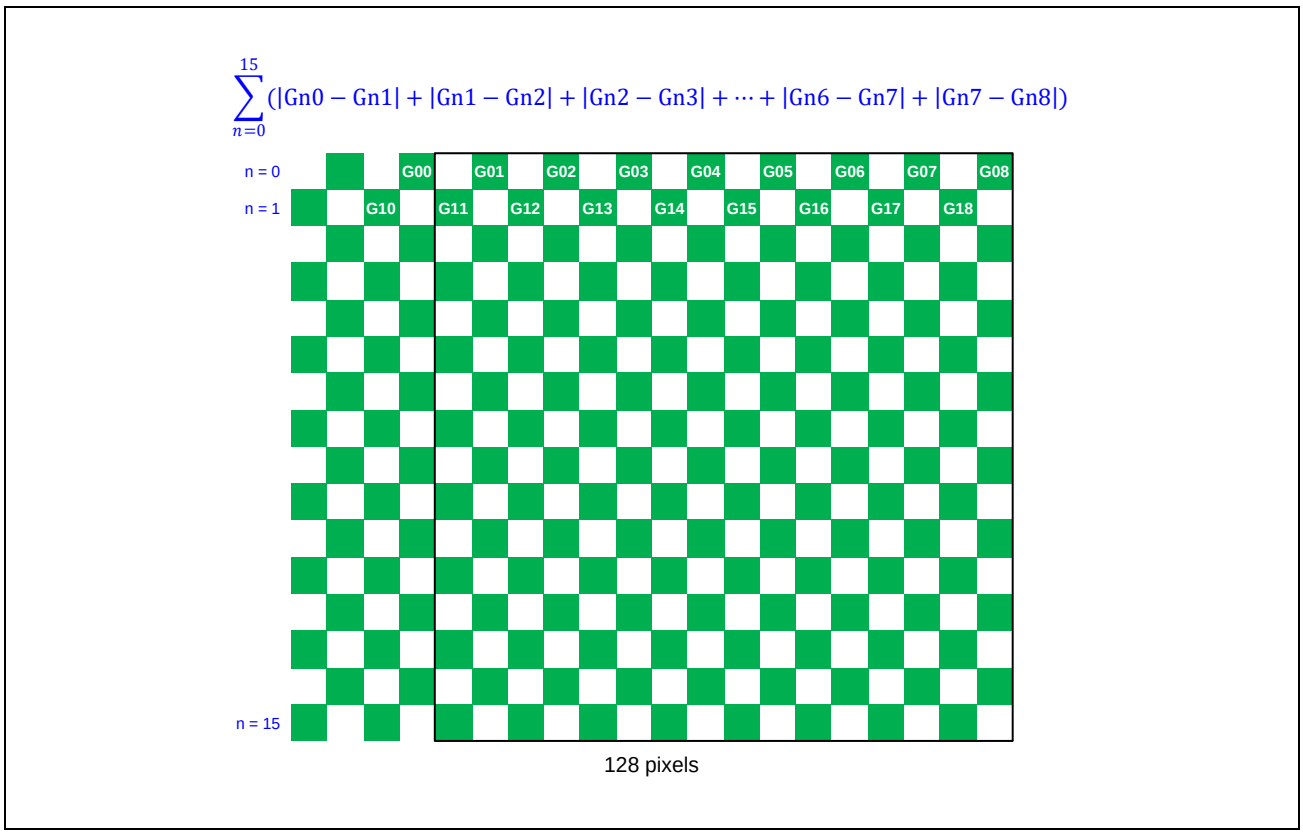

Figure 9.2-49 Illustration Diagram of Sum of Absolute Differences for Adjacent Pixels when the Block Size is 16×16

(3) Statistics data generated image

The following describes the amounts of data in the operations when a 1920×1080 pixel area is set as 16×16 blocks and as 128×128 blocks for the statistics function. The numerals in the figures below represent the block numbers. In processing of the right end or bottom of the image, if the input image size is greater than the size specified as the number of blocks in the horizontal direction, that difference does not fall within the target range for arithmetic processing. This also applies in the vertical direction.

- **In the case of operations for a 1920×1080 pixel area as 16×16 pixels:**

As shown in **Figure 9.2-50**, the calculated values for each of the blocks are transferred sequentially. A total of 31 Kbytes of data are transferred for one frame. For the format of data for transmission, see **Table 9.2-15**.

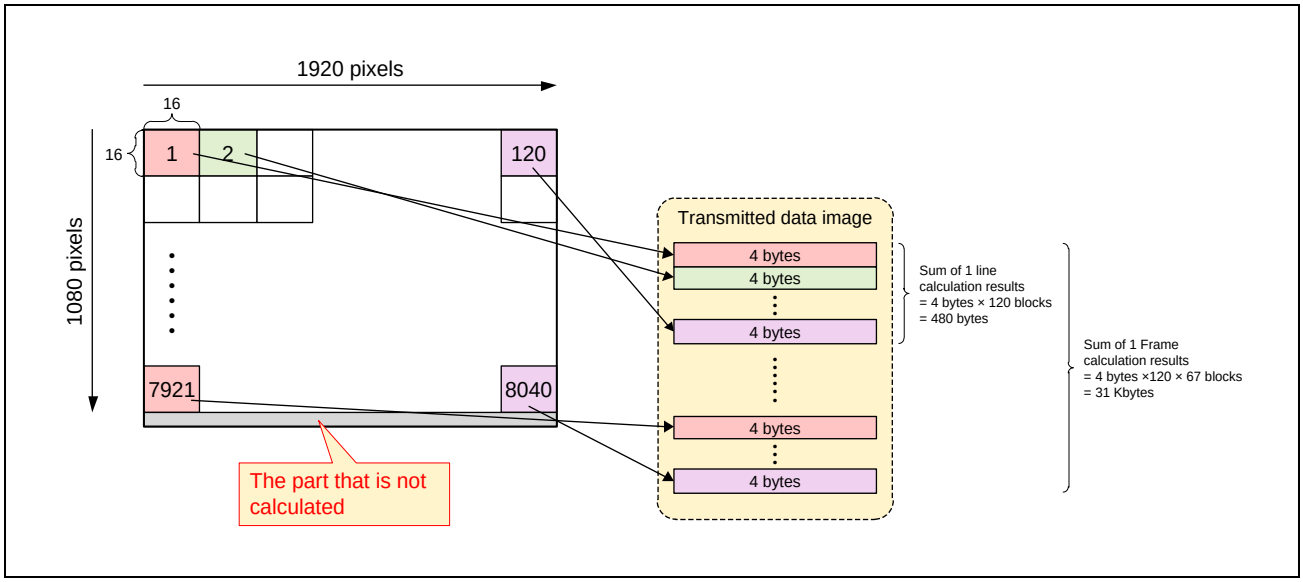

Figure 9.2-50 Illustration Diagram of the Amounts of Data in the Operations when a 1920×1080 Pixel Area is Set as 16×16 Blocks

● **In the case of operations for a 1920×1080 pixel area as 128×128 pixels:**

The calculated values for the corresponding blocks are sequentially transferred. A total of 480 bytes of data are transferred for one frame.

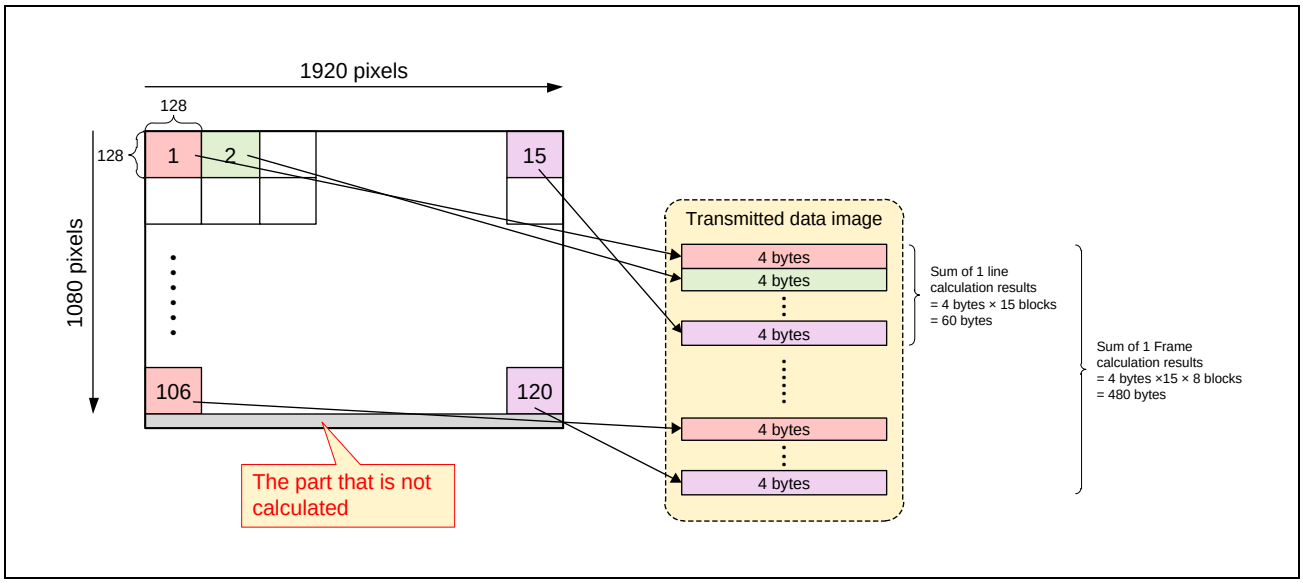

Figure 9.2-51 Illustration Diagram of the Amounts of Data in the Operations when a 1920×1080 Pixel Area is Set as 128×128 Blocks

Confirm the completion of transfer for one frame by setting the specified address interrupt described in **9.2.4.4.2 Designated address forwarding completion interrupt**.

9.2.4.4 Interrupts

9.2.4.4.1 Interrupt list

Table 9.2-23 lists the interrupt sources and registers, and the interrupt signals to the interrupt controller.

Table 9.2-23 Interrupt Sources and Registers, and Interrupt Signals (1/2) [n = 0]

Internal Signal Name	Kind	Item	Interrupt Source Status/Clear	Interrupt Enable Register Field	Generated Blocks	Conditions for Occurrence
axi_mst_err_int	Level	FIFO-VD overflow (video data) (for debugging)	CRUnINTS1.FOS	CRUnIE1.FOE	FIFO-VD	When Video data FIFO-VD overflows.
		SLVERR error (video data)	CRUnINTS1.SLVES	CRUnIE1.SLVEE	AXI-VD	When Video Data AXI-VD SLVERR error occurs.
		DECERR error (video data)	CRUnINTS1.DECES	CRUnIE1.DECEE	AXI-VD	When Video Data AXI-VD DECERR error occurs.
		FIFO-SD overflow (statistics data) (for debugging)	CRUnINTS1.SDFOS	CRUnIE1.SDFOE	FIFO-SD	When Statistics Data FIFO-SD overflows.
		SLVERR error (statistics data)	CRUnINTS1.SDSLVES	CRUnIE1.SDSLVEE	AXI-SD	When the SLVERR error of Statistics Data AXI-SD occurs.
		DECERR error (statistics data)	CRUnINTS1.SDDECES	CRUnIE1.SDDECEE	AXI-SD	When the Statistics Data AXI-SD DECERR error.
image_conv_int *1	Level	SVC0 frame start	CRUnINTS2.FS0S	CRUnIE2.FS0E	Image Clipping	When SVC0 frame starts
	Level	SVC0 frame end	CRUnINTS2.FE0S	CRUnIE2.FE0E	Image Clipping	When SVC0 frame ends
	Level	SVC0 scan line	CRUnINTS2.SL0S	CRUnIE2.SL0E	Image Clipping	When the SVC0 register (ICnSI_C0.SI[11:0]) matches the set number of lines
	Level	SVC1 frame start	CRUnINTS2.FS1S	CRUnIE2.FS1E	Image Clipping	When SVC1 frame starts
	Level	SVC1 frame end	CRUnINTS2.FE1S	CRUnIE2.FE1E	Image Clipping	When SVC1 frame ends
	Level	SVC1 scan line	CRUnINTS2.SL1S	CRUnIE2.SL1E	Image Clipping	When the SVC1 register (ICnSI_C1.SI[11:0]) matches the set number of lines
	Level	SVC2 frame start	CRUnINTS2.FS2S	CRUnIE2.FS2E	Image Clipping	When SVC2 frame starts
	Level	SVC2 frame end	CRUnINTS2.FE2S	CRUnIE2.FE2E	Image Clipping	When SVC2 frame ends
	Level	SVC2 scan line	CRUnINTS2.SL2S	CRUnIE2.SL2E	Image Clipping	When the SVC2 register (ICnSI_C2.SI[11:0]) matches the set number of lines
	Level	SVC3 frame start	CRUnINTS2.FS3S	CRUnIE2.FS3E	Image Clipping	When SVC3 frame starts
	Level	SVC3 frame end	CRUnINTS2.FE3S	CRUnIE2.FE3E	Image Clipping	When SVC3 frame ends
	Level	SVC3 scan line	CRUnINTS2.SL3S	CRUnIE2.SL3E	Image Clipping	When the SVC3 register (ICnSI_C3.SI[11:0]) matches the set number of lines
cru_vd_addr_wend	Edge	Specified address 0 write completed (video data)	—	CRUnIE2.VDADR0WE	AXI-VD	When AXI-VD bus write to AXI-VD Bus Transfer Completion Event Address 0 Higher/Lower Register (AMnIVT0ADDRH/L) address is completed.
cru_sd_addr_wend	Edge	Specified address 0 write completed (statistics data)	—	CRUnIE2.SDADR0WE	AXI-SD	When AXI-SD bus write to AXI-SD Bus Transfer Completion Event Address 0 Higher/Lower Register (AMnSDIVT0ADDRH/L) address is completed.

Table 9.2-23 Interrupt Sources and Registers, and Interrupt Signals (2/2) [n = 0]

Internal Signal Name	Kind	Item	Interrupt Factor Status/Clear	Interrupt Enable Register Field	Generation Blocks	Conditions of Occurrence
cru_vsd_addr_wend	Level	Specified address 1 write completed (video data)	CRUnINTS2. VDADR1WS	CRUnIE2.VDADR1WE	AXI-VD	When AXI-VD bus write to AXI-VD Bus Transfer Completion Event Address 1 Higher/Lower Register (AMnIVT1ADDRH/L) address is completed.
		Specified address 2 write completed (video data)	CRUnINTS2. VDADR2WS	CRUnIE2.VDADR2WE	AXI-VD	When AXI-VD bus write to AXI-VD Bus Transfer Completion Event Address 2 Higher/Lower Register (AMnIVT2ADDRH/L) address is completed..
		Specified address 3 write completed (video data)	CRUnINTS2. VDADR3WS	CRUnIE2.VDADR3WE	AXI-VD	When AXI-VD bus write to AXI-VD Bus Transfer Completion Event Address 3 Higher/Lower Register (AMnIVT3ADDRH/L) address is completed..
		Specified address 4 write completed (video data)	CRUnINTS2. VDADR4WS	CRUnIE2.VDADR4WE	AXI-VD	When AXI-VD bus write to AXI-VD Bus Transfer Completion Event Address 4 Higher/Lower Register (AMnIVT4ADDRH/L) address is completed.
		Specified address 1 write completed (statistics data)	CRUnINTS2. SDADR1WS	CRUnIE2.SDADR1WE	AXI-SD	When AXI-SD bus write to AXI-SD Bus Transfer Completion Event Address 1 Higher/Lower Register (AMnSDIVT1ADDRH/L) address is completed.

Note 1. An interrupt from SVC is detected in image processing. It is not detected in non-image processing/full bypass. The ICnINTCTRL.DECINT register allows you to set whether or not interrupts are issued for subsampled frames.

9.2.4.4.2 Designated address forwarding completion interrupt

This interrupt function is used to notify the CPU of the timing of fetching video and statistics data by using an interrupt.

Set the desired addresses in the DRAM as the destinations for data transfer by using the AMnIVT0/1/2/3/4ADDRH/L (for video data) and AMnSDIVT0ADDRH/L (for statistics data) registers. Up to four addresses can be set for video data and up to two addresses can be set for statistics data. These must be set according to the number of memory banks and the speed of reading by the CPU. An interrupt is generated upon the completion of writing to the address set by the AXI master (AXI-VD, AXI-SD).

Figure 9.2-52 shows an example when the number of memory banks is 4 for video data and the last addresses of memory banks 2 and 4 are set as the completion addresses.

The CPU reads data from the initial data in bank 1 in response to the first interrupt as a trigger and then reads up to the end of bank 2. When the next interrupt arrives, the CPU reads data from the initial data in bank 3 and then reads up to the end of bank 4. This is thereafter repeated and consecutive data can thus be read.

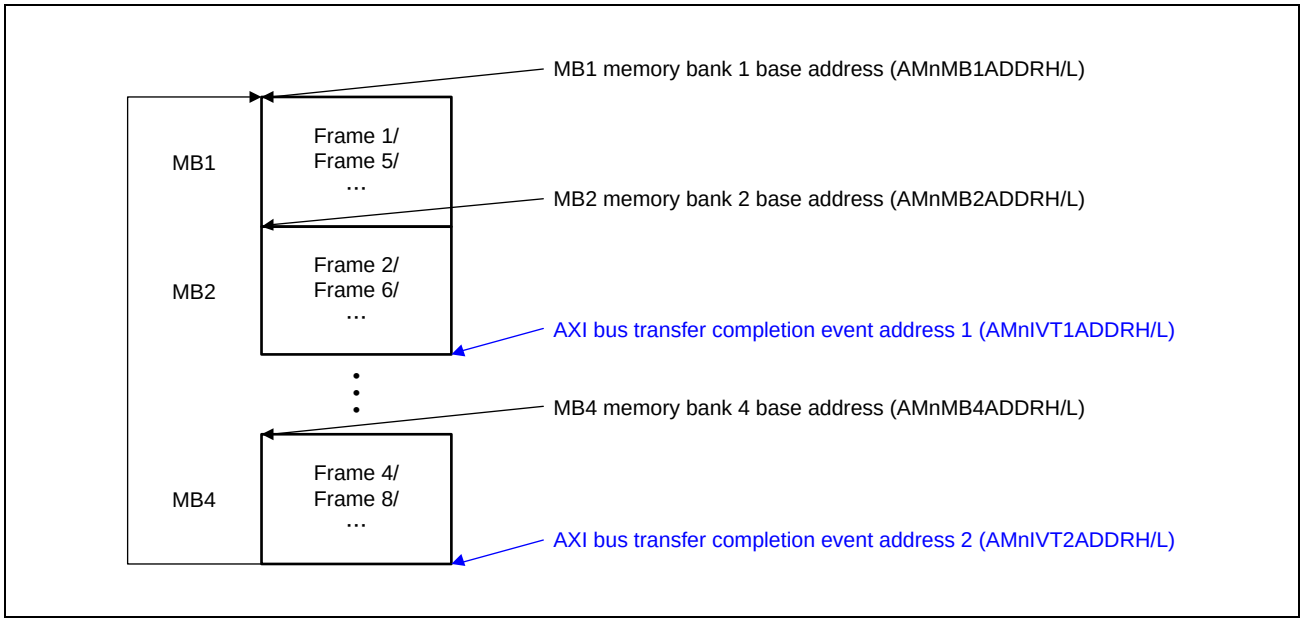

Figure 9.2-52 Example when the Number of Memory Banks is 4 for Video Data and the Last Addresses of Memory Banks 2 and 4 are Set as the Completion Addresses

9.2.4.5 Usage Notes

Use of this CRU requires caution on the following points.

(1) The following functions can only be used with SVC0 (that is, they cannot be used with SVC1 to SVC3).
- Demosaicing
- Statistics
- Changing the frame synchronization

(2) The same data (the same data type for the same VC) cannot be set for image processing and non-image processing. For example, making the following register settings is prohibited.

(Case1) This is an example of setting the same VC data type in Image Process to SVC0 and SVC1.
- SVC0: VC0, YUV422 8-bit: ICnSVC.SVC0[3:0] = 0h, ICnIPMC_C0.INF[5:0] = 1Eh
- SVC1: VC0, YUV422 8-bit: ICnSVC.SVC1[3:0] = 0h, ICnIPMC_C1.INF[5:0] = 1Eh

(Case2) This is an example of setting the same VC data type in Non Image Process to SVC0 and SVC1.
- SVC0: VC0, YUV422 8-bit: ICnSVC.SVC0[3:0] = 0h, ICnNIPDT_C0L.NIPDT_C0L[30] = 1b
- SVC1: VC0, YUV422 8-bit: ICnSVC.SVC1[3:0] = 0h, ICnNIPDT_C1L.NIPDT_C1L[30] = 1b

(Case3) This is an example of setting the same VC data type in Image Process and Non Image Process on the same SVC0.
- SVC0: VC0, YUV422 8-bit: ICnSVC.SVC0[3:0] = 0h, ICnIPMC_C0.INF[5:0] = 1Eh
- SVC1: VC0, YUV422 8-bit: ICnNIPDT_C0L.NIPDT_C0L[30]=1b

(3) Interlacing is not supported.

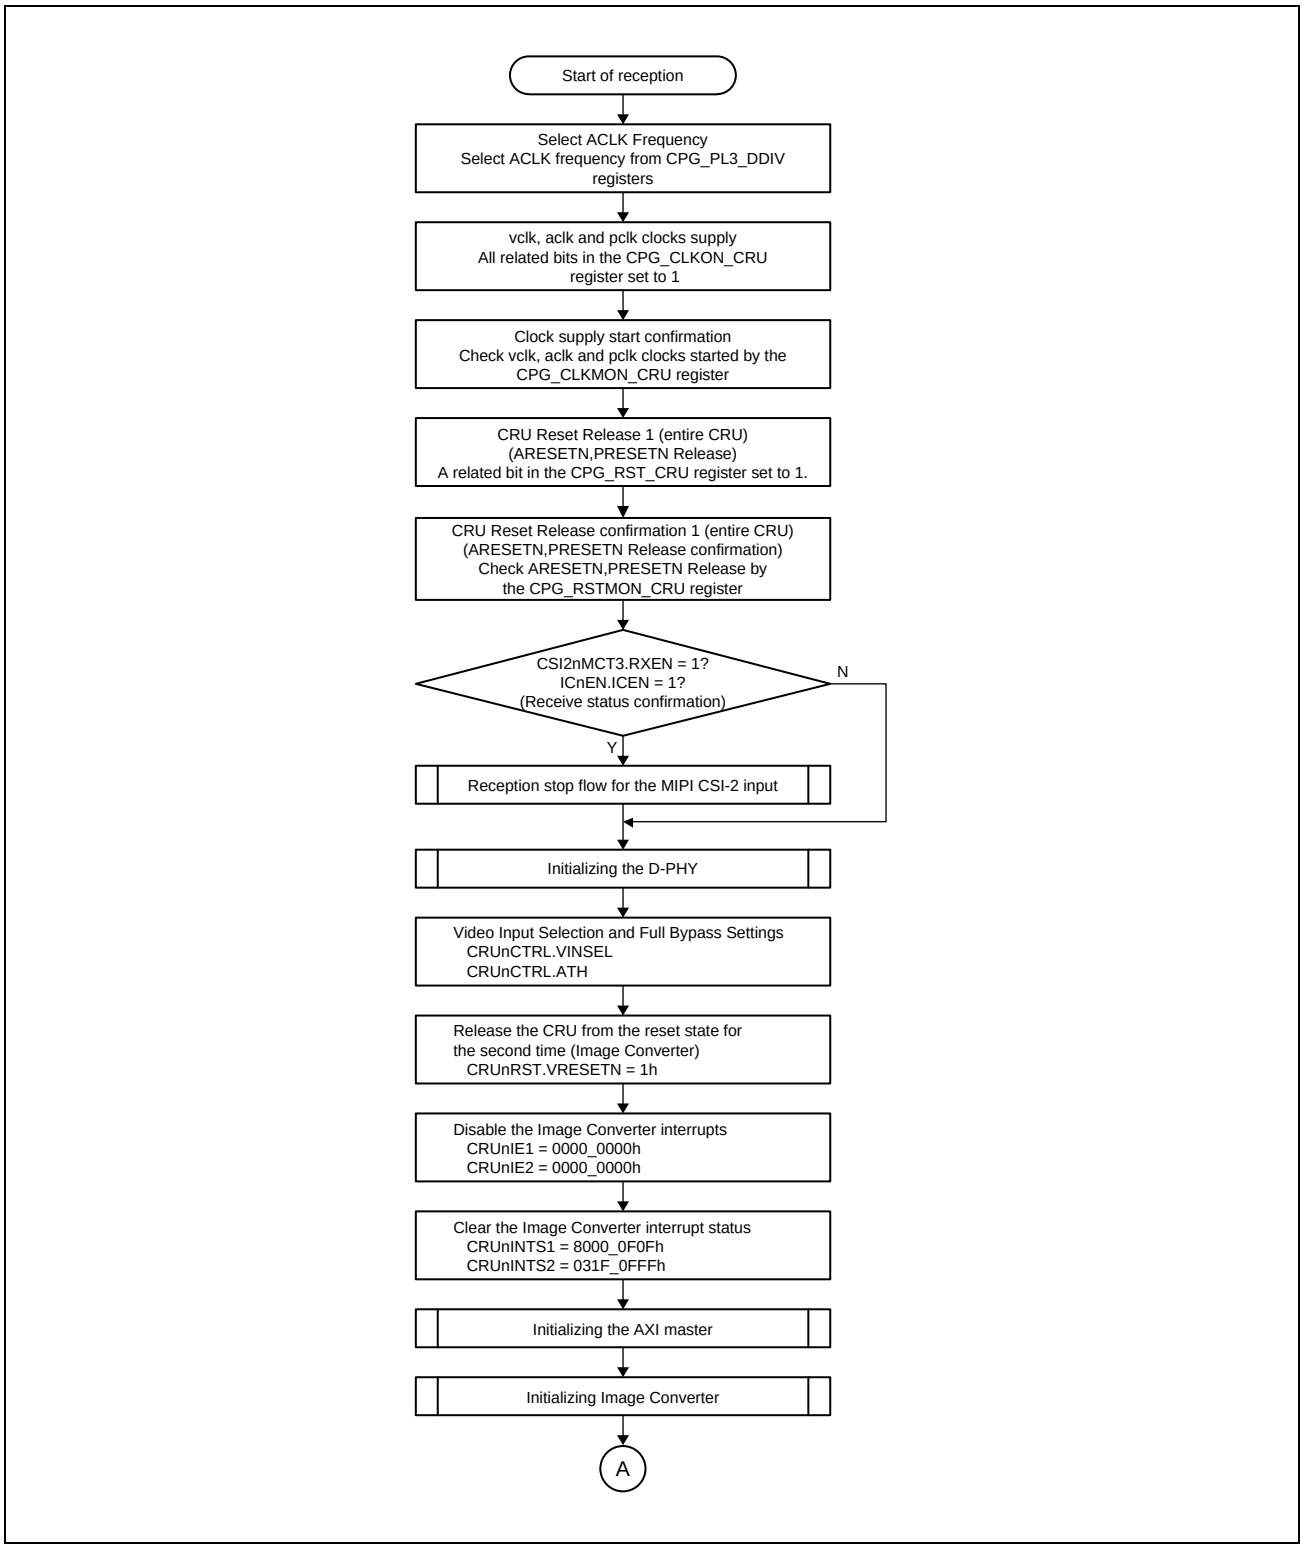
(4) When FIFO-VD and FIFO-SD are in use, make sure that they do not overflow. In the event that an overflow occurs during operation with footers appended, the footer value following the overflow is not guaranteed. In such cases, reset the CRU after it has been stopped.

(5) An interrupt will not occur unless the addresses that are set for the specified address 0 to 4 write completed interrupt are set as addresses to which video or statistics data are to be written, so take care on this point. For example, an interrupt will not occur if video or statistics data are not written to the address which has been set for the specified address 0 to 4 write completed interrupt and the address jumps to the start of the next line due to the image-stride setting.

(6) For the order of the startup of the sensor and CRU, be sure to initialize the CRU before sending data from the sensor, as stated in **9.2.5.1 Starting Reception for the MIPI CSI-2 Input**. If this order is not observed, the CRU may receive incomplete packets of MIPI CSI-2 signals and various errors may occur.

(7) Parameter setting of the SVCs are as follows.

Table 9.2-24 Parameter Setting of the SVCs



Function	SVC0	SVC1	SVC2	SVC3	Note
Image Clipping	(A)	(A)	(A)	(A)	—
Frame Subsampling	(B)	(B)	(B)	(B)	—
Data Arrange 1/2	(B)	(B)	(B)	(B)	—
Data Clip	(B)	(B)	(B)	(B)	—
Color Space Conversion	(B)	(B)	(B)	(B)	—
Demosaic	(C)	(D)	(D)	(D)	When any of the Demosaic, Linear Matrix, and Statistic functions are used, SVC1 to SVC3 cannot be used for other functions.
Linear Matrix	(C)	(D)	(D)	(D)	
Statistics	(C)	(D)	(D)	(D)	
LUT	(B)	(B)	(B)	(B)	—
YCbCr422 to a420	(A)	(A)	(A)	(A)	—
Y/C Separation	(A)	(A)	(A)	(A)	—
Only Y	(A)	(A)	(A)	(A)	—

Note: (A): Can be set independently of other SVCs
(B): Parameter setting common to SVC0 to SVC3
(C): Functions only with SVC0
(D): Cannot be set

(8) Image Stride when output format is YUV420
Note that when the output format is set to YUV420 (ICnDMR.YCMODE[2:0] = 110b), the U/V side is written to RAM as Image Stride (AMnIS) × 2.
See **Image Stride** in **9.2.4.3.3(5)(a) Video data frame** for details.

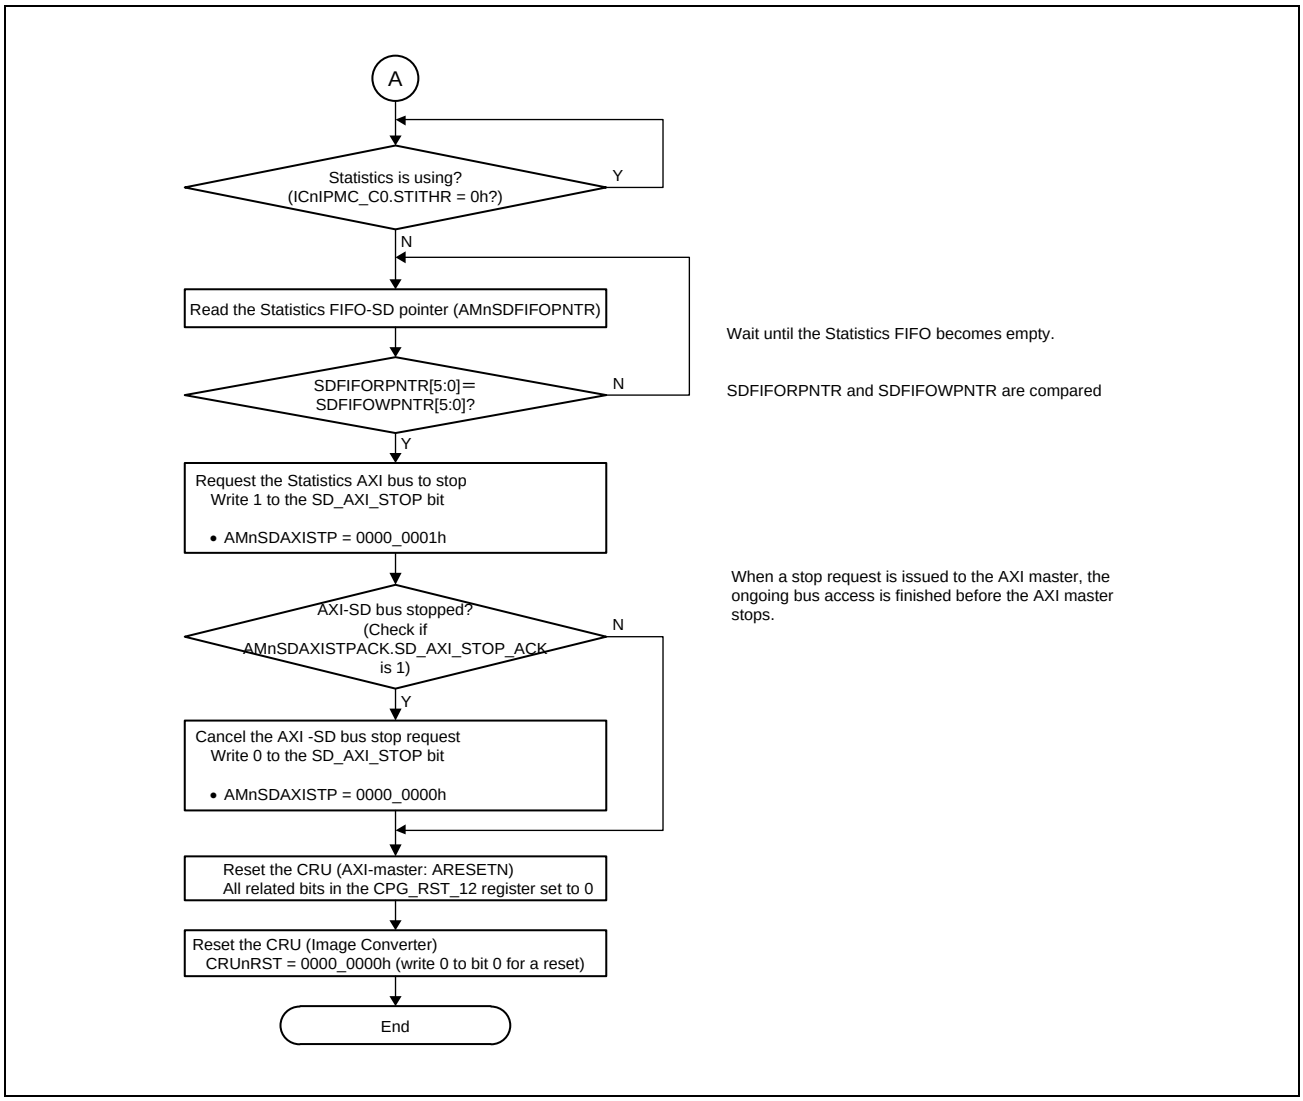

Figure 9.2-62 Stopping Image Processing Reception

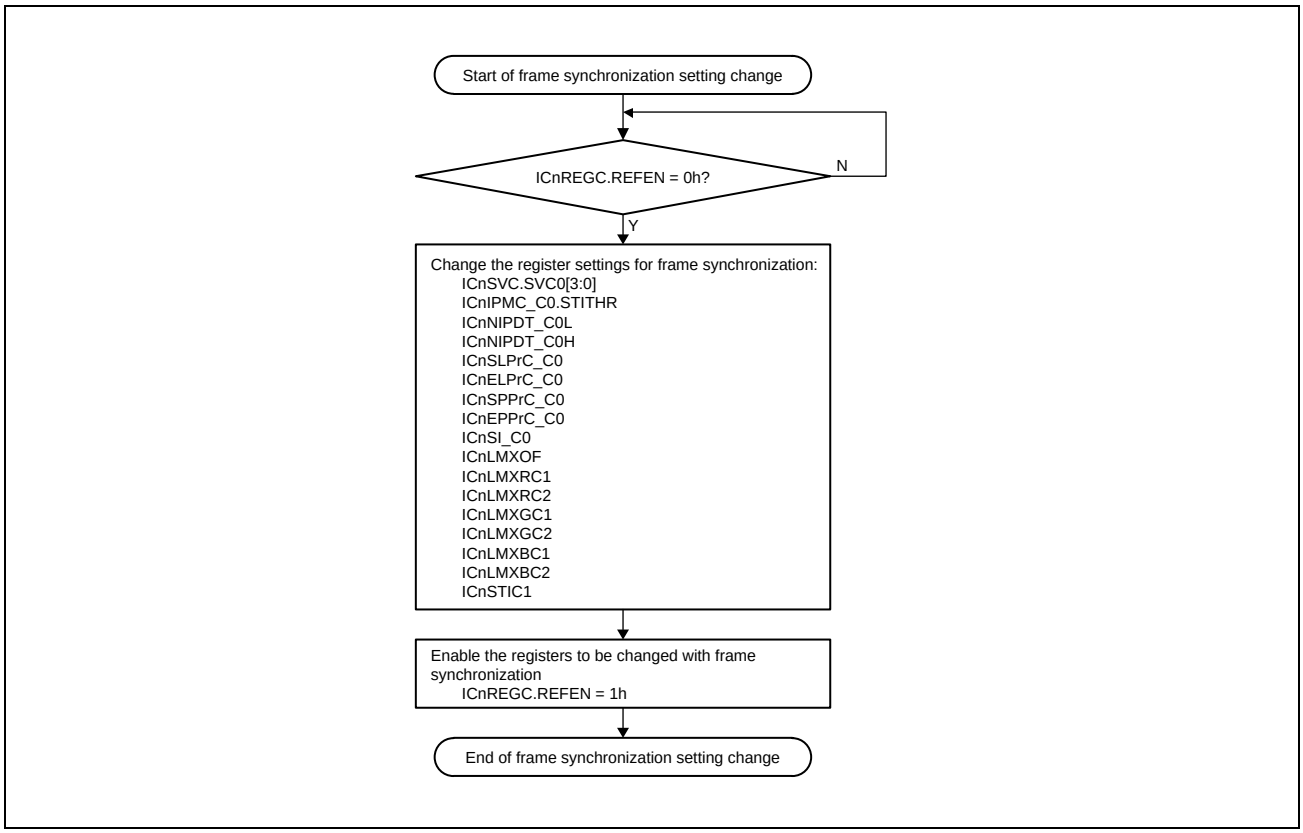
9.2.5.3 Frame Synchronization Settings

While the CRU is receiving data using SVC0, the following registers can only be changed with frame synchronization:

- ICnSVC.SVC0[3:0]
- ICnIPMC_C0.STITHR
- ICnNIPDT_C0L
- ICnNIPDT_C0H
- ICnSLPrC_C0
- ICnELPrC_C0
- ICnSPPrC_C0
- ICnEPPrC_C0
- ICnSI_C0
- ICnLMXOF
- ICnLMXRC1
- ICnLMXRC2
- ICnLMXGC1
- ICnLMXGC2
- ICnLMXBC1
- ICnLMXBC2
- ICnSTIC1

9.2.5.3.1 Changing Frame Synchronization Settings (by Setting Registers)



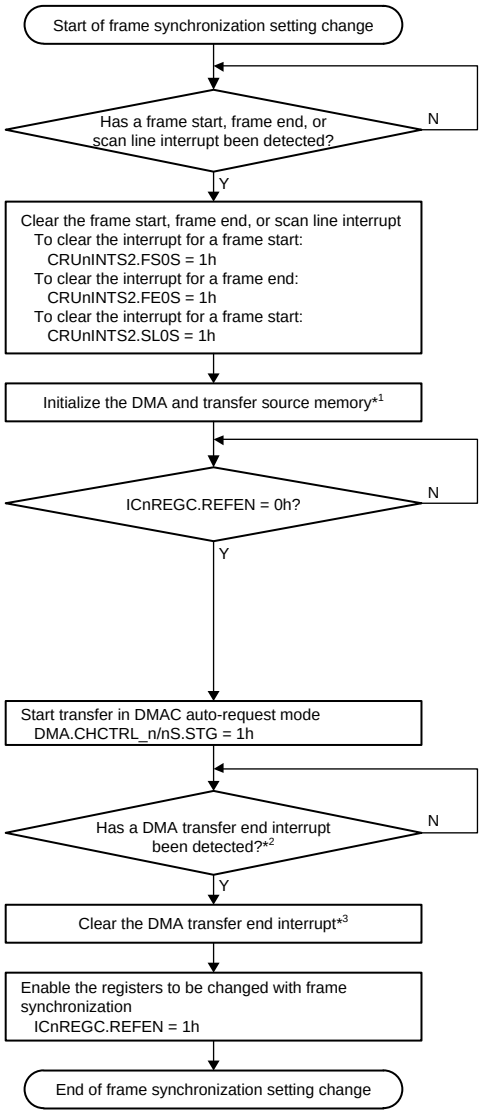


Figure 9.2-63 Flow for Changing the Frame Synchronization Settings (by Setting Registers)

9.2.5.3.2 Changing Frame Synchronization Settings (by Using the DMAC)

NOTES:

1. This flow for changing the frame synchronization settings is only valid for the MIPI CSI-2 input. It cannot be used for the parallel input.
2. In the initial settings when the CRU starts, interrupts for a frame start, frame end and scan line must be set.

   To set an interrupt for a frame start:
   CRUnIE2.FS0E = 1h

   To set an interrupt for a frame end:
   CRUnIE2.FE0E = 1h

   To set an interrupt for a frame start:
   CRUnIE2.SL0E = 1h

   In addition, CRU and DMA interrupts must be enabled by seeing the section about the interrupt controller.

Note 1. Perform initialization by seeing the section about DMA.

- Note that the following register settings are required:
  DMA.CHCFG_n/nS.DAD = 0h: Increment
  DMA.CHCFG_n/nS.SAD = 0h: Increment
  DMA.CHCFG_n/nS.DDS = 3h: 32 bits
- Set the DMA transfer size to 32 bits for both transfer destination and transfer source
- In transfer source memory initialization, store the values that set the following register: (Start address: Up to 68 bytes in ICnSVC)

  ICnSVC.SVC0[3:0]
  ICnIPMC_C0.STITHR
  ICnNIPDT_C0L
  ICnNIPDT_C0H
  ICnSLPrC_C0
  ICnELPrC_C0
  ICnSPPrC_C0
  ICnEPPrC_C0
  ICnSI_C0
  ICnLMXOF
  ICnLMXRC1
  ICnLMXRC2
  ICnLMXGC1
  ICnLMXGC2
  ICnLMXBC1
  ICnLMXBC2
  ICnSTIC1

Note 2. A setting is required in advance (see the sections about DMA and interrupt controller).

Note 3. Clear the interrupt by seeing the section about DMA and interrupt controller.

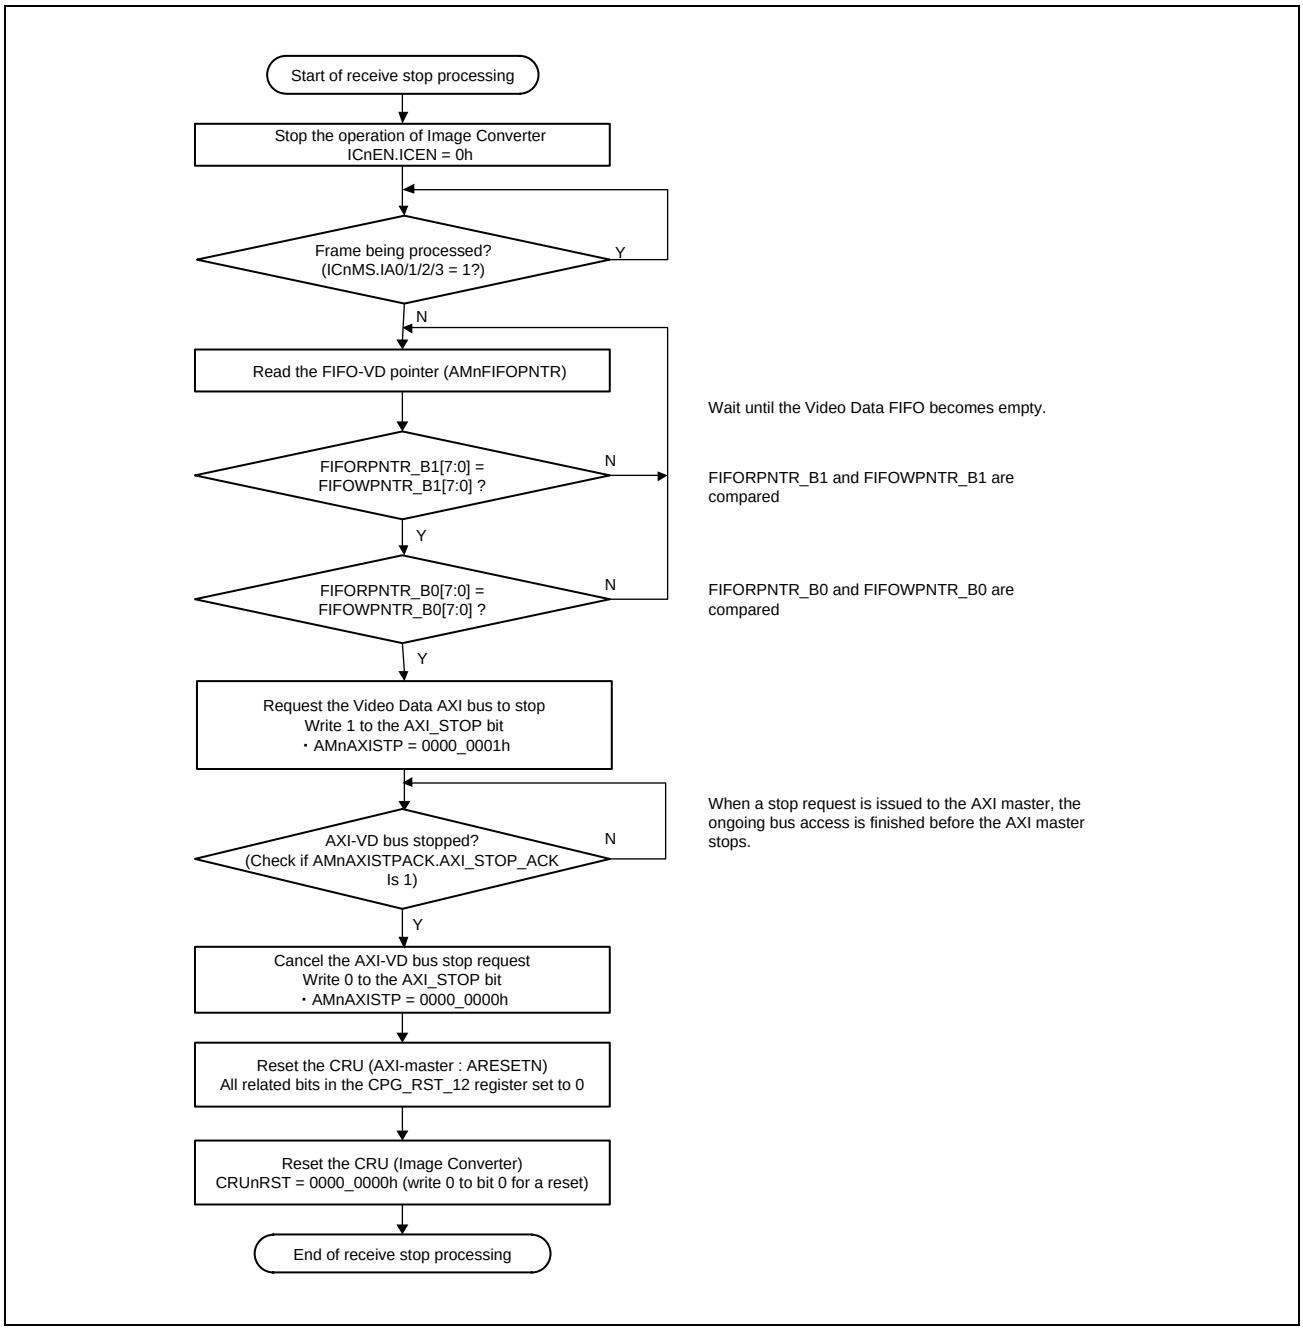

Figure 9.2-66 Flow of Stopping Reception for the Pattern Generator Input

SECTION 9 IMAGE

9.3 Image Scaling Unit (ISU2)

The ISU2 is a module that reads out the image stored in the external DRAM, scales up or down image size, and outputs the reduced image into the DRAM. The ISU2 also support a color format conversion and cropping image.

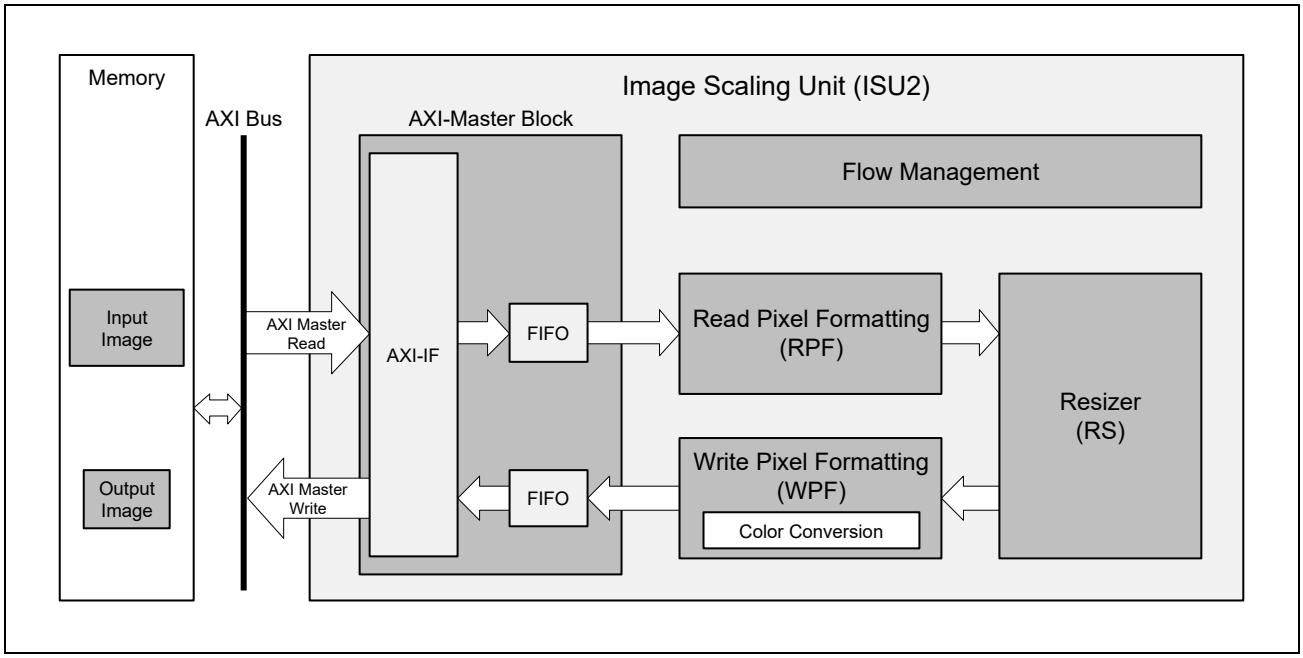

Figure 9.3-1 ISU2 Block Diagram

9.3.1 Features

The ISU2 functionality consists of “Resizer” and “Color Format Conversion”. “Color Format Conversion” can convert color space and color format (RGB/ARGB, YCbCr/YUV, RAW).

- Resizer
  - Scaling ratio: ×1/15 to 2
  - Scaling algorithm: Bilinear
  - Horizontal and Vertical image scaling ratio are adjustable individually.
  - Cropping image

- Color Space and Color Format Conversion
  - Supported color format: RGB/ARGB, YCbCr/YUV, RAW (Grayscale)
    A (Alpha) of ARGB format is transparency. Zero is transparent (colorless).
  - Color space conversion by using 3 × 3 matrix which coefficients can be set arbitrary.
  - Convert color space and color format each other.
  - Endian correction

Table 9.3-1 Supported Image Format

Item	Description
Input	• Color Format – RGB/ARGB: 8 formats RGB565, RGB888, BGR888, BGR666, ARGB8888, ARGB1555, RGBA8888, ABGR8888 – YCbCr/YUV: 4 formats YCbCr422 (Interleave) = UYVY YCbCr422 (Interleave) = YUY2 (YUYV) YCbCr422 (Semi-Planar) = NV16 YCbCr420 (Semi-Planar) = NV12 – RAW: 8 formats RAW6, RAW7, RAW8, RAW10, RAW12, RAW14, RAW16, RAW20 (Grayscale)*1 • Maximum Size 2048 × 2048
Output	• Color Format – RGB/ARGB: 8 formats RGB565, RGB888, BGR888, BGR666, ARGB8888, ARGB1555, RGBA8888, ABGR8888 – YCbCr/YUV: 4 formats YCbCr422 (Interleave) = UYVY YCbCr422 (Interleave) = YUY2 (YUYV) YCbCr422 (Semi-Planar) = NV16 YCbCr420 (Semi-Planar) = NV12 – RAW: 8 formats RAW6, RAW7,RAW8, RAW10, RAW12, RAW14, RAW16, RAW20 (Grayscale)*1 • Maximum Size 2048 × 2048

Note 1. RAW10, RAW12, RAW14, RAW16, and RAW20 are rounded to 8-bit, and RAW6 and RAW7 are expanded to 8-bit internally.

9.3.1.1 Flow Management (FM)

Controls the processing of the entire ISU2. The frame processing is controlled by receiving the frame processing start instruction from the register. There are three types of frame processing:

1. Register Mode
2. Descriptor Mode (without automatic start of next frame)
3. Descriptor Mode (with automatic start of next frame)

9.3.1.1.1 Frame Processing Mode

There are the following three types of frame processing methods depending on the register settings.

- Register Setting Mode (1) is one-time processing operation according to register setting at once.
- Descriptor Mode without Auto-start (2) is also one-time processing operation according descriptor, not register setting. Descriptor Mode with Auto-start (3) automatically reads out the descriptor and continues its operation until all descriptors have been processed.

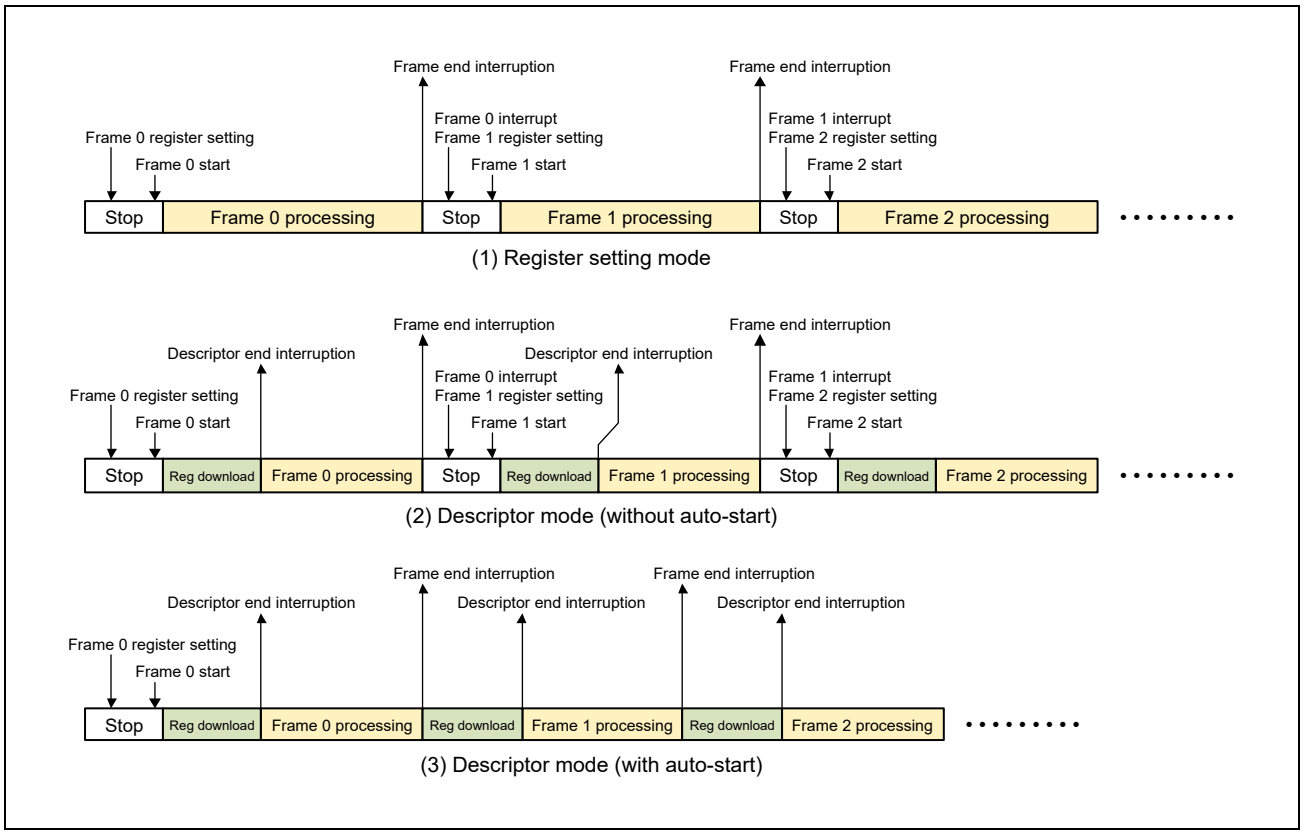

Figure 9.3-2 Frame Processing Mode

9.3.1.1.2 Descriptor

Descriptor Mode is the processing which reads out the descriptor format data stored in the memory and sets the registers automatically. It also includes the Auto-start setting for the next frame.

Flow Management (FM) reads this descriptor setting data while not frame processing.

(1) Descriptor format

The descriptor format is shown below.

Table 9.3-2 Descriptor Format

No.	Category	Item	Byte	Setting Range	Description
1	Header*1,*2	Descriptor Table Byte Count Setting	4 bytes	0000_0000h to 0000_2000h	Up to 8 Kbytes. The total number of bytes of register address and register setting data.
2	Register Setting Main body*3,*4,*5	Register Address 1	4 bytes	0000_0100h to 0000_01F0h	1st Register Setting Address
		Register Setting Data 1	4 bytes	0000_0000h to FFFF_FFFFh	1st Register Setting Data
		Register Address 2	4 bytes	0000_0100h to 0000_01F0h	2nd Register Setting Address
		Register Setting Data 2	4 bytes	0000_0000h to FFFF_FFFFh	2nd Register Setting Data
		Register Address 3	4 bytes	0000_0100h to 0000_01F0h	3rd Register Setting Address
		Register Setting Data 3	4 bytes	0000_0000h to FFFF_FFFFh	3rd Register Setting Data
		Register Address 4	4 bytes	0000_0100h to 0000_01F0h	4th Register Setting Address
		Register Setting Data 4	4 bytes	0000_0000h to FFFF_FFFFh	4th Register Setting Data
		•	•	•	•
		•	•	•	•
		•	•	•	•
3	Footer*2	Next Descriptor Table Address	8 bytes	0000_0000_0000_0000h to 0000_0002_3FFF_FFFFh	The next address is a multiple of 32 bytes. The setting range will be changed according to the product specifications.
		Control identifier register	4 bytes	0000_0000h to 0000_0003h	b31 to 2: All-0
					b1: Select bit to generate a frame end interruption. 0: Does not generate a Frame end interruption. 1: Generate a Frame end interruption.
					b0: Select bit for auto-start of next frame or end at this frame. 0: Disable next frame auto-start. (Exit without next frame operation.) 1: Enable next frame auto-start.

Note 1. The location of the Descriptor List is a 32-byte boundary. (Address that is a multiple of 32-byte) 0,32,64 ...

Note 2. The number of bytes is fixed for the header and footer. The register body is 8 bytes per set (address 4 bytes, data 4 bytes)

Note 3. The registers that can be set in the descriptor are limited to the Common register.

Note 4. Operation when the same register address is described in multiple addresses is not guaranteed.

Note 5. Specify in the offset address to be added to the ISU2 Base Address. Specifically, the lower 10 bits [9:0] should be the address of the register map, and the higher 22 bits [31:10] should be the address of All 0b. If the higher 22 bits are other than All 0b, it will be out of the register area and a list error will occur.

(2) Descriptor error

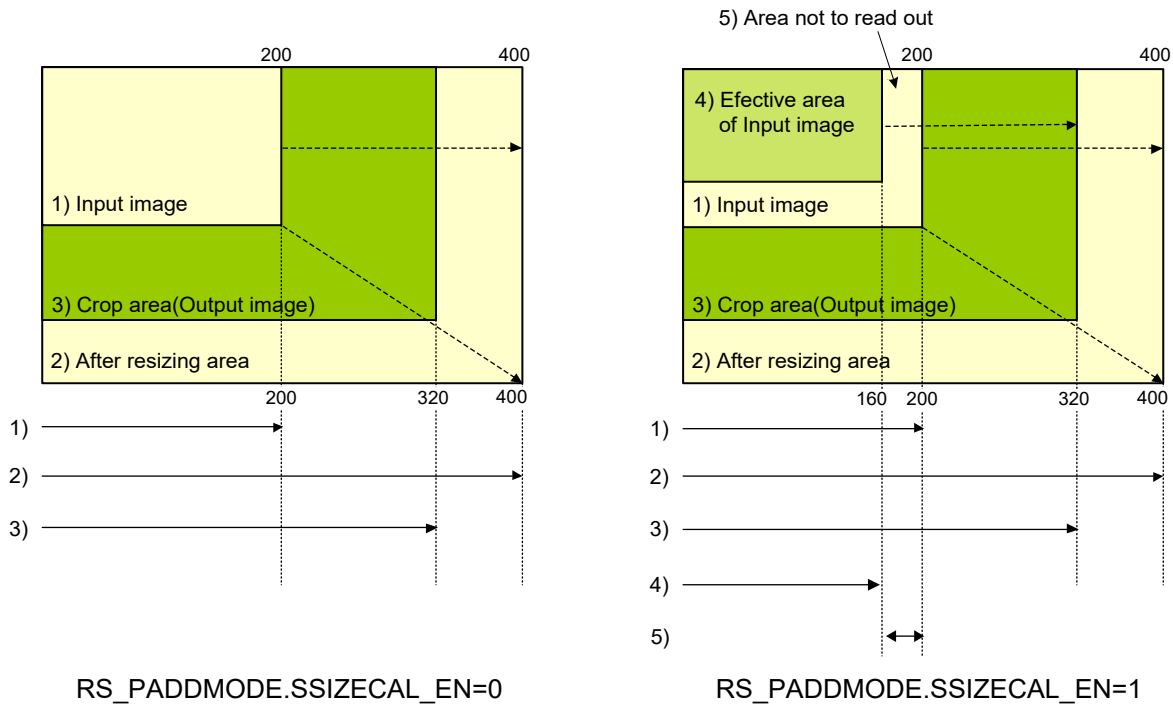
An error flag is issued in the following cases.

a) When the number of bytes in the header exceeds the limit, or when the value is not in units of 8 bytes

- An error interrupt is generated, and subsequent frame processing is not executed.
- Normal operation and recovery are not guaranteed unless the system is reset.

b) When the register address is outside the specified address

- A decoding error will occur if decoding is performed for items outside the register area.
- Ignore the write to the register where the error occurred and continue the process itself.



9.3.1.1.3 Input image size calculation

The FM block instructs the AXI-Master (AXIRX) on the size of the image readout.

The size of the input image is controlled differently by the RS_PADDMODE.SSIZECAL_EN.

The following explanation is based on **Figure 9.3-3**.

For the sake of simplicity, only the horizontal direction is illustrated in the following explanation, but the same concept applies to the vertical direction.

Note: Difference in image readout method by setting RS_PADDMODE.SSIZECAL_EN

Figure 9.3-3 Difference in image readout method by setting RS_PADDMODE.SSIZECAL_EN

(1) Operation when RS_PADDMODE.SSIZECAL_EN=0

a) Input image

This area is the input image.
The AXI-Master block reads data for the size indicated by RPF_SRC_SIZE.

b) After resizing area

Resize operation is performed based on the magnification factor of RS_HSCALE and RS_VSCALE for 1) Input image.
This resizing operation is performed in the RS block.
In this example, the horizontal magnification is set to 2x, so the number of pixels in the horizontal direction is 400.

c) Crop Area

When storing a resized image to external memory, a cropped image with the size specified by RS_CROP_SIZE is sent out from the RS block.

(2) Operation when RS_PADDMODE.SSIZECAL_EN=1

a) Input image

The AXI-Master block does not read this size, but reads an image of size 4) described below.

b) After resizing area

Resize operation is performed based on the magnification factor of RS_HSCALE and RS_VSCALE for 1) Input image. This resizing operation is performed in the RS block.
In this example, the horizontal magnification is set to 2x, so the number of pixels in the horizontal direction is 400.

c) Crop Area

When storing a resized image to external memory, a cropped image with the size specified by RS_CROP_SIZE is sent out from the RS block.

d) Input image effective area

In the FM block, the area is obtained by multiplying 1) Input area (RPF_SRC_SIZE) by 2) RS_HSCALE and RS_VSCALE to 3) Crop area (RS_CROP_SIZE) by the reciprocal.
The result is determined if the area is narrower than 1) RPF_SRC_SIZE.
If the area is judged to be narrow, the FM block sets the area in that range for the AXI-Master.
If the area is not judged to be narrow, the FM block instructs the AXI-Master to read the data of the size specified by 1) RPF_SRC_SIZE.
In this example, 320 pixels / (400 pixels / 200 pixels) = 160 pixels.

e) Area not to read out

If the valid image area is smaller than the input image area as calculated and determined in 4), the area not read out is the area in 5). This prevents images from being read from unnecessary areas, thus increasing the bus efficiency of external memory access.

9.3.1.2 AXI-Master

In response to a descriptor read request or input image read request from Flow Management (FM), the descriptor or input image is read from the DRAM. It also writes a reduced image to DRAM in response to a reduced image write request from the WPF.

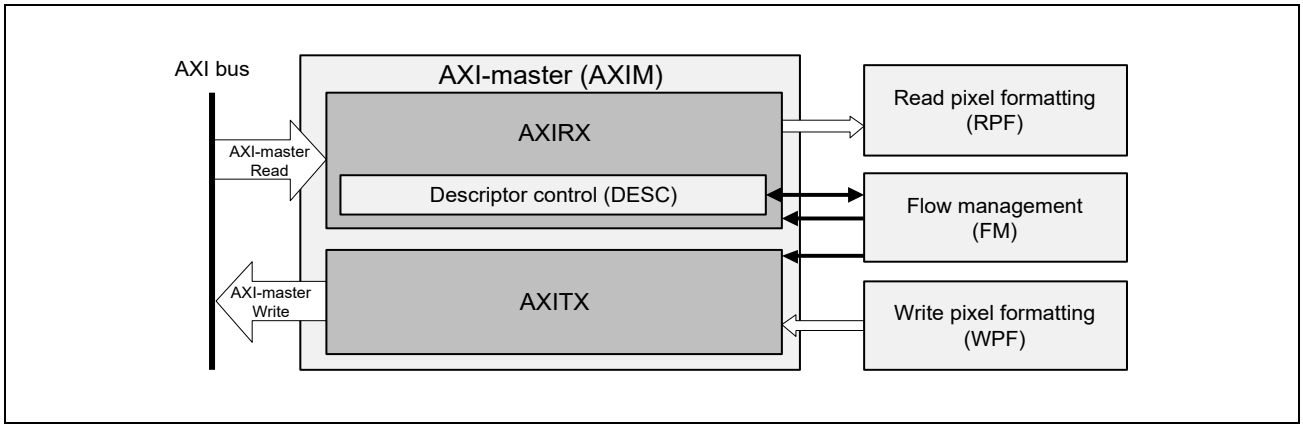


Figure 9.3-4 AXI-Master Block Diagram

9.3.1.2.1 Read input image (AXIRX)

In response to the descriptor read request from FM or the frame transfer start request, the descriptor or input image data is read from DRAM by AXI.

(1) Image input format

AXIRX support to read following formats from memory.

Table 9.3-3 Input Image Format

Read Method	Image Format	Variation
Interleave (Plane Number = 1)	ARGB (8 types)	• The order of colors is different / the number of color bits is different. • There may or may not be A.
	YCbCr422 8-bit (2 types)	The two types differ only in the order of the colors of Cb and Cr.
	RAW (8 types)	Grayscale 6-/7-/8-/10-/12-/14-/16-/20-bit.
Semi-Planner (Plane Number = 2)	YCbCr422 8-bit (1 type)	
	YCbCr420 8-bit (1 type)	

- Interleave

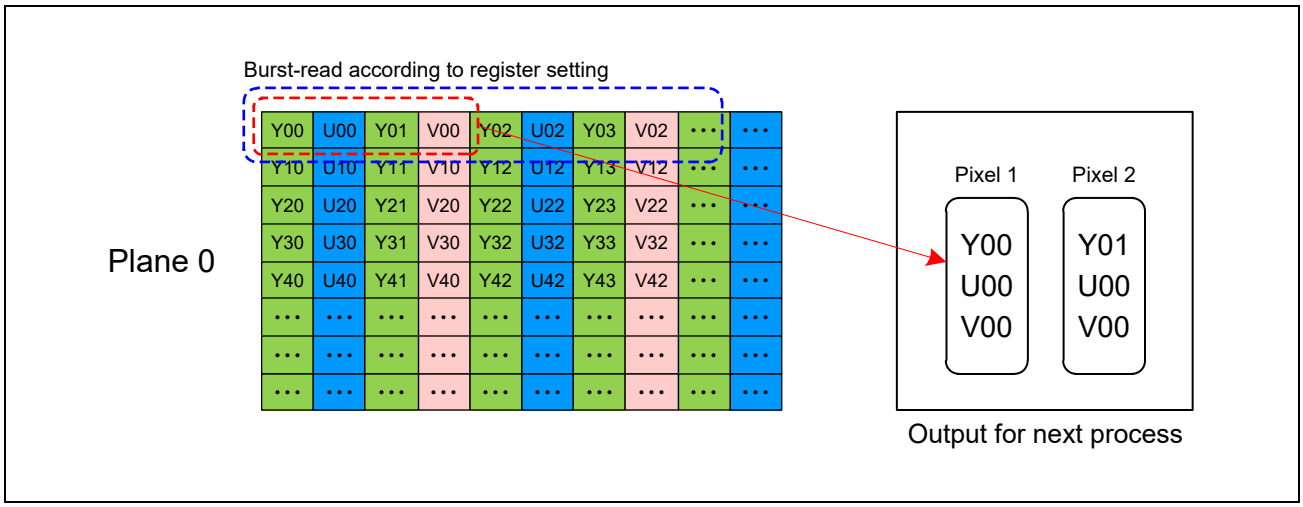

Figure 9.3-5 Example of Interleave Format for YCbCr422 (YUV422)

- Semi-planar

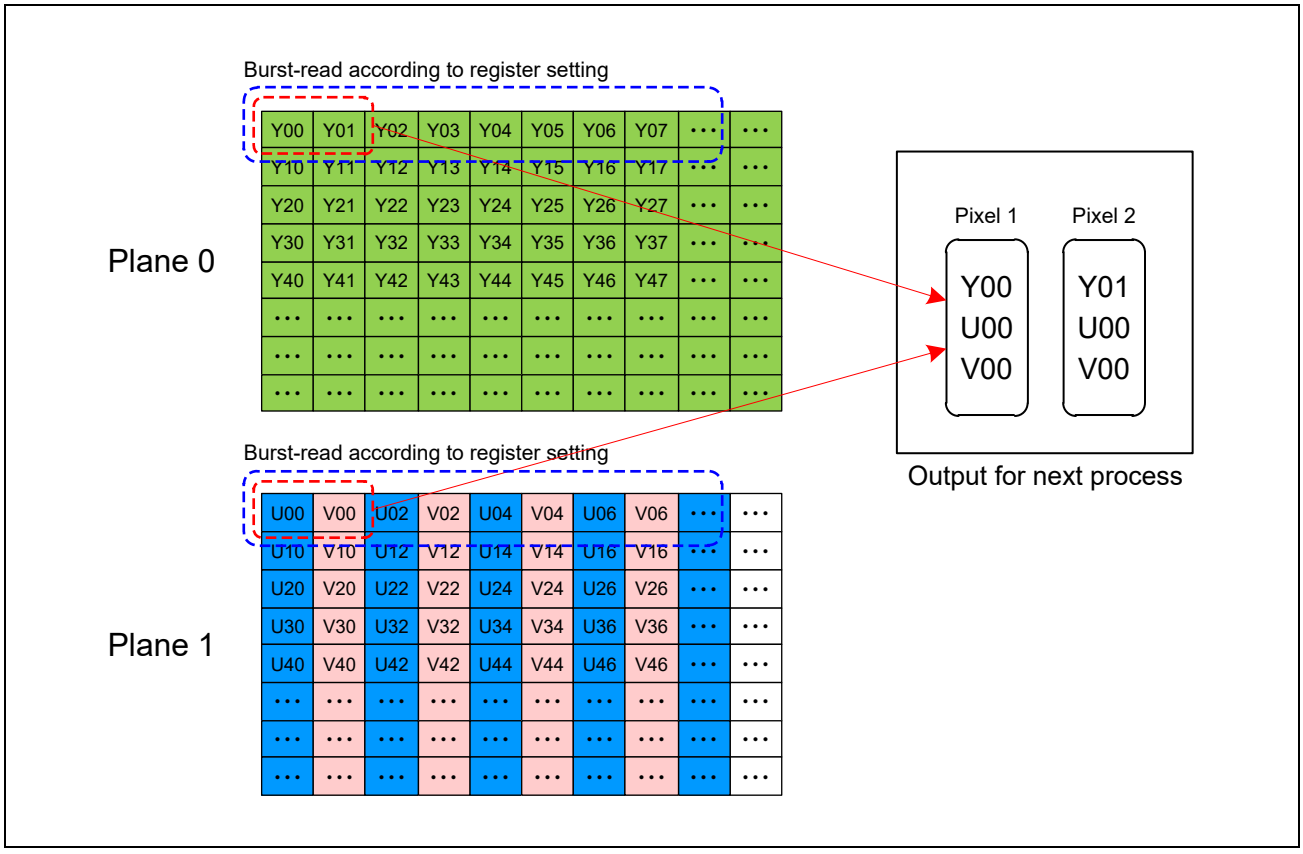

Figure 9.3-6 Example of Semi-planar Format for YCbCr422 (YUV422)

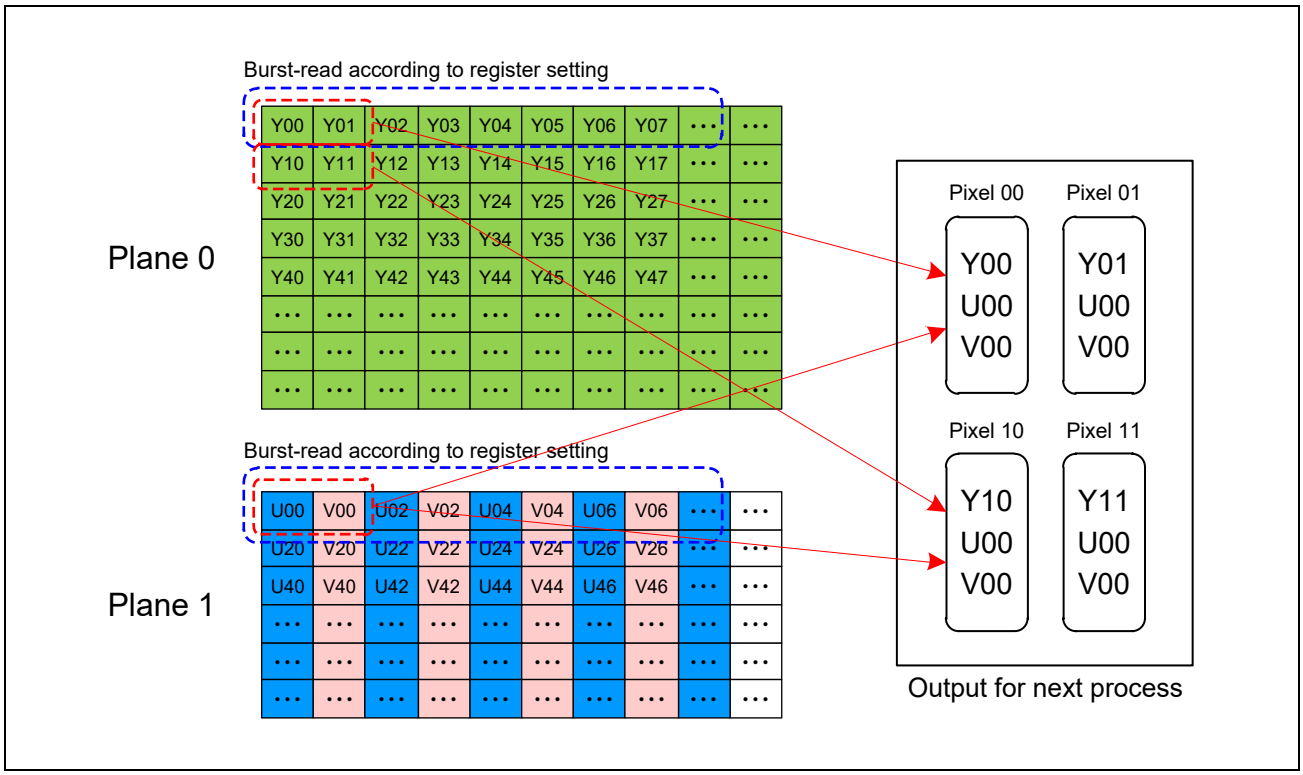

Figure 9.3-7 Example of Semi-planar format for YCbCr420 (YUV420)

(2) Input setting

Data is read from each plane according to the following register setting. Registers are required to set for each plane (Max 2 Plane).

Table 9.3-4 Input Image Setting

No.	Category	Register	Variation
(1)	Start Address	ISU_RPF_SRC_ADDH_PL0.SADD_PL0[2:0] ISU_RPF_SRC_ADDL_PL0.SADD_PL0[31:0]	• Start address for Plane 0 of input image.
		ISU_RPF_SRC_ADDH_PL0.SADD_PL1[2:0] ISU_RPF_SRC_ADDL_PL0.SADD_PL1[31:0]	• Start address for Plane 1 of input image.
(2)	Image Stride	ISU_RPF_SRC_STRD.SSTRPL0[15:0]	• Image stride of Plane 0 [Byte]
		ISU_RPF_SRC_STRD.SSTRPL1[15:0]	• Image stride of Plane 1 [Byte]
(3)	Input Area	ISU_RPF_SRC_SIZE.S_HSIZE[12:0]	• Horizontal size of processing area [Pixel] • Max 2048 pixels
(4)		ISU_RPF_SRC_SIZE.S_VSIZE[12:0]	• Vertical size of processing area [Pixel] • Max 2048 pixels

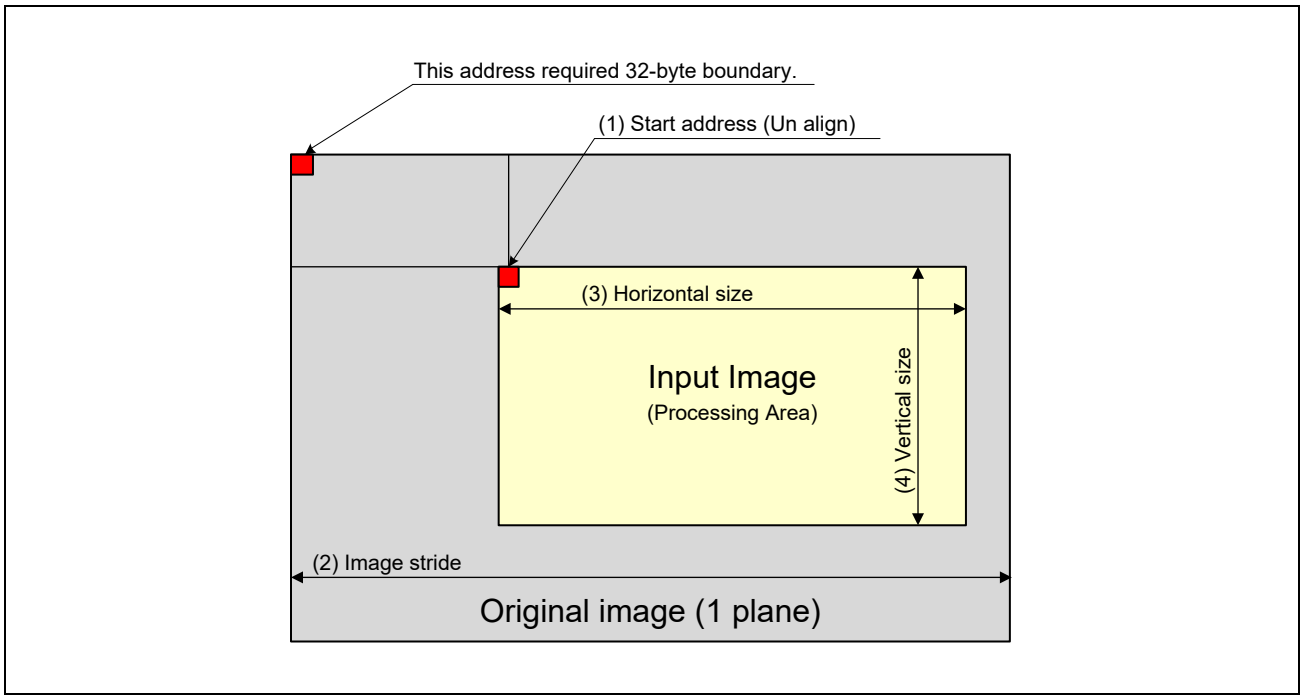

Figure 9.3-8 Input Area (Processing Area) Setting

(3) Write output image (AXITX)

This function write the resized (reduced) image data to DRAM.

(4) Support format

AXITX support the same format as AXIRX.

(5) Output setting

Data is written out for each plane according to the following setting. Registers are required to set for each plane (Max plane number is 2).

Table 9.3-5 Output Image Setting

No.	Category	Register	Variation
(1)	Start Address	ISU_WPF_DST_ADDH_PL0.DADD_PL0[2:0] ISU_WPF_DST_ADDL_PL0.DADD_PL0[31:0]	• Start address of Plane 0 for output image.
		ISU_WPF_DST_ADDH_PL1.DADD_PL1[2:0] ISU_WPF_DST_ADDL_PL1.DADD_PL1[31:0]	• Start address of Plane 1 for output image.
(2)	Image Stride	ISU_WPF_DST_STRD.DSTRPL0[15:0]	• Image stride of Plane 0 [Byte]
		ISU_WPF_DST_STRD.DSTRPL1[15:0]	• Image stride of Plane 1 [Byte]
(3)	Processing Area	ISU_RS_OS_CROP.O_HSIZE[12:0]	• Horizontal crop size [Pixel] • Max 2048 pixels
(4)		ISU_RS_OS_CROP.O_VSIZE[12:0]	• Vertical crop size [Pixel] • Max 2048 pixels

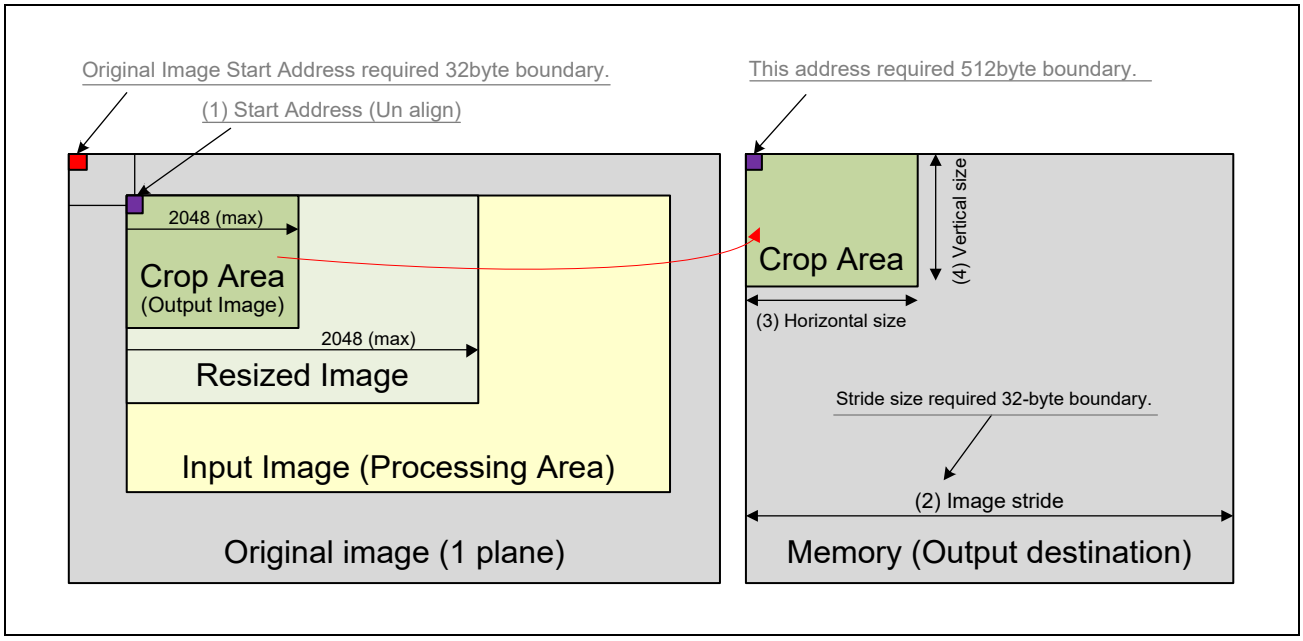

Figure 9.3-9 Output Setting

9.3.1.3 Read Pixel Formatting (RPF)

This function converts the input image data from the AXI-Master and outputs it to the resizer. There are four types of conversion: Data swap, Data extraction, Offset binary conversion (YCbCr only), and pixel normalization. RPF also includes a test pattern generation function.

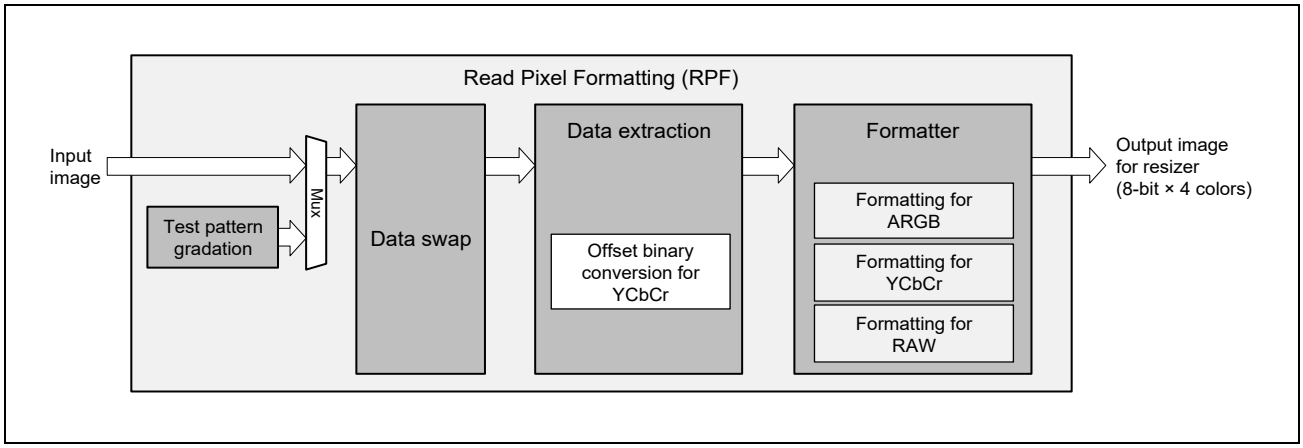

Figure 9.3-10 RPF Block Diagram

9.3.1.3.1 Data swap (endian correction)

This function corrects byte order so that image data can be handled by the ISU2. Each bytes can be arranged any order according the register setting of ISU_RPF_SRC_DSWAP.RD_SWAP[2:0].

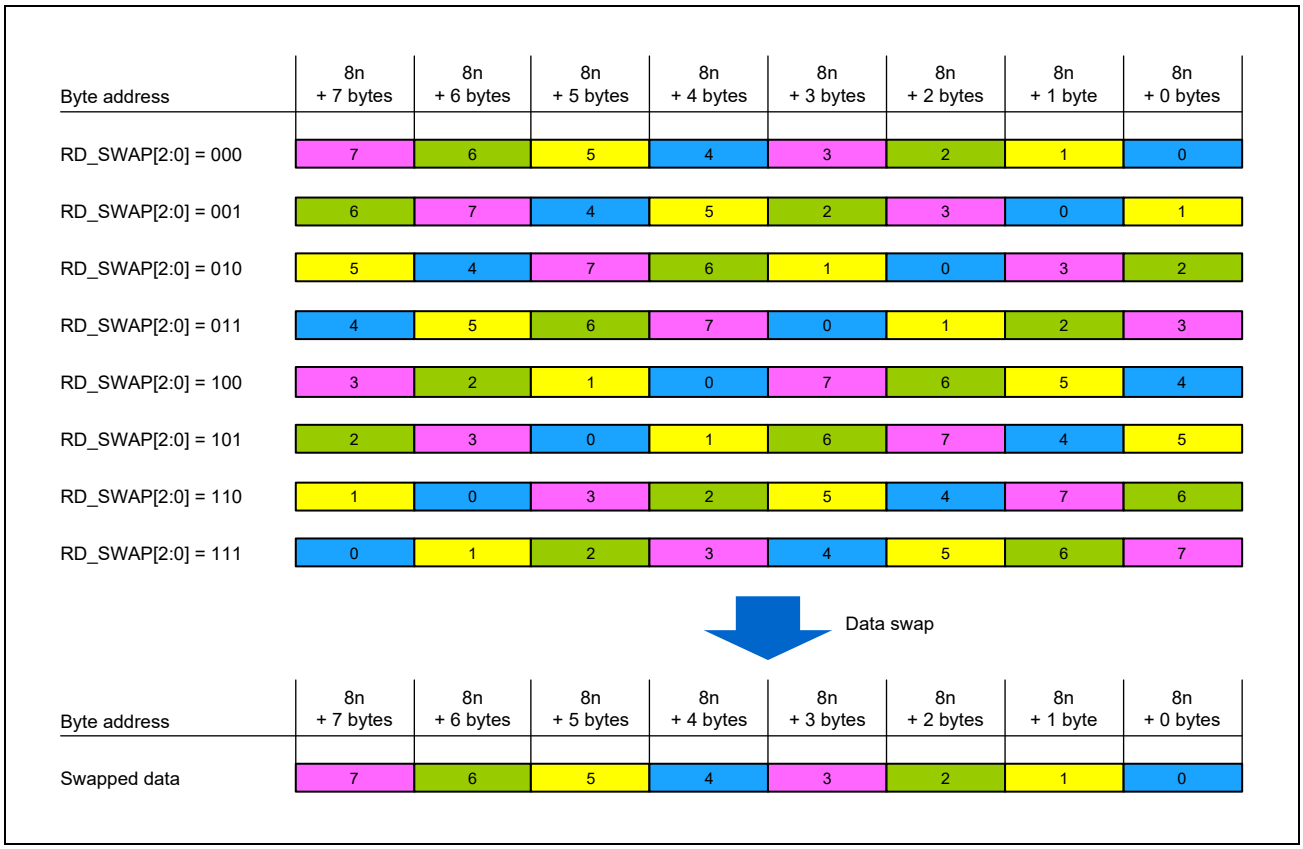

Figure 9.3-11 Data Swap Correction

9.3.1.3.2 RPF Formatter

These functions extract each color components (ex. R, G, B) and normalized as 8-bit for each so that image data can be handled by Resizer. Appropriate processing is performed for each input color format (RGB/ARGB, YCbCr/YUV, RAW) by setting of ISU_RPF_FMT.RDFMT[5:0].

■ RGB/ARGB

This function supports 8 ARGB/RGB formats as shown below. All formats are “Number of planes = 1”.

Table 9.3-6 ARGB Support Format

	Format				n								n + 1								n + 2								n + 3							
RDFMT [5:0]	Color Format	Padding	bit/pixel	phase	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

■ YCbCr/YUV

This function supports 4 YCrCb/YUV formats as shown bellow.

Table 9.3-7 YCbCr/YUV Support Format

Data Format	RDFMT[5:0]	Color Format	Alias	Figure Index
Interleave (Number of Planes = 1)	20h	YCbCr422 8-bit	UYVY	(1)
	21h	YCbCr422 8-bit	YUY2	(2)
Semi-Planar (Number of Planes = 2)	22h	YCbCr422 8-bit	NV16	(3)
	23h	YCbCr420 8-bit	NV12	(4)

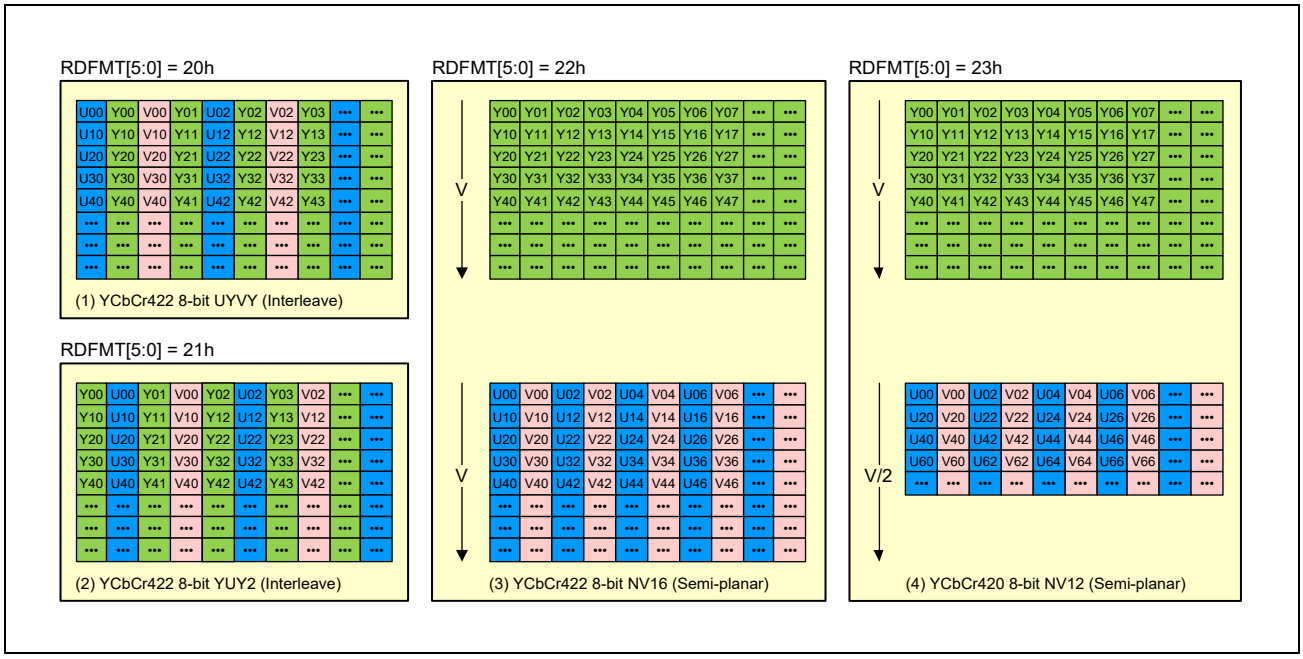

Figure 9.3-12 YCbCr/YUV Support Format

ISU2 can handle only Offset Binary as the chroma data format (CbCr/UV). Therefore, it is necessary to convert from Two's Complement Binary to Offset Binary.

■ ISU_RPF_UVBIN.UVCHG = 0 (Default)

ISU2 uses original data on DRAM as chroma value when RDFMT = 20h to 23h.
(CrCb/UV is Offset Binary.)

■ ISU_RPF_UVBIN.UVCHG = 1

ISU2 convert chroma data (CrCb/UV) from Two's Complement Binary to Offset Binary.

Decimal Number	Offset Binary	Decimal Number	Two's Compliment Binary
127	1111 1111	127	0111 1111
126	1111 1110	126	0111 1110
1	1000 0001	1	0000 0001
0	1000 0000	0	0000 0000
–1	0111 1111	–1	1111 1111
–128	0000 0000	–128	1000 0000

Figure 9.3-13 Types of Binary Expression

■ RAW

This function supports 8 RAW formats as shown bellow. All formats are “Number of planes = 1”.

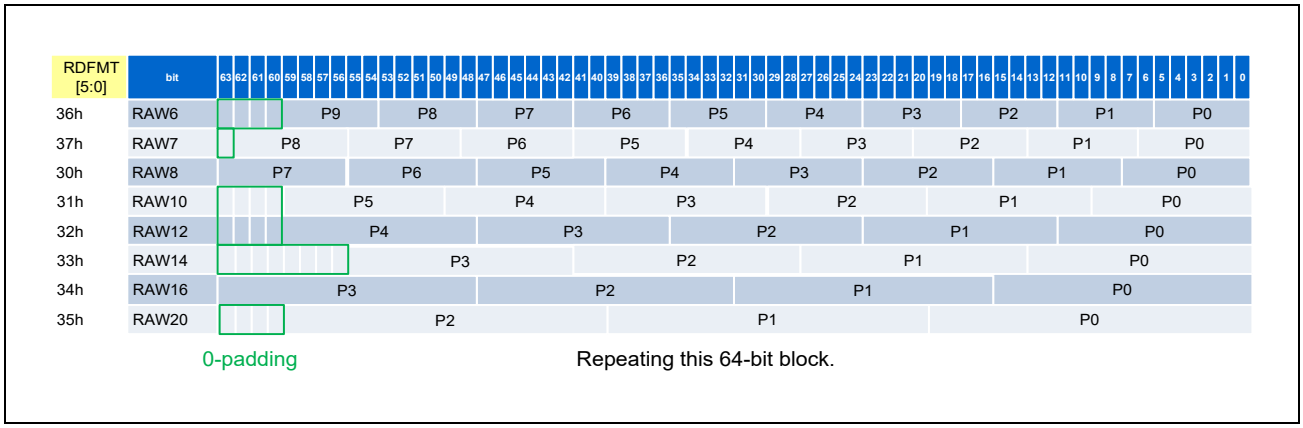

Figure 9.3-14 RAW Support Format

9.3.1.3.3 Data extraction

The 8-bit normalization is required for ARGB/RGB and RAW formats since Resizer can handle the 8-bit format only.

On the other hand, although YCbCr/YUV does not need the 8-bit normalization since its components are already 8-bit, it is necessary to exchange into the YCbCr/YUV444 format.

■ **RGB/ARGB**

For the RGB/ARGB format normalization, higher bits are copied to lower bits.

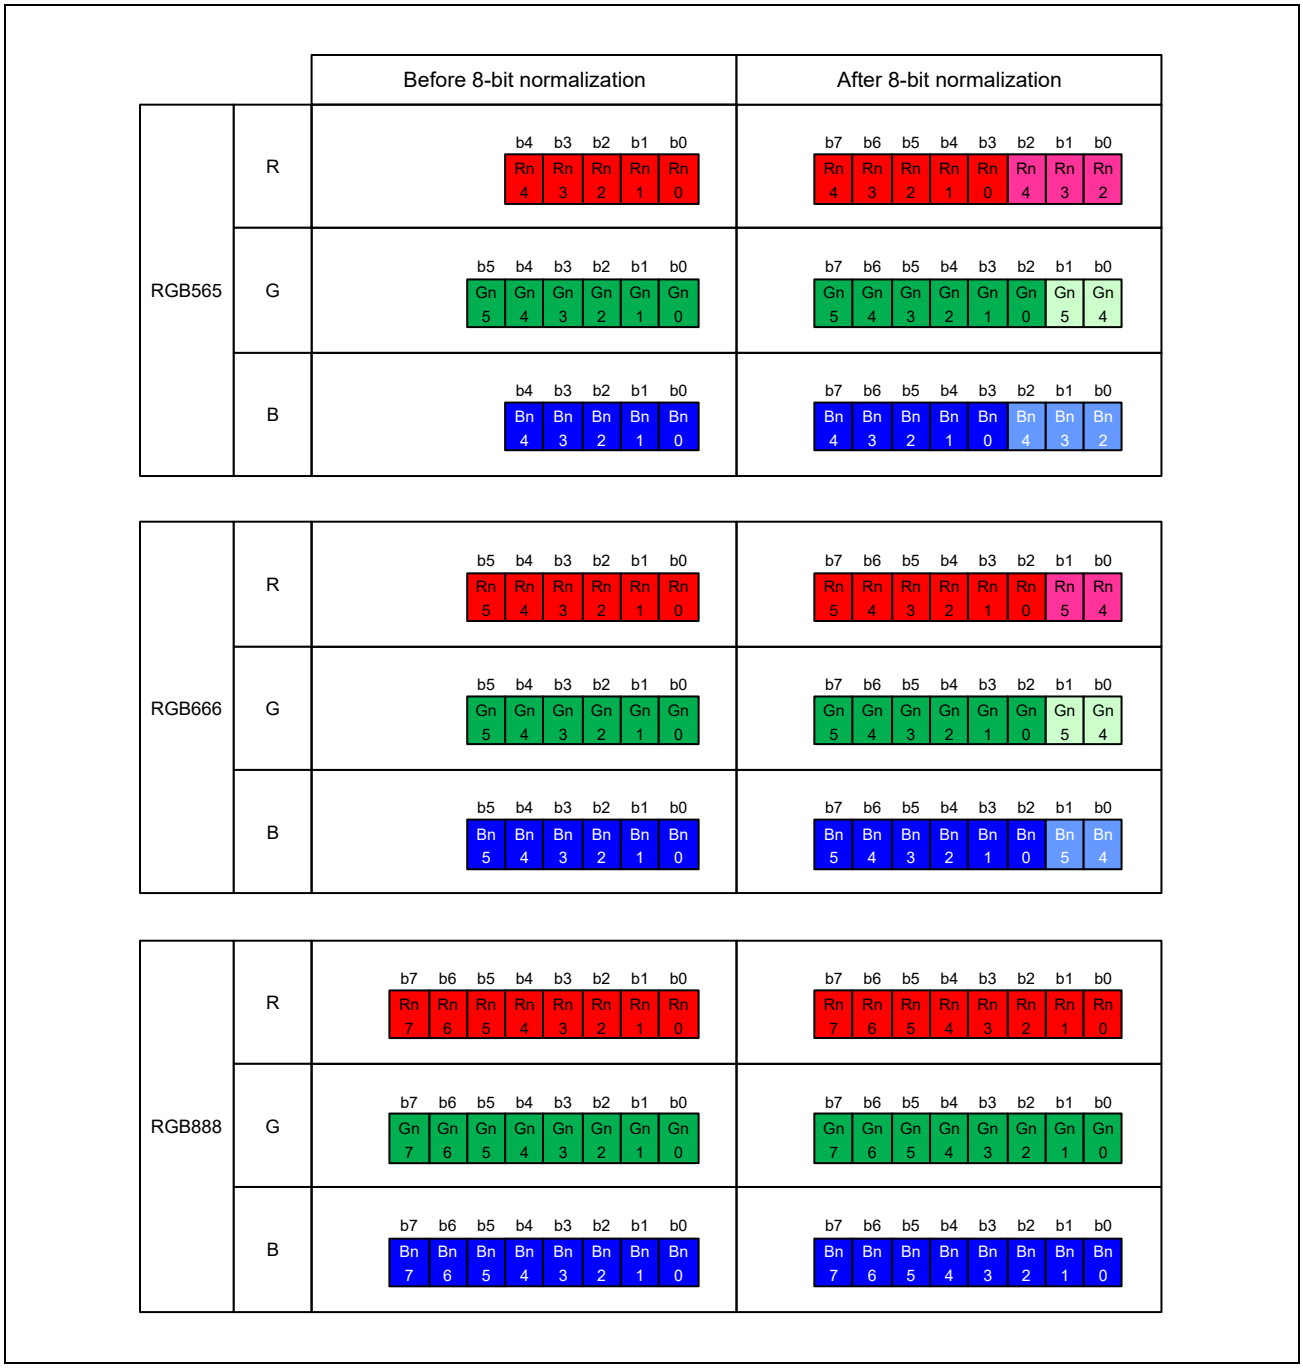

Figure 9.3-15 8-bit Normalization for RGB Format

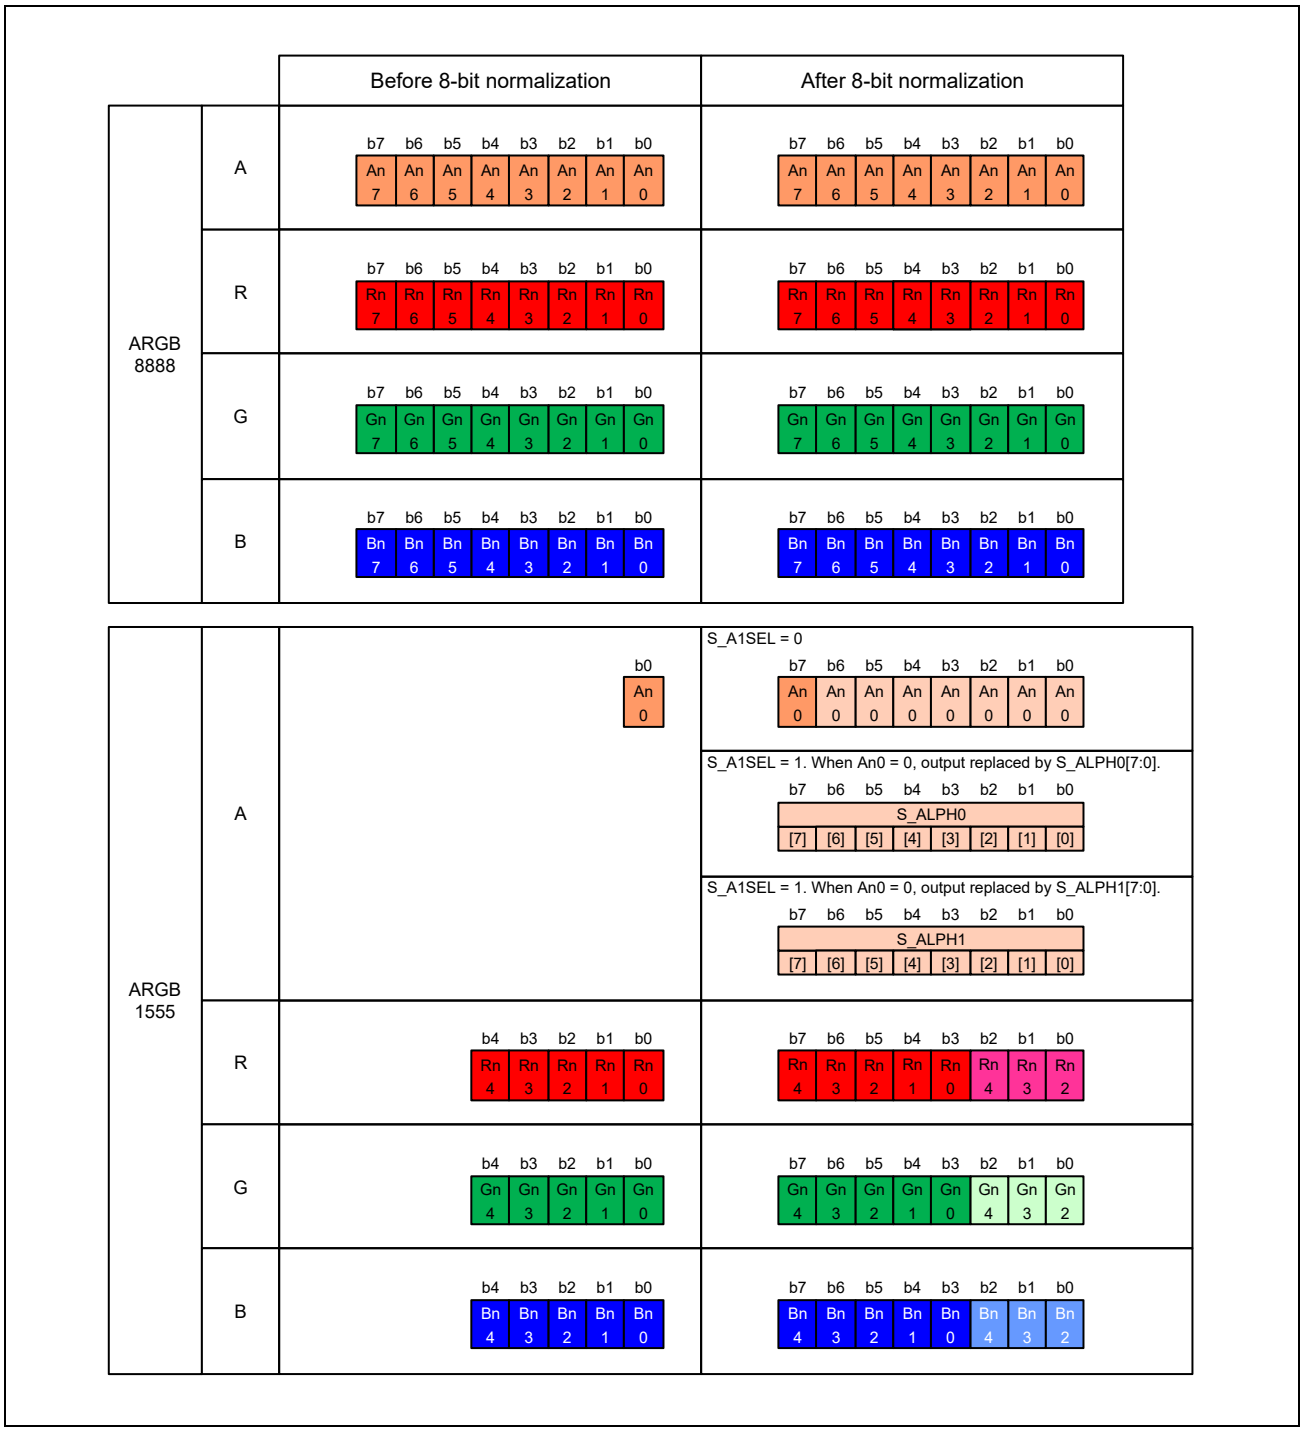

Figure 9.3-16 8-bit Normalization for ARGB Format

■ YCbCr/YUV

For YCbCr/YUV420 Semi-Planar format, even line re-use previous odd line's chroma information.

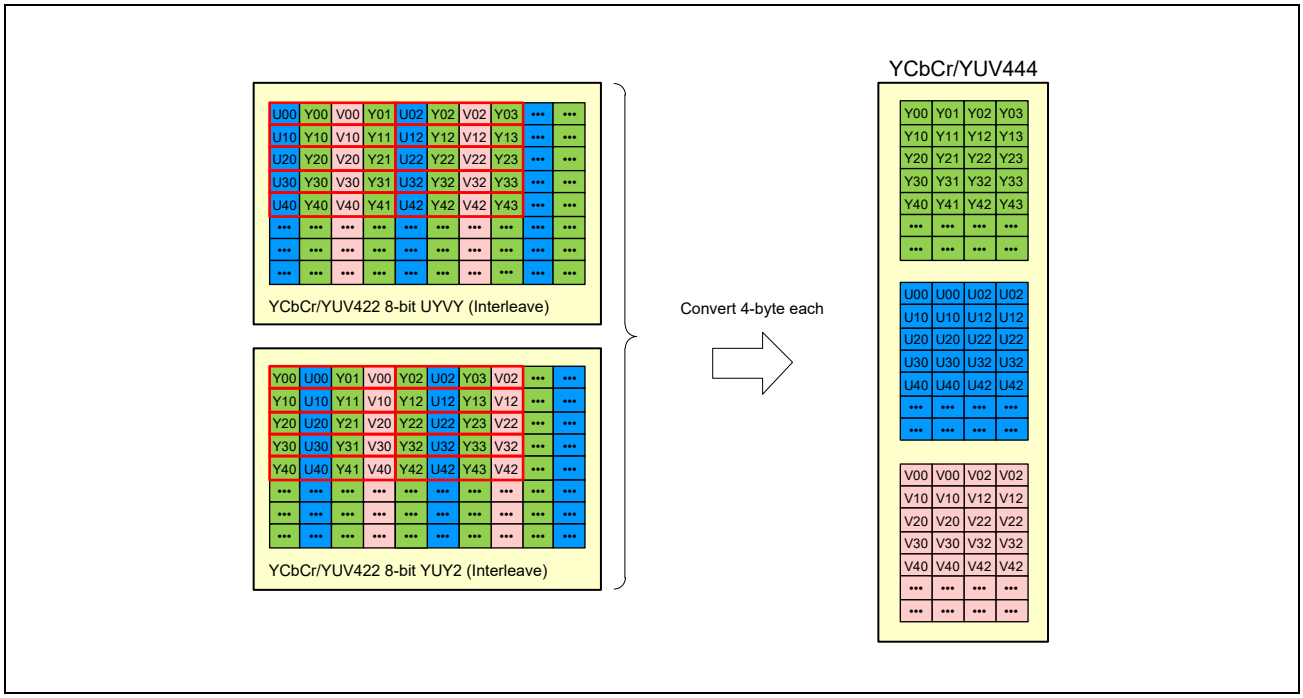

Figure 9.3-17 YCbCr/YUV444 Conversion from YCbCr/YUV422 Format

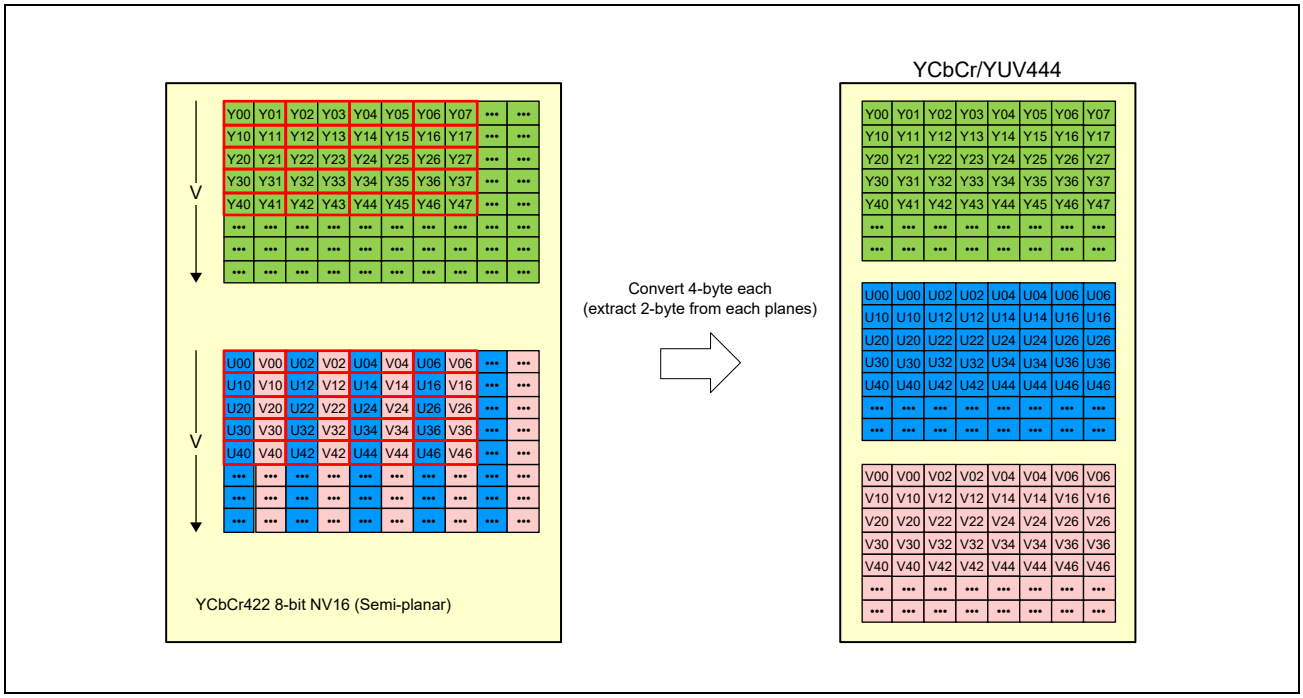

Figure 9.3-18 YCbCr/YUV444 Conversion from YCbCr/YUV422 Semi-Planar Format

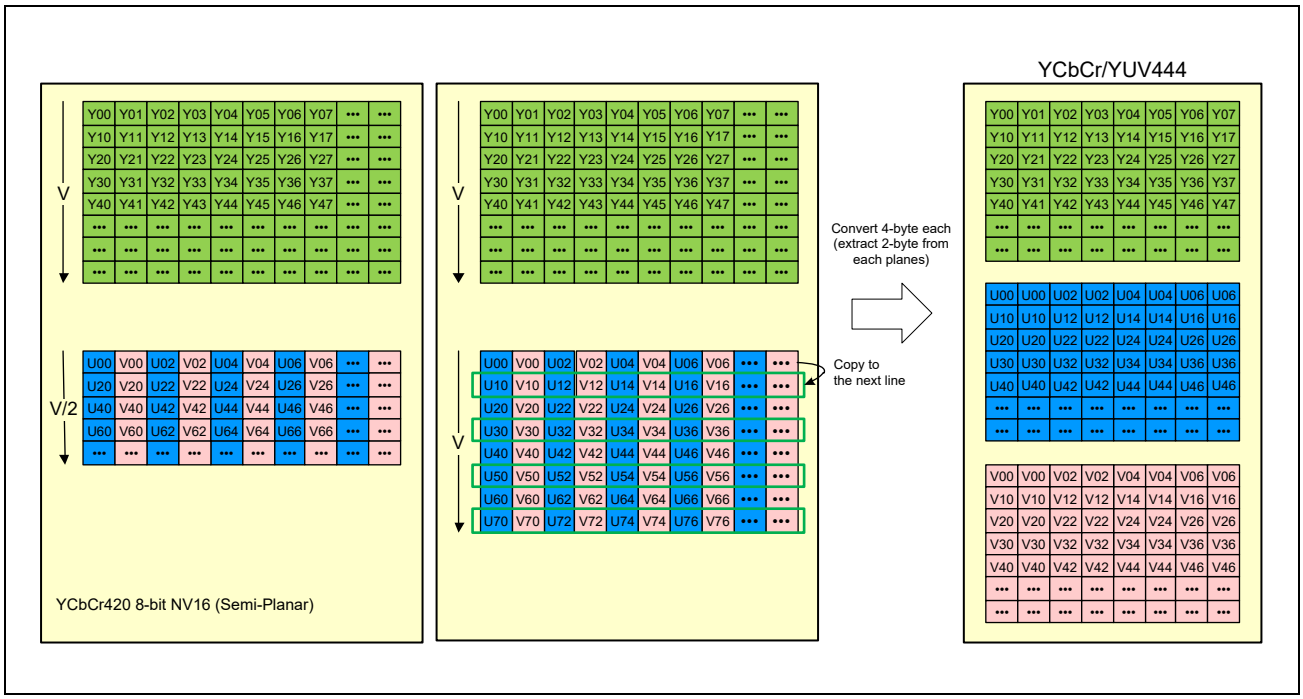

Figure 9.3-19 YCbCr/YUV444 Conversion from YCbCr/YUV420 Semi-Planar Format

■ RAW

RAW is converted to 8 bits by using higher 8 bits of RAW6-/7-/8-/10-/12-/14-/16-/20-bit data.

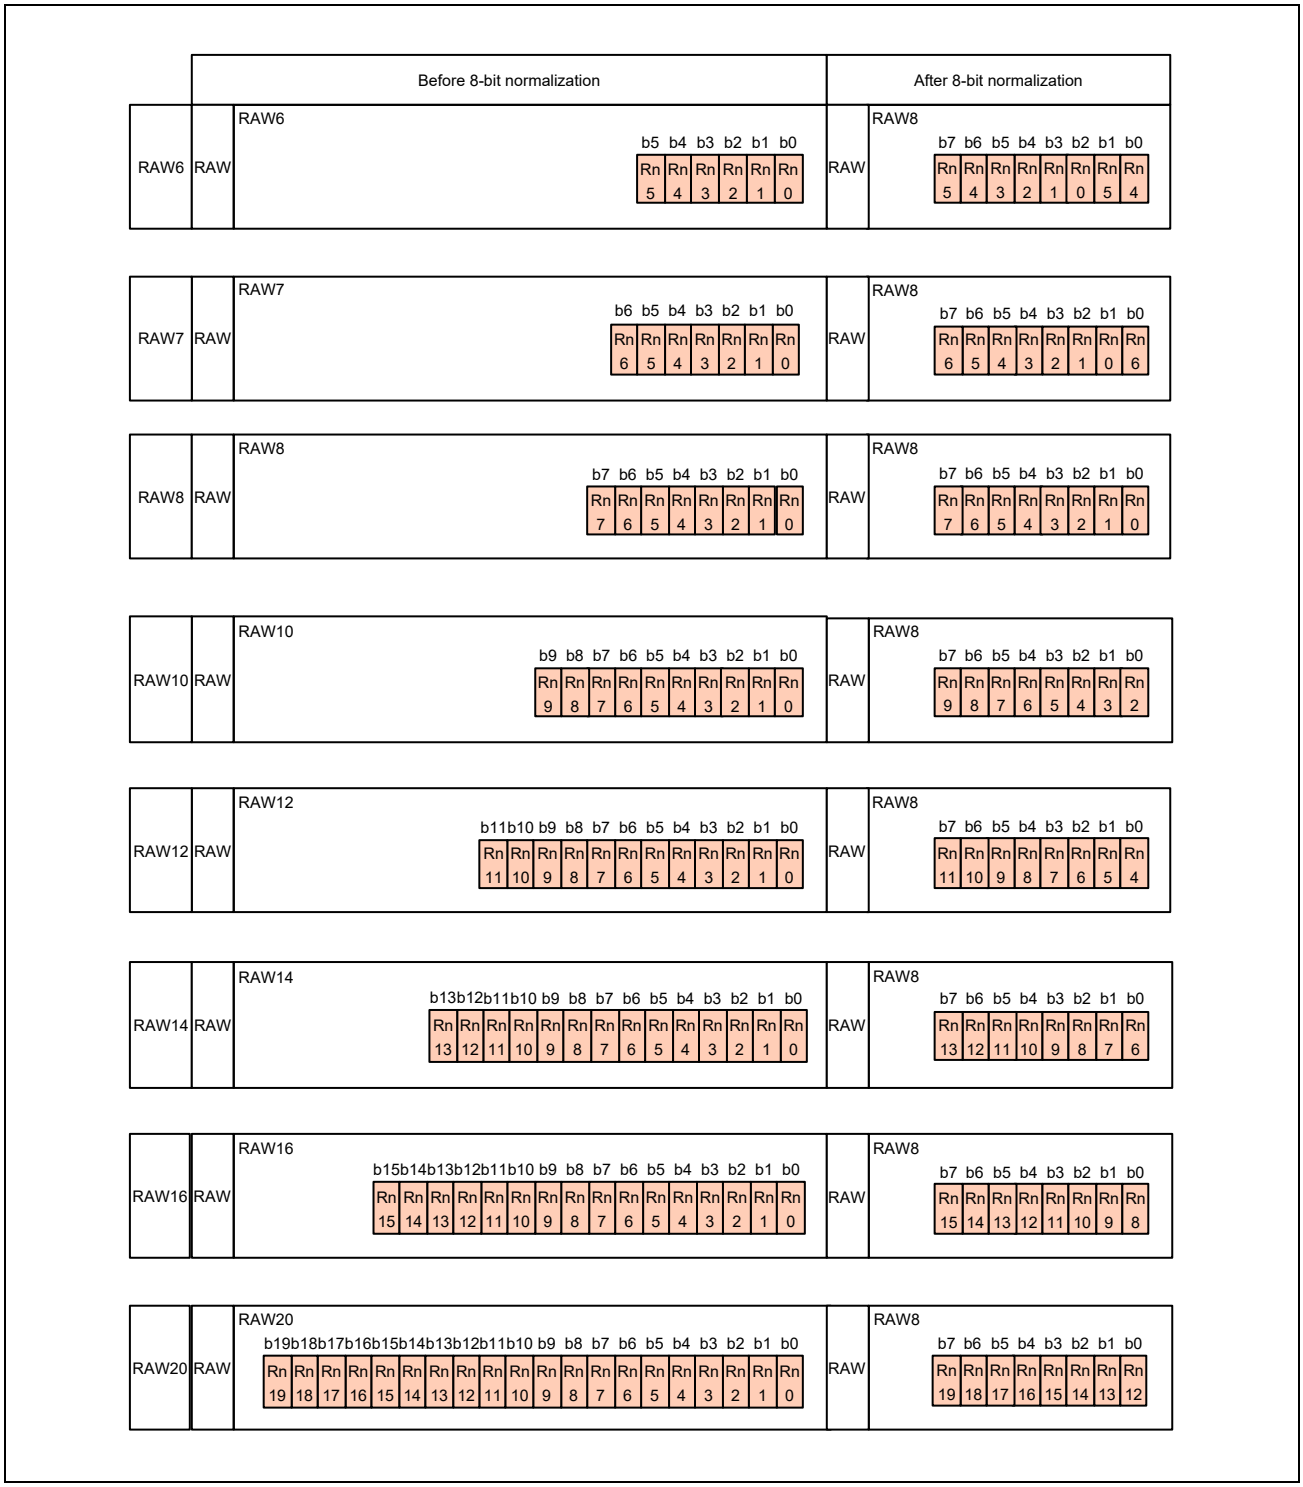

Figure 9.3-20 8-bit Normalization for RAW Format

9.3.1.3.4 Test Pattern Generation

Instead of the input image data from the AXI-Master, RPF can generates a test pattern and outputs it to the Resizer.

The test pattern is an 8-bit gradation image from the upper left to the lower right in the ARGB8888 format according to the register setting.

Please switch between the test pattern and the input image data from the AXI-Master according below procedure.

1. Enable the test pattern. (ISU_RPF_SRC_TD1.TMODE_EN = 1b)
2. Start the resizing process. (ISU_FM_FRCON.START = 1b)

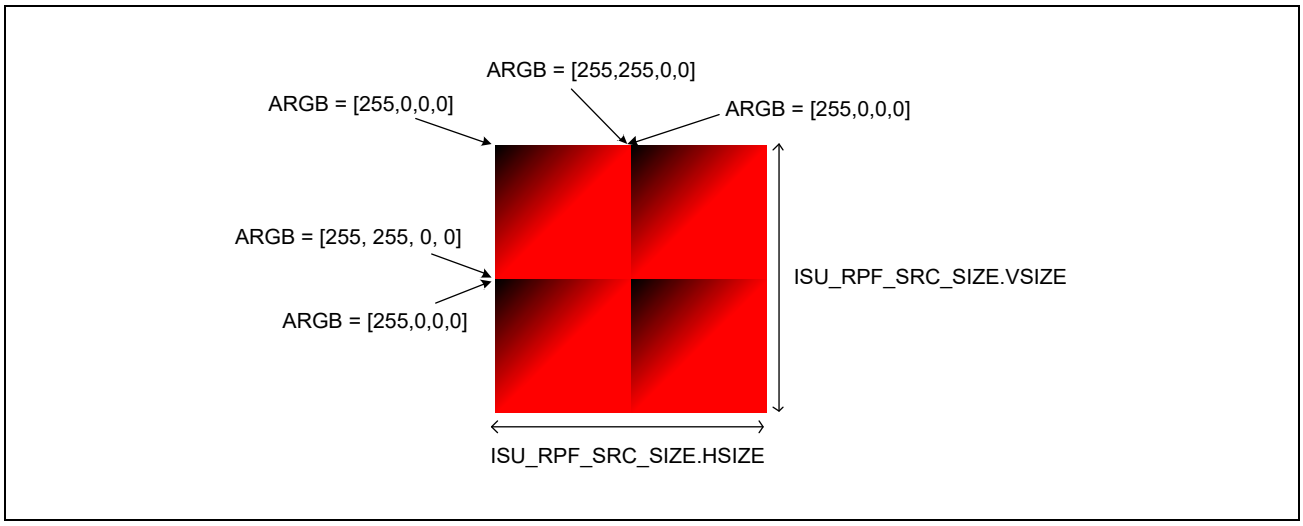

Figure 9.3-21 Test Pattern of R Gradation

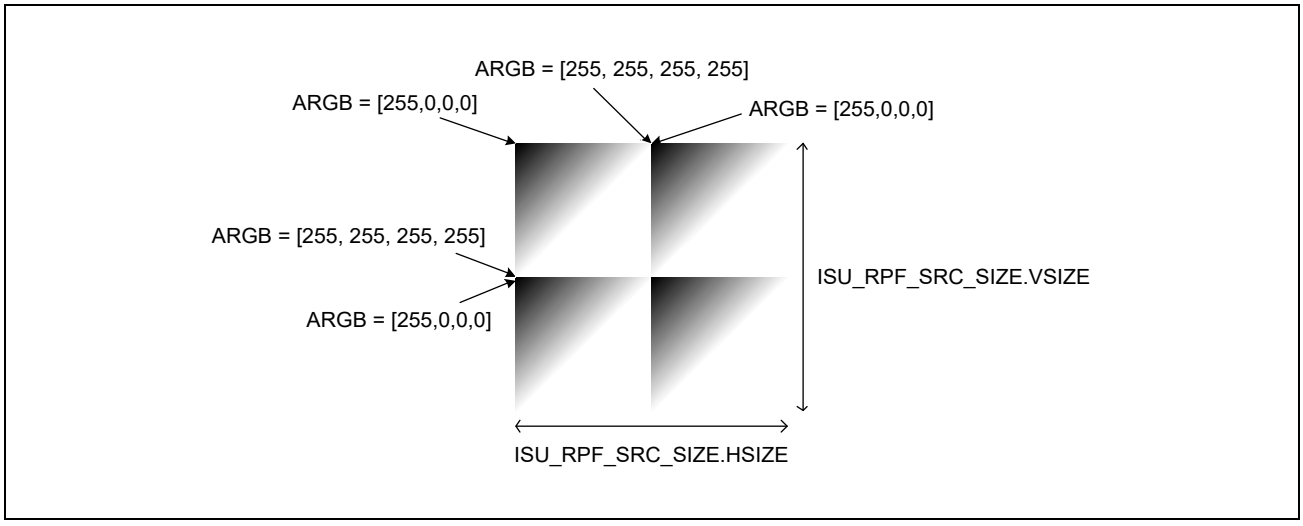

Figure 9.3-22 Pattern of R,G,B Gradation

9.3.1.4 Resizer (RS)

Resizer (RS) reduces the image size by using bi-linear algorithm (4-point linear interpolation) according to register setting of horizontal / vertical resize ratio.

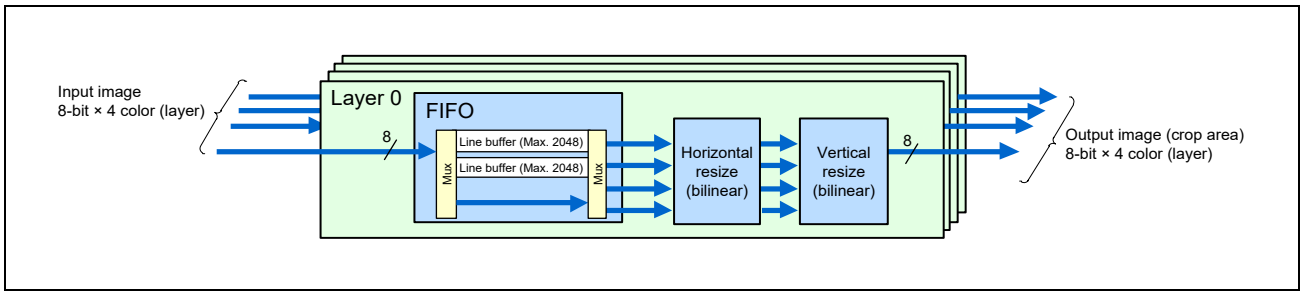

Figure 9.3-23 Resizer Block Diagram

The resize processing is different whether the Resized image size is smaller or larger than the Crop area.

If the Resized image size is smaller than the Crop area, fill in the missing edge pixels according to the register settings below.

When ISU_RS_PADDMODE.PADDSEL = 00b, fill in the padding area by copying the right / bottom edge pixels after the reduction.

When ISU_RS_PADDMODE.PADDSEL = 01b, fill in the padding area with the value specified by the register.

When ISU_RS_PADDMODE.PADDSEL = 10b, fill in the padding area with the copying pixecl ati the edges of the input image .

If the Resized image size is larger than the Crop area, it will be cut off by the Crop area.

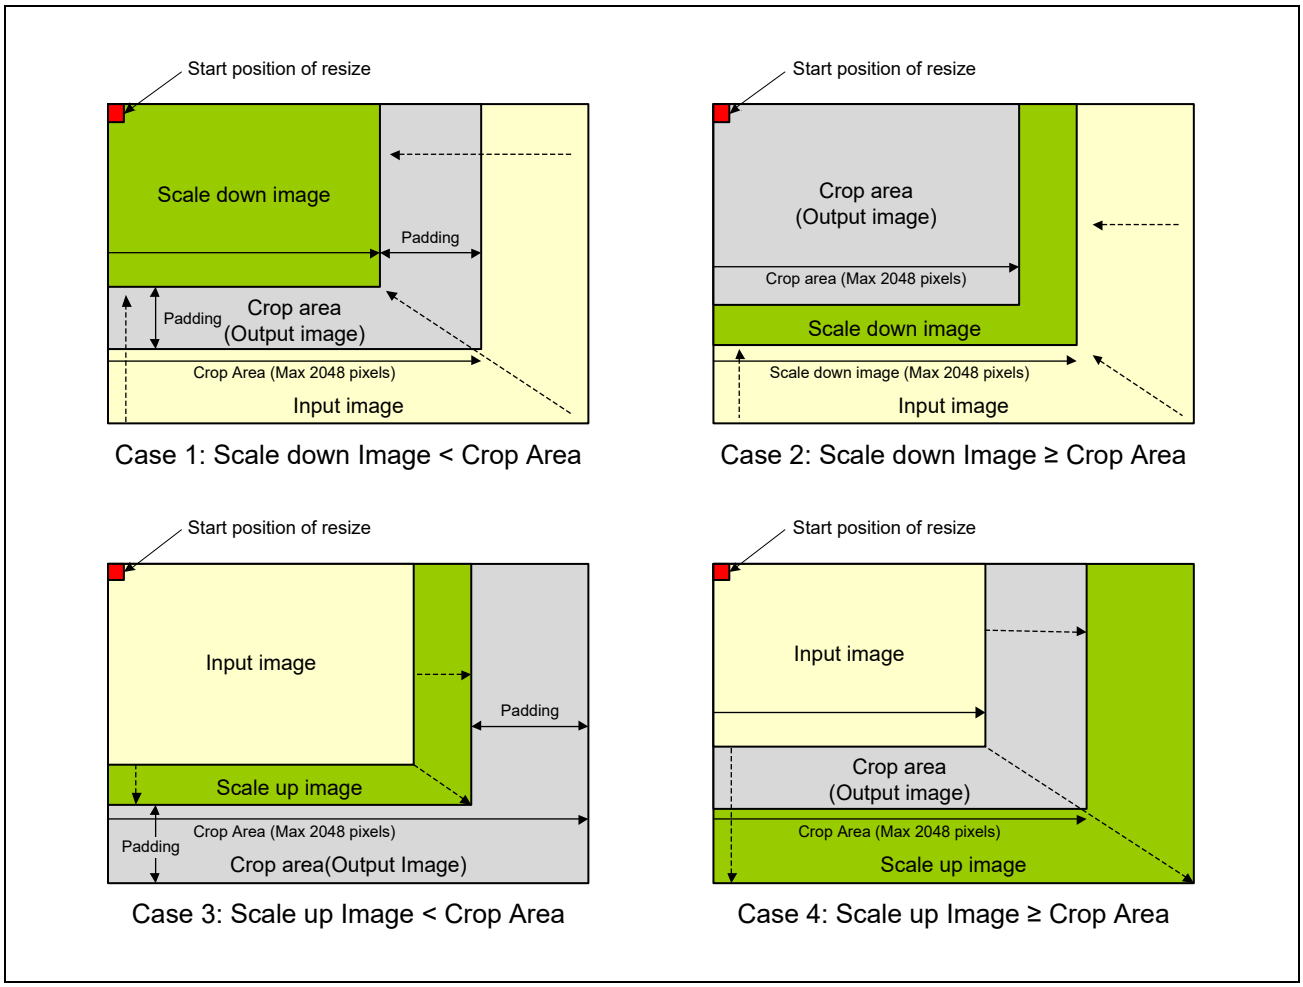

Figure 9.3-24 Relationship of Resized Image and Crop Area

9.3.1.4.1 Resize start position

The resize processing start from Resize Start Position (ISU_RS_STPOS) on the input image in according to the register setting. This position setting is specified in pixel coordinates from the top left of the image. If 0 is specified, the input image will be the Resizer (RS) target image as it is.

Padding area will be filled based on the setting of ISU_RS_PADDMODE.PADDSEL.

- Register ISU_RS_STPOS.HSTART = Resize Start H position
- Register ISU_RS_STPOS.VSTART = Resize Start V position

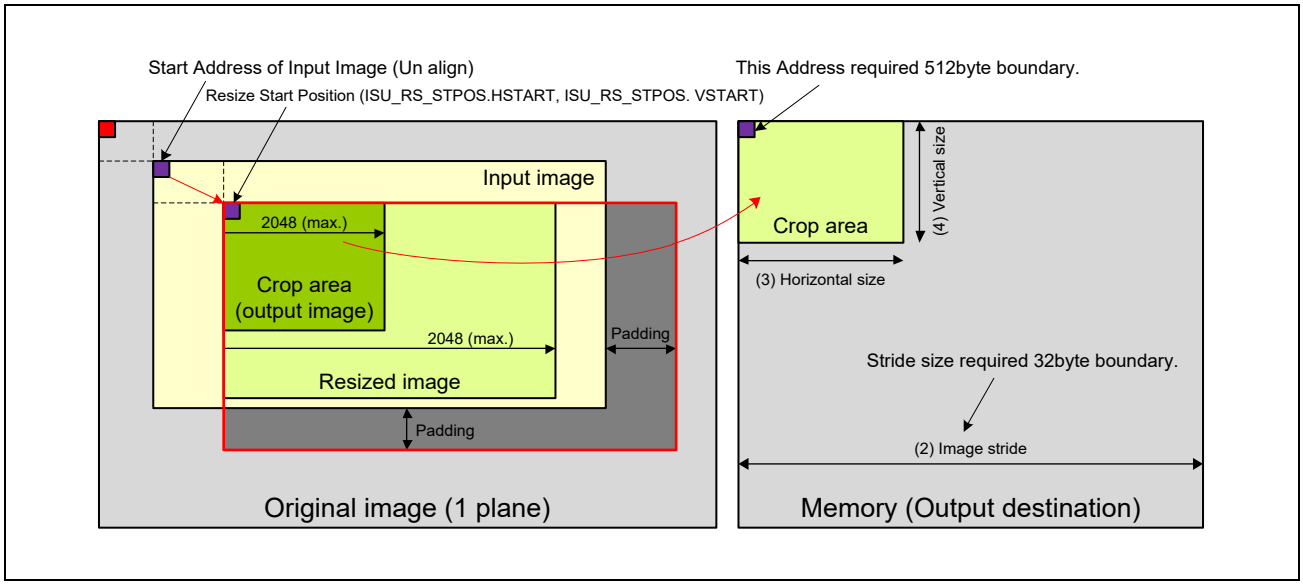

Figure 9.3-25 Resize Start Position

9.3.1.4.2 Sub pixel offset

The Resize Start Position Tuning (ISU_RS_POS_TUNE) can be used to adjust the start position by sub pixel level to reduce moiré.

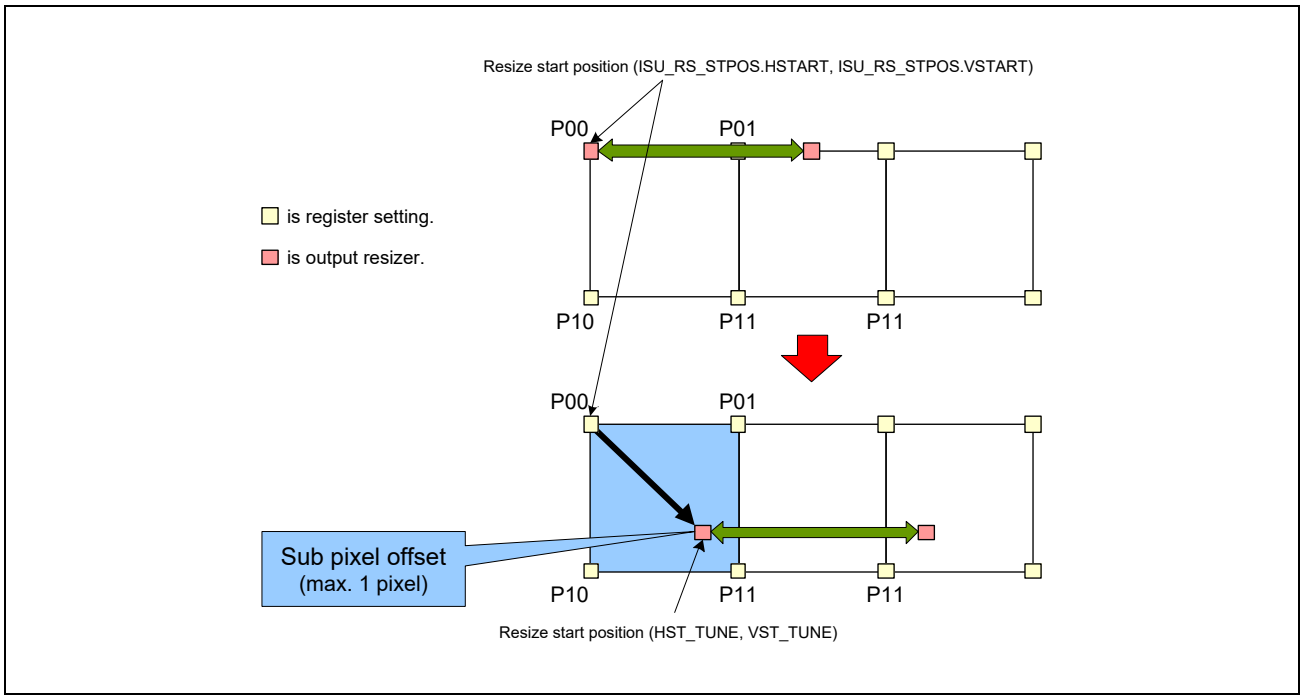

Figure 9.3-26 Sub Pixel Position Adjustment

9.3.1.4.3 Scaling calculation

The coefficients are defined in **Table 9.3-8**.

Table 9.3-8 Scaling Coefficient Setting

No.	Category	Register	Variation
(1)	Horizontal Scaling Ratio	RS_HSCALE.HMANT[3:0]	• m_h: Integer part of Horizontal scaling coefficient
		RS_HSCALE.HFRAC[11:0]	• f_h: Fraction part of Horizontal scaling coefficient
(2)	Vertical Scaling Ratio	RS_VSCALE.VMANT[3:0]	• m_v: Integer part of Vertical scaling coefficient
		RS_VSCALE.VFRAC[11:0]	• f_v: Fraction part of Vertical scaling coefficient

Follow the procedure below to set the coefficients.

Step 1: Estimation of scaling factor

The resizer can be handled resizing magnification independently for horizontally and vertically. The image size of this processing result can be calculated approximately by using “Input image horizontal size × hscale” and “Input image vertical size × vscale”.

$$\text{hascale} = \frac{4096}{4096 \times m_h + f_h} \qquad \text{vscale} = \frac{4096}{4096 \times m_v + f_v}$$

Figure 9.3-27 Sub Pixel Position Adjustment

Step 2: Conversion of setting values

Convert the set values according to **Table 9.3-9**.

Table 9.3-9 m_h' or m_v' Setting

ISU_RS_HSCALE.HMANTsetting (ISU_RS_VSCALE.VMANTsetting)	m_h' (m_v')
1 to 3	1
4 to 7	2
8 to 15	4

Step3: Fine-tuning of size calculations

- Definitions

  $hsize_{org}$: Input horizontal image size
  $vsize_{org}$: Input vertical image size
  $hsize_{down_scaled}$: Horizontal image size after scale down
  $vsize_{down_scaled}$: Vertical image size after scale down
  < >: Rounding down to the decimal point

- Formula

$$hsize_{down_scaled} = \langle 1 + \left[\left[\langle 1 + \frac{hsize_{org} - 1}{m_{\acute{h}}} \rangle - 1 \right] \times m_{\acute{h}} \times 4096 \right] / (4096 \times m_h + f_h) \rangle$$

$$vsize_{down_scaled} = \langle 1 + \left[\left[\langle 1 + \frac{vsize_{org} - 1}{m_{\acute{v}}} \rangle - 1 \right] \times m_{\acute{v}} \times 4096 \right] / (4096 \times m_v + f_v) \rangle$$

Step 4: Adjustment

If the down scaled image size does not match the intention, the values of f_h and f_v are fine-tuned and recalculated to find the f_h and f_v that result in the desired output down scaled size.

The values thus obtained are set to the corresponding register values RS_HSCALE and RS_VSCALE.

9.3.1.4.4 Resize processing

The following figure shows the processing image of bi-linear algorithm (4-point interpolation).

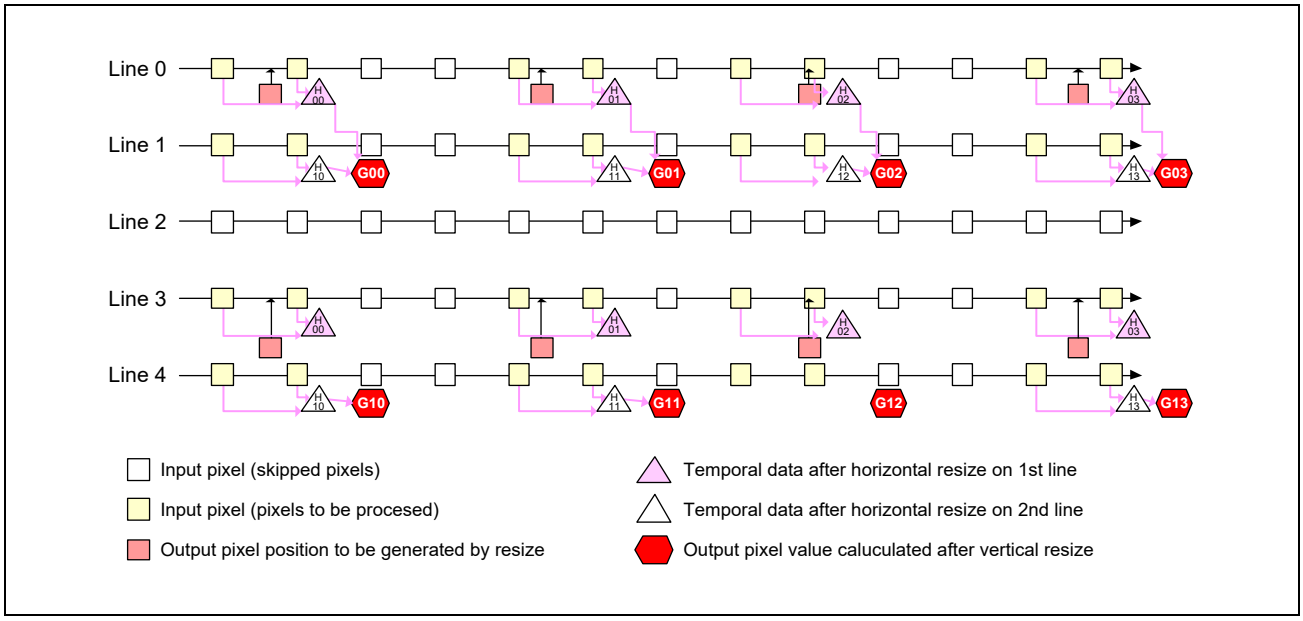

Figure 9.3-28 Points Bi-Linear Resize

The outline of the calculation procedure of 4-point linear interpolation is shown below.

Although dH and dV are not exist actually, it is used to help understanding for this algorithm. The pixel value of the target pixel position G00 will be calculated from the nearest 4 input pixels, and dH and dV indicate sub pixel position of G00 calculated from Horizontal/Vertical scaling ratio.

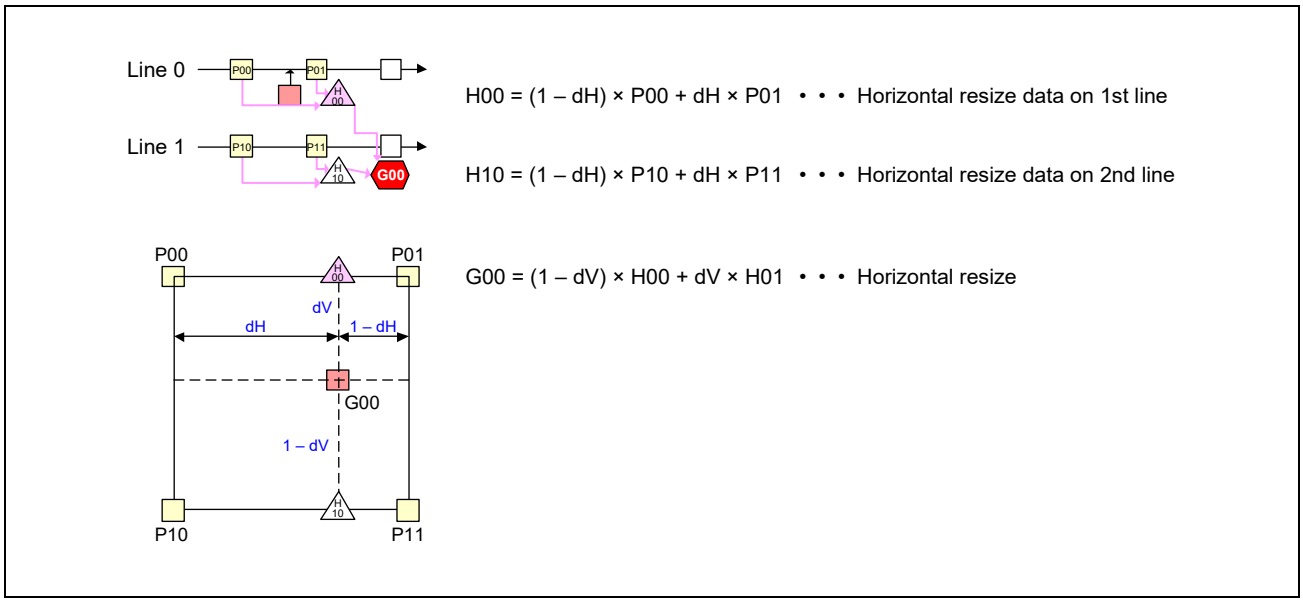

Figure 9.3-29 Calculation for 4 Points Bi-linear Resize

9.3.1.5 Write Pixel Formatting (WPF)

The WPF converts the resized image data from RS and outputs it to the AXI-Master.

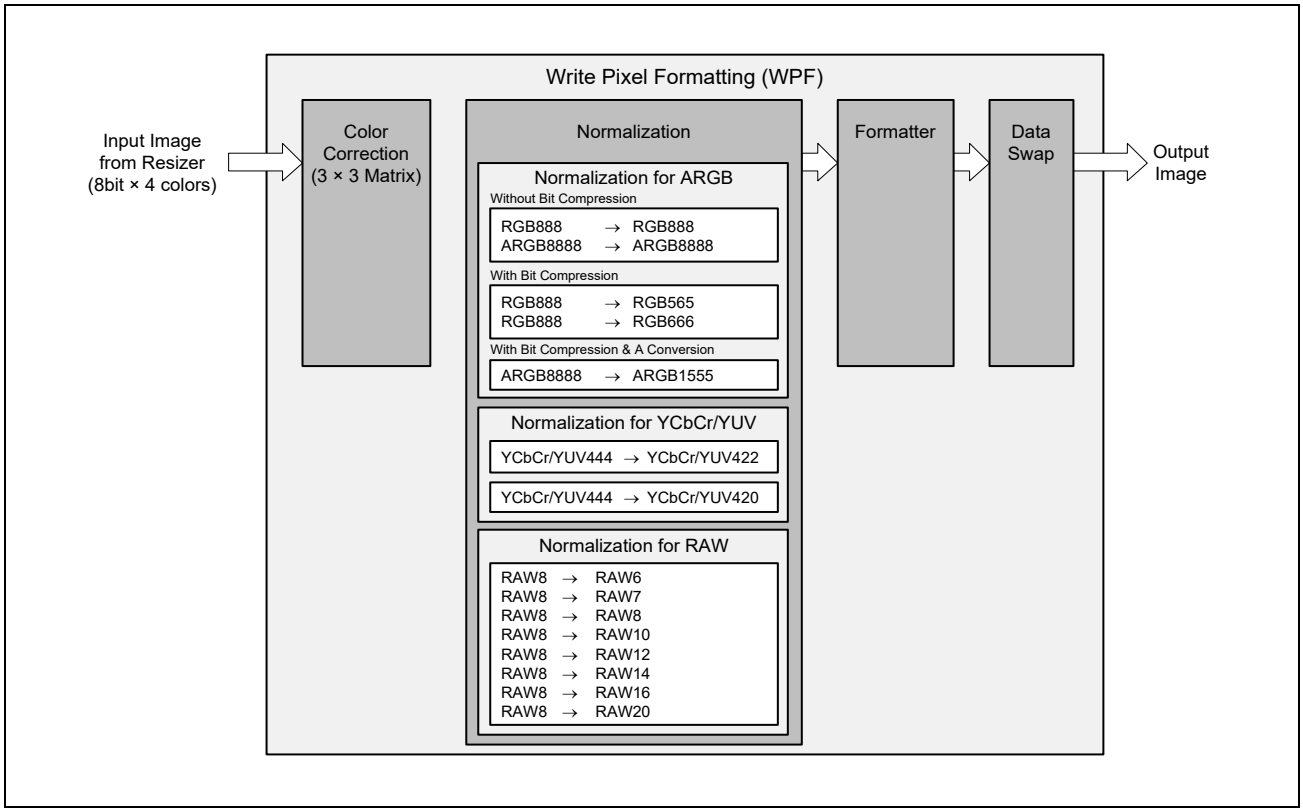

Figure 9.3-30 WPF Block Diagram

9.3.1.5.1 Color correction

This function is for the color space conversion among RGB, YCbCr, and YUV by using 3 × 3 color matrix. Matrix coefficients can be set by registers. The matrix calculation formula and circuit block diagram are shown below.

3 × 3 matrix

$$\begin{bmatrix} C1' \\ C2' \\ C3' \end{bmatrix} = \begin{bmatrix} K11 & K12 & K13 \\ K21 & K22 & K23 \\ K31 & K32 & K33 \end{bmatrix} \cdot \begin{bmatrix} A - OFST_A1 \\ B - OFST_B1 \\ C - OFST_C1 \end{bmatrix} + \begin{bmatrix} OFST_A2 \\ OFST_B2 \\ OFST_C2 \end{bmatrix}$$

Level clipping

$$C1'' = MAX\ (CLPMIN_A, MIN\ (CLPMAX_A, C1'))$$
$$C2'' = MAX\ (CLPMIN_B, MIN\ (CLPMAX_B, C2'))$$
$$C3'' = MAX\ (CLPMIN_C, MIN\ (CLPMAX_C, C3'))$$

Figure 9.3-31 Color Correction Equation

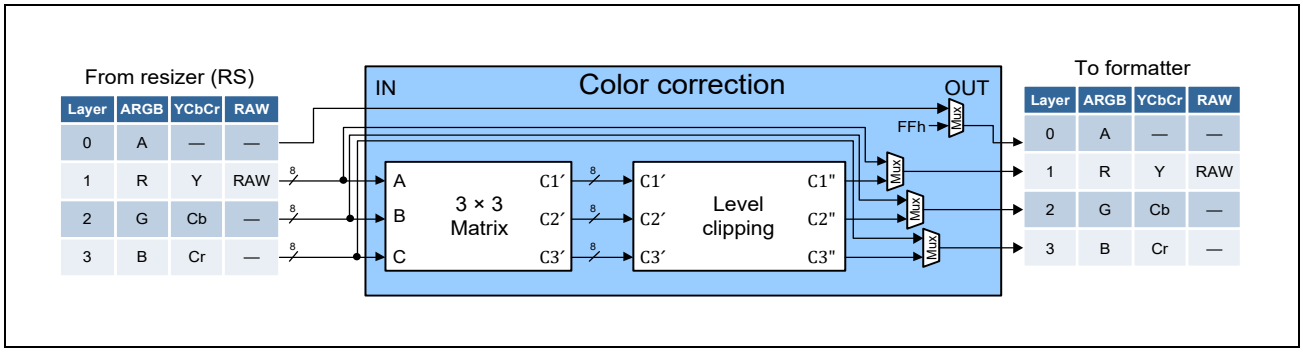

Figure 9.3-32 Color Correction Block Diagram

Sample settings of color matrix are shown below.

Conversion between RGB and YUV (PAL, SECAM)

$$\begin{bmatrix} Y_{OUT} \\ U_{OUT} \\ V_{OUT} \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.147 & -0.289 & 0.436 \\ 0.615 & -0.515 & -0.100 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix} \qquad \begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \begin{bmatrix} 1.000 & 0.000 & 1.140 \\ 1.000 & -0.395 & -0.580 \\ 1.000 & 2.032 & -0.000 \end{bmatrix} \begin{bmatrix} Y_{in} \\ (U_{in} - 128) \\ (V_{in} - 128) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Conversion between RGB and YCbCr ITU-R BT.601 / BT.709 (1250/50/2:1)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.169 & -0.331 & 0.500 \\ 0.500 & -0.419 & -0.081 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix} \qquad \begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \begin{bmatrix} 1.000 & 0.000 & 1.402 \\ 1.000 & -0.344 & -0.714 \\ 1.000 & 1.772 & -0.000 \end{bmatrix} \begin{bmatrix} Y_{in} \\ (Cb_{in} - 128) \\ (Cr_{in} - 128) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Conversion between RGB and YCbCr ITU-R BT.709 (1125/60/2:1)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \begin{bmatrix} 0.213 & 0.715 & 0.072 \\ -0.115 & -0.385 & 0.500 \\ 0.500 & -0.454 & -0.046 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix} \qquad \begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \begin{bmatrix} 1.000 & 0.000 & 1.575 \\ 1.000 & -0.187 & -0.468 \\ 1.000 & 1.856 & -0.000 \end{bmatrix} \begin{bmatrix} Y_{in} \\ (Cb_{in} - 128) \\ (Cr_{in} - 128) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Conversion from RAW to RGB or YCbCr/YUV (Grayscale)

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \begin{bmatrix} 1.000 & 0.000 & 0.000 \\ 1.000 & 0.000 & 0.000 \\ 1.000 & 0.000 & 0.000 \end{bmatrix} \begin{bmatrix} RAW_{in} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \qquad \begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \begin{bmatrix} 1.000 & 0.000 & 0.000 \\ 0.000 & 0.000 & 0.000 \\ 0.000 & 0.000 & 0.000 \end{bmatrix} \begin{bmatrix} RAW_{in} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix}$$

9.3.1.5.2 Normalization

This function converts each color data into appropriate bit depth.

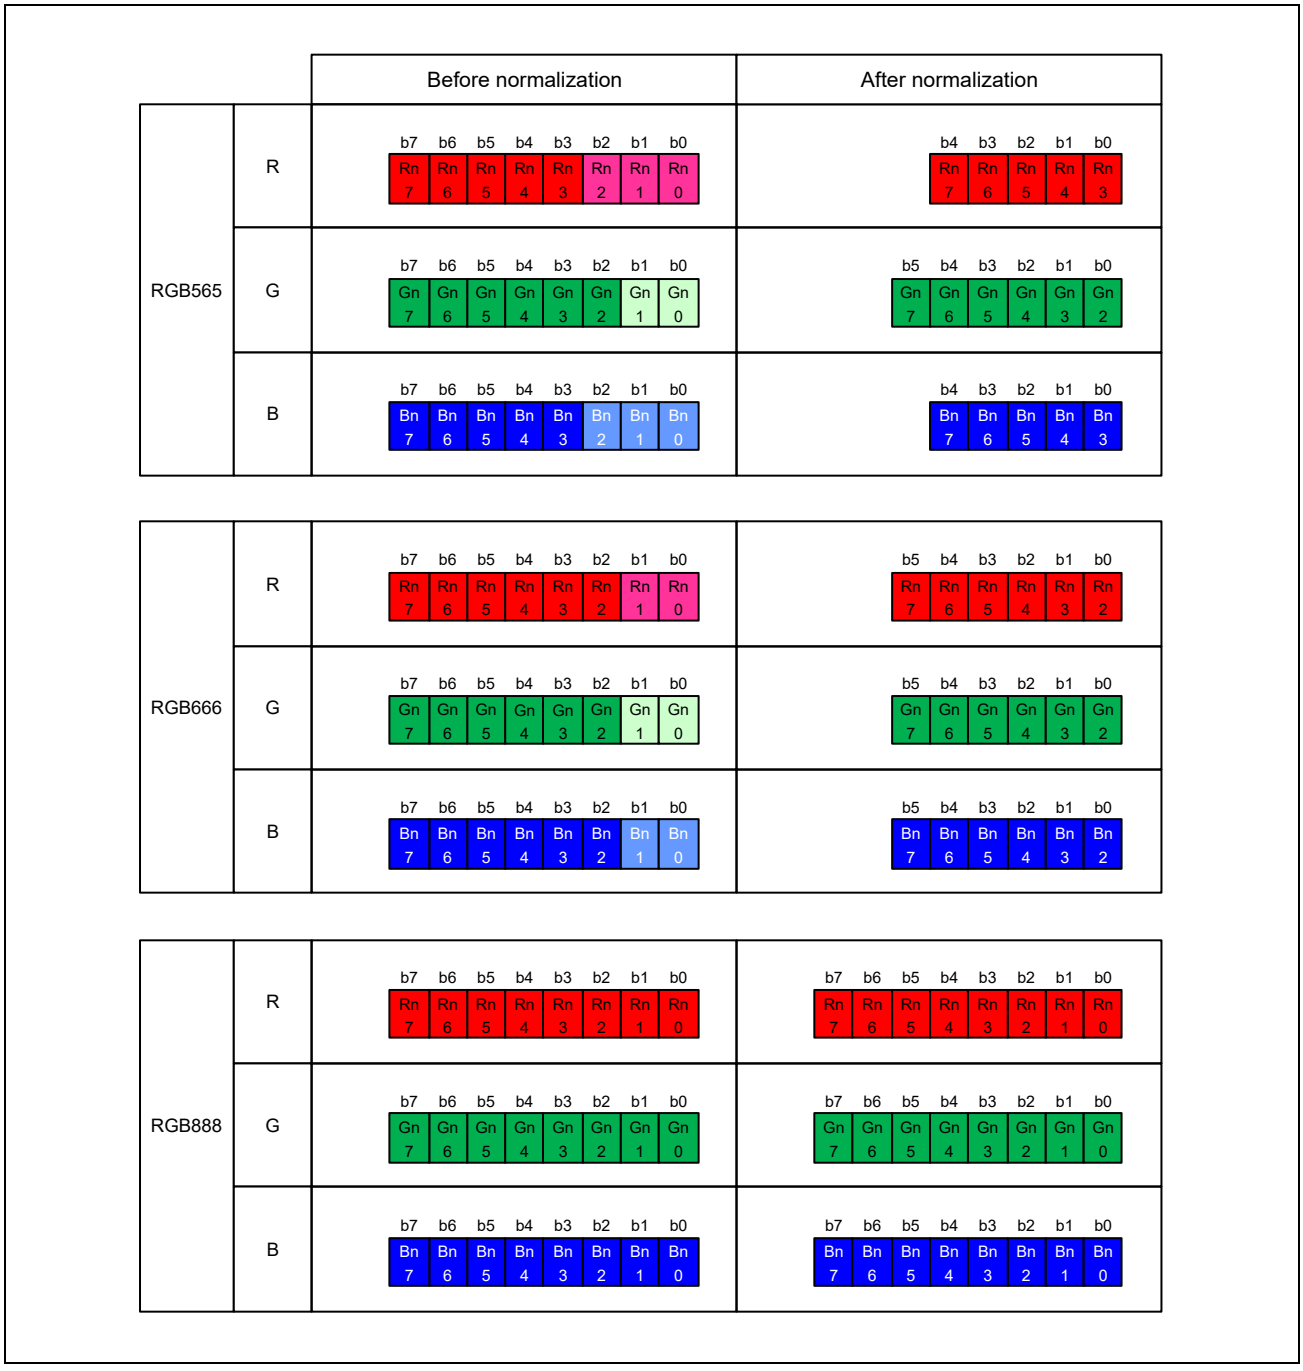

Figure 9.3-33 Normalization for RGB Format

■ **ARGB**

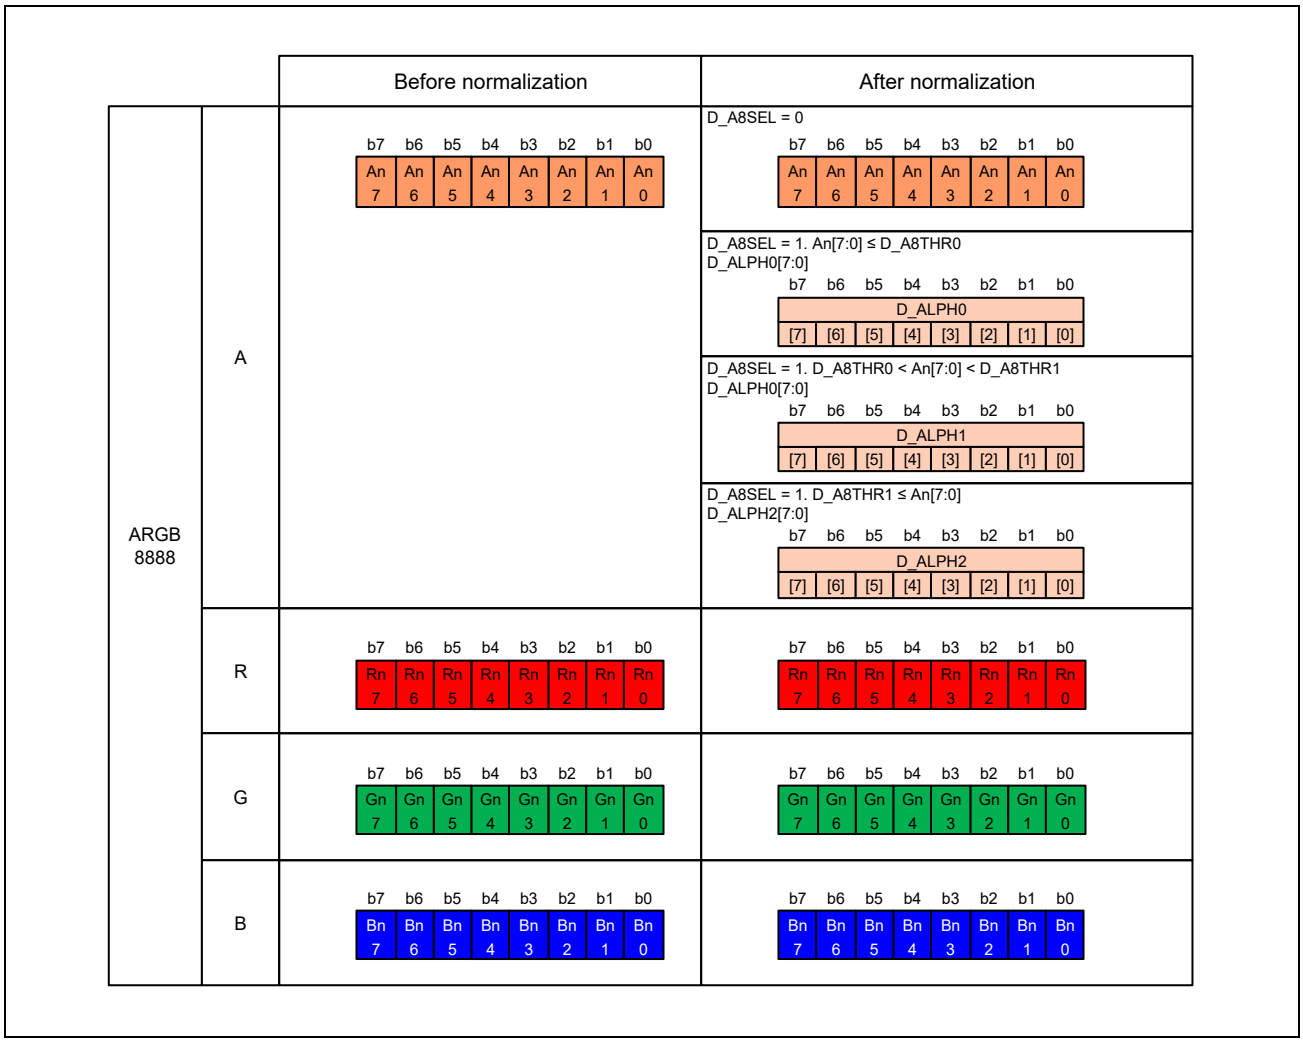

Figure 9.3-34 Normalization for ARGB8888 Format

"A(An)" of ARGB8888 is normalized according to the following logic.

If ISU_WPF_ALPH_SEL2.D_A8SEL = 0b, An is output as it is.

If ISU_WPF_ALPH_SEL2.D_A8SEL = 1b, replace it with the following value according to the relationship between ISU_WPF_ALPH_SEL2.D_A8THR0 to 1 and An.

If An ≤ D_A8THR0, replace it with ISU_WPF_ALPH_VAL.D_ALPH0.

If D_A8THR0 < An <D_A8THR1, replace it with ISU_WPF_ALPH_VAL.D_ALPH1.

If D_A8THR1 ≤ An, replace it with ISU_WPF_ALPH_VAL.D_ALPH2.

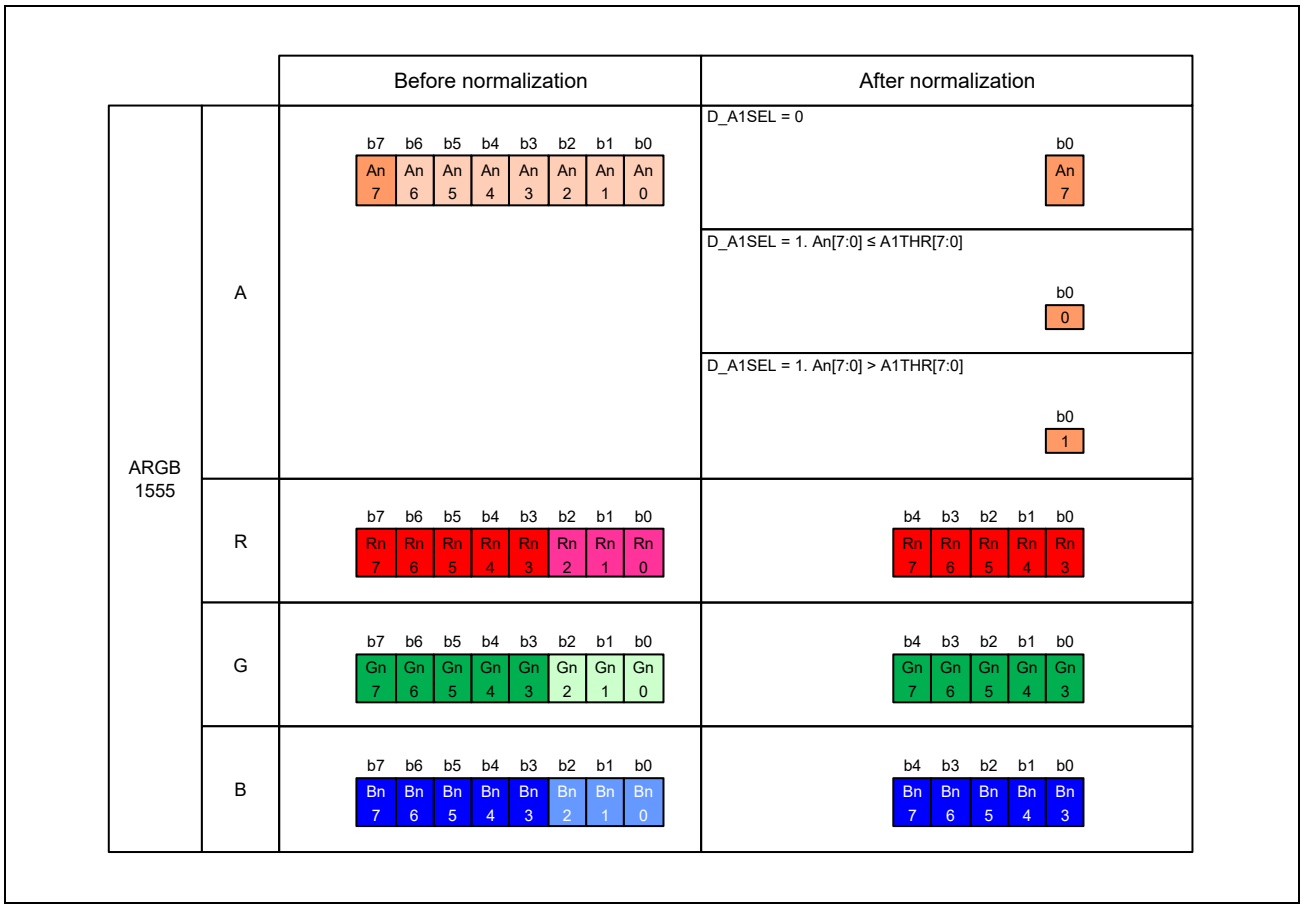

Figure 9.3-35 Normalization for ARGB1555 Format

“A(An)” of ARGB1555 A is compressed according to the following.

If ISU_WPF_ALPH_SEL1.D_A1SEL = 0b, An7 is output.

If ISU_WPF_ALPH_SEL1.D_A1SEL = 1b, replace it with the following value according to the relationship between ISU_WPF_ALPH_SEL1.D_A1THR and An.

If An ≤ D_A1THR, 0 is output.

If D_A1THR < An, 1 is output.

■ **YCbCr/YUV**

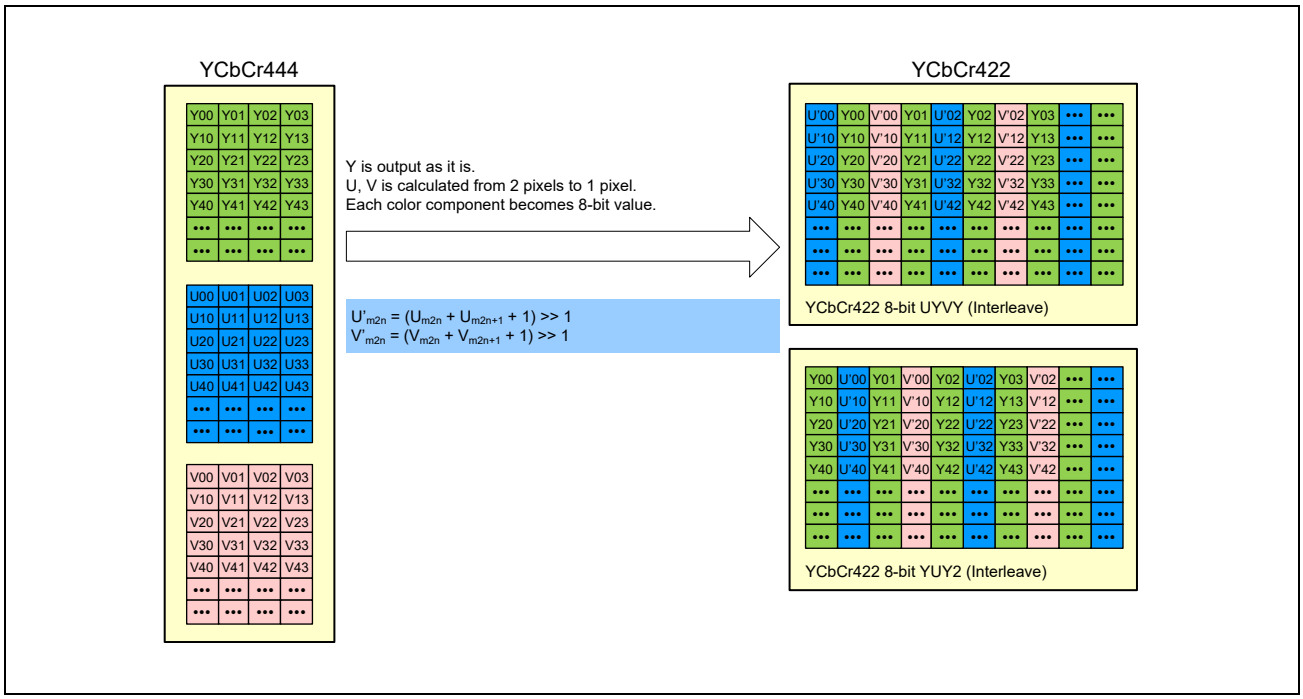

Figure 9.3-36 Normalization for YCbCr/YUV422 (Interleave) Format

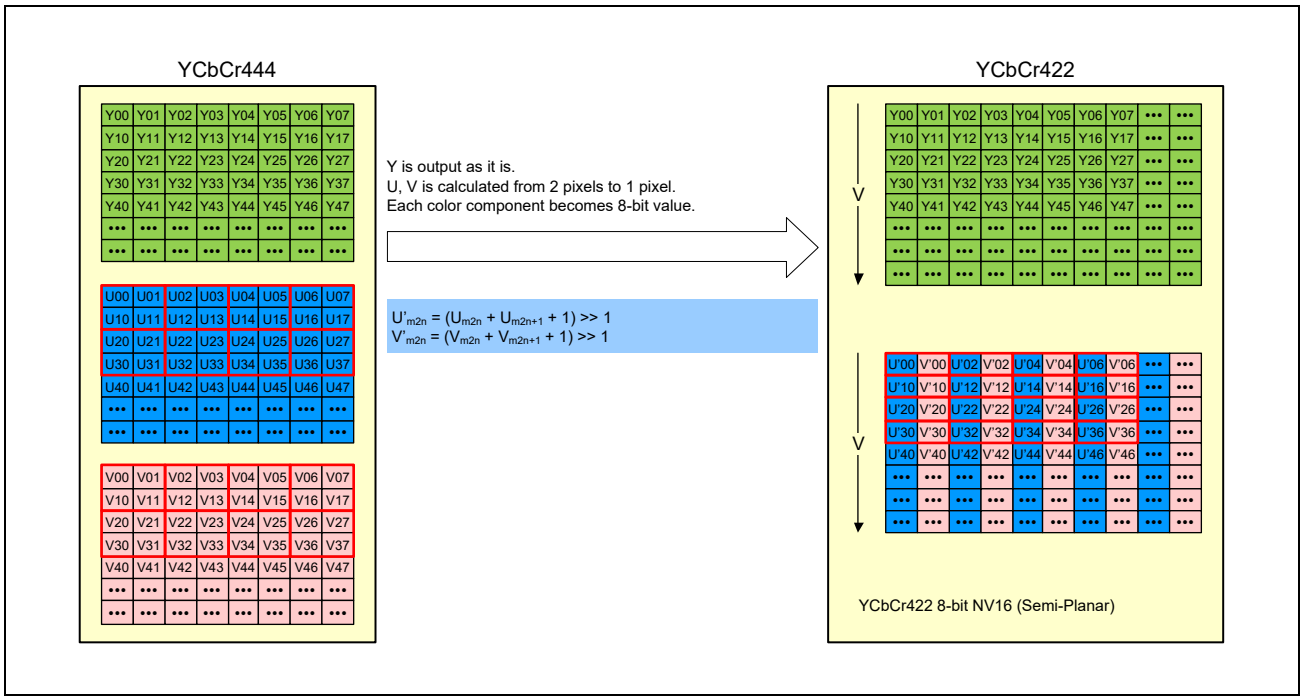

Figure 9.3-37 Normalization for YCbCr/YUV422 (Semi-Planar) Format

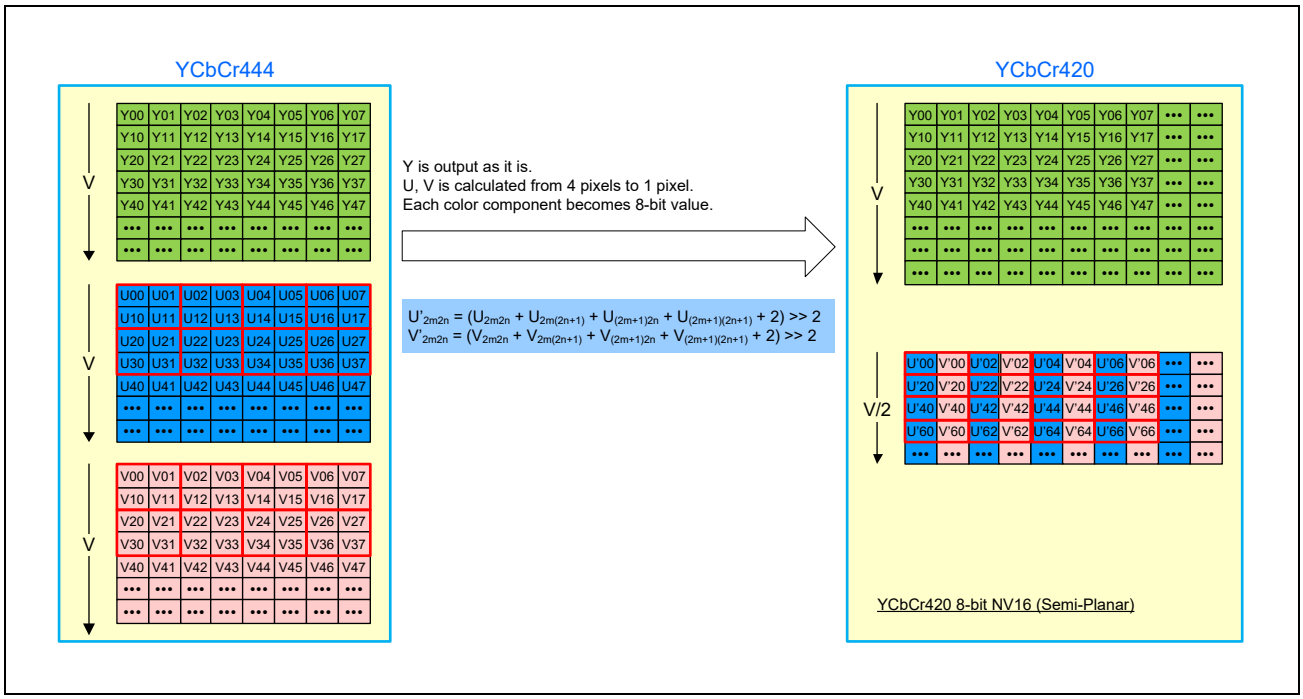

Figure 9.3-38 Normalization for YCbCr/YUV420 Format

■ RAW

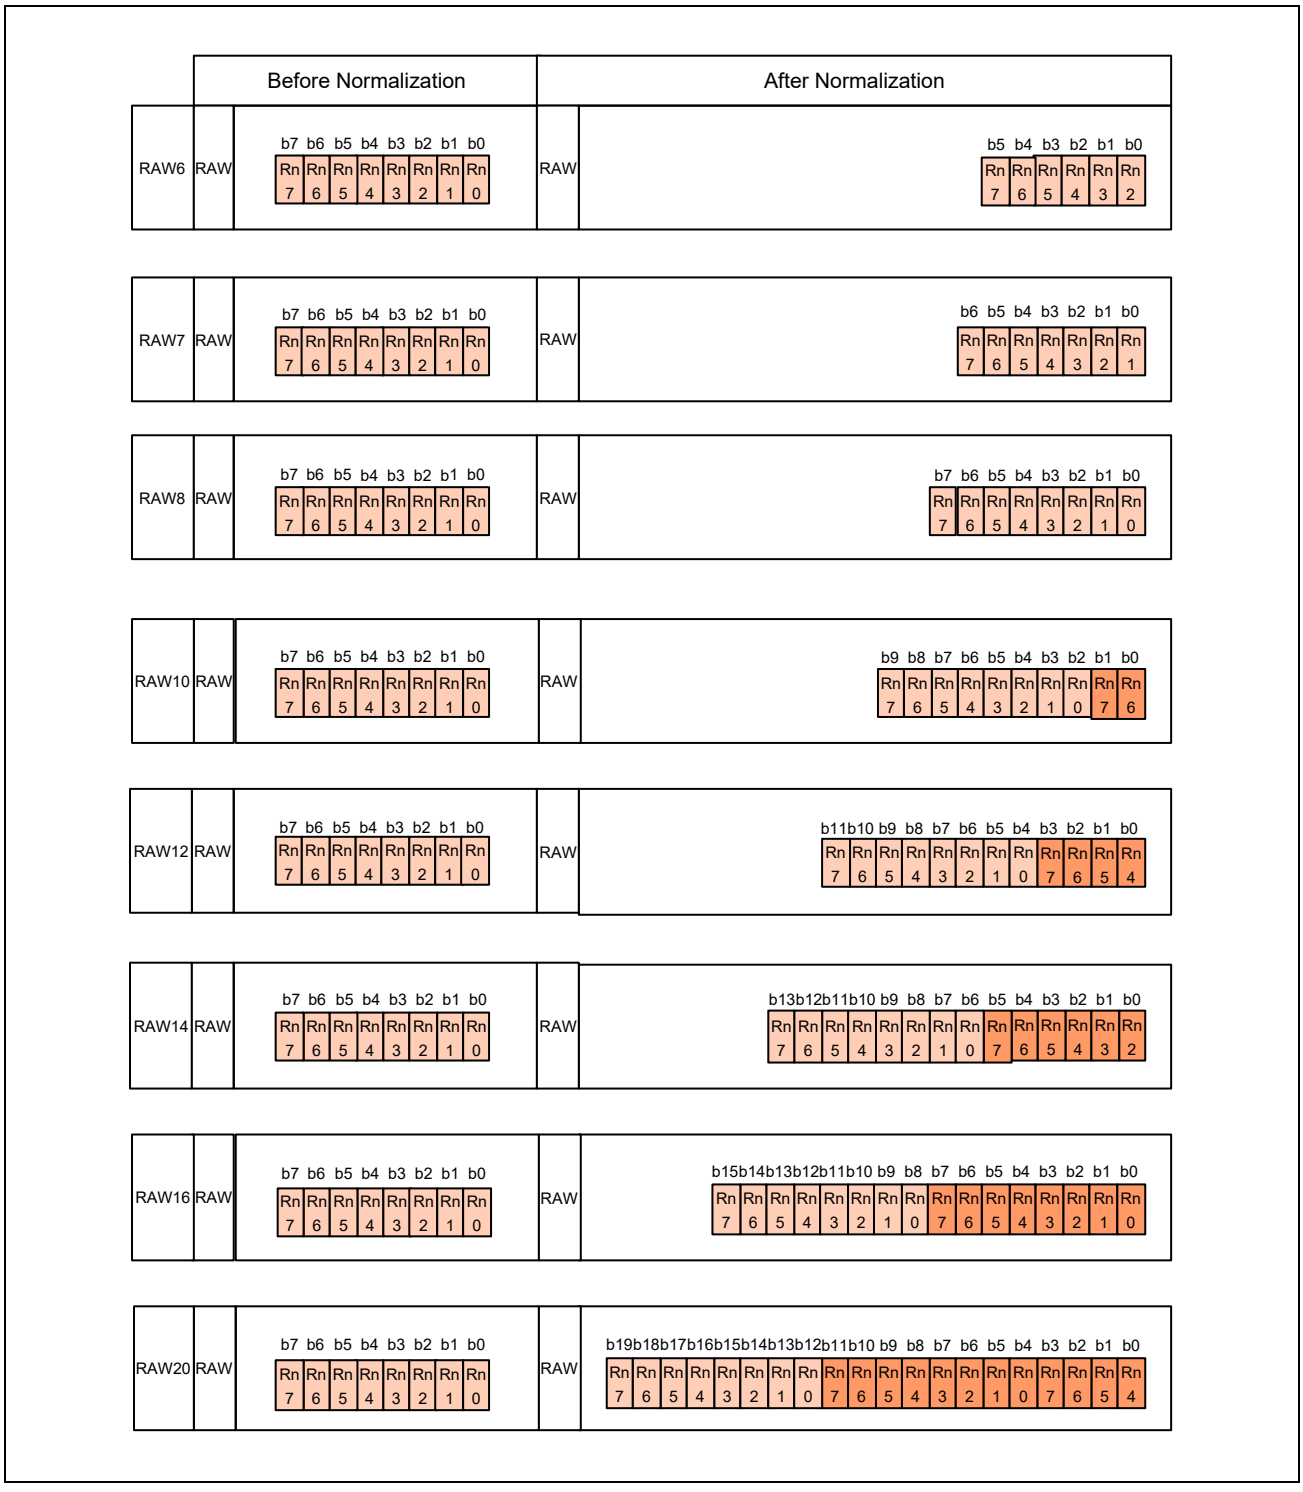

Figure 9.3-39 Normalization for RAW Format

9.3.1.5.3 WPF Formatter

The following data formats are described as 2-/3-/4-/8-byte per unit. Eventually, these data unit are packed in 32-byte (256-bit) each so that it can be handled in next process. Image format setting is indicated by ISU_WPF_FMT.WDFMT[5:0].

■ RGB/ARGB

This function supports 8 ARGB/RGB formats as shown below. All formats are “Number of planes = 1”.

Table 9.3-10 ARGB Support Format

	Format				n								n + 1								n + 2								n + 3							
WDFMT [5:0]	Color Format	Padding	bit/pixel	phase	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

Semi-Planar (Number of Planes = 2)	22h	YCbCr422 8-bit	NV16	(3)
	23h	YCbCr420 8-bit	NV12	(4)

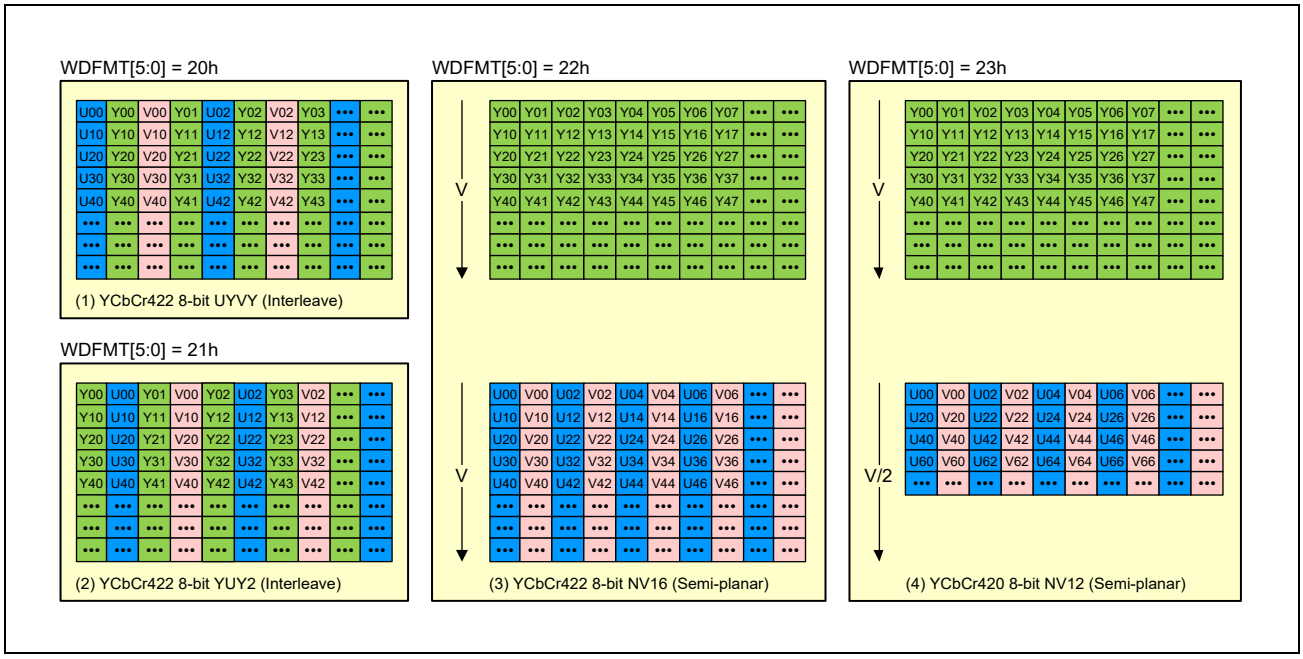

Figure 9.3-40 YCbCr/YUV Support Format

■ RAW

This function supports 8 RAW formats as shown bellow. All formats are “Number of planes = 1”.

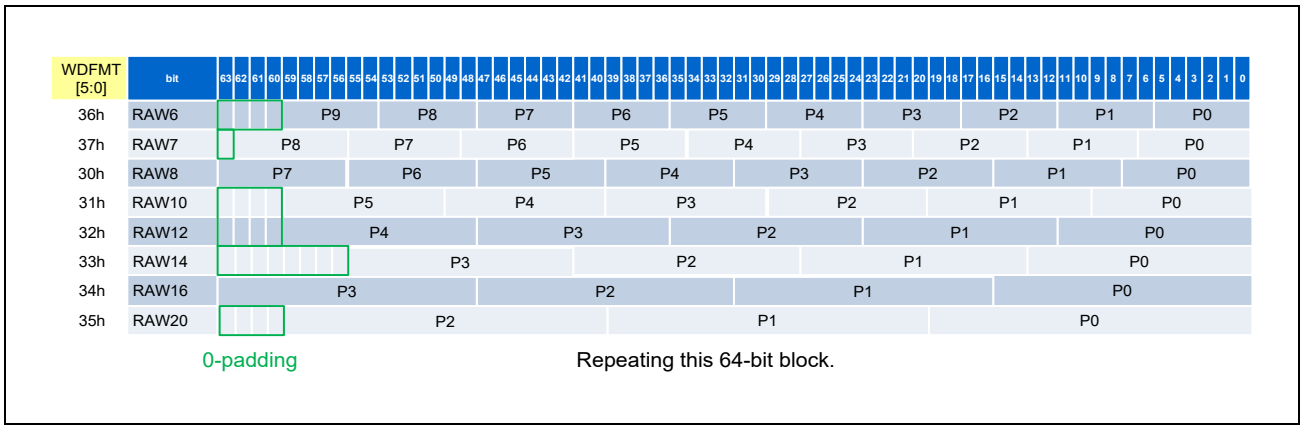

Figure 9.3-41 RAW Support Format

9.3.1.5.4 Data Swap (Endian Correction)

This function corrects the byte order so that modify endian of data on memory. Each bytes can be arranged any order according the register setting.

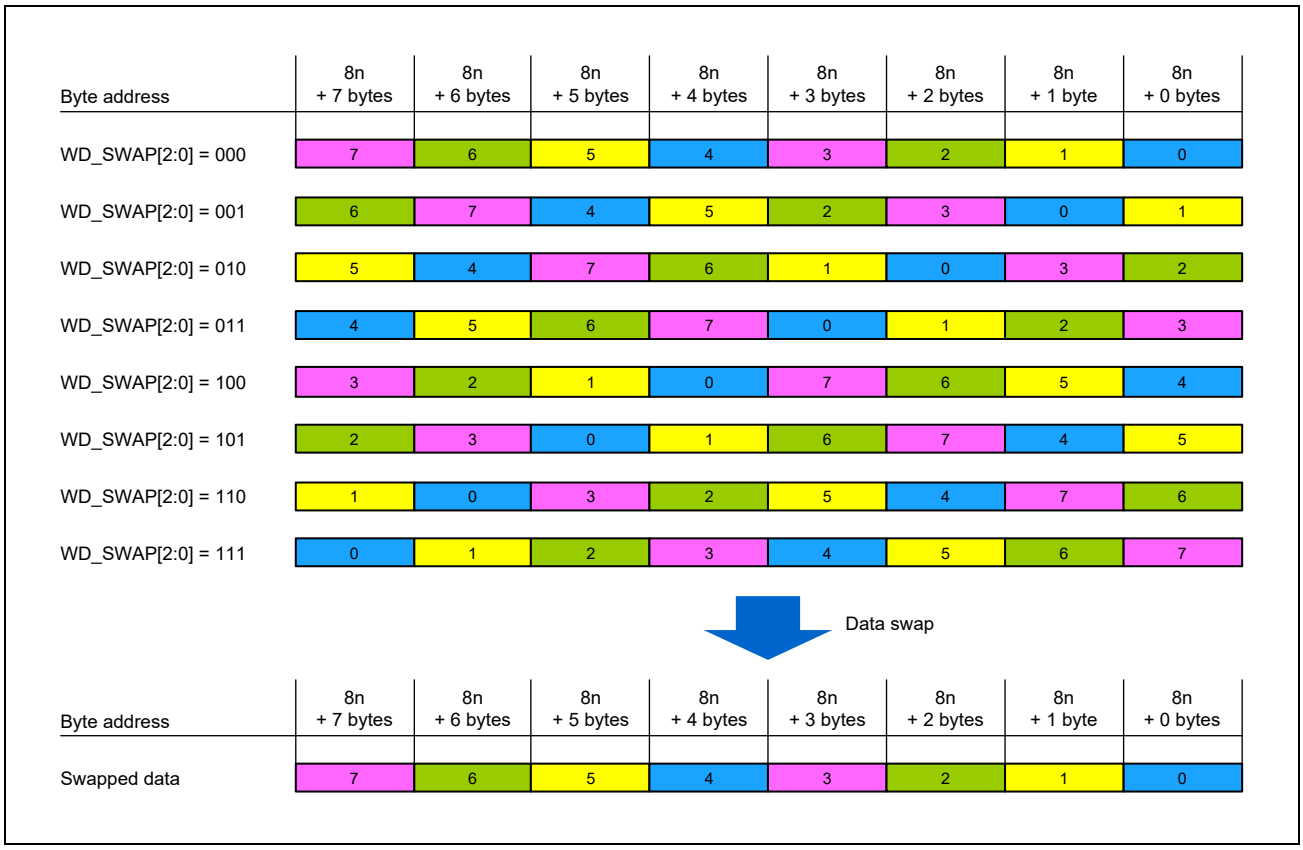

Figure 9.3-42 Data Swap Correction

9.3.2 Registers

The address of the ISU2 register is represented by the offset address from the base address. ISU2 base address is as follows:

Table 9.3-12 Register Base Address

Base Register Name	Base Address
<ISU_base>	0_1084_0000h (5084_0000h*1, 4084_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.3.2.1 List of Registers

9.3.2.1.1 System Management Register

“System Management Register” sets descriptor processing and interrupts control.

The descriptor cannot access these registers.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
FM Descriptor List Address Register 0	ISU_FM_DL_STADDH	0000_0000h	0000h	32
FM Descriptor List Address Register 1	ISU_FM_DL_STADDL	0000_0000h	0004h	32
FM Frame Control Register	ISU_FM_FRCON	0000_0000h	0008h	32
FM Module Stop Register	ISU_FM_STOP	0000_0000h	000Ch	32
FM Interrupt Enable Register	ISU_FM_INT_EN	0000_0000h	0010h	32
FM Interrupt Status Register	ISU_FM_INT_STA	0000_0000h	0014h	32
FM Frame End Interrupt Control Register	ISU_FM_INT_FREC	0000_0000h	0018h	32
Reserve	-	-	001Ch to 001Fh	-
AXI Error Action Register	ISU_AXI_ERACT	0000_0000h	0020h	32
Reserve	-	-	0024h to 002Bh	-
AXI FIFO Capability Register	ISU_AXI_FIFO_CAP	4000_4000h	002Ch	32
Reserve	-	-	0030h to 00EFh	-
ID Register	ISU_OTH_ID	0000_0200h	00F0h	32
Reserve	-	-	00F4h to 00FFh	-

9.3.2.1.2 Common Register

“Common Register” sets input/output, reduction ratio and color conversion coefficient.

Prohibits write to these registers during frame processing.

The descriptor can access these registers.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
RPF Source Image Size Register	ISU_RPF_SRC_SIZE	0000_0000h	0100h	32
RPF Source Stride Register	ISU_RPF_SRC_STRD	0000_0000h	0104h	32

9.3.2.2 Register Descriptions

9.3.2.2.1 FM Descriptor List Address Register 0 (ISU_FM_DL_STADDH)

This register sets the start address [34:32] of the “Descriptor List”.

Access Size : 32 bits
Address : <ISU_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	DLADD[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	DLADD[34:32]	0h	RW	Set the start address [34:32] of the “Descriptor-List”.

9.3.2.2.2 FM Descriptor List Address Register 1 (ISU_FM_DL_STADDL)

This register sets the start address [31:0] of the “Descriptor List”.

Access Size : 32 bits
Address : <ISU_base> + 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DLADD[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DLADD[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DLADD[31:0]	0h	RW	Set the start address [31:0] of the “Descriptor List”. Note: Set an address that is a multiple of 32 bytes.

9.3.2.2.3 FM Frame Control Register (ISU_FM_FRCON)

This register controls the frame processing method selection and processing start.

Access Size : 32 bits
Address : <ISU_base> + 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DESON
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	START
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	DESON	0h	RW	Processing method selection Select “Register Mode” or “Descriptor Mode”. 0b: Register Mode When executing in this mode, set the register before starting frame processing. 1b: Descriptor Mode When executing in this mode, write a “Descriptor List” before starting frame processing.
15 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	START	0h	RW	Frame processing start instruction [Write] 0b: NOP 1b: Start frame processing [Read] This bit is always read as 0. Note: If 1 is written during frame processing, it will be ignored. Note: When 1 is written, the descriptor footer read completion interrupt (ISU_FM_INT_STA.DESEND) is automatically cleared.

9.3.2.2.4 FM Module Stop Register (ISU_FM_STOP)

This register controls an emergency stop.

Access Size : 32 bits
Address : <ISU_base> + 000Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	STOP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	STOP	0h	RW	Emergency stop instruction [Write] 0b: NOP 1b: Start emergency stop [Read] This bit is always read as 0. Note: It will be cleared automatically after the emergency stop is completed. If 1 is written during the emergency stop process, it will be ignored. Note: If you want to stop frame synchronously, you can stop it by setting the footer of the "Descriptor List" not to process the next frame.

9.3.2.2.5 FM Interrupt Enable Register (ISU_FM_INT_EN)

This register controls the interrupt factor.

Access Size : 32 bits
Address : <ISU_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	AXIRXERRE	-	-	-	AXITXERRE	-	-	-	-	-	-	-	LISTERRE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	R	RW	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SRSTENDE	-	-	-	-	-	-	DESENDE	FRENDE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	AXIRXERRE	0h	RW	Control of AXI bus read error interrupt (ISU_INT_ERR) Controls interrupt by "ISU_FM_INT_STA.RRESPERR". 0b: Do not output interrupt factors 1b: Output interrupt factor
27 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	AXITXERRE	0h	RW	Control of AXI bus write error interrupt (ISU_INT_ERR) Controls interrupt by "ISU_FM_INT_STA.BRESPERR". 0b: Do not output interrupt factors 1b: Output interrupt factor
23 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	LISTERRE	0h	RW	Control of "Descriptor List" format violation interrupt (ISU_INT_ERR) Controls interrupt by the number of bytes set in the header exceeding the limit or not being in 8-byte units. 0b: Do not output interrupt factors 1b: Output interrupt factor
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	SRSTENDE	0h	RW	Control of emergency stop completion interrupt (ISU_INT_STOPE) Controls interrupt by the completion of emergency stop. 0b: Do not output interrupt factors 1b: Output interrupt factor
7 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	DESENDE	0h	RW	Control of descriptor footer read completion interrupt (ISU_INT_DESE) Controls interrupt by the completion of descriptor footer read. 0b: Do not output interrupt factors 1b: Output interrupt factor Note: When an error occurs due to a format violation of "Descriptor List", the ISU_INT_DESE interrupt does not occur even if this bit is set to 1.
0	FRENDE	0h	RW	Control of frame processing end interrupt (ISU_INT_FRE) Controls interrupt by the frame processing end. 0b: Not output interrupt factor 1b: Output interrupt factor Note: This bit is updated according to the setting of the footer, if the descriptor mode is set.

9.3.2.2.6 FM Interrupt Status Register (ISU_FM_INT_STA)

This register displays the status of the interrupt factors.

Access Size : 32 bits
Address : <ISU_base> + 0014h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	RRESPERR[2:0]			-	BRESPERR[2:0]			-	-	-	-	-	-	LISTERR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R0W	R0W	R0W	R	R0W	R0W	R0W	R	R	R	R	R	R	R0W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SRSTEND	-	-	-	-	-	-	DESEND	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R0W	R	R	R	R	R	R	R0W	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29 to 27	RRESPERR[2:0]	0h	R0W	Displays the status of the AXI read response. Each bit means the following. [0] EXOKAY 0b: No EXOKAY response 1b: EXOKAY response [1] SLVERR 0b: No SLVERR response 1b: SLVERR response [2] DECERR 0b: No DECERR response 1b: DECERR response Note: If you want to clear these bits, clear the 3 bits at the same time.
26	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25 to 23	BRESPERR[2:0]	0h	R0W	Displays the status of the AXI write response. Each bit means the following. [0] EXOKAY 0b: No EXOKAY response 1b: EXOKAY response [1] SLVERR 0b: No SLVERR response 1b: SLVERR response [2] DECERR 0b: No DECERR response 1b: DECERR response Note: If you want to clear these bits, clear the 3 bits at the same time.
22 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	LISTERR	0h	R0W	Displays the status of “Descriptor List” format violation (ISU_INT_ERR). 0b: Descriptor list does not violate format 1b: Descriptor list does violate format
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	SRSTEND	0h	R0W	Displays the status of the emergency stop completion (ISU_INT_STOPE). 0b: Emergency stop not completed 1b: Emergency stop completed
7 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
1	DESEND	0h	R0W	Displays the status of the descriptor footer read completion (ISU_INT_DESE). 0b: Descriptor footer read incomplete 1b: Descriptor footer read completed
0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.3.2.2.7 FM Frame End Interrupt Control Register (ISU_FM_INT_FREC)

This register sets the number of toggles when issuing an ISU_INT_FRE interrupt.

Access Size : 32 bits
Address : <ISU_base> + 0018h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	FREC[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1 to 0	FREC[1:0]	0h	RW	Sets the number of ISU_INT_FRE interrupt toggles. ISU_INT_FRE interrupt toggle counter is reset by writing 1b to ISU_FM_FRCON.START. 0: Always outputs a frame end interrupt from ISU_INT_FRE0. 1: A frame end interrupt is output from ISU_INT_FRE0 to FRE1. ISU_INT_FRE0 to FRE1 are toggled in order each time the frame ends. 2: A frame end interrupt is output from ISU_INT_FRE0 to FRE2. ISU_INT_FRE0 to FRE2 are toggled in order each time the frame ends. 3: A frame end interrupt is output from ISU_INT_FRE0 to FRE3. ISU_INT_FRE0 to FRE3 are toggled in order each time the frame ends.

9.3.2.2.8 AXI Error Action Register (ISU_AXI_ERACT)

This register sets the operation of the AXI-Master after an AXI error occurs.

For each AXI error condition, choose whether to ignore and continue or stop subsequent transactions.

Transaction continuation settings are used for debugging purposes.

Access Size : 32 bits

Address : <ISU_base> + 0020h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	RRESPEXO_ACT	RRESPSLV_ACT	RRESPDEC_ACT	-	BRESPEXO_ACT	BRESPSLV_ACT	BRESPDEC_ACT	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	R	RW	RW	RW	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29	RRESPEXO_ACT	0h	RW	Operation setting after AXI read response EXOKAY occurs 0b: Transaction stop 1b: Transaction continuation (For debugging)
28	RRESPSLV_ACT	0h	RW	Operation setting after AXI read response SLVERR occurs 0b: Transaction stop 1b: Transaction continuation (For debugging)
27	RRESPDEC_ACT	0h	RW	Operation setting after AXI read response DECERR occurs 0b: Transaction stop 1b: Transaction continuation (For debugging)
26	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25	BRESPEXO_ACT	0h	RW	Operation setting after AXI write response EXOKAY occurs 0b: Transaction stop 1b: Transaction continuation (For debugging)
24	BRESPSLV_ACT	0h	RW	Operation setting after AXI write response SLVERR occurs 0b: Transaction stop 1b: Transaction continuation (For debugging)
23	BRESPDEC_ACT	0h	RW	Operation setting after AXI write response DECERR occurs 0b: Transaction stop 1b: Transaction continuation (For debugging)
22 to 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.3.2.2.9 AXI FIFO Capability Register (ISU_AXI_FIFO_CAP)

This register is a register that displays the free space of the FIFO in the AXI-Master.

Access Size : 32 bits
Address : <ISU_base> + 002Ch
Initial Value : 4000_4000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	SCAP_PL0[6:0]							-	-	SCAP_PL1[5:0]					
Initial Value	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	DCAP_PL0[6:0]							-	-	DCAP_PL1[5:0]					
Initial Value	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30 to 24	SCAP_PL0 [6:0]	40h	R	Free space in FIFO of the input image “Plane 0” 0 to 32 in Semi-Planar mode. 0 to 64 in other modes. The result of multiplying the value of this register by 32 bytes indicates the free space of the FIFO.
23 to 22	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
21 to 16	SCAP_PL1 [5:0]	0h	R	Free space in FIFO of the input image “Plane 1” 0 to 32 in Semi-Planar mode. 0 in other modes. The result of multiplying the value of this register by 32 bytes indicates the free space of the FIFO.
15	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
14 to 8	DCAP_PL0 [6:0]	40h	R	Free space in FIFO of the output image “Plane 0” 0 to 32 in Semi-Planar mode. 0 to 64 in other modes. The result of multiplying the value of this register by 32 bytes indicates the free space of the FIFO.
7 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5 to 0	DCAP_PL1 [5:0]	0h	R	Free space in FIFO of the output image “Plane 1” 0 to 32 in Semi-Planar mode. 0 in other modes. The result of multiplying the value of this register by 32 bytes indicates the free space of the FIFO.

9.3.2.2.10 ID Register (ISU_OTH_ID)

This register indicates the IP Version and Revision.

Access Size : 32 bits
Address : <ISU_base> + 00F0h
Initial Value : 0000_0200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

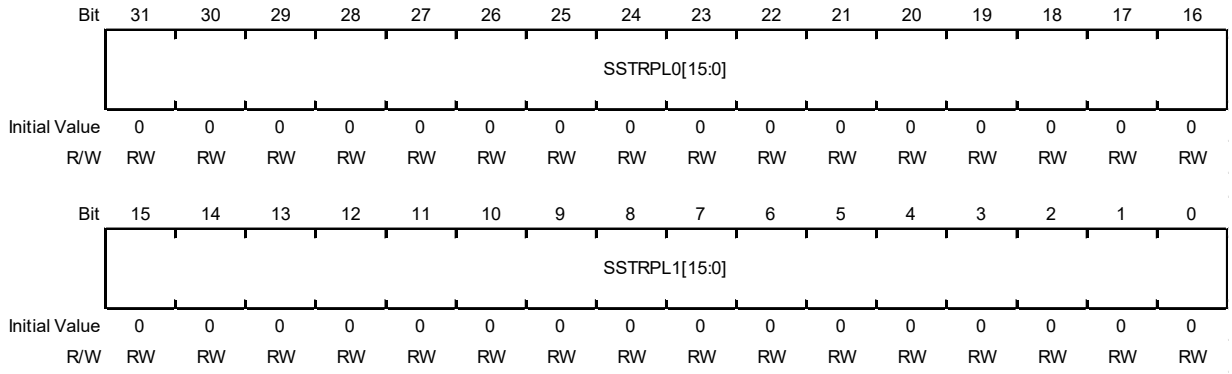
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 8	Version[7:0]	2h	R	This register indicates the IP Version . RZG3L :2h
7 to 0	Revision[7:0]	0h	R	This register indicates the IP Revision . RZG3L :0h

9.3.2.2.11 RPF Source Image Size Register (ISU_RPF_SRC_SIZE)

This register sets the size of the input image.

Access Size : 32 bits
Address : <ISU_base> + 0100h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	S_HSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	S_VSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	S_HSIZE[12:0]	0h	RW	Horizontal size of the input image Set the horizontal size of the input image in pixels. Set the size from 1 to 2048. 0: Setting prohibited 2049 or higher: Setting prohibited Note 1. For YCbCr type, set it to an even number.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	S_VSIZE[12:0]	0h	RW	Vertical size of the input image Set the vertical size of the input image in pixels. Set the size from 1 to 2048. 0: Setting prohibited 2049 or higher: Setting prohibited Note 1. For YCbCr420, set it to an even number.

9.3.2.2.12 RPF Source Stride Register (ISU_RPF_SRC_STRD)

This register sets the stride of the input image.

Access Size : 32 bits
Address : <ISU_base> + 0104h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	SSTRPL0[15:0]	0h	RW	Set the “Plane 0 (Y/RGB/RAW)” stride Set the “Plane 0 (Y/RGB/RAW)” stride in bytes. Note: The setting must be a multiple of 32 bytes and at least the number of horizontal pixels (ISU_RPF_SRC_SIZE.S_HSIZE).
15 to 0	SSTRPL1[15:0]	0h	RW	Set the “Plane 1 (C(Cb/Cr))” stride Set the “Plane 1 (C(Cb/Cr))” stride in bytes. Note: The setting must be a multiple of 32 bytes and at least the number of horizontal pixels (ISU_RPF_SRC_SIZE.S_HSIZE).

9.3.2.2.13 RPF Source Plane 0 Address Register 0 (ISU_RPF_SRC_ADDH_PL0)

This register sets the start address [34:32] of the input image of “Plane 0”.

Access Size : 32 bits
Address : <ISU_base> + 0108h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SADD_PL0[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	SADD_PL0 [34:32]	0h	RW	Set the start address [34:32] for “Plane 0 (Y/RGB/RAW)”.

9.3.2.2.14 RPF Source Plane 0 Address Register 1 (ISU_RPF_SRC_ADDL_PL0)

This register sets the start address [31:0] of the input image of “Plane 0”.

Access Size : 32 bits
Address : <ISU_base> + 010Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SADD_PL0[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SADD_PL0[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SADD_PL0 [31:0]	0h	RW	Set the start address [31:0] of “Plane 0 (Y/RGB/RAW)”. Note: Set an address that is a multiple of 32 bytes.

9.3.2.2.15 RPF Source Plane 1 Address Register 0 (ISU_RPF_SRC_ADDH_PL1)

This register sets the start address [34:32] of the input image of “Plane 1”.

Access Size : 32 bits
Address : <ISU_base> + 0110h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SADD_PL1[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	SADD_PL1 [34:32]	0h	RW	Set the start address [34:32] of “Plane 1 (C(Cb/Cr))”.

9.3.2.2.16 RPF Source Plane 1 Address Register 1 (ISU_RPF_SRC_ADDL_PL1)

This register sets the start address [31:0] of the input image of “Plane 1”.

Access Size : 32 bits
Address : <ISU_base> + 0114h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SADD_PL1[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SADD_PL1[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SADD_PL1 [31:0]	0h	RW	Set the start address [31:0] for “Plane 1 (C(Cb/Cr))”. Note: Set an address that is a multiple of 32 bytes.

9.3.2.2.17 RPF Source Image Format Register (ISU_RPF_FMT)

This register sets the color format of the input image.

For details, see **9.3.1.3.2 RPF Formatter**.

Access Size : 32 bits
Address : <ISU_base> + 0118h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	RDFMT[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5 to 0	RDFMT[5:0]	0h	RW	Color format of input image The following formats can be configured. 00h: ARGB1555 01h: RGB565 02h BGR666 03h: RGB888 04h: BGR888 05h: ARGB8888 06h: RGBA8888 07h: ABGR8888 20h: YCbCr422 8-bit UYVY 21h: YCbCr422 8-bit YUY2 22h: YCbCr422 8-bit NV16 23h: YCbCr420 8-bit NV12 30h: RAW8 31h: RAW10 32h: RAW12 33h: RAW14 34h: RAW16 35h: RAW20 36h: RAW6 37h: RAW7 Others: Setting prohibited

9.3.2.2.18 RPF Source Image UV Format Register (ISU_RPF_UVBIN)

This register sets whether to convert CbCr/UV to offset binary.

For details, see **9.3.1.3.2 RPF Formatter**.

Access Size : 32 bits

Address : <ISU_base> + 011Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	UVCHG
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	UVCHG	0h	RW	Offset binary conversion selection for CbCr / UV data 0b: No conversion 1b: Conversion

9.3.2.2.19 RPF Source Image Data Swap Register (ISU_RPF_SRC_DSWAP)

This register sets the data swap of the input image.

For details, see **9.3.1.3.1 Data swap (endian correction)**.

Access Size : 32 bits

Address : <ISU_base> + 0120h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	RD_SWAP[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	RD_SWAP[2:0]	0h	RW	Data swap for input images When changing the settings of this register to a value other than 0, set ISU_RPF_SRC_ADDL_PL0 and ISU_RPF_SRC_ADDL_PL1 to multiples of 8 bytes.

9.3.2.2.20 RPF Source ALPHA Data Selection Register (ISU_RPF_ALPH_SEL)

This register sets the extension method from A (Alpha) 1-bit to 8-bit at the time of ARGB1555 input.

For details, see **9.3.1.3.3 Data extraction**.

Access Size : 32 bits
Address : <ISU_base> + 0124h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	S_A1SEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	S_ALPH1[7:0]								S_ALPH0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	S_A1SEL	0h	RW	Setting of how to extend A(Alpha) from 1-bit to 8-bit 0b: Copy input Alpha value 1-bit to all 8-bit 1b: Select the register value according to the input Alpha value 1 bit S_ALPH0 when Alpha = 0b S_ALPH1 when Alpha = 1b
15 to 8	S_ALPH1[7:0]	0h	RW	Extended Alpha value when S_A1SEL = 1b and input Alpha value is 1b.
7 to 0	S_ALPH0[7:0]	0h	RW	Extended Alpha value when S_A1SEL = 1b and input Alpha value is 0b.

9.3.2.2.21 RPF Source TEST Data Register 1 (ISU_RPF_SRC_TD1)

This register controls the test pattern generation.

For details, see **9.3.1.3.4 Test Pattern Generation**.

Access Size : 32 bits

Address : <ISU_base> + 0128h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMODE_EN	-	-	-	-	-	-	-	-	-	-	-	GRADA_A	GRADA_R	GRADA_G	GRADA_B
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	GRADA_TYPE	GRADA_STEP [3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	TMODE_EN	0h	RW	Control of test pattern generation 0b: Normal operation 1b: Test pattern generation After one frame of the test pattern is generated, it is automatically cleared to 0b. Note: Setting in descriptor mode is prohibited.
30 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	GRADA_A	0h	RW	A color when generating a test pattern 0b: Fixed initial value (ISU_RPF_SRC_TD2.INIT_A) 1b: Gradation
18	GRADA_R	0h	RW	R color when generating a test pattern 0b: Fixed initial value (ISU_RPF_SRC_TD2.INIT_R) 1b: Gradation
17	GRADA_G	0h	RW	G color when generating a test pattern 0b: Fixed initial value (ISU_RPF_SRC_TD2.INIT_G) 1b: Gradation
16	GRADA_B	0h	RW	B color when generating a test pattern 0b: Fixed initial value (ISU_RPF_SRC_TD2.INIT_B) 1b: Gradation
15 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GRADA_TYPE	0h	RW	Gradient type 0b: Gradation from 0 to 255 1b: Gradation from 255 to 0
3 to 0	GRADA_STEP [3:0]	0h	RW	Gradient step Note: If the setting is 0b, the initial value (ISU_RPF_SRC_TD2.INIT_*) is entered.

9.3.2.2.22 RPF Source TEST Data Register 2 (ISU_RPF_SRC_TD2)

This register sets the initial value of each color of ARGB for test pattern generation.

For details, see **9.3.1.3.4 Test Pattern Generation**.

Access Size : 32 bits
Address : <ISU_base> + 012Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INIT_A[7:0]								INIT_R[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INIT_G[7:0]								INIT_B[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	INIT_A[7:0]	0h	RW	Initial value of A color
23 to 16	INIT_R[7:0]	0h	RW	Initial value of R color
15 to 8	INIT_G[7:0]	0h	RW	Initial value of G color
7 to 0	INIT_B[7:0]	0h	RW	Initial value of B color

9.3.2.2.23 RS Scaling Factor Register 0 (ISU_RS_HSCALE)

This register sets the reduction factor of the input image in the horizontal direction.

For details, see **9.3.1.4.3 Scaling calculation**.

Access Size : 32 bits
Address : <ISU_base> + 0140h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	HMANT[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	HFRAC[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19 to 16	HMANT[3:0]	0h	RW	Horizontal reduction factor (integer part)
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	HFRAC[11:0]	0h	RW	Horizontal multiplication factor (decimal part) A value from 800h to FFFh can be specified when an image is upscaled (the HMANT value is 0) in the horizontal direction. A value from 000h to FFFh can be specified when an image is downscaled (the HMANT value is not 0) in the horizontal direction.

9.3.2.2.24 RS Scaling Factor Register 1 (ISU_RS_VSCALE)

This register sets the reduction factor of the input image in the vertical direction.

For details, see **9.3.1.4.3 Scaling calculation**.

Access Size : 32 bits
Address : <ISU_base> + 0144h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	VMANT[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	-	-	-	-	VFRAC[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19 to 16	VMANT[3:0]	0h	RW	Vertical reduction factor (integer part)
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	VFRAC[11:0]	0h	RW	Vertical reduction factor (decimal part) A value from 800h to FFFh can be specified when an image is upscaled (the VMANT value is 0) in the vertical direction. A value from 000h to FFFh can be specified when an image is downscaled (the VMANT value is not 0) in the vertical direction.

9.3.2.2.25 RS Output Image Start Position Register (ISU_RS_STPOS)

This register sets the resize start position.

For details, see **9.3.1.4.1 Resize start position**.

Access Size : 32 bits
Address : <ISU_base> + 0148h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	HSTART[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	VSTART[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 16	HSTART[11:0]	0h	RW	Resize start horizontal position Set the resizing start horizontal position by the number of pixels with the upper left of the input image as the origin. Set it with less than the number of input horizontal pixels (ISU_RPF_SRC_SIZE.S_HSIZE).
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	VSTART[11:0]	0h	RW	Resize start vertical position Set the resizing start vertical position by the number of pixels with the upper left of the input image as the origin. Set it with less than the number of input vertical pixels (ISU_RPF_SRC_SIZE.S_VSIZE).

9.3.2.2.26 RS Output Image Start Position Tuning Register (ISU_RS_POS_TUNE)

This register sets the offset for fine adjustment of the reduction start position.

For details, see **9.3.1.4.2 Sub pixel offset**.

Access Size : 32 bits
Address : <ISU_base> + 014Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	HST_TUNE[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	VST_TUNE[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 16	HST_TUN [11:0]	0h	RW	Offset from the resize-starting horizontal position (ISU_RS_STPOS.HSTART) Set the offset to be added to the horizontal position at the start of resizing in 4,096 steps (0 to less than 1 pixel of the input image).
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	VST_TUNE [11:0]	0h	RW	Offset from the resize-starting vertical position (ISU_RS_STPOS.VSTART) Set the offset to be added to the vertical position at the start of resizing in 4,096 steps (0 to less than 1 pixel of the input image).

9.3.2.2.27 RS Output Size Crop Register (ISU_RS_OS_CROP)

This register sets the crop size of the reduced image.

For details, see **9.3.1.4 Resizer (RS)**.

Access Size : 32 bits
Address : <ISU_base> + 0150h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	O_HSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	O_VSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	O_HSIZE[12:0]	0h	RW	Horizontal crop size Set the horizontal crop size in pixels. Set it in the range of 1 to 2048. 0: Setting prohibited 2049 or higher: Setting prohibited Note 1. For YCbCr type, set it to an even number.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	O_VSIZE[12:0]	0h	RW	Vertical crop size Set the vertical crop size in pixels. Set it in the range of 1 to 2048. 0: Setting prohibited 2049 or higher: Setting prohibited Note 1. For YCbCr420, set it to an even number.

9.3.2.2.28 RS CROP Padding Mode Register (ISU_RS_PADDMODE)

This register sets the padding method when the reduced image is smaller than the set crop size.

For details, see **9.3.1.4 Resizer (RS)**.

Access Size : 32 bits

Address : <ISU_base> + 0154h

Initial Value : 0001_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SSIZECAL_EN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	PADDSEL[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	SSIZECAL_EN	1h	RW	Controls the input image size calculation function Controls the function to calculate the required input image size from the output image size and the scaling factor. When set to ON, performance is improved because areas determined to be unnecessary image areas are not read. 0b: Function OFF The input images are read out according to the size specified by ISU_RPF_SRC_SIZE 1b: Function ON The valid input image area is calculated from the parameters RS_OS_CROP, RS_HSCALE, and RS_VSCALE. The size of the input image is limited to that area.
15 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1 to 0	PADDSEL[1:0]	0h	RW	Selecting a padding method Set the padding method when the reduced image is smaller than the set crop size. 0h: Fill in the padding area by copying the edge pixels after the reduction. 1h: Fill in the padding area with the color specified by the register (ISU_RS_PADDVAL.VAL_*). 2h:Fill the padding area with the copying pixels at the edges of the input image. 3h:Setting prohibited

9.3.2.2.29 RS CROP Padding Value Register (ISU_RS_PADDVAL)

This register sets the color that fills the edges with padding.

For details, see **9.3.1.4 Resizer (RS)**.

Access Size : 32 bits
Address : <ISU_base> + 0158h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VAL_L3[7:0]								VAL_L2[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VAL_L1[7:0]								VAL_L0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	VAL_L3[7:0]	0h	RW	The value to fill Layer 3, if the reduced image is smaller than the set crop size.
23 to 16	VAL_L2[7:0]	0h	RW	The value to fill Layer 2, if the reduced image is smaller than the set crop size.
15 to 8	VAL_L1[7:0]	0h	RW	The value to fill Layer 1, if the reduced image is smaller than the set crop size.
7 to 0	VAL_L0[7:0]	0h	RW	The value to fill Layer 0, if the reduced image is smaller than the set crop size.

9.3.2.2.30 WPF Destination Plane 0 Address Register 0 (ISU_WPF_DST_ADDH_PL0)

This register sets the start address [34:32] of the output image of “Plane 0”.

Access Size : 32 bits
Address : <ISU_base> + 0180h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	DADD_PL0[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	DADD_PL0 [34:32]	0h	RW	Set the write start address [34:32] for “Plane 0 (Y/RGB/RAW)”.

9.3.2.2.31 WPF Destination Plane 0 Address Register 1 (ISU_WPF_DST_ADDL_PL0)

This register sets the start address [31:0] of the output image of “Plane 0”.

Access Size : 32 bits
Address : <ISU_base> + 0184h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DADD_PL0[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DADD_PL0[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DADD_PL0 [31:0]	0h	RW	Set the write start address [31:0] for “Plane 0 (Y/RGB/RAW)”. Note: Set an address that is a multiple of 512 bytes.

9.3.2.2.32 WPF Destination Plane 1 Address Register 0 (ISU_WPF_DST_ADDH_PL1)

This register sets the start address [34:32] of the output image of “Plane 1”.

Access Size : 32 bits
Address : <ISU_base> + 0188h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	DADD_PL1[34:32]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

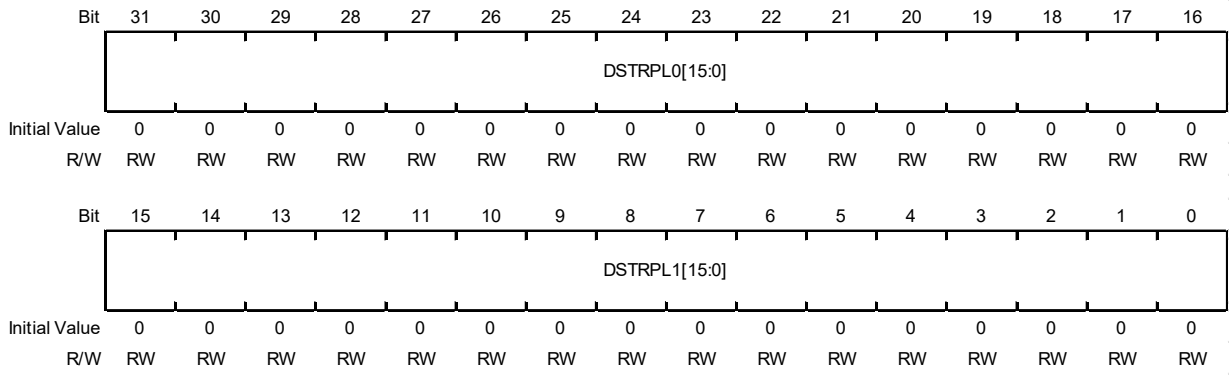
Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	DADD_PL1 [34:32]	0h	RW	Set the write start address [34:32] for “Plane 1 (C(Cb/Cr))”.

9.3.2.2.33 WPF Destination Plane 1 Address Register 1 (ISU_WPF_DST_ADDL_PL1)

This register sets the start address [31:0] of the output image of “Plane 1”.

Access Size : 32 bits
Address : <ISU_base> + 018Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DADD_PL1[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DADD_PL1[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DADD_PL1 [31:0]	0h	RW	Set the write start address [31:0] for “Plane 1 (C(Cb/Cr))”. Note: Set an address that is a multiple of 512 bytes.

9.3.2.2.34 WPF Destination Stride Register (ISU_WPF_DST_STRD)

This register sets the stride of the output image.

Access Size : 32 bits
Address : <ISU_base> + 0190h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DSTRPL0[15:0]	0h	RW	Set the “Plane 0 (Y/RGB/RAW)” stride Set the “Plane 0 (Y/RGB/RAW)” stride in bytes. Note: The setting must be a multiple of 32 bytes and at least the number of horizontal crop size (ISU_RS_OS_CROP.O_HSIZE).
15 to 0	DSTRPL1[15:0]	0h	RW	Set the “Plane 1 (C(Cb/Cr))” stride Set the “Plane 1 (C(Cb/Cr))” stride in bytes. Note: The setting must be a multiple of 32 bytes and at least the number of horizontal crop size (ISU_RS_OS_CROP.O_HSIZE).

9.3.2.2.35 WPF Destination Image Format Register (ISU_WPF_FMT)

This register sets the color format of the output image.

For details, see **9.3.1.5.3 WPF Formatter**.

Access Size : 32 bits
Address : <ISU_base> + 0194h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	WDFMT[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5 to 0	WDFMT[5:0]	0h	RW	Color format of output image The following formats can be configured. 00h: ARGB1555 01h: RGB565 02h: BGR666 03h: RGB888 04h: BGR888 05h: ARGB8888 06h: RGBA8888 07h: ABGR8888 20h: YCbCr422 8-bit UYVY 21h: YCbCr422 8-bit YUY2 22h: YCbCr422 8-bit NV16 23h: YCbCr420 8-bit NV12 30h: RAW8 31h: RAW10 32h: RAW12 33h: RAW14 34h: RAW16 35h: RAW20 36h: RAW6 37h: RAW7 Others: Setting prohibited

9.3.2.2.36 WPF Color Correction Control Register (ISU_WPF_CCOL)

This register sets the color conversion correction control.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 0198h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CMAT_SEL	CMAT_ASEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	CMAT_SEL	0h	RW	Color conversion correction control 0b: No conversion 1b: Conversion
0	CMAT_ASEL	0h	RW	A (Alpha) color conversion correction control 0b: No conversion 1b: Conversion

9.3.2.2.37 WPF Color Correction MUL Coefficient Register 1 (ISU_WPF_MUL1)

This register sets the matrix value K11 for the color conversion correction.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 019Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	K11[13:0]													
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 0	K11[13:0]	0h	RW	Color Correction Coefficient K11 Signed fixed point: 4-bit integer part, 10-bit decimal part

9.3.2.2.38 WPF Color Correction MUL Coefficient Register 2 (ISU_WPF_MUL2)

This register sets the matrix values K12 and K13 for the color conversion correction.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 01A0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	K12[13:0]													
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	K13[13:0]													
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29 to 16	K12[13:0]	0h	RW	Color Correction Coefficient K12 Signed fixed point: 4-bit integer part, 10-bit decimal part
15 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 0	K13[13:0]	0h	RW	Color Correction Coefficient K13 Signed fixed point: 4-bit integer part, 10-bit decimal part

9.3.2.2.39 WPF Color Correction MUL Coefficient Register 3 (ISU_WPF_MUL3)

This register sets the matrix value K21 for the color conversion correction.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 01A4h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29 to 16	K32[13:0]	0h	RW	Color Correction Coefficient K32 Signed fixed point: 4-bit integer part, 10-bit decimal part
15 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 0	K33[13:0]	0h	RW	Color Correction Coefficient K33 Signed fixed point: 4-bit integer part, 10-bit decimal part

9.3.2.2.43 WPF Color Correction Offset Coefficient Register 1 (ISU_WPF_OFST1)

This register sets the offset 1 of the color conversion correction.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 01B4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OFST_A1[7:0]								OFST_B1[7:0]

R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OFST_A1[7:0]	0h	RW	Color Correction Offset value A1 Unsigned integer 8-bit
23 to 16	OFST_B1[7:0]	0h	RW	Color Correction Offset value B1 Unsigned integer 8-bit
15 to 8	OFST_C1[7:0]	0h	RW	Color Correction Offset value C1 Unsigned integer 8-bit
7 to 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.3.2.2.44 WPF Color Correction Offset Coefficient Register 2 (ISU_WPF_OFST2)

This register sets the offset 2 of the color conversion correction.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 01B8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OFST_A2[7:0]	0h	RW	Color Correction Offset value A2 Unsigned integer 8-bit
23 to 16	OFST_B2[7:0]	0h	RW	Color Correction Offset value B2 Unsigned integer 8-bit
15 to 8	OFST_C2[7:0]	0h	RW	Color Correction Offset value C2 Unsigned integer 8-bit
7 to 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.3.2.2.45 WPF Color Correction Clip Register 1 (ISU_WPF_CLP1)

This register sets the maximum and minimum values of the color conversion correction for Layer 1.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 01BCh
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 8	CLPMAX_A [7:0]	0h	RW	Color Correction maximum clip level value A Set the value to CLPMAX_A ≥ CLPMIN_A
7 to 0	CLPMIN_A [7:0]	0h	RW	Color Correction minimum clip level value A Set the value to CLPMAX_A ≥ CLPMIN_A

9.3.2.2.46 WPF Color Correction Clip Register 2 (ISU_WPF_CLP2)

This register sets the maximum and minimum values of the color conversion correction for Layer 2 and Layer 3.

For details, see **9.3.1.5.1 Color correction**.

Access Size : 32 bits
Address : <ISU_base> + 01C0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CLPMAX_B [7:0]	0h	RW	Color Correction maximum clip level value B Set the value to CLPMAX_B ≥ CLPMIN_B
23 to 16	CLPMIN_B [7:0]	0h	RW	Color Correction minimum clip level value B Set the value to CLPMAX_B ≥ CLPMIN_B
15 to 8	CLPMAX_C [7:0]	0h	RW	Color Correction maximum clip level value C Set the value to CLPMAX_C ≥ CLPMIN_C
7 to 0	CLPMIN_C [7:0]	0h	RW	Color Correction minimum clip level value C Set the value to CLPMAX_C ≥ CLPMIN_C

9.3.2.2.47 WPF Destination Image Data Swap Register (ISU_WPF_DST_DSWAP)

This register sets the data swap of the output image data.

For details, see **9.3.1.5.4 Data Swap (Endian Correction)**.

Access Size : 32 bits
Address : <ISU_base> + 01C4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	WD_SWAP [2:0]	0h	RW	Data swap for output images

9.3.2.2.48 WPF Destination ALPHA Selection Register 1 (ISU_WPF_ALPH_SEL1)

This register sets the method of compressing the A (Alpha) value at the ARGB1555 output from 8-bit to 1-bit.

For details, see **9.3.1.5.2 Normalization**.

Access Size : 32 bits
Address : <ISU_base> + 01C8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	D_A1SEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	D_A1THR[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	D_A1SEL	0h	RW	Setting of how to compress A (Alpha) from 8-bit to 1-bit 0b: Outputs the MSB of alpha value 1b: Selects the output according to the alpha value and threshold level Outputs 0b when Alpha ≤ D_A1THR Outputs 1b when Alpha > D_A1THR
15 to 8	D_A8THR1 [7:0]	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7 to 0	D_A8THR0 [7:0]	0h	RW	Threshold level value Value used to determine when D_A1SEL = 1b.

9.3.2.2.49 WPF Destination ALPHA Selection Register 2 (ISU_WPF_ALPH_SEL2)

This register sets the 8-bit A (Alpha) value at the time of ARGB8888 output.

For details, see **9.3.1.5.2 Normalization**.

Access Size : 32 bits
Address : <ISU_base> + 01CCh
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	D_A8SEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D_A8THR1[7:0]								D_A8THR0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	D_A8SEL	0h	RW	A (Alpha) 8-bit output selection 0b: Output Alpha value as it is 1b: Outputs the register value according to the alpha value and the threshold level (D_A8THR0 and D_A8THR1) Outputs D_ALPH2 when D_A8THR1 ≤ Alpha Outputs D_ALPH1 when D_A8THR0 < Alpha < D_A8THR1 Outputs D_ALPH0 when Alpha ≤ D_A8THR0
15 to 8	D_A8THR1 [7:0]	0h	RW	Threshold level value 1 Value used to determine which register value is output as Alpha when D_A8SEL = 1b. Set the value to D_A8THR0 < D_A8THR1.
7 to 0	D_A8THR0 [7:0]	0h	RW	Threshold level value 0 Value used to determine which register value is output as Alpha when D_A8SEL = 1b. Set the value to D_A8THR0 < D_A8THR1.

9.3.2.2.50 WPF Destination ALPHA Value Register (ISU_WPF_ALPH_VAL)

This register sets the A (Alpha) value to be output when ARGB8888 and D_A8SEL = 1.

For details, see **9.3.1.5.2 Normalization**.

Access Size : 32 bits

Address : <ISU_base> + 01D0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D_ALPH1[7:0]								D_ALPH0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 16	D_ALPH2 [7:0]	0h	RW	Conversion Alpha value 2 The value to be output when D_A8THR1 ≤ Alpha.
15 to 8	D_ALPH1 [7:0]	0h	RW	Conversion Alpha value 1 The value to be output when D_A8THR0 < Alpha < D_A8THR1.
7 to 0	D_ALPH0 [7:0]	0h	RW	Conversion Alpha value 0 The value to be output when Alpha ≤ D_A8THR0.

9.3.2.2.51 AXI Max Burst Length Register (ISU_AXI_BLEN)

This register sets the upper limit to the burst length of the AXI-Master.

Access Size : 32 bits
Address : <ISU_base> + 01F0h
Initial Value : 000F_000Fh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	ARLEN_MAX[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	AWLEN_MAX[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19 to 16	ARLEN_MAX [3:0]	Fh	RW	Upper limit of read data burst length 3h: Up to 4-beat burst 7h: Up to 8-beat burst Fh: Up to 16-beat burst Others: Setting prohibited
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	AWLEN_MAX [3:0]	Fh	RW	Upper limit of write data burst length 3h: Up to 4-beat burst 7h: Up to 8-beat burst Fh: Up to 16-beat burst Others: Setting prohibited

9.3.3 Operation

9.3.3.1 Start Processing

After setting various registers, write 1b to the start instruction bit to start.

At that time, start it together with the setting of whether to execute by the descriptor method.

Table 9.3-13 Explanation for ISU2 FM Frame Control Register (ISU_FM_FRCON)

ISU_FM_FRCON		Description
Bit 16	DESON	0b: Execute with Descriptor read OFF. 1b: Execute with Descriptor read ON.
Bit 0	START	When the frame processing start is executed, the frame completion interrupt and descriptor capture completion interrupt are automatically cleared. [Write] 0b: NOP 1b: Start Frame Processing [Read] Always Zero is read.

9.3.3.1.1 Descriptor List Address

In the case of the descriptor method (DESON = 1 and START is set to 1), the access to acquire the descriptor list is performed first. The access destination is set in advance in the following register.

- FM Descriptor List Address Register 0 (ISU_FM_DL_STADDH [2: 0])
- FM Descriptor List Address Register 1 (ISU_FM_DL_STADDL [31: 0])

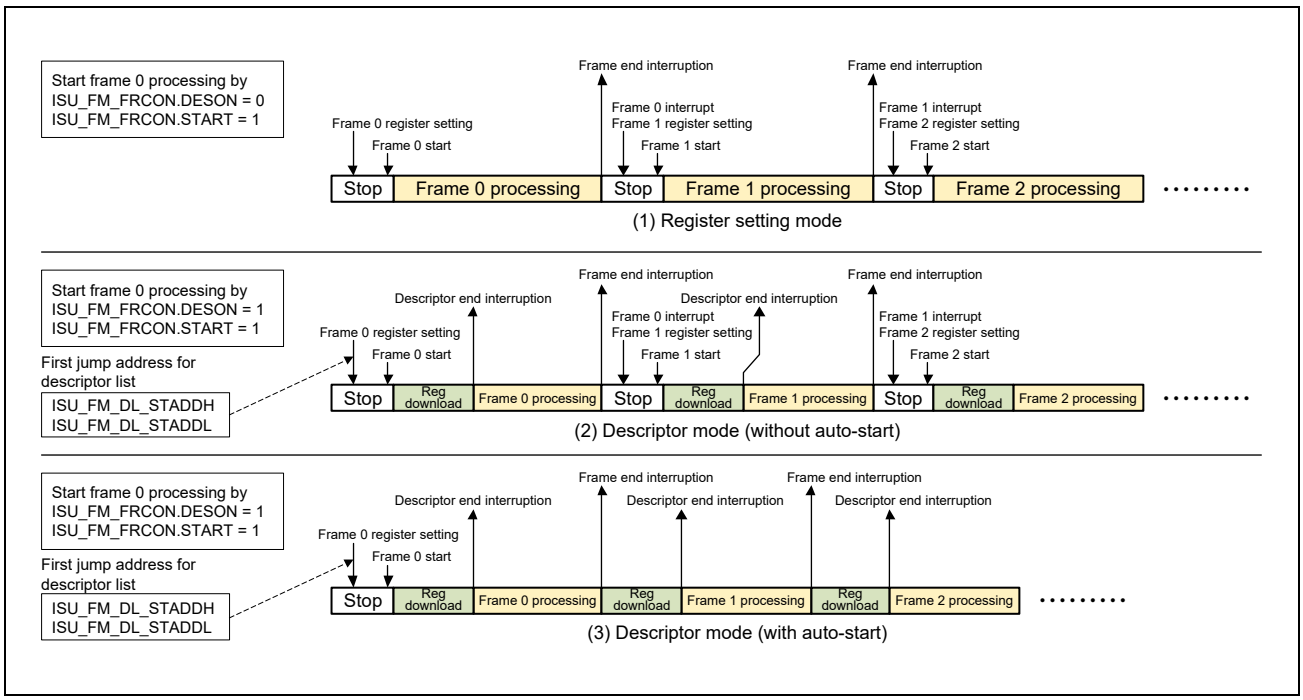

Figure 9.3-43 Relationship Between Register ISU_FM_FRCON Setting and Frame Processing Mode

9.3.3.1.2 Frame End Interruption

- When started with ISU_FM_FRCON.DESON = 0
  - An interrupt is generated when one frame processing is completed inside the ISU2.
  - Completion of 1-frame processing shall meet the following conditions.
    1) Write the reduced data from the AXI bus and receive the response of the response channel.
    2) The FIFO pointer of the input image is in the initial state (empty state), and the FIFO pointer of the output image is also in the initial state (empty state).
    3) You have not accidentally started capturing the image of the next frame.
  - Always generate an interrupt from ISU_INT_FRE0, regardless of ISU_FM_INT_FREC.

- When started with ISU_FM_FRCON.DESON = 1
  - One frame processing by the descriptor is completed, and an interrupt is issued in the descriptor list. An interrupt is generated when it is enabled (see the corresponding bit in the footer).
  - In the descriptor method, it advances to the next frame without doing anything after the interrupt occurs. In this case, the interrupt remains on.
  - ISU_INT_FRE0 to 3 (maximum) will be issued in sequence each time the frame ends.
  - The number of toggles for ISU_INT_FRE0 to 3 can be set in the register ISU_FM_INT_FREC.
  - ISU_INT_FRE interrupt toggle counter is reset by writing 1 to ISU_FM_FRCON.START.

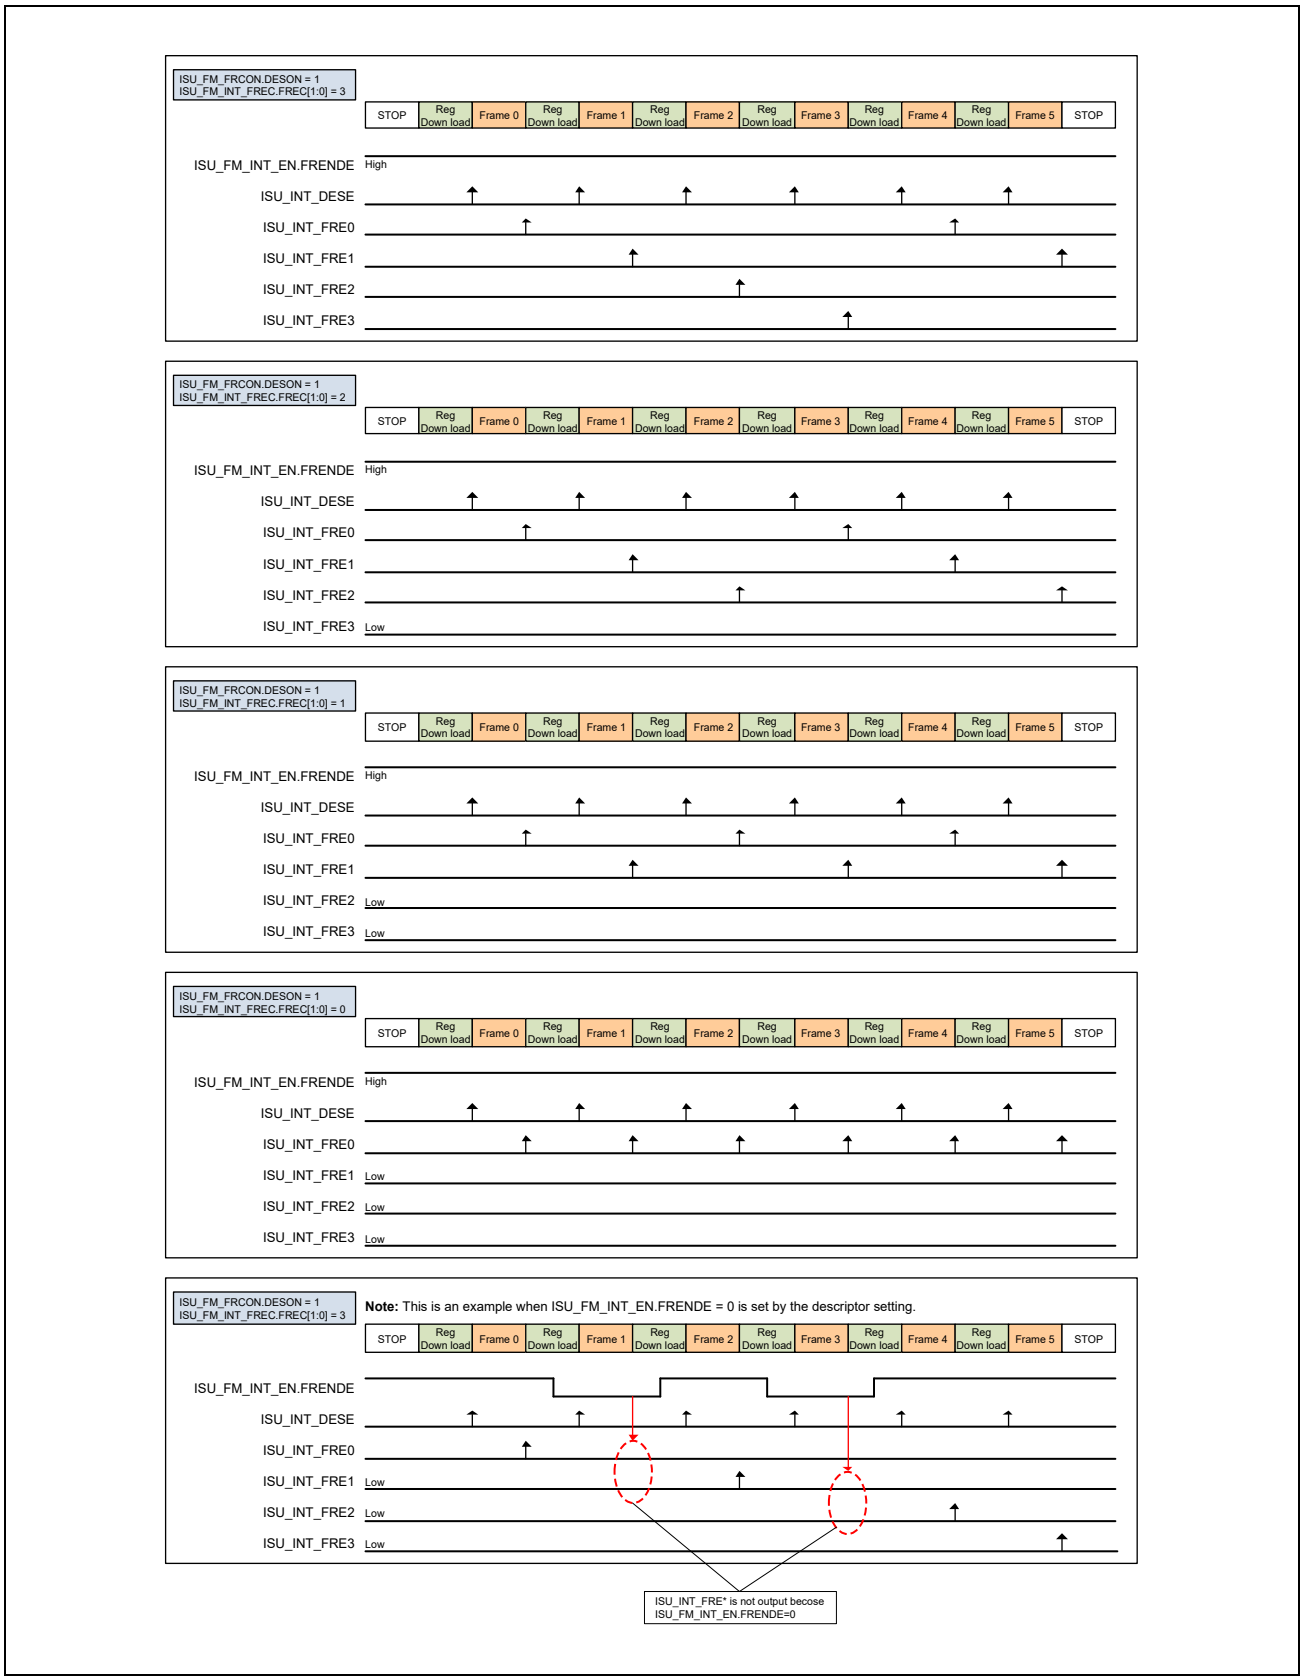

Figure 9.3-44 Relationship Between Register ISU_FM_INT_FREC Setting and ISU_INT_FRE0 to FRE3

9.3.3.2 Stop Processing

There are two ways to stop it.

- Normal stop
  - When started with ISU_FM_FRCON.DESON = 0b
    It will end automatically when the processing of one frame is completed. After completion, the read and write FIFOs on the AXI-Master side will also be empty.
  - When started with ISU_FM_FRCON.DESON = 1b
    If there is no instruction to execute the next frame in the footer of the descriptor, it will automatically end after executing one frame. After completion, the read and write FIFOs on the AXI-Master side will also be empty.

- Emergency stop

  Emergency stop will be stopped by register setting from APB.
  In response to the instruction from APB, the transfer to the bus in process of the AXI-Master is executed until a correct response is made, and after it is completed, an interrupt signal is issued. After that, when restarting from the system side, the ISU2 system reset is always applied from the outside and executed from initialization.
  If the APB instructs the emergency stop again during the emergency stop process, only the first emergency stop instruction will be valid.

9.3.3.3 Interrupt

Table 9.3-14 lists the interrupt sources, registers, and interrupt signals to the ICU.

Table 9.3-14 List of Interrupts

Interrupt Signal	Function	Interrupt Source Status/clear	Interrupt Enable register	Pulse/ Level	Min Pulse	Active Level	Clock
ISU_INT_FRE0	ISU Frame end interrupt 0	—	ISU_FM_INT_EN. FRENDE	Pulse	1	High	ACLK
ISU_INT_FRE1	ISU Frame end interrupt 1	—		Pulse	1	High	ACLK
ISU_INT_FRE2	ISU Frame end interrupt 2	—		Pulse	1	High	ACLK
ISU_INT_FRE3	ISU Frame end interrupt 3	—		Pulse	1	High	ACLK
ISU_INT_ERR	ISU AXI bus read error interrupt	ISU_FM_INT_STA. RRESPERR[2:0]	ISU_FM_INT_EN. AXIRXERRE	Level	—	High	PCLK
	ISU AXI bus write error interrupt	ISU_FM_INT_STA. BRESPERR[2:0]	ISU_FM_INT_EN. AXITXERRE	Level	—	High	PCLK
	ISU Descriptor List format violation interrupt	ISU_FM_INT_STA. LISTERR	ISU_FM_INT_EN. LISTERRE	Level	—	High	PCLK
ISU_INT_STOPE	ISU Stop completion interrupt	ISU_FM_INT_STA. SRSTEND	ISU_FM_INT_EN. SRSTEND	Level	—	High	PCLK
ISU_INT_DESE	ISU Descriptor footer receive interrupt	ISU_FM_INT_STA. DESEND	ISU_FM_INT_EN. DESENDE	Level	—	High	PCLK

9.3.4 Usage Notes

This section shows examples of converting image size and color format using the image scaling unit (ISU2).

9.3.4.1 List of Setting Examples

Table 9.3-15 List of Examples

Item	Exec. Mode	Description
Image Size Conversion 1	Descriptor Mode Next frame auto-start off	Input size: 1920 × 1080 (ARGB8888) Output size: 960 × 540 (ARGB8888) Scaling Ratio 1st frame: H = 1/1.5, V = 1/1.5 2nd frame: H = 1/2.0, V = 1/2.0
Image Size Conversion 2	Descriptor Mode Next frame auto-start on	Input size: 640 × 480 (YUV422 UYVY) Output size: 1280 × 720 (ARGB8888) Scaling Ratio 1st frame: H = 1.875/1, V = 1.25/1 2nd frame: H = 2/1, V = 1.5/1
Color format Conversion 1	Register Mode	YCbCr422 → YCbCr420 Input size: 320 × 240 (YCbCr422 UYVY) Output size: 320 × 240 (YCbCr420 NV12) Scaling Ratio 1st frame: H = 1/1, V = 1/1
Color format Conversion 2	Register Mode	YCbCr422 → ARGB8888 Input size: 320 × 240 (YCbCr422 UYVY) Output size: 320 × 240 (ARGB8888) Scaling Ratio 1st frame: H = 1/1, V = 1/1
Color format Conversion 3	Register Mode	BGR888 → YCbCr422 Input size: 320 × 240 (BGR888) Output size: 320 × 240 (YCbCr422 UYVY) Scaling Ratio 1st frame: H = 1/1, V = 1/1

For details on the settings, refer to each setting example.

9.3.4.2 Image Size Conversion

9.3.4.2.1 Example 1: Scale down without Automatic start of the next frame

Set as follows to handle image size conversion.

Table 9.3-16 Image Size Conversion Example 1

Item	Description
Assuming that the following image is stored in DDR memory	
Input size	1920 × 1080
Input format	ARGB8888
Input start address	1st frame: Plane 0 = 0_1000_0000h 2nd frame: Plane 0 = 0_3000_0000h
Input stride	7680 (1E00h) *Note*: 1920 × 4 bytes/pixel
ISU2 setting	
Output (CROP) size	960 × 540
Output format	ARGB8888
Output start address	1st frame: Plane 0 = 0_2000_0000h 2nd frame: Plane 0 = 0_4000_0000h
Output stride	Plane 0 = 3840 (0F00h) *Note*: 960 × 4 bytes/pixel
Scaling ratio	1st frame: H = 1/1.5, V = 1/1.5 2nd frame: H = 1/2.0, V = 1/2.0
Processing method	Descriptor method without automatic start of the next frame
Color format conversion	None
Descriptor address	Table 1: 0_8000_0000h Table 2: 0_8000_0100h
Padding mode	PADDSEL = 1 (Register value)

Set as follows to handle color format conversion.

Table 9.3-24 Color Format Conversion Example 2

Item	Description
Assuming that the following image is stored in DDR memory	
Input size	320 × 240
Input format	YCbCr422 8-bit UYVY (Interleave)
Input start address	Plane 0 = 0_5000_0000h
Input stride	Plane 0 = 280h
ISU2 setting	
Output (CROP) size	320 × 240
Output format	ARGB8888
Output start address	Plane 0 = 0_6000_000h
Output stride	Plane 0 = 500h
Processing method	Register
Color format conversion	YCbCr → RGB (BT.601 SDTV)

The following shows the matrix operation formula for conversion and color correction.

$$\begin{bmatrix} C1' \\ C2' \\ C3' \end{bmatrix} = \begin{bmatrix} K11 & K12 & K13 \\ K21 & K22 & K23 \\ K31 & K32 & K33 \end{bmatrix} \cdot \begin{bmatrix} A - OFS_A1 \\ B - OFS_B1 \\ C - OFS_C1 \end{bmatrix} + \begin{bmatrix} OFST_A2 \\ OFST_B2 \\ OFST_C2 \end{bmatrix}$$

$$C1'' = MAX\,(CLPMIN_A, Min\,(CLPMAX_A, C1'))$$
$$C2'' = MAX\,(CLPMIN_B, Min\,(CLPMAX_B, C2'))$$
$$C3'' = MAX\,(CLPMIN_C, Min\,(CLPMAX_C, C3'))$$

Figure 9.3-50 Matrix Operation Formula for Conversion and Color Correction

The following shows the YCbCr422-to-RGB conversion formula (BT.601 SDTV).

$R = 1.164\,(Y - 16) + 1.596\,(Cr - 128)$
$G = 1.164\,(Y - 16) - 0.391\,(Cb - 128) - 0.813\,(Cr - 128)$
$B = 1.164\,(Y - 16) + 2.018\,(Cb - 128)$

Note: R/G/B: 0 to 255

Perform YCbCr-to-RGB conversion with the following allocation.

$R = K11\,(Y - OFST_A1) + K12\,(Cb - OFST_B1) + K13\,(Cr - OFST_C1) + OFST_A2$
$G = K21\,(Y - OFST_A1) + K22\,(Cb - OFST_B1) + K23\,(Cr - OFST_C1) + OFST_B2$
$B = K31\,(Y - OFST_A1) + K32\,(Cb - OFST_B1) + K33\,(Cr - OFST_C1) + OFST_C2$

Note: K** is set by signed fixed point Q10.
Example: K11 = 1.164 × 1024 = 1191.936 = 4A8h
Rounded to the nearest whole number.

9.3.4.3.3 Example 3: BGR888 → YCbCr422

Set as follows to handle color format conversion.

Table 9.3-26 Color Format Conversion Example 3

Item	Description
Assuming that the following image is input from the CRU	
Input size	320 × 240
Input format	BGR888
Input start address	Plane 0 = 0_5000_0000h
Input stride	Plane 0 = 03C0h
ISU2 setting	
Output (CROP) size	320 × 240
Output format	YCbCr422 8-bit UYVY (Interleave)
Output start address	Plane 0 = 0_6000_000h
Output stride	Plane 0 = 0280h
Processing method	Register
Color format conversion	RGB → YCbCr (BT.601 SDTV)

The following shows the matrix operation formula for conversion and color correction.

$$\begin{bmatrix} C1' \\ C2' \\ C3' \end{bmatrix} = \begin{bmatrix} K11 & K12 & K13 \\ K21 & K22 & K23 \\ K31 & K32 & K33 \end{bmatrix} \cdot \begin{bmatrix} A - OFS_A1 \\ B - OFS_B1 \\ C - OFS_C1 \end{bmatrix} + \begin{bmatrix} OFST_A2 \\ OFST_B2 \\ OFST_C2 \end{bmatrix}$$

$$C1'' = MAX\,(CLPMIN_A, Min\,(CLPMAX_A, C1'))$$
$$C2'' = MAX\,(CLPMIN_B, Min\,(CLPMAX_B, C2'))$$
$$C3'' = MAX\,(CLPMIN_C, Min\,(CLPMAX_C, C3'))$$

Figure 9.3-52 Matrix Operation Formula for Conversion and Color Correction

The following shows the RGB-to-YCbCr422 conversion formula (BT.601 SDTV).

$$Y = 0.257R + 0.504G + 0.098B + 16$$
$$Cb = -0.148R - 0.291G + 0.439B + 128$$
$$Cr = 0.439R - 0.368G - 0.071B + 128$$

Note: Brightness: 16 to 235
Color difference: 16 to 240

Perform RGB-to-YCbCr conversion with the following allocation.

$$Y = K11\,(R - OFST_A1) + K12\,(G - OFST_B1) + K13\,(B - OFST_C1) + OFST_A2$$
$$Cb = K21\,(R - OFST_A1) + K22\,(G - OFST_B1) + K23\,(B - OFST_C1) + OFST_B2$$
$$Cr = K31\,(R - OFST_A1) + K32\,(G - OFST_B1) + K33\,(B - OFST_C1) + OFST_C2$$

Note: K** is set by signed fixed point Q10.
Example: K11 = 0.257 × 1024 = 263.168 = 107h
Rounded to the nearest whole number.

SECTION 9 IMAGE

9.4 LCD Controller (LCDC)

9.4.1 Overview

This chapter describes the features of the LCDC unit of this LSI.

This unit is an LCD controller and it is composed of Frame Compression Processor (FCPVD), Video Signal Processor (VSPD), and Display Unit (DU).

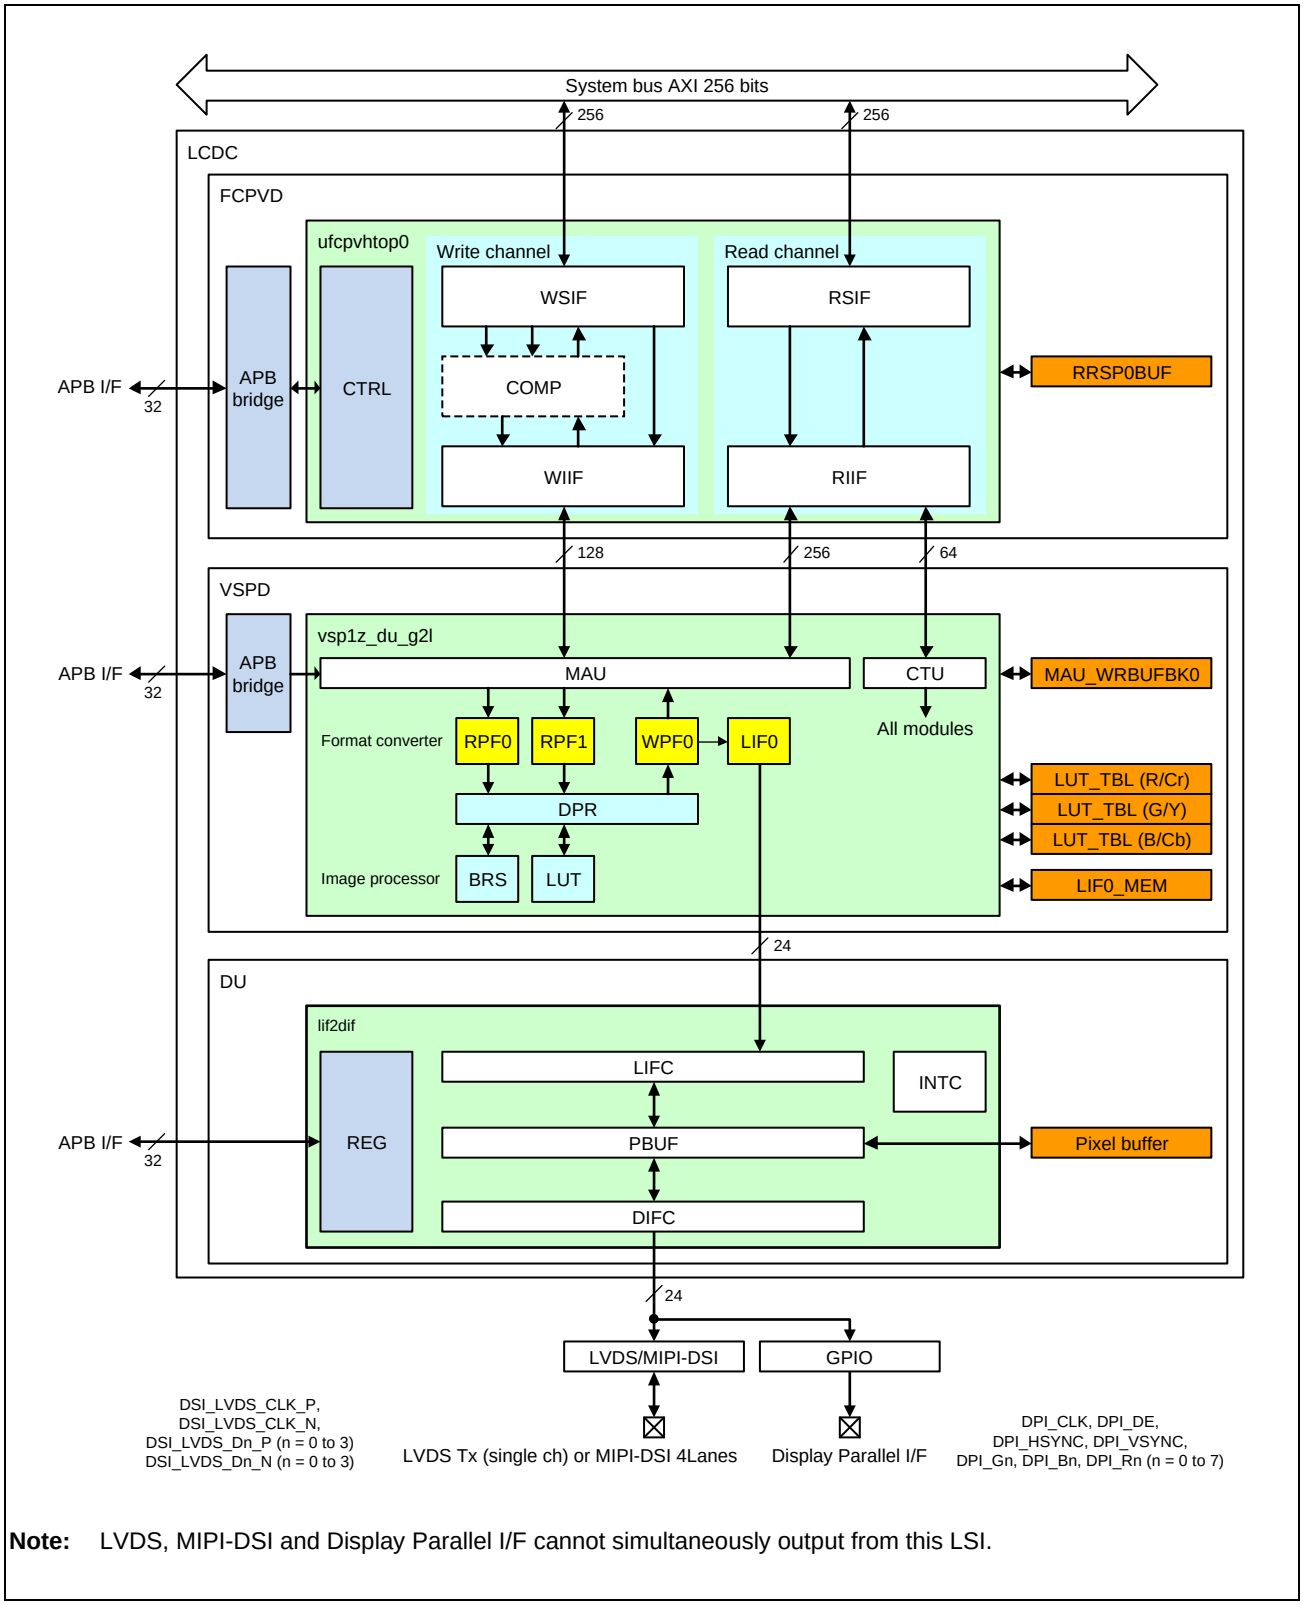
This LSI has one unit, it is called as LCDC. LCDC is connected to LVDS (single ch) or DSI, and GPIO (Parallel I/F). The video data, which is output by this unit, is input to DSI or LVDS, and GPIO, and DSI converts to MIPI DSI (Display Serial Interface), LVDS converts to single channel (Low Voltage Differential Signaling), GPIO converts only the IO voltage, and output.

LVDS, MIPI-DSI and GPIO (Display Parallel I/F) cannot simultaneously output from this LSI. When using LVDS or MIPI-DSI, unused IP should be changed to the reset status.

9.4.1.1 Features

The following is key features of this unit.

- FCPVD
  - Supports out-of-order for the whole outstanding transactions
  - Read linear addressing image data
  - Read display list data
  - Write image data



- VSPD
  - Supports various data formats and conversion
    - Supports YCbCr444/422/420, RGB, α RGB, α plane
    - Color space conversion and changes to the number of colors by dithering
    - Color keying
    - Supports combination between pixel alpha and global alpha
    - Supports generating pre multiplied alpha
  - Video processing
    - Blending of two picture layers and raster operations (ROPs)
    - Clipping
    - 1D look up table
    - Vertical flipping in case of output to memory
  - Direct connection to display module

- Supports up to 1920 pixels in horizontal direction
- Writing back image data which is transferred to Display Unit (DU) to memory

- DU
  - Supports Display Parallel Interface (DPI), and inputs the video data to DSI or LVDS
  - Display timing master
    - Generates video timings (Front porch, Back porch, Sync active, Active video area)
    - Selects the polarity of output DCLK, HSYNC, VSYNC, and DE
  - Supports Progressive (Non-interlace)
  - Not supports Interlace
  - Input data format (from VSPD): RGB888, RGB666 (not supports dithering of RGB565)
  - Output data format: same as Input data format
  - Supports up to 187.5 MHz of the pixel clock frequency
  - Examples of the supported resolutions is below if using DSI:
    - RGB888, 1920 pixels × 1200 lines, 60 fps
    - RGB888, 1920 pixels × 1080 lines, 60 fps (FHD)
    - RGB888, 1280 pixels × 1024 lines, 120 fps
  - Examples of the supported resolutions is below if using LVDS single ch or Parallel I/F:
    - RGB888, 1366 pixels × 768 lines, 60 fps (WXGA)
    - RGB888, 1280 pixels × 800 lines, 60 fps (WXGA)
    - RGB888, 800 pixels × 480 lines, 60 fps (WVGA)
    - RGB888, 640 pixels × 480 lines, 60 fps (VGA)

9.4.1.2 Block Diagram

Figure 9.4-1 shows block diagrams.

Note: LVDS, MIPI-DSI and Display Parallel I/F cannot simultaneously output from this LSI.

Figure 9.4-1 Block Diagram (LCDC)

9.4.1.2.1 FCPVD

FCPVD has the following sub modules.

Table 9.4-1 Sub Modules in FCPVD

Abbreviation	Description
CTRL	FCPVD controller
WIIF	VSPD write channel interface
WSIF	System AXI write channel interface
RIIF	VSPD read channel interface
RSIF	System AXI read channel interface
COMP	Compression module (This is a dummy module)

9.4.1.2.2 VSPD

VSPD has the following sub modules.

(1) Memory Access Unit (MAU)

The VSPD applies processing to the image data stored in the external memory and writes the resultant data back to the external memory. The data transfer between the external memory and VSPD necessary for this operation is done by the MAU, which works as the bus master, according to the register settings. The MAU executes this data transfer between the external memory and VSPD.

(2) Command Transfer Unit (CTU)

The VSPD can directly read register parameters for image processing by display lists stored in external memory. The CTU module is a bus interface and controls display lists when the CTU reads display lists as a bus master.

(3) Read Pixel Formatter (RPF)

The RPF reads image data from the external memory through the MAU, unpacks data according to the specified format, converts the color space, converts the number of colors, executes color keying, ROP operation, Multiply-alpha and OSD processing, and outputs the resultant data to the DPR. The RPF has an input format unpacking unit, a 1-bit mask generator, a raster operation unit (ROP unit), a color keying unit, a color space converter and multiply-alpha. **Figure 9.4-2** show the processing flow in the RPF.

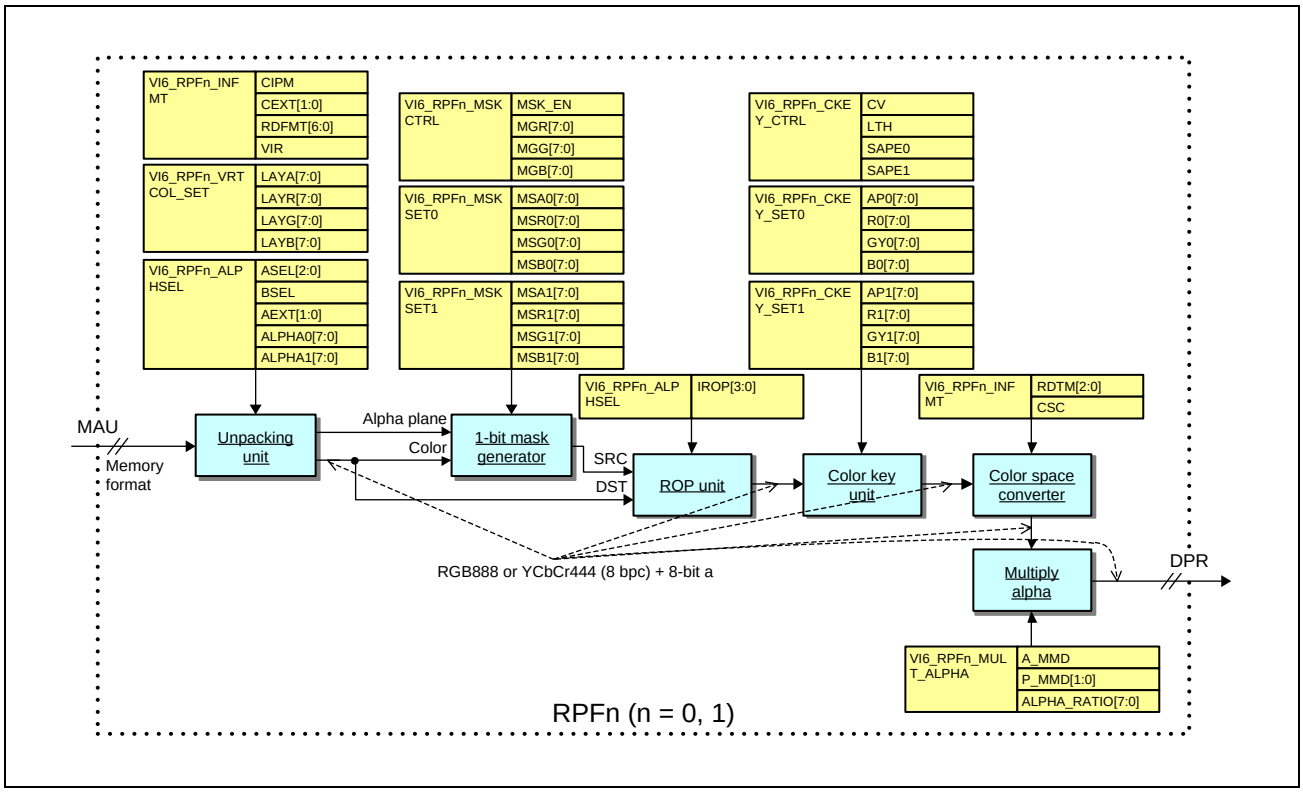


Figure 9.4-2 RPF Processing Flow

The input format unpacking unit expand the image data input from the MAU into the image format for internal processing (YCbCr444 8bpc or RGB888 8bpc), and the 1-bit mask generator generates a 1-bit image mask from the image data expanded through the unpacking unit. Alternately, a 1-bit image mask can be generated from the alpha plane that is different from the picture plane read through the MAU.

The raster operation unit (ROP unit) executes raster operation between the data from the 1-bit mask generator and the image data expanded from the input format, and the color keying unit applies color replacement and specifies the transparent color for the image data input from the ROP unit. The color space converter converts the color space (RGB-YCbCr) of the image data input from the color keying unit as necessary. The multiply-alpha unit multiplies pixel-alpha by specified alpha or/and multiplies image data by pixel-alpha or/and specified alpha.

The VSPD provides maximum two RPF modules (RPF0 to RPF1).

(4) Data Path Router (DPR)

The DPR controls the data paths among RPFs, function modules, and WPFs. The DPR selects one of the images input from RPFs, outputs it to a function module (BRS or LUT), and selects one of WPFs as the destination where the image data processed in the function module will be output. Before output to the WPF, the output from each function module can be input to another function module, which enables multiple image processing functions to be executed continuously without involving the external memory.

(5) Look Up Table (LUT)

This is a 1D-LUT that converts each of three color components by using a lookup table. The LUT is connected to the DPR and can be used for gamma correction, negative-positive conversion, posterization, and binarization through desired tone curve settings.

The LUT supports local area processing for Y component. The LUT can apply 1D look up table for Y component per area where a image is divided into multiple area specified by registers and command list.

(6) Blend ROP Sub Unit (BRS)

The BRS is a module connected to the DPR, which executes the image blending processing and ROP operation. The BRS has two blend/ROP operation units (blend/ROP unit m, m = A to B), a blend/ROP input switch (SEL) for selecting the input to these operation units, and a divider for normalization (div unit).

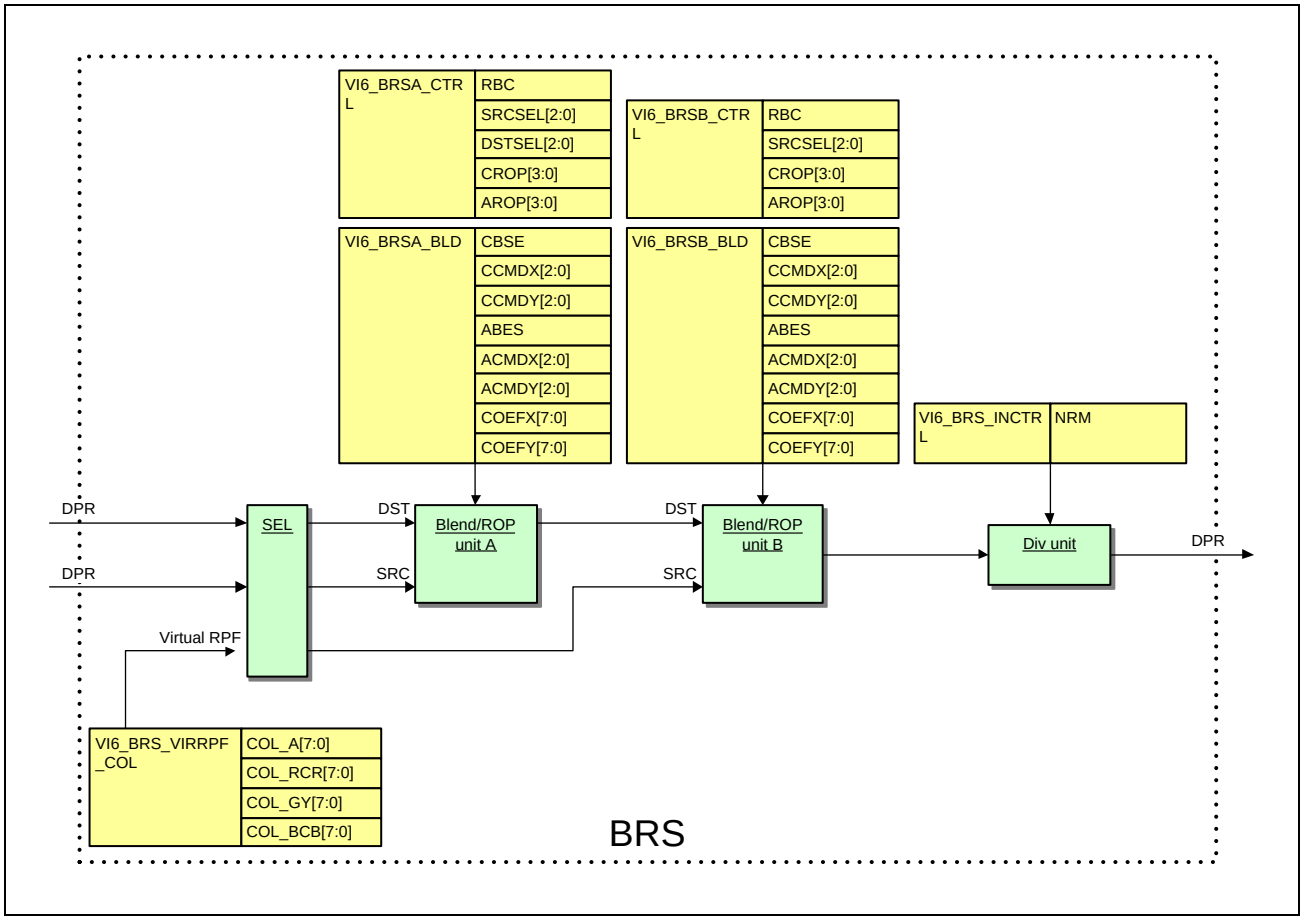

Figure 9.4-3 BRS Processing Flow

Each of the two blend-ROP operation units (blend/ROP unit m) receives the output from the SEL or blend/ROP Unit m, and executes blending or raster operation (ROP) of images.

The divider for normalization (div unit) divides the pixel value by the α value.

(7) Write Pixel Formatter (WPF)

The WPF is an output module that receives 32bits image data (YCbCr444 or RGB888 + 8-bitα) from the DPR, converts the color space, number of colors, and format of the data, and outputs the results of VSPD image processing to external memory through the MAU. The WPF is mainly configured from a color space converter and an output format converter (the packing unit).

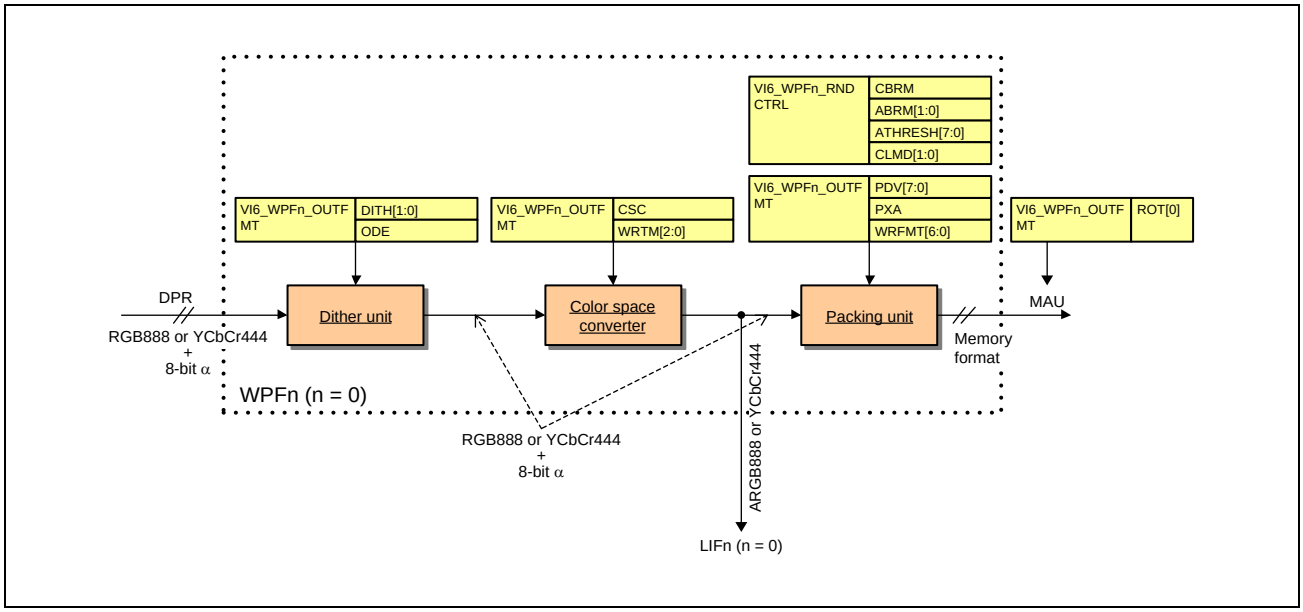

Figure 9.4-4 WPF Processing Flow

The color space converter converts the color space between RGB and YCbCr, and the packing unit converts the format into the picture plane storing format. The VSPD provides one WPF (WPF0). The WPF has the output to LIF module after the color space conversion for transferring the video data to the display module. Image data to LIF is 24bits (YCbCr444 or RGB888) format, and its' color space is after color space conversion.

(8) Display Unit Interface (LIF)

The LIF module is used for transferring image data to the display module. The input port of the LIFn (n = 0) module is connected to WPFn (n = 0), and the output port of the LIF module is connected to DU (Display Unit). Data flow in LIF is shown in **Figure 9.4-30**.

(9) Detail Function

Table 9.4-2 Detail Function of VSPD (1/4)

• Image Data Transfer Function			
Bus interface	Protocol		AXI 256 bits through FCPVD
	Data alignment	Conversion method	Byte, Word, LW, or LLW data swapping
		Channel	Data alignment can be specified separately for each input/output channel
Image memory	Input	Address setting	1-byte units
	Output	Address setting	1-byte units
		Memory area	Images can be written to the same memory area where the master layer is stored. Note the restrictions shown in **Table 9.4-39**
Tile transfer mode			Supported by RPF0 to RPF1
YCbCr memory storage format			Interleaved, planar, or semi-planar
• Display list/Extended Display List Transfer Function			
Bus interface	Protocol		AXI 256 bits through FCPVD
	Data alignment	Conversion method	Byte, Word, LW data swapping
		Channel	Data alignment can be specified separately for display list and each entry of extended display list
Data memory	Load	Address setting	8-byte units
	Store	—	Not available

Table 9.4-2 Detail Function of VSPD (2/4)

• Read Pixel Formatter (RPF)			
Number of channels			Two channels (RPF0 to RPF1)
Input color bit-depth		Color	2- to 8-bit
		Alpha	1-/2-/4-/8-bit
Operation bit-depth		Color	8-bit
		Alpha	8-bit
Image format	Input	RGB	RGB888, RGB565, RGB666, αRGB8888, αRGB4444, αRGB1555 α plane (8 bpp, 1 bpp)
		YCbCr	• YCbCr4:4:4 (8 bpc) Planar/Semi planar/Interleaved • YCbCr4:2:2 (8 bpc) Planar/Semi planar/Interleaved • YCbCr4:2:0 (8 bpc) Planar/Semi planar/Interleaved α plane (8 bpp, 1 bpp)
		Maximum size	1920 × 1200 pixels, 1200 × 1920 pixels The internal data path modules have separate restrictions on the maximum image size. For details, refer to **9.4.6.3 Input Image Size**.
		Minimum size	1 × 1 pixel The internal data path modules have separate restrictions on the minimum image size. For details, refer to **9.4.6.3 Input Image Size**.
		Size setting unit	• YCbCr420: 2-pixel units both horizontally and vertically. • YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. In other formats, the size can be set in 1-pixel units.
Color keying	Color replacement	Compared data	RGB or Y (8 bpc)
		Replaced data	αRGB or αYCbCr (8 bpc for R, G, B, Y, Cb, Cr, α)
		Comparison Mode	Matched color mode
		Input source	RPF0 to RPF1
	Transparent color	Compared data	RGB or Y (8 bpc)
		Replaced data	α 8 bpp
		Comparison Mode	Matched color mode, Luma threshold mode
		Input source	RPF0 to RPF1
Raster operation	ROP2 (within input channels)	Operator	16 types (OpenGL2.0 is supported)
		Sources of operation	ROP2 operation between the 1-bpp α plane and RGB/YCbCr data in RPF0 to RPF1. Note that 1-bpp α is converted to αRGB or αYCbCr4:4:4. (8 bpc)
Color space conversion	RGB to YCbCr	Conversion expression	• RGB (0, $2^n - 1$) to BT601 (2^{n-4}, $235\times2^{n-8}$/$240\times2^{n-8}$) • RGB (0, $2^n - 1$) to BT709 (2^{n-4}, $235\times2^{n-8}$/$240\times2^{n-8}$) • RGB (0, $2^n - 1$) to BT601 (0, $2^n - 1$) • RGB (2^{n-4}, $235\times2^{n-8}$) to BT709 (2^{n-4}, $235\times2^{n-8}$/$240\times2^{n-8}$) (n = 8)
		Target of conversion	RPF0 to RPF1
	YCbCr to RGB	Conversion expression	• BT.601 (2^{n-4}, $235\times2^{n-8}$/$240\times2^{n-8}$) to RGB (0, $2^n - 1$) • BT.709 (2^{n-4}, $235\times2^{n-8}$/$240\times2^{n-8}$) to RGB (0, $2^n - 1$) • BT.601 (0, $2^n - 1$) to RGB (0, $2^n - 1$) • BT.709 (2^{n-4}, $235\times2^{n-8}$/$240\times2^{n-8}$) to RGB (2^{n-4}, $235\times2^{n-8}$) (n = 8)
		Target of conversion	RPF0 to RPF1

Table 9.4-2 Detail Function of VSPD (3/4)

• Read Pixel Formatter (RPF)			
Changing number of colors	Bit extension	Extended bits	Input bitdepth (2bpc to 6bpc) to operation bitdepth 8bpc
		Target format	RGB666, RGB565, RGB555, RGB444, or RGB332
		Bit reduction method	Padded with 0. Copied from the most significant bits.
		Target of conversion	RPF0 to RPF1
	YCbCr444 generation	Vertical	CbCr copying
		Horizontal	copying or interpolation.
α bit count conversion	Bit extension	Extended bits	Input bitdepth 1bpc to operation bitdepth 8bpc
		Method	Padded with 0. Copied from the most significant bits.
Multiply-alpha function	Fade-alpha		RPF0 to RPF1 Available for straight pixel and pre-multiplied pixel.
	Generate pre-multiplied alpha		RPF0 to RPF1
Virtual display	RPF0 to RPF1	Color format	αRGB8888 or αYCbCr4:4:4 single-color
		Display size	Same as the size of the input channel
	Virtual RPF	Color format	αRGB8888 or αYCbCr4:4:4 single-color
		Display size	Maximum: 1920 × 1200 pixels, 1200 × 1920 pixels Minimum: 4 × 4 pixels
• Write Pixel Formatter (WPF)			
Number of channels			One channel (WPF0)
Image format	Output	RGB	RGB332, RGB444, RGB565, RGB666, RGB888, αRGB8666, αRGB8888, αRGB4444, αRGB1555
		YCbCr	YCbCr4:4:4, YCbCr4:2:2, YCbCr4:2:0
		Maximum size	1920 × 1200 pixels, 1200 × 1920 pixels The internal data path modules have separate restrictions on the maximum image size. For details, refer to **9.4.6.4 Output Image Size**.
		Minimum size	1 × 1 pixel The internal data path modules have separate restrictions on the minimum image size. For details, refer to **9.4.6.4 Output Image Size**.
		Size setting unit	• YCbCr420: 2-pixel units both horizontally and vertically. • YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. In other formats, the size can be set in 1-pixel units.
Color space conversion	RGB to YCbCr	Conversion expression	• RGB (0, 255) to BT.601 (16, 235/240) • RGB (0, 255) to BT.709 (16, 235/240) • RGB (0, 255) to BT.601 (0, 255) • RGB (16, 235) to BT.709 (16, 235/240)
		Target of conversion	WPF0
	YCbCr to RGB	Conversion expression	• BT.601 (16, 235/240) to RGB (0, 255) • BT.709 (16, 235/240) to RGB (0, 255) • BT.601 (0, 255) to RGB (0, 255) • BT.709 (16, 235/240) to RGB (16, 235)
		Target of conversion	WPF0
Changing number of colors	Output	Reducing RGB color depth	Dithering, lower-order bit truncation, or rounding
		YCbCr422/420	CbCr skipping or CbCr vertical skipping and horizontal skipping
α bit count conversion	Output	Bit reduction	Truncation, rounding, or comparison with threshold (for 1 bpp)

Table 9.4-2 Detail Function of VSPD (4/4)

• Image Compositing			
α blending	Input α value selection	RGB	Pixel α, fixed α value, α plane, or 1-bit α converted from the color specified for pixels
		YCbCr	α plane, fixed α value, or 1-bit α converted from the color specified for pixels
	α blending expression	Layer A: Upper layer Layer B: Lower layer	xA + yB, xA − yB Coefficients x and y should be selected from the following. Fixed α value, (α for layer A), (1 − α for layer A), (α for layer B), (1 − α for layer B)
	Output α value selection	RGB	Fixed α value, x (α for layer A) + y (α for layer B), x (α for layer A) – y (α for layer B) Coefficients x and y should be selected from the following. Fixed α value, (α for layer A), (1 − α for layer A), (α for layer B), (1 − α for layer B)
	Blending layers	Number of layers	Two layers selected from RPF0 to RPF1 and video processing function output, and virtual RPF; three layers in total
		Order of layers	The order of three layers selected from RPF0 to RPF1, virtual RPF, and video processing function output can be changed as desired.
	α plane	Format	8 bpp or 1 bpp (α value can be specified through register)
		Input source	RPF0 to RPF1
	Fixed α value	Format	8 bpp
		Input source	RPF0 to RPF1, virtual RPF, or video processing function output
Raster operation	ROP2 (between input channels)	Operator	16 types (OpenGL2.0 is supported)
		Sources of operation	RPF0 to RPF1, virtual RPF, and video processing function output
		Operation control	RGB/YCbCr and α are operated separately.
	ROP3 (between input channels)	Operator	256-type ROP3 is available by combining ROP2 operations
		Sources of operation	RPF0 to RPF1, virtual RPF, and video processing function output
		Operation control	RGB/YCbCr and α are operated separately.
• Color Adjustment Function			
1D-LUT	LUT configuration		Independent R/Y, G/Cb, and B/Cr. 256 entries each
• Direct connection to Display module			
Display I/F	Destination		DU
	Direct connection		Can transfer data without going through external memory to DU
Line padding	Padding cycles		1 to 32 cycles
	Padding pattern		Arbitrarily setting up to 32 cycles

9.4.1.2.3 DU

DU has the following sub modules.

(1) REG

The REG controls registers for DU. The DU has APB4 interface, its transaction is transfer with no wait states.

(2) LIFC

The LIFC is the interface block from/to VSPD. The LIFC receives image data from VSPD, sends to PBUF in a pixel unit. The LIFC continues to receive the image data from VSPD unless FIFO will be full.

(3) PBUF

The PBUF is the asynchronous FIFO which convert clock domain of image data from System Bus Clock to Video Clock. The PBUF monitors the FIFO underflow.

(4) DIFC

The DIFC is the display timing master. The DIFC controls the polarity and the timing of the Video Output signals. Controllable timings are the followings.

- Hfront: Horizontal front porch (pixels)
- Hback: Horizontal back porch (pixels)
- Hsync: Horizontal sync active (pixels)
- Hactive: Horizontal active area (pixels)
- Vfront: Vertical front porch (lines)
- Vback: Vertical back porch (lines)
- Vsync: Vertical sync active (lines)
- Vactive: Vertical active area (lines)

(5) INTC

The INTC generates the interrupt when PBUF will detect a FIFO underflow. The interrupt is level signal.

9.4.1.3 Clock and Interrupt signal

The following clocks are supplied to the LCDC.

Table 9.4-3 Clock List

Clock Name	Description	Frequency (MHz)
LCDC_CLK_A	AXI clock.	200/100
LCDC_CLK_P	APB clock.	100/50
LCDC_CLK_D	Video clock.	MIPI-DSI: 5.44 to 187.5 LVDS: 25 to 87 DPI: 5.44 to 87

The LCDC transmits the following interrupt signals to the interrupt controller.

Table 9.4-4 Interrupt List

Signal Name	Interrupt Condition	Interrupt Source Register
VSPD_INT	Frame End	VI6_WPF0_IRQ_STA.FRE
	Display List Frame End	VI6_WPF0_IRQ_STA.DFE
	DU Connection UnderRun Error	VI6_WPF0_IRQ_STA.UND
DU_INT	PBUF FIFO Underflow	DU_MSR0.ST_PB_RUF

Note: Refer to **(13) WPF0 Interrupt Status Register (LCDC_VSPD_VI6_WPF0_IRQ_STA)** and **9.4.4.2.1 DU Module Control Register 0 (LCDC_DU_MCR0)** for details.

9.4.1.4 Input/Output Pins

The following table show pin configuration of LCDC.

Table 9.4-5 Pin Configuration

Pin Name	Signal Name in This Section	Input/ Output	Functional Description
DPI_CLK	DCLK	Output	Display parallel interface clock
DPI_HSYNC	HSYNC	Output	Display parallel interface horizontal synchoronous signal
DPI_VSYNC	VSYNC	Output	Display parallel interface vertical synchoronous signal
DPI_DE	DE	Output	Display parallel interface signal data outuput enable
DPI_Gn (n = 0 to 7)	— (Not listed in this section)	Output	Display parallel interface color (Gn) (n = 0 to 7) signals
DPI_Bn (n = 0 to 7)	— (Not listed in this section)	Output	Display parallel interface color (Bn) (n = 0 to 7) signals
DPI_Rn (n = 0 to 7)	— (Not listed in this section)	Output	Display parallel interface color (Rn) (n = 0 to 7) signals

9.4.2 FCPVD Registers

The FCPVD contains the registers which can directly be read and written to by the host CPU. The host can access any long word (32 bits) in the registers. Therefore, read-modify-write is needed to change partial bits in the 32-bit register.

Never access the registers when the FCPVD is in the module standby mode (with the operation clock placed in hold status).

Table 9.4-6 FCPVD Register Base Address

Base Register Name	LCDC Ch.	Base Address
<LCDC_fcpvd_base>	FCPVD (LCDC)	0_1088_0000h (5088_0000h*1, 4088_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.4.2.1 List of FCPVD Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
FCPV version control register	LCDC_FCPVD_FCP_VCR	0000_0109h	0000h	32

9.4.2.2 FCPVD Register Description

The prefix (LCDC_FCPVD_) of the register names is omitted in this and subsequent sections.

9.4.2.2.1 FCPVD Version Control Register (LCDC_FCPVD_FCP_VCR)

FCP_VCR is the version control register of the FCPVD. The value read is fixed.

Access Size : 32 bits
Address : <LCDC_fcpvd_base> + 0000h
Initial Value : 0000_0109h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CATEGORY[7:0]								REVISION[7:0]							
Initial Value	0	0	0	0	0	0	0	1	0	0	0	0	1	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 8	CATEGORY [7:0]	1h	R	FCP use case category.
7 to 0	REVISION[7:0]	9h	R	Version of LSI product 09h: FCP revision is the Simple LCDC

9.4.3 VSPD Registers

In the following, “n” in a register name or a offset address indicates an integer, and the range of value n is defined when necessary. For RPFn and WPFn, when the range of value n is not defined, RPFn (n = 0, 1) and WPFn (n = 0) are assumed.

Table 9.4-7 VSPD Register Base Address

Base Register Name	LCDC Ch.	Base Address
<LCDC_vspd_base>	LCDC	0_1087_0000h (5087_0000h*1, 4087_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.4.3.1 List of VSPD Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
VSPD Start Register 0	LCDC_VSPD_VI6_CMD0	0000_0000h	0000h	32
Reserve	-	-	0004h to 000Fh	-
Clock Control Register 0	LCDC_VSPD_VI6_CLK_CTRL0	0000_0000h	0010h	32
Clock Control Register 1	LCDC_VSPD_VI6_CLK_CTRL1	0000_0000h	0014h	32
Dynamic Clock Stop Control Register	LCDC_VSPD_VI6_CLK_DCSWT	0000_0000h	0018h	32
Dynamic Clock Stop Disable Register 0	LCDC_VSPD_VI6_CLK_DCSM0	0000_0000h	001Ch	32
Dynamic Clock Stop Disable Register 1	LCDC_VSPD_VI6_CLK_DCSM1	0000_0000h	0020h	32
Reserve	-	-	0024h to 0027h	-
Software Reset Register	LCDC_VSPD_VI6_SRESET	0000_0000h	0028h	32
Module Reset Enable Register 0	LCDC_VSPD_VI6_MRESET_ENB 0	0000_0000h	002Ch	32
Module Reset Enable Register 1	LCDC_VSPD_VI6_MRESET_ENB 1	0000_0000h	0030h	32
Module Reset Issuing Register	LCDC_VSPD_VI6_MRESET	0000_0000h	0034h	32
Operating Status Register	LCDC_VSPD_VI6_STATUS	0000_0000h	0038h	32
Reserve	-	-	003Ch to 0047h	-
WPF0 Interrupt Enable Register	LCDC_VSPD_VI6_WPF0_IRQ_EN B	0000_0000h	0048h	32
WPF0 Interrupt Status Register	LCDC_VSPD_VI6_WPF0_IRQ_ST A	0000_0000h	004Ch	32
Reserve	-	-	0050h to 0077h	-
Display-0 Interrupt Enable Register	LCDC_VSPD_VI6_DISP0_IRQ_EN B	0000_0000h	0078h	32
Display-0 Interrupt Status Register	LCDC_VSPD_VI6_DISP0_IRQ_ST A	0000_0000h	007Ch	32
Reserve	-	-	0080h to 00FFh	-
Display List Control Register	LCDC_VSPD_VI6_DL_CTRL	0000_0000h	0100h	32
Reserve	-	-	0108h to 0113h	-

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Display List-0 Data Swapping Register	LCDC_VSPD_VI6_DL_SWAP0	0000_0000h	0114h	32
Reserve	-	-	0118h to 011Bh	-
Extended Display List-0 Control Register	LCDC_VSPD_VI6_DL_EXT_CTRL0	0000_0000h	011Ch	32
Display List Body Size Register 0	LCDC_VSPD_VI6_DL_BODY_SIZE0	0000_0000h	0120h	32
Display List-0 Header Address Register	LCDC_VSPD_VI6_DL_HDR_ADDR0	0000_0000h	0104h	32
Reserve	-	-	0124h to 012Fh	-
Display List-0 Header Reference Address Register	LCDC_VSPD_VI6_DL_HDR_REF_ADDR0	0000_0000h	0130h	32
Reserve	-	-	0134h to 02FFh	-
RPF0 Basic Read Size Register	LCDC_VSPD_VI6_RPF0_SRC_BSIZE	0000_0000h	0300h	32
RPF0 Extended Read Size Register	LCDC_VSPD_VI6_RPF0_SRC_ESIZE	0000_0000h	0304h	32
RPF0 Input Format Register	LCDC_VSPD_VI6_RPF0_INFMT	0000_0000h	0308h	32

LIF0 Padding Line Size Register	LCDC_VSPD_VI6_LIF0_PADLN_SIZE	0000_0000h	3B3Ch	32

Note: Read only bits or write only bits or read/write bits are mixed in the registers.

9.4.3.2 VSPD Register Description

The prefix (LCDC_VSPD_) of the register names is omitted in this and subsequent sections.

9.4.3.2.1 Notational Conventions for Registers and Bit Fields

This section uses the following notational conventions for the VSPD registers and bit fields.

1. The names of registers and bits are written in uppercase.
2. A bit or bit field in a register is indicated as [register name.bit name]. For example, the STRCMD bit in the VI6_CMD0 register is indicated as VI6_CMD0.STRCMD.
3. Lowercase “n” in a register name or a bit name indicates an integer and the range of value n is defined when necessary. For RPFn, and WPFn, when the range of value n is not defined, RPFn (n = 0, 1), WPFn (n = 0) are assumed.
4. In each subsection for register description in **9.4.3.2 VSPD Register Description**, when only a bit name is written without showing its register name, the bit is in the register described in that subsection.
5. A wildcard (*) indicates any characters in a name and represents all registers or bits that match the specified first part of a name. For example, when there are two registers VI6_RPF_SRC_BSIZE and VI6_RPF_SRC_ESIZE, VI6_RPF_SRC_* indicates both registers.

9.4.3.2.2 Register Classification

The VSPD registers are arranged in the following order; the general control registers to display list control registers control operation of the entire VSPD, and the other registers control each image processing and specify parameters for the processing. The functions of the registers are described in this order starting from **9.4.3.2.4 General Control Registers**.

1. General control registers (VI6_CMDn (n = 0, 1), VI6_SRESET, VI6_STATUS, VI6_WPFn_IRQ_* (n = 0))
2. Display list control registers (VI6_DL_*)
3. RPF control registers (VI6_RPFn_* (n = 0, 1))
4. WPF control registers (VI6_WPFn_* (n = 0))
5. DPR control registers (VI6_DPR_*)
6. LUT control register (VI6_LUT_CTRL)
7. BRS control registers (VI6_BRS_*)
8. LIFn control registers (VI6_LIFn_* (n = 0))

The VSPD has two RPF channels and the register configuration is the same for all of RPFn (n = 0, 1). However, some bit fields have restrictions in certain RPFs. These restrictions are included in the description of the corresponding bit fields and registers. Likewise, the register configuration is the same for all WPFn (n = 0), but some bit fields have restrictions in certain WPFs; the restrictions are included in the description of the corresponding bit fields and registers.

For each register address, refer to **9.4.3.1 List of VSPD Registers**.

9.4.3.2.3 Restrictions on Access to Registers and Lookup Tables

The VSPD has control registers and lookup tables. All VSPD registers are writable and readable by only 32 bits unit. To write partial bits in each register, read-modify-write is needed. When accessing the addresses where these registers and lookup tables are allocated, the following restrictions should be satisfied. If any restriction is violated, the VSPD will not operate correctly.

1. For the read-only bits and reserved bits in all VSPD registers, writing 1 is prohibited unless otherwise specified.
2. Addresses undefined in **9.4.3.1 List of VSPD Registers** are reserved areas and write access is prohibited in these areas.
3. For all registers and lookup tables, except VI6_CMDn, VI6_SRESET, VI6_*IRQ* and two plane registers such as VI6_DL_HDR_ADDRn, VI6_DL_BODY_SIZE0, modifying register values during operation of the module is prohibited. Modify registers while the corresponding module is stopped. For the operating status of the target module, refer to **9.4.5.4 Concept of VSPD Operation Starting and Stopping**.
4. There are three types about General control registers (**9.4.3.2.4 General Control Registers**) and Display List Control Registers (**9.4.3.2.5 Display List Control Registers**) as below.
   - Controlling WPF0 (ex. VI6_CMD0, VI6_SRESET.SRST0)
   - Common setting of WPF0 (ex. VI6_DL_CTRL.AR_WAIT [15:0])

Table 9.4-8 Correspondence between Modules and Register Names

Module Name	Register Name
RPFn (n = 0, 1)	VI6_RPFn_*
WPFn (n = 0)	VI6_WPFn_*
DPR	VI6_DPR_*
LUT	VI6_LUT_CTRL
BRS	VI6_BRS_*
LIFn (n = 0)	VI6_LIFn_*

9.4.3.2.4 General Control Registers

(1) VSPD Start Register 0 (LCDC_VSPD_VI6_CMD0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	UPDHDR	-	-	-	STRCMD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	RW	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	UPDHDR	0h	RW	Reserved state of updating Display List Header (DLH) address. UPDHDR can be negated by software reset (VI6_SRESET.SRST0). [Write] 0b: NOP 1b: Do not set 1b to this bit [Read] 0b: Not reserved to update DLH address. 1b: Reserved to update DLH address. Set 0b to this bit when STRCMD bit is set to 1b.
3 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	STRCMD	0h	RW	Start reservation of WPF VI6_CMD0.STRCMD controls WPF0. Writing 1b to this bit starts WPF0 in VSPD. Set this bit for activation only after all register settings in each output channel have been completed. If WPF0 is idle, WPF0 starts right after this bit is set to 1b. If WPF0 is active, writing 1b to this bit reserves starting WPF0 operation. Wait to set 1b to VI6_CMD0.STRCMD until this bit is read as 0b. VI6_CMD0.STRCMD can be negated by software reset (VI6_SRESET.SRST0). [Write] 0b: Start reservation of WPF0 is canceled. 1b: Start reservation of WPF0 is set. [Read] 0b: Starting VSPD is not reserved. 1b: Starting VSPD is reserved.

The basic concept of image processing operation started by activating the VSPD is shown in **Figure 9.4-5**. The actual data input/output is executed by the MAU, which is the bus interface module, as described in **9.4.1.2 Block Diagram**, but conceptually the RPF works as the data entry point to the VSPD and the WPF works as the data exit point. To process images through the VSPD, the RPF (entrance) and WPF (exit) should be connected and a data path from the RPF to the WPF should be formed.

To connect RPFn to WPFn, specify RPFn as the source RPF for WPFn in VI6_WPFn_SRCRPF, which is a register for WPFn (refer to **(1) WPF0-Source-RPF Register (LCDC_VSPD_VI6_WPF0_SRCRPF)**). This setting determines that RPFn will be started when WPFn is started through VI6_CMDn.

A data path to execute desired image processing should then be formed between the RPF (entrance) and WPF (exit). To form a data path, connect the necessary function modules in the VSPD between RPF and WPF. This function is

provided by the DPR; specify the information for each module connection in data path routing registers VI6_DPR_*_ROUTE (refer to **9.4.3.2.8 DPR Control Registers**).

After a data path is formed (RPFn → WPFn) as described above, starting output module WPFn in the VSPD through VI6_CMDn starts all function modules connected to WPFn and the desired image processing is executed. According to this design concept, starting a WPF module means starting the VSPD.

There are two types of data path configuration in the VSPD; one is “a single input module to a single output module” as shown in **Figure 9.4-5** (A), and the other is “multiple input modules to a single output module” as shown in **Figure 9.4-5** (B).

Figure 9.4-5 (A) shows an example of a configuration where modules with single input and single output are implemented through the DPR.

Figure 9.4-5 (B) shows another configuration example where the module with multiple input and single output is implemented through the DPR.

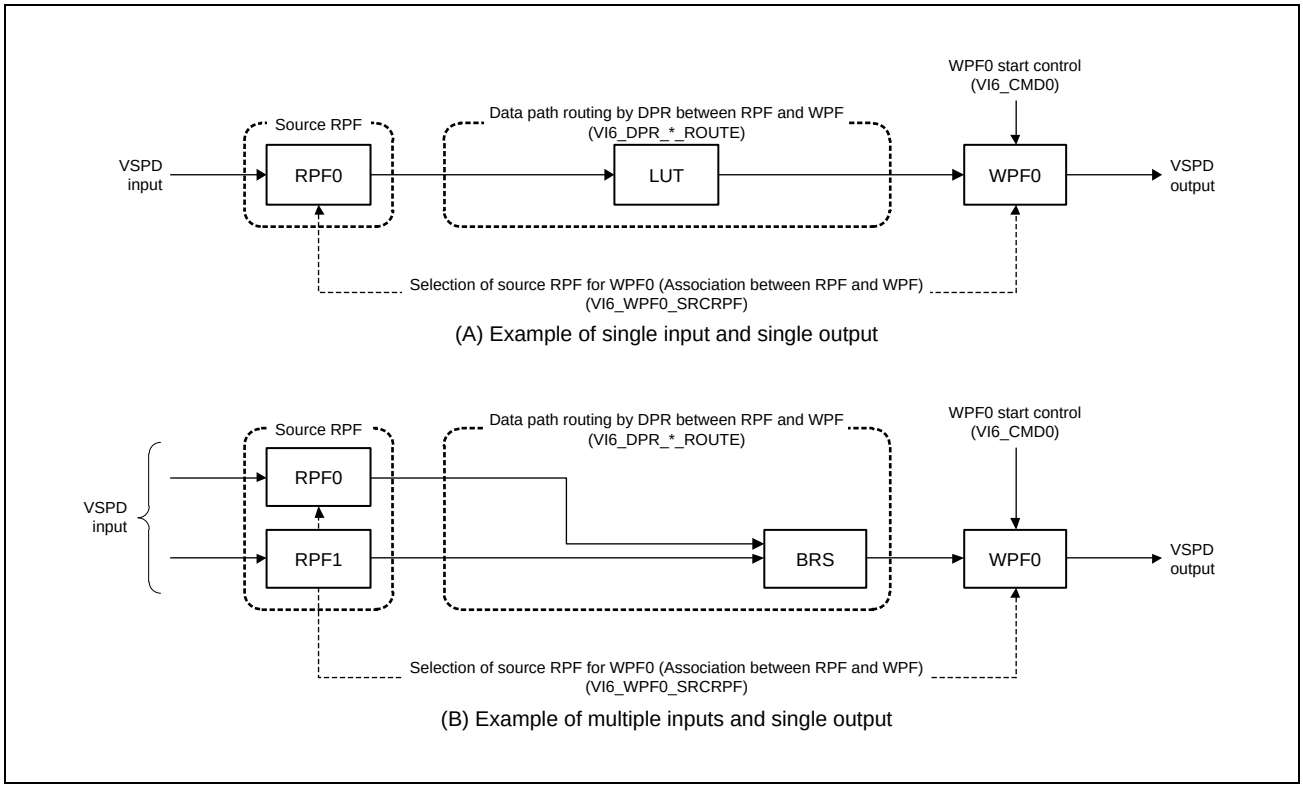

Figure 9.4-5 Basic Concept of VSPD Startup

(2) Clock Control Register 0 (LCDC_VSPD_VI6_CLK_CTRL0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	GCS0	-	-	-	-	-	-	-	-	-	-	-	GCS1
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	GCS2[3:0]				-	-	-	GCS3[4:0]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	R	R	R	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	GCS0	0h	RW	Clock Control Setting0
27 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	GCS1	0h	RW	Clock Control Setting1
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 8	GCS2[3:0]	0h	RW	Clock Control Setting2
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4 to 0	GCS3[4:0]	00h	RW	Clock Control Setting3

VSPD can stop its operating clock for reducing power consumption.

To enable clock stop function, set following registers:

- VI6_CLK_CTRL0 = 0000_0000h
- VI6_CLK_CTRL1 = 0000_0000h
- VI6_CLK_DCSWT = 0000_0808h
- VI6_CLK_DCSM0 = 0000_0000h
- VI6_CLK_DCSM1 = 0000_0000h

To disable clock stop function, set following registers:

- VI6_CLK_CTRL0 = 1001_0F1Fh
- VI6_CLK_CTRL1 = FF10_FFFFh
- VI6_CLK_DCSWT = 0033_0808h
- VI6_CLK_DCSM0 = 1FFF_0F1Fh
- VI6_CLK_DCSM1 = FF10_FFFFh

When the clock gating is enabled, the supply of the clock signal is stopped for the module which is not operated. If the bit field of this register is changed from 0 to 1, the supply of the clock signal for the module is immediately started. If

the bit field of the register is changed from 1 to 0, the clock supply is immediately stopped. Therefore, please do not change this register field from 1 to 0 in operation because the VSPD may be stalled.

(3) Clock Control Register 1 (LCDC_VSPD_VI6_CLK_CTRL1)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0014h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GCS4[7:0]								-	-	-	GCS6	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	RW	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GCS5[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	GCS4[7:0]	00h	RW	Clock Control Setting4
23 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	GCS6	0h	RW	Clock Control Setting6
19 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 0	GCS5[15:0]	0000h	RW	Clock Control Setting5

See **(2) Clock Control Register 0 (LCDC_VSPD_VI6_CLK_CTRL0)** for detail.

(4) Dynamic Clock Stop Control Register (LCDC_VSPD_VI6_CLK_DCSWT)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0018h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	DCC0[1:0]		-	-	DCC1	DCC2
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	RW	RW	R	R	RW	RW

23 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	DCD5	0h	RW	Dynamic Clock Stop Disable Setting5
19 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 0	DCD4[15:0]	0000h	RW	Dynamic Clock Stop Disable Setting4

See **(2) Clock Control Register 0 (LCDC_VSPD_VI6_CLK_CTRL0)** for detail.

(7) Software Reset Register (LCDC_VSPD_VI6_SRESET)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0028h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SRST0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	SRST0	0h	RW	WPF0 Software Reset Writing 1b to this bit aborts the current processing in WPF0 (the partially-completed image undergoing processing is output). The period until this software reset processing is completed depends on the bus state. When this reset processing is completed, the VI6_WPF0_IRQ_STA.FRE interrupt source bit is set to 1b; when the FRE interrupt is enabled, the FRE end interrupt is output to notify the end of the reset processing. This bit is always read as 0b. 0b: NOP 1b: WPF0 software reset*[1]

Note 1. Applying a software reset to each WPF has the following restrictions.

1. A software reset can be applied to only one of WPF0 through single write access to VI6_SRESET.
2. After a software reset is issued, no more software reset can be issued to another WPF until the issued software reset processing is completed
3. The end of software reset processing is notified through the FRE bit in VI6_WPFn_IRQ_STA, but the software reset issued while WPF is stopped is ignored as NOP. As it takes a while until the reset is actually issued after the reset bit is set, the VSPD may complete operation before the reset is actually issued. In this case, no interrupt is output for the software reset that is issued after the VSPD completes operation.
4. If a software reset is issued during downloading of a display list, the downloading processing is not aborted. After the end of downloading that is in progress when a software reset is issued, a frame end interrupt is output.

(8) Module Reset Enable Register 0 (LCDC_VSPD_VI6_MRESET_ENB0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 002Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	MRSTE0[1:0]		-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

23 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 0	MRSTE4[15:0]	0000h	RW	Module Reset Enable 4

This register is for purpose of h/w debugging.

(10) Module Reset Issuing Register (LCDC_VSPD_VI6_MRESET)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0034h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	MRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	MRST	0h	RW	Module Reset Assertion

This register is for purpose of h/w debugging.

(11) Operating Status Register (LCDC_VSPD_VI6_STATUS)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0038h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	FLDST0	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SYS0_ACT	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	FLDST0	0h	R	Field status of previous frame of WPF0. 0b: Previous finished frame is TOP field. 1b: Previous finished frame is BOT field. This bit can be referred in case of AUTO-FLD or AUTO-DISP. This bit is changed at the timing of VI6_WPF0_IRQ_STA.FRE.
27 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	SYS0_ACT	0h	R	WPF0 Operating Status Each bit indicates the operating or stopped state of control channel n (WPF0). 0b: WPF0 is stopped. 1b: WPF0 is operating.
7 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(12) WPF0 Interrupt Enable Register (LCDC_VSPD_VI6_WPF0_IRQ_ENB)

Each bit controls the interrupt enable of the corresponding interrupt source.

0: Interrupt disabled
1: Interrupt enabled

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0048h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	UNDE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DFEE	FREE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	UNDE	0h	RW	Interrupt Enable for WPF0 Underrun in case of DU connection.
15 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	DFEE	0h	RW	Interrupt Enable for WPF0 Display List Frame End
0	FREE	0h	RW	Interrupt Enable for WPF0 Frame End

Each bit in VI6_WPFn_IRQ_STA is set to 1 when the corresponding interrupt source is generated. VI6_WPFn_IRQ_ENB specifies whether to output an interrupt signal for the generated source. When an interrupt is disabled in this register, no interrupt signal is generated even when the corresponding bit in VI6_WPFn_IRQ_STA is set to 1. When an interrupt is enabled in this register, an interrupt signal is output when the corresponding bit in VI6_WPFn_IRQ_STA is set to 1.

(13) WPF0 Interrupt Status Register (LCDC_VSPD_VI6_WPF0_IRQ_STA)

The read value from each bit is the status of the interrupt source, and the write access to each bit controls the interrupt status.

[Read Access] Interrupt Status

0: No interrupt
1: Interrupt activated

[Write Access] Interrupt Clear

0: The interrupt status is cleared to 0
1: Hold the interrupt status value

Access Size : 32 bits
Address : <LCDC_vspd_base> + 004Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	UND
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DFE	FRE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	UND	0h	RW	Interrupt Status and Clear for WPF0 Underrun in case of DU connection. This interrupt source bit is set to 1b when data underrun occurs in case of DU connection. Timing that this bit is set to 1b is at end of 1 frame.
15 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	DFE	0h	RW	Interrupt Status and Clear for WPF0 Display List Frame End This interrupt source bit is set to 1b when VSPD completes one-frame processing while the current frame in enable value stored in the display list header is 1 (refer to **9.4.5.4 Concept of VSPD Operation Starting and Stopping**). When display lists are not used, this bit is not used. In this case, clear VI6_WPF0_IRQ_ENB.DFEE to 0b to mask the interrupt generation by this interrupt source. This bit can hold the most recent of two times of interrupt status at the maximum. When writing 0b to this bit, the oldest interrupt status is cleared. And the status bit becomes 0b after all interrupt statuses are cleared.
0	FRE	0h	RW	Interrupt Status and Clear for WPF0 Frame End This interrupt source bit is set to 1b when VSPD completes one-frame processing. This bit is also set to 1b when one-frame processing using a display list is completed. The interrupt status is set to 1b by any of the following conditions. a) Processing one frame is finished normally b) Software reset is issued during VSPD is processing. c) One frame's data from DU is displayed while VSPD couldn't transfer one frame data to DU. (in case of Linked with DU) This bit can hold the most recent of two times of interrupt status at the maximum. When writing 0b to this bit, the oldest interrupt status is cleared. And the status bit becomes 0b after all interrupt statuses are cleared.

VI6_WPFn_IRQ_STA indicates the state of the interrupt sources generated in the VSPD. Whether to output a VSPD interrupt when an interrupt source is generated and the corresponding bit is set to 1 is determined by the corresponding bit setting in VI6_WPFn_IRQ_ENB. While an interrupt is disabled in VI6_WPFn_IRQ_ENB, the VSPD does not output an interrupt signal even when an interrupt source is generated, but the source flag in this register is set to 1.

Note that the interrupt source bits in this register cannot be cleared by write access using a display list.

(14) Display-0 Interrupt Enable Register (LCDC_VSPD_VI6_DISP0_IRQ_ENB)

Each bit controls the interrupt enable of the corresponding interrupt source.

0: Interrupt disabled
1: Interrupt enabled

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0078h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	DSTE	-	-	MAEE	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	RW	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	DSTE	0h	RW	Interrupt Enable for Display Start
7 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5	MAEE	0h	RW	Interrupt Enable for Display Read Data End
4 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(15) Display-0 Interrupt Status Register (LCDC_VSPD_VI6_DISP0_IRQ_STA)

The read value from each bit is the status of the interrupt source, and the write access to each bit controls the interrupt status.

[Read Access] Interrupt Status

0: No interrupt
1: Interrupt activated

[Write Access] Interrupt Clear

0: The interrupt status is cleared to 0
1: Hold the interrupt status value

Access Size : 32 bits
Address : <LCDC_vspd_base> + 007Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	DST	-	-	MAE	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	RW	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	DST	0h	RW	Interrupt Status and Clear for Display Start This bit is set to 1b when LIF module transfers the first data to the display module at the beginning of each frame. The timing depends on the output buffer status of LIF module.
7 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5	MAE	0h	RW	Interrupt Status and Clear for Display Read Data End This bit is set to 1b when all RPFs transfer the last data of the frame to LIF module. The RPF module which is not used by LIF module does not affect this bit.
4 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.4.3.2.5 Display List Control Registers

(1) Display List Control Register (LCDC_VSPD_VI6_DL_CTRL)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0100h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AR_WAIT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	DC2	-	-	-	DC1	-	-	-	DLE1	RLM0	CFM0	NH0	DLE0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	R	RW	R	R	R	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	AR_WAIT[15:0]	0000h	RW	Display List Control Setting Always specify 256.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12	DC2	0h	RW	This bit doesn't affect anything to VSPD (NOP)
11 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	DC1	0h	RW	This bit doesn't affect anything to VSPD (NOP)
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	DLE1	0h	RW	This bit doesn't affect anything to VSPD (NOP)
3	RLM0	0h	RW	Loading two plane Registers Mode for WPF0. 0b: Reserved status (VI6_CMD0.UPDHDR) is accepted by next frame auto start. Two plane registers are downloaded by next_frame_start also. 1b: Reserved status (VI6_CMD0.UPDHDR) is not accepted by next frame auto start. pNextHeader in previous frame's DLH is used for loading DisplayList. Two plane registers are not downloaded by next_frame_start also.
2	CFM0	0h	RW	Continuous Frame Mode for Header-less Display List for WPF0 This bit determines whether the next frame is automatically started or not. When the updated flag of the display list, VI6_DL_BODY_SIZE0.UPD0, is not updated, the display list of the next frame is not transferred and the same register values are used for the next frame. When the value of VI6_DL_BODY_SIZE0.UPD0 is updated, the new display list is transferred. 0b: Stopped at the end of every frame 1b: The next frame is automatically started
1	NH0	0h	RW	Header-less Display List Mode This bit is used for specifying the header-less display list mode. In case of header-less mode, the number of the display lists is 1. The address of the display body is set in VI6_DL_HDR_ADDR0 register, and the body size is set in VI6_DL_BODY_SIZE0 register. When this bit is changed, make sure that VSPD is stopped. And also make sure the following before starting VSPD. - Header Address (VI6_DL_HDR_ADDR0) - Body Size (VI6_DL_BODY_SIZE0) in case of header-less mode 0b: Use Display List Header (Normal DL Mode) 1b: Do not use Display List Header (Header-less Mode) Note: When DLE0 bit is 0b, set 0b to NH0 bit.

Bit	Bit Name	Initial Value	R/W	Description
0	DLE0	0h	RW	Display List Enable/Disable for WPF0 Enables or disables the WPF0 display list function. When the display list function is enabled through this bit, all WPF processing channels work in display list mode. When using display lists, note the restrictions in **9.4.3.2.3 Restrictions on Access to Registers and Lookup Tables**. 0b: The display list function is disabled 1b: The display list function is enabled

(2) Display List-0 Header Address Register (LCDC_VSPD_VI6_DL_HDR_ADDR0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0104h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DL_HDR_PTR-0[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DL_HDR_PTR-0[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DL_HDR_PTR-0[31:0]	0000_0000h	RW	Display List-0 Header Address These bits specify the address of the display list header to be read for display list-n in 16-byte units (the lower-order four bits are read-only). When WPF0 is first started in display list mode, the display list header is loaded from the address specified in this register. After loading of the header is completed, the register value of the display list address is updated to the next header address stored in the loaded header to prepare for loading of the next display list header. After that, this header address updating is repeated. A value from 0000_0000h to FFFF_FFF0h can be specified.

(3) Display List-0 Data Swapping Register (LCDC_VSPD_VI6_DL_SWAP0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0114h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	LWS	WDS	BTS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	LWS	0h	RW	Display List Data Swapping in long word Units The effect of this bit setting is defined in **Table 9.4-8**. 0b: Data swapping in long word (32-bit) units is disabled 1b: Data swapping in long word (32-bit) units is enabled
1	WDS	0h	RW	Display List Data Swapping in Word Units The effect of this bit setting is defined in **Table 9.4-8**. 0b: Data swapping in word (16-bit) units is disabled 1b: Data swapping in word (16-bit) units is enabled
0	BTS	0h	RW	Display List Data Swapping in Byte Units The effect of this bit setting is defined in **Table 9.4-8**. 0b: Data swapping in byte (8-bit) units is disabled 1b: Data swapping in byte (8-bit) units is enabled

Table 9.4-9 shows the data order before and after swapping according to the long word, word, and byte swapping settings.

When data order in memory for each format is the same as **Table 9.4-35**, set 111b to {LWS, WDS, BTS}. If data order is not the same as the definition, change data order within 8byte unit by these bits as shown in **Table 9.4-9**.

Table 9.4-9 Changing Data Order According to Display List Swap Register

Data order in memory											
Byte address	8n+0	8n+1	8n+2	8n+3	8n+4	8n+5	8n+6	8n+7	*_LWS	*_WDS	*_BTS
Data	0	1	2	3	4	5	6	7	1	1	1
	1	0	3	2	5	4	7	6	1	1	0
	2	3	0	1	6	7	4	5	1	0	1
	3	2	1	0	7	6	5	4	1	0	0
	4	5	6	7	0	1	2	3	0	1	1
	5	4	7	6	1	0	3	2	0	1	0
	6	7	4	5	2	3	0	1	0	0	1
	7	6	5	4	3	2	1	0	0	0	0

Data order defined in **Table 9.4-35**								
Byte address	8n+0	8n+1	8n+2	8n+3	8n+4	8n+5	8n+6	8n+7
Data	0	1	2	3	4	5	6	7

(4) Extended Display List-0 Control Register (LCDC_VSPD_VI6_DL_EXT_CTRL0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 011Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	NWE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	POLINT[5:0]						-	-	DLPRI	EXPRI	-	-	-	EXT
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	R	R	RW	RW	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	NWE	0h	RW	No Wait for Polling When this bit is set to 1b, the polling condition for extended display lists is always assumed to be true.
15 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 8	POLINT[5:0]	00h	RW	Extended Display List Command Control Always specify 2h.
7 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5	DLPRI	0h	RW	Display List Control 0 Always specify 1b.
4	EXPRI	0h	RW	Display List Control 1 Always specify 0b.
3 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	EXT	0h	RW	Extended Display List for WPF0 Enables or disables the extended display list function. When extended display lists are used, the display list header size is 96 bytes; when they are not used, the header size is 80 bytes. 0b: No extended display lists are used 1b: Extended display lists are used [Note] When using extended display lists, be sure to also use normal display list mode (VI6_DL_CTRL.DLE0); executing only extended display lists is not possible. When the header-less display list mode is activated, this bit should be set to 0. The extended display list cannot be used with the header-less display list mode. Extended Display List is available only for VSPD/LIF0 to realized AUTO-FLD or AUTO-DISP.

(5) Display List Body Size Register-0 (LCDC_VSPD_VI6_DL_BODY_SIZE0)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 0120h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	UPD0	-	-	-	-	-	-	-	BS0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	UPD0	0h	RW	Update Flag This bit controls the download of the display list at the next downloading timing in case that the header-less display list mode is used. Set 1b to this bit when display list need to be downloaded for next frame. This bit is automatically cleared to 0b after VI6_DL_HDR_ADDRn and VI6_DL_BODY_SIZE0.BS0 is downloaded in H/W side. When this bit is set to 1b, the value of VI6_DL_HDR_ADDR0 and VI6_DL_BODY_SIZE0.BS0 should not be changed. 0b: Updating display list for the next frame is not reserved 1b: Updating display list for the next frame is reserved
23 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16 to 0	BS0[16:0]	00000h	RW	Header-less Display List Body Size (WPF0) These bits are used for specifying the body size of the display list in case of header-less display list mode. The unit of the size is byte. The value should be set in multiples of 8.

See **9.4.5.8.2 Controlling two register planes using display lists** for detail.

(6) Display List-0 Header Reference Address Register (LCDC_VSPD_VI6_DL_HDR_REF_ADDR0)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0130h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DL_HDR_REF_PTR-0[31:16]

	DL_HDR_REF_PTR-0[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DL_HDR_REF_ PTR-0[31:0]	00000000h	R	Display List-n reference Header Address Following value is read out from the VI6_DL_HDR_REF_ADDR0 for each period. (1) When H/W is reading display list from external memory, header address of the display list referred by VSPD-H/W is read out. (2) When H/W is not reading display list from external memory, the value of VI6_DL_HDR_ADDR0 is read out. For details, refer to **9.4.5.8.1 Operation flow of VSPD and DU**.

9.4.3.2.6 RPF Control Registers

(1) RPFn Basic Read Size Registers (LCDC_VSPD_VI6_RPFn_SRC_BSIZE) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0300h (n = 0)
<LCDC_vspd_base> + 0400h (n = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	BHSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	BVSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	BHSIZE[12:0]	0000h	RW	Horizontal Size of RPF Basic Read Area These bits specify the horizontal size of the basic area to be read from the external RAM by the RPFn. When the input format is YCbCr4:2:2 or YCbCr4:2:0, specify the size in 2-pixel units. A value from 1 to 1920 can be specified. Specify a value equal to or smaller than the extended read size (VI6_RPFn_SRC_ESIZE.EHSIZE).
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	BVSIZE[12:0]	0000h	RW	Vertical Size of RPF Basic Read Area These bits specify the vertical size of the basic area to be read from the external RAM by the RPFn. When the input format is YCbCr4:2:0, specify the size in 2-pixel units. A value from 1 to 1920 can be specified. Specify a value equal to or smaller than the extended read size (VI6_RPFn_SRC_ESIZE.EVSIZE).

Figure 9.4-6 shows the relationship between the basic read size and extended read size. The RPF reads data from the source memory area specified by the basic read size. The RPF repeats reading the basic read area in the horizontal and vertical directions up to the extended read size and sends the read data to the processing modules in the VSPD.

For basic read size reading, the reading start address, called the RPFn source image storing address, should be specified in VI6_RPFn_SRCM_ADDR_*. In the memory area where the basic read area image is stored, the distance (number of bytes) between addresses for lines n and n + 1 of two-dimensional image data, called the memory stride, should be specified in VI6_RPFn_SRCM_PSTRIDE.

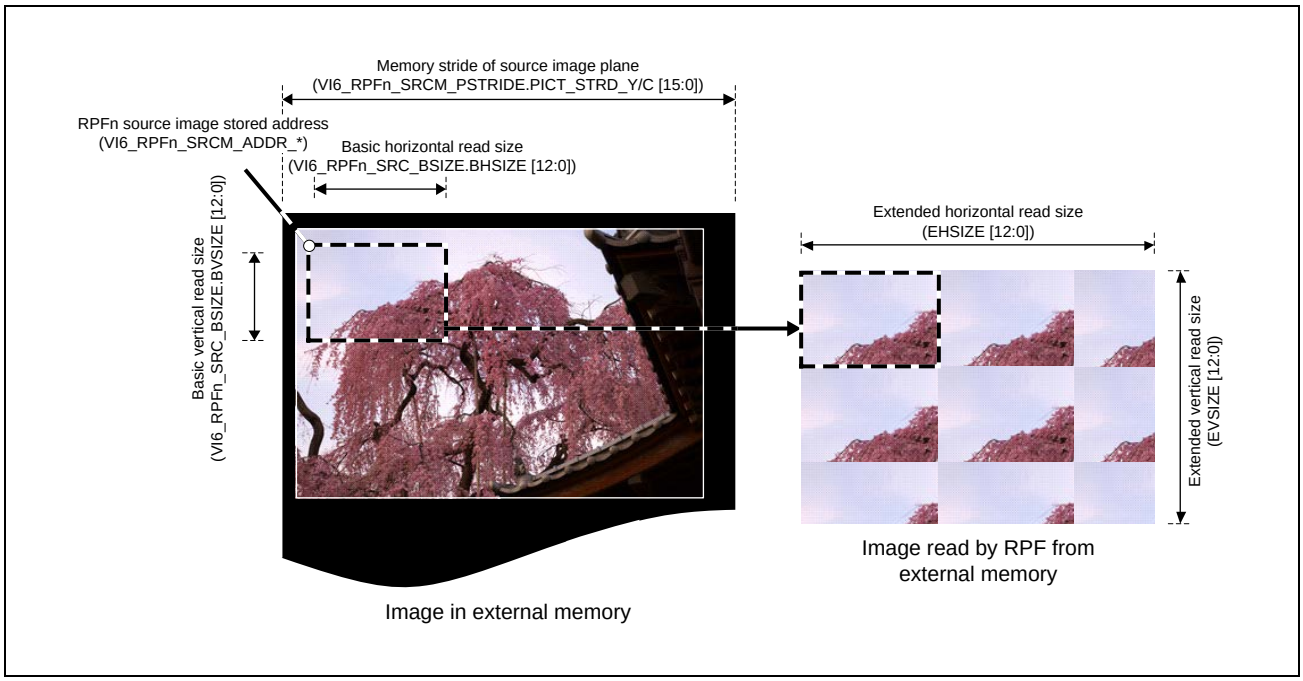

Figure 9.4-6 Relationship between Basic Read Size and Extended Read Size

	-	-	-	EVSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	EHSIZE[12:0]	0000h	RW	RPF Extended Horizontal Read Size These bits specify the horizontal size of the extended read area to which the RPFn reads data from the external RAM. As shown in **Figure 9.4-7**, the basic read area image is repeatedly placed in the extended read area; in the EHSIZE bits, specify a value not smaller than the horizontal size of the basic read area. When the input format is YCbCr4:2:2 or YCbCr4:2:0, specify the size in 2-pixel units (an even value). A value from 1 to 1920 can be specified.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	EVSIZE[12:0]	0000h	RW	RPF Extended Vertical Read Size These bits specify the vertical size of the extended read area to which the RPFn reads data from the external RAM. As shown in **Figure 9.4-7**, the basic read area image is repeatedly placed in the extended read area; in the EVSIZE bits, specify a value not smaller than the vertical size of the basic read area. When the input format is YCbCr4:2:0, specify the size in 2-pixel units (an even value). A value from 1 to 1920 can be specified.

VI6_RPFn_SRC_ESIZE specifies the extended size for RPFn. The extended horizontal and vertical sizes should be equal to or greater than the basic sizes specified in VI6_RPFn_SRC_BSIZE. The RPF internal data processing described later and image processing described in **9.4.3.2.8 DPR Control Registers** and later sections are all applied to the image in the extended read size shown on the right side in **Figure 9.4-6**.

(3) RPFn Input Format Registers (LCDC_VSPD_VI6_RPFn_INFMT) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0308h (n = 0)
<LCDC_vspd_base> + 0408h (n = 1)

Initial Value : 0000_0000h

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	VIR	0h	RW	Virtual Input Enable Enables or disables the virtual input function of the RPFn. The image to be processed by the RPFn is usually read from the external memory by the MAU. Instead of this input, the virtual input function generates a single-color image within the RPFn and sends it to the modules in VSPD. When the virtual input function is enabled, the fixed value specified in VI6_RPFn_VRTCOL_SET is used as the input to the RPFn. While the virtual input function is enabled, data is not read from the external memory; that is, the α plane is not read and the IROP calculation thus cannot be executed. In this case, set VI6_RPFn_ALPH_SEL.ASEL to 4. Neither the color space conversion through CSC nor the color keying described in **9.4.3.2.6 (11) RPFn Color Keying Control Registers (VI6_RPFn_CKEY_CTRL)** can be used. 0b: RPFn uses general input. 1b: RPFn uses virtual input.
27 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	CIPM	0h	RW	Horizontal Chrominance Interpolation Method Setting Image data is processed in the YCbCr444 format inside VSPD in case of YCbCr color space. When the chrominance format of the input image is YCbCr422 or YCbCr420, data is up-sampled as shown in **Figure 9.4-8** for internal processing. This bit specifies the method of up-sampling for this purpose. 0b: The nearest-neighbor method is used for horizontal chrominance interpolation. 1b: The bilinear method is used for horizontal chrominance interpolation.
15	SPYCS	0h	RW	RPF Input Mode Setting 1 When the input format is YUY2, set this bit to 1b and set the RDFMT bits to 71 (47h). When the input format is YVYU, set this bit and the SPUVS bit to 1b and set the RDFMT bits to 71 (47h). In other cases, set this bit to 0b.
14	SPUVS	0h	RW	RPF Input Mode Setting 2 When the input format is NV61, set this bit to 1b and set the RDFMT bits to 65 (41h). When the input format is NV21, set this bit to 1b and set the RDFMT bits to 66 (42h). When the input format is YVYU, set this bit and the SPYCS bit to 1b and set the RDFMT bits to 71 (47h). In other cases, set this bit to 0b.
13, 12	CEXT[1:0]	0h	RW	Lower-Bit Color Data Extension Method Setting When an RGB input format where each color component is expressed in less than 8 bits are selected from **Table 9.4-10** through the RDFMT bits, VSPD internally extends each color component to 8 bits before using the data. These bits select this extension method. 00b: Lower-order bits of color data are extended with 0. 01b: Upper-order bits of color data are copied to the lower -order bits. 10b: Lower-order bits of color data are extended with 0. The maximum value is limited to FFh. 11b: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
11 to 9	RDTM[2:0]	0h	RW	CSC Conversion Expression Setting These bits select the expression used for color space conversion. The conversion direction is RGB → YCbCr when RGB is selected through the RDFMT bits; the direction is YCbCr → RGB when YCbCr is selected. 0h: BT.601 YCbCr [16,235/240] ↔ RGB [0,255] 1h: BT.601 YCbCr [0,255] ↔ RGB [0,255] 2h: BT.709 YCbCr [16,235/240] ↔ RGB [0,255] 3h: BT.709 YCbCr [16,235/240] ↔ RGB [16,235] 4h to 7h: Setting prohibited
8	CSC	0h	RW	Color Space Conversion Enable Enables or disables color space conversion between YCbCr and RGB to be executed in RPFn. The characteristics of color space conversion are determined by the RDTM bit setting.*1 When using the virtual input (VIR = 1b), specify 0b. 0b: Color space conversion is disabled. 1b: Color space conversion is enabled.
7	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6 to 0	RDFMT[6:0]	00h	RW	RPF Input Image Format Setting These bits select the format of the image input from the external RAM to the RPFn. Select a value corresponding to the desired format from those shown in **Table 9.4-10**, **Table 9.4-11**, and **Table 9.4-12**. When the virtual input function is used (VIR = 1b), the color information for the virtual input should be specified in VI6_RPFn_VRTCOL_SET. If this color information is in the RGB format, set the RDFMT bits to 19. If the color information is in the YCbCr format, set these bits to 64. [Note] Number of input pixels When YCbCr4:2:2 is selected through the RDFMT bits, the horizontal size of the input image should be specified in 2-pixel units. When YCbCr4:2:0 is selected, the vertical and horizontal sizes should be specified in 2-pixel units. Observe these restrictions when specifying the image size in VI6_RPFn_SRC_BSIZE and VI6_RPFn_SRC_ESIZE.

Note 1. Note on color space settings

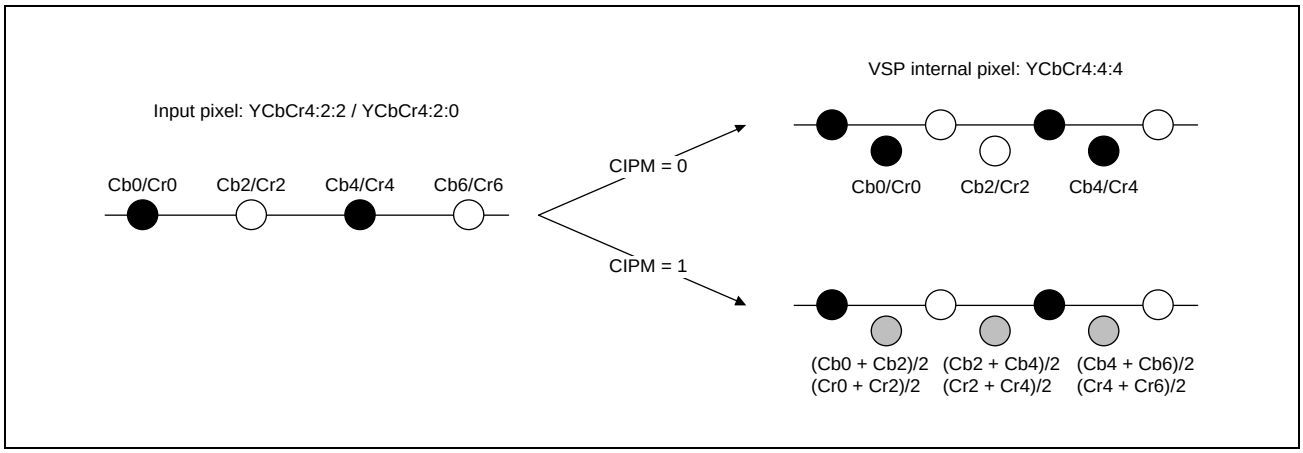

Figure 9.4-7 Chrominance Interpolation Methods Selectable through CIPM Setting

The color space for the image output from the RPF to VSPD internal modules is determined by the combination of the color space for the image input to the RPF, which is selected through the VI6_RPFn_INFMT.RDFMT setting, and the enabled or disabled state of the color space conversion function, which is selected through the VI6_RPFn_INFMT.CSC setting (**Table 9.4-10**). For example, when the image input to the RPF is in the YCbCr format, the RPF outputs data to VSPD internal modules in the YCbCr format if color space conversion is disabled through the CSC bit, and the RPF outputs data in the RGB format if color space conversion is enabled. When the image input to the RPF is in the RGB format, the relationship between the output format and the color space conversion setting is the opposite of the YCbCr case. For some VSPD internal modules, the YCbCr format is recommended for image processing because of the characteristics of the processing, or the same color space needs to be specified between multiple RPF outputs. In these

cases, set VI6_RPFn_INFMT.RDFMT and VI6_RPFn_INFMT.CSC appropriately so that the RPFs can output the required color space according to the color space conditions described above.

Table 9.4-10 RPFn Input Color Space and Output Color Space

RPFn Input Color Space (VI6_RPFn_INFMT. RDFMT)		Color Space Conversion Setting (VI6_RPFn_INFMT.CSC)		RPFn Output Color Space
RGB	(00h to 3Fh)*1	Disabled	(0)*1	RGB
		Enabled	(1)*1	YCbCr
YCbCr	(40h to 7Fh)*1	Disabled	(0)*1	YCbCr
		Enabled	(1)*1	RGB

Note 2. Value specified in the register

A color space conversion function equivalent to that in the RPFn is also provided by the WPF. As shown in **Table 9.4-10**, the color space (YCbCr or RGB) output from the RPF becomes the input format for the WPF. Here, the color space of the output image obtained by the color space conversion function of the WPF must match the color space of the format specified through VI6_WPFn_OUTFMT.WRFMT.

Figure 9.4-8 shows the relationship between the input/output format and color space. The input color space for the RPF is determined when the input image format for the RPF is specified through the RDFMT bits. The color space for the image output from the RPF to subsequent VSPD internal modules depends on the combination of the RPF input format and CSC (color space conversion function) enabled or disabled state in the RPF as shown in **Table 9.4-10** and **Figure 9.4-8**. The user should first determine whether the image processing in the VSPD is done in YCbCr or RGB, and then specify the RPF input format and CSC enabled or disabled state to obtain the desired color space. The color space of the RPF output image is also that of the WPF input image; the color space of the data output from the WPF to the outside of VSPD depends on the combination of the WPF input color space and the enabled or disabled state of the CSC implemented in the WPF as shown in **Figure 9.4-8**. The color space of the WPF output image must match that of the WPF output format (determined by VI6_WPFn_OUTFMT.WRFMT). For example, in the flow shown in **Figure 9.4-8**, YCbCr should not be specified as the WPF output format regardless of the fact that the color space of the WPF output image is in RGB format.

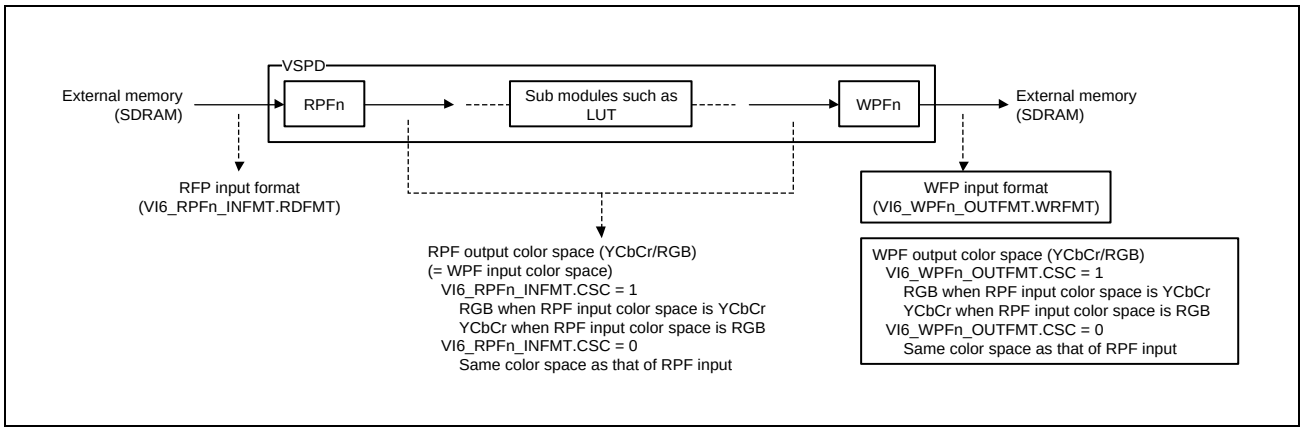

Figure 9.4-8 Relationship between Input/output Format and Color Space

7 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	P_LLS	0h	RW	Picture Plane Data Swapping in LONG LWORD Units The effect of this bit setting is defined in **Table 9.4-14**. 0b: Data swapping in LONG LWORD (64-bit) units is disabled 1b: Data swapping in LONG LWORD (64-bit) units is enabled This register is available for only Luma plane (Y) in the case input data format is YUV Planar or Semi-Planar and input bit-depth is 2bypc (IPBD_Y != 0 or IPBD_C != 0), and available for both Luma plane (Y) and Chroma plane (CbCr/U/V) in other cases.
2	P_LWS	0h	RW	Picture Plane Data Swapping in long word Units The effect of this bit setting is defined in **Table 9.4-14**. 0b: Data swapping in long word (32-bit) units is disabled 1b: Data swapping in long word (32-bit) units is enabled This register is available for only Luma plane (Y) in the case input data format is YUV Planar or Semi-Planar and input bit-depth is 2bypc (IPBD_Y != 0 or IPBD_C != 0), and available for both Luma plane (Y) and Chroma plane (CbCr/U/V) in other cases.
1	P_WDS	0h	RW	Picture Plane Data Swapping in Word Units The effect of this bit setting is defined in **Table 9.4-14**. 0b: Data swapping in Word (16-bit) units is disabled 1b: Data swapping in Word (16-bit) units is enabled This register is available for only Luma plane (Y) in the case input data format is YUV Planar or Semi-Planar and input bit-depth is 2bypc (IPBD_Y != 0 or IPBD_C != 0), and available for both Luma plane (Y) and Chroma plane (CbCr/U/V) in other cases.

Bit	Bit Name	Initial Value	R/W	Description
0	P_BTS	0h	RW	Picture Plane Data Swapping in Byte Units The effect of this bit setting is defined in **Table 9.4-14**. 0b: Data swapping in Byte (8-bit) units is disabled 1b: Data swapping in Byte (8-bit) units is enabled This register is available for only Luma plane (Y) in the case input data format is YUV Planar or Semi-Planar and input bit-depth is 2bypc (IPBD_Y != 0 or IPBD_C != 0), and available for both Luma plane (Y) and Chroma plane (CbCr/U/V) in other cases.

When the virtual input function of the RPFn is used (VI6_RPFn_INFMT.VIR = 1), this register setting is ignored. Swapping of RPF input data can be specified separately for the α plane and picture plane.

Table 9.4-14 shows the data order before and after swapping according to the long long word, long word, word, and byte swapping settings.

When data order in memory for each format is the same as **Table 9.4-11** for RGB format and **Figure 9.4-9** to **Figure 9.4-12** for YCbCr format, set 1111b to {*_LLS, *_LWS, *_WDS, *_BTS}. If data order is not the same as the definition, change data order within 16byte unit by these bits as shown in **Table 9.4-14**.

Table 9.4-14 Changing Data Order According to Swap Register

Data order in memory																				
Byte address	16n+0	16n+1	16n+2	16n+3	16n+4	16n+5	16n+6	16n+7	16n+8	16n+9	16n+10	16n+11	16n+12	16n+13	16n+14	16n+15	*_LLS	*_LWS	*_WDS	*_BTS

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	VCOORD[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	HCOORD[12:0]	0000h	RW	Horizontal Coordinate of Sublayer Display Location on Master Layer These bits specify the left-end location of the sublayer displayed by the RPFn and the subsequent module connected through the DPR. Specify the horizontal coordinate of the location in pixel units with the left-end pixel of the master layer set at coordinate 0. When the RPFn is the master layer, set these bits to 0b. If the sublayer extends beyond the master layer according to the HCOORD setting, the extended section is cut off at the right end of the master layer. Even in this case, however, a bus transfer that is unnecessary for output image generation is executed since the whole sublayer data is read from the external memory. Appropriate coordinate setting is required so that the sublayer does not extend beyond the right end of the master layer. A value from 0 to 1919 can be specified.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	VCOORD[12:0]	0000h	RW	Vertical Coordinate of Sublayer Display Location on Master Layer These bits specify the top-end location of the sublayer displayed by the RPFn and the subsequent module connected through the DPR. Specify the vertical coordinate of the location in pixel units with the top-end pixel of the master layer set at coordinate 0. When the RPFn is the master layer, set these bits to 0b. If the sublayer extends beyond the master layer according to the VCOORD setting, the extended section is cut off at the bottom end of the master layer. Even in this case, however, a bus transfer that is unnecessary for output image generation is executed since the whole sublayer data is read from the external memory. Appropriate coordinate setting is required so that the sublayer does not extend beyond the bottom end of the master layer. A value from 0 to 1919 can be specified.

Figure 9.4-13 shows an example of RPF1 offsets with respect to master layer RPF0. Although this figure only shows sublayers RPF1, specify offsets for all RPFs other than the master layer in the same way as shown in this example.

Whether an RPFn is the master layer or a sublayer is determined through the selection of the source RPF for WPFn (the VI6_WPFn_SRCRPF setting). For details, refer to **(1) WPF0-Source-RPF Register (LCDC_VSPD_VI6_WPF0_SRCRPF)**.

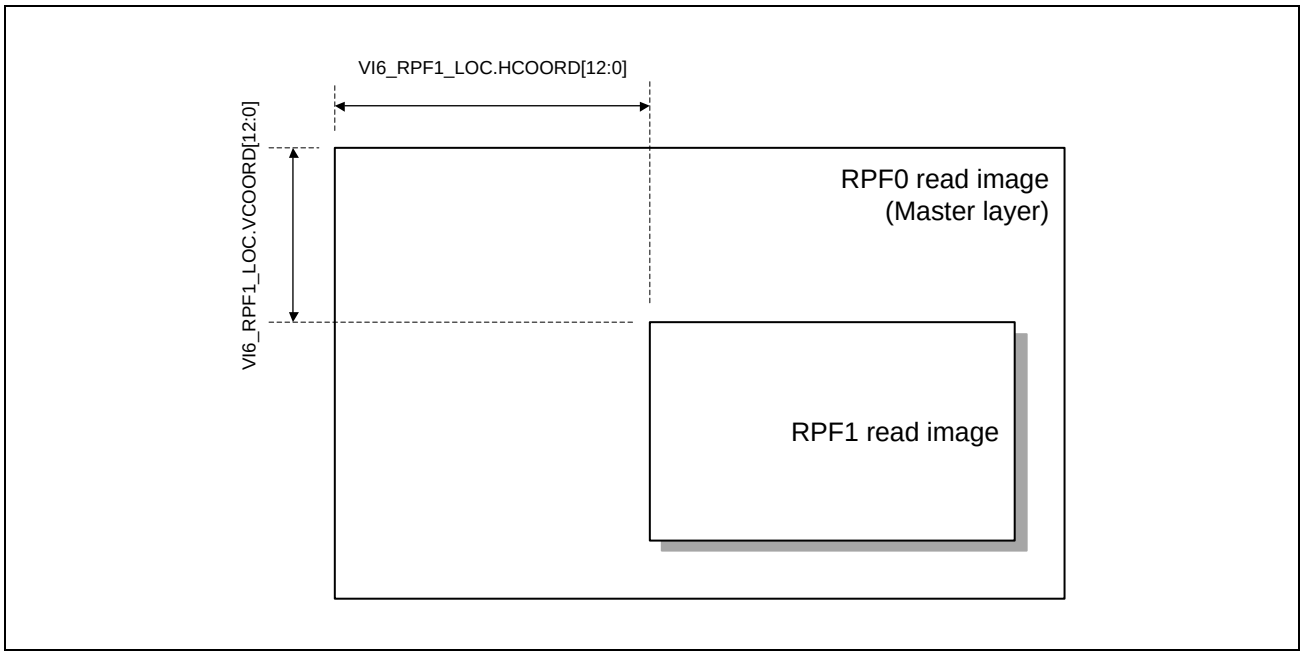

Figure 9.4-13 RPF1 Offsets from Master Layer

	ALPHA1[7:0]								ALPHA0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30 to 28	ASEL[2:0]	0h	RW	α Format and Processing Method Select These bits select how to handle the α value to be used. The RPF handles two types of α value; 8-bit and 1-bit values. When a 1-bit α value is used, VSPD assumes that the 1-bpp α value for each pixel is stored in the order from MSB to LSB in each byte (big endian). The α value is used as either transparency information or mask information. Transparency information is included in the α plane read from external memory when the ASEL bits are set to 1 or 3 and in the α value stored in the packed RGB bit field when these bits are set to 0 or 2. The α value as transparency information is sent as the destination value to the IROP as shown in **Figure 9.4-15** and then output to the subsequent modules. The output α value is used, for example, for blending in the BRS. The α value as mask information is used for IROP operation in the RPF. The mask information is included in the α plane read from external RAM when the ASEL bits are set to 0 or 2 and the source value is used in IROP operation (IROP setting other than 0, 5, 10, or 15). This α value is sent as the source value to the IROP as shown in **Figure 9.4-15**. Note that the α value selected through the ASEL bits has a lower priority than the VI6_RPFn_CKEY_SET*.AP* value replaced through the color keying function. When the color keying function is used, the α value may be replaced with the VI6_RPFn_CKEY_SET*.AP* value regardless of the ASEL bit setting. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1b), specify 4. 0h: 1, 4, or 8-bit packed α + plane α (IROP ! = 0, 5, 10, 15) The α bit field in 1, 4, or 8-bit packed α is handled as transparency information. Be sure to specify the packed format that includes α through VI6_RPFn_INFMT.RDFMT. When VI6_RPFn_MSKCTRL.MSK_EN is 0b and the IROP bit value is not 0, 5, 10, or 15, the α plane should be read as mask information. Specify the number of α data bits (BSEL) stored in the α plane and the α plane read start address (VI6_RPFn_SRCM_ADDR_AI). When the IROP bits are set to 0, 5, 10, or 15, the α plane is not read. 1h: 8-bit plane α The 8-bit α plane is read from external RAM as transparency information. When the packed RGB format has a bit field for α, the information in the α bit field is discarded. The α plane read start address (VI6_RPFn_SRCM_ADDR_AI) should be specified. The α value goes through the 8-bit transparent α generator shown in **Figure 9.4-15** without change. When VI6_RPFn_MSKCTRL.MSK_EN is 0b, IROP operation cannot be executed; set the IROP bits to 0 in this case. When VI6_RPFn_MSKCTRL.MSK_EN is 1b. IROP operation can be executed.

Bit	Bit Name	Initial Value	R/W	Description
				2h: 1-bit packed α + plane α (IROP ! = 0, 5, 10, 15) The 1-bit packed α input is converted by the 8-bit transparent α generator shown in **Figure 9.4-15** according to the ALPHA0/1 setting into the 8-bit α value as transparency information. Select the packed input format that includes a 1-bit α field. When VI6_RPFn_MSKCTRL.MSK_EN is 0b and the IROP value is not 0, 5, 10, or 15, the α plane should be read as mask information. Specify the number of α data bits (BSEL) stored in the α plane and the α plane read start address (VI6_RPFn_SRCM_ADDR_AI). When the IROP bits are set to 0, 5, 10, or 15, the α plane is not read. 3h: 1-bit plane α The 1-bit α plane is read from external RAM and converted by the 8-bit transparent α generator shown in **Figure 9.4-15**. according to the ALPHA0/1 setting into the 8-bit α value as transparency information. When the packed RGB format has a bit field for α, the information in the α bit field is discarded. The α plane read start address (VI6_RPFn_SRCM_ADDR_AI) should be specified. When VI6_RPFn_MSKCTRL.MSK_EN is 0b, IROP operation cannot be executed; set the IROP bits to 0b in this case. When VI6_RPFn_MSKCTRL.MSK_EN is 1b. IROP operation can be executed. 4h: Fixed α The fixed α value (VI6_RPFn_VRTCOL_SET.LAYA value) is output from the RPF. IROP operation cannot be executed; set the IROP bits to 0 in this case. 5 to 7: Setting prohibited.
27 to 24	IROP[3:0]	0h	RW	IROP Operation Setting These bits specify the operator to be executed in the IROP operation unit shown in **Figure 9.4-15**. The source (S) for the IROP operation is the pixel data and α data specified in the VI6_RPFn_MSKSET0 or VI6_RPFn_MSKSET1 IROP input value register, which is selected according to the value (0 or 1) generated by the 1-bit mask generator. The destination (D) is the image data (RGB/YCbCr) and 8-bit α data output from the unpack/OSD processor. IROP operation is applied both for the image data and α data between the source and destination data. If these bits are set to the operation that involves the source (S) (IROP setting other than 0, 5, 10, or 15) while VI6_RPFn_MSKCTRL.MSK_EN is 0b, the α plane is read from the external RAM to be used for the α value for IROP operation; specify the α plane read start address (VI6_RPFn_SRCM_ADDR_A). When the virtual input function is used (VI6_RPFn_INFMT.VIR = 1b), IROP operation is not available; set these bits to 0000b. 0000b: NOP(D) 0001b: AND(S & D) 0010b: AND_REVERSE(S & ~D) 0011b: COPY(S) 0100b: AND_INVERTED(~S & D) 0101b: CLEAR(0) 0110b: XOR(S ^ D) 0111b: OR(S | D) 1000b: NOR(~(S | D)) 1001b: EQUIV(~(S ^ D)) 1010b: INVERT(~D) 1011b: OR_REVERSE(S | ~D) 1100b: COPY_INVERTED(~S) 1101b: OR_INVERTED(~S | D) 1110b: NAND(~(S & D)) 1111b: SET(all 1)
23	BSEL	0h	RW	α Bit Count Conversion Selection for 1-Bit Mask Generator Specifies the number of bits in the α plane to be read as mask information from the external RAM. The α value in mask information is used for the source (S) in IROP. When α plane data is 8 bits, it is converted to one bit through the 1-bit mask generator shown in **Figure 9.4-15**. Note that this bit setting is valid when the ASEL bits are set to 0 or 2 and VI6_RPFn_MSKCTRL.MSK_EN is set to 0b. In other cases, this bit setting has no effect. 0b: 8-bit α is converted to 1-bit α through the 1-bit mask generator. When the 8-bit α value input to the RPF is not 0, it is converted to 1b; when the value is 0, it is converted to 0b. 1b: α value goes through the 1-bit mask generator. The 1-bit α value input to the RPF is output through the 1-bit mask generator without change.
22 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
19, 18	AEXT[1:0]	0h	RW	Lower-Bit α Value Extension Method Set These bits specify the method for extending the input α data to 8 bits through the unpack processing. 00b: The lower-order bits of α value are extended with 0. 01b: The upper-order bits of α value are copied to the lower-order bits. 10b: The lower-order bits of α value are extended with 0. The maximum value is limited to FFh. 11b: Setting prohibited
17, 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 8	ALPHA1[7:0]	00h	RW	8-Bit α Value Output when 1-Bit α Value is 1 These bits specify the 8-bit α value to be output when 1-bit α data is input and the α value input to the 8-bit transparent α generator shown in **Figure 9.4-15** is 1b. This setting is valid when the ASEL bits are set to 010b or 011b. A value from 0 to 255 can be specified.
7 to 0	ALPHA0[7:0]	00h	RW	8-Bit α Value Output when 1-Bit α Value is 0 These bits specify the 8-bit α value to be output when 1-bit α data is input and the α value input to the 8-bit transparent α generator shown in **Figure 9.4-15** is 0b. This setting is valid when the ASEL bits are set to 010b or 011b. A value from 0 to 255 can be specified.

Figure 9.4-14 shows the relationship between the α selector, IROP operation unit, color keying unit, and related registers. The IROP operation unit receives two inputs, source and destination. The image data input from the external memory is processed through the unpack processor and 8-bit transparent α generator and then input to the IROP operation unit as destination data. The α plane data input from the external memory is sent to the 8-bit transparent α generator when the ASEL bits are set to 1 or 3, or sent to the 1-bit mask α generator when the ASEL bits are set to 0 or 2. For the pixel data and 8-bit α value on the source side of the IROP operation unit, either the VI6_RPFn_MSKSET0 value or VI6_RPFn_MSKSET1 values will be selected according to the 1-bit α value output by the 1-bit mask α generator.

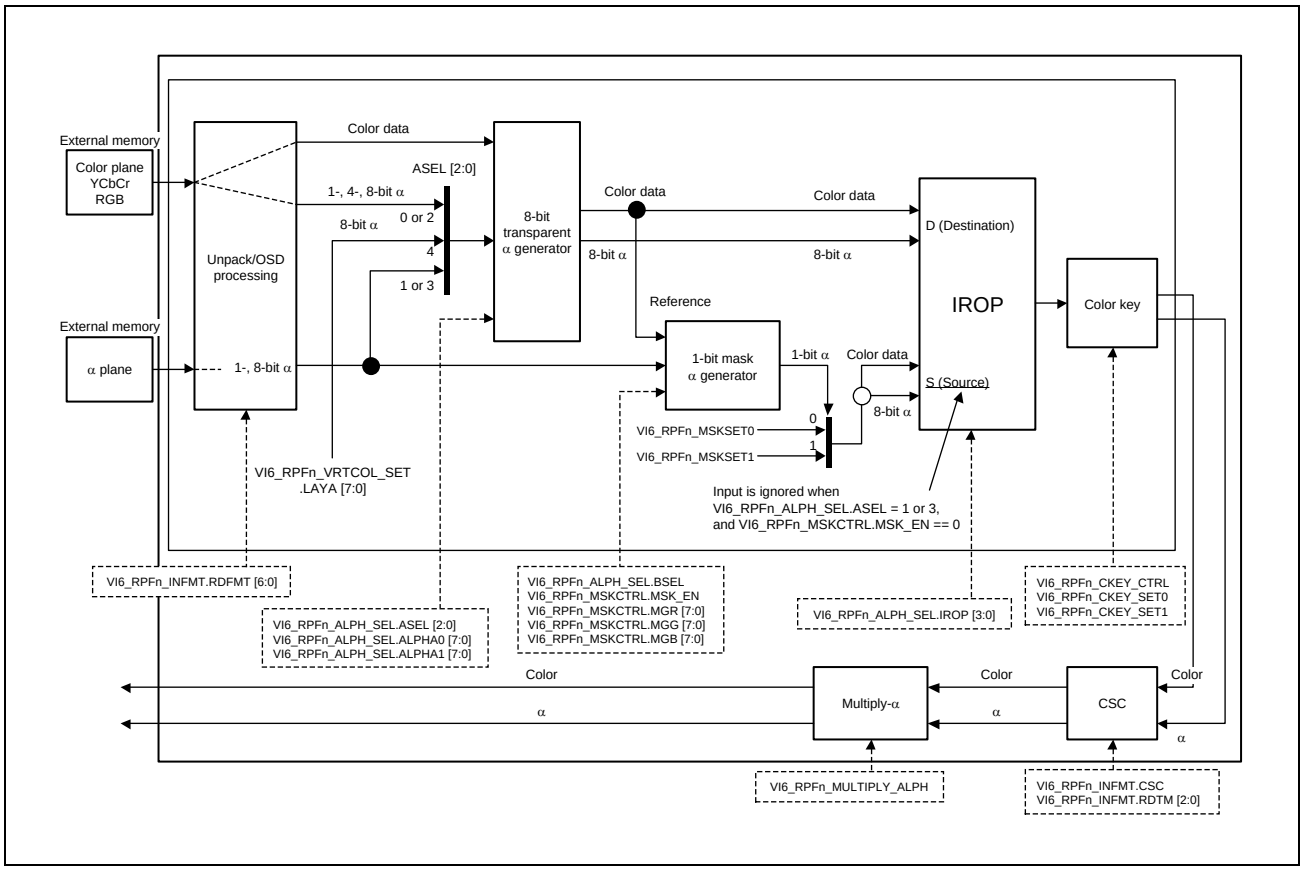

Figure 9.4-14 Configuration of alpha Selector and IROP Operation Unit in RPF

The following describes the function of each block shown in **Figure 9.4-14**. Read the following while referring to the figure as necessary.

Unpack/OSD processor:

Unpacks each component and α value of the image data according to the packed format specified in VI6_RPFn_INFMT.RDFMT.

8-bit transparent α generator:

Converts the input α value into 8-bit α when the input α is four bits or one bit.

When VI6_RPFn_ALPH_SEL.ASEL are set to 0 (8-, 4-, or 1-bit packed α), this generator outputs the input α value without change if the α bit field in the packed α data is 8 bits; if the α bit field is less than 8 bits, it is converted to an 8-bit α value by extending the LSB side according to the VI6_RPFn_ALPH_SEL.AEXT setting.

When VI6_RPFn_ALPH_SEL.ASEL are set to 1 (8-bit plane α) or 4 (fixed α), this generator outputs the input 8-bit plane α without change. If a packed α value is included in RGB data, it is discarded.

When VI6_RPFn_ALPH_SEL.ASEL are set to 2 (1-bit packed α) or 3 (8-bit α generated from 1-bit plane α), an 8-bit α value is generated by using the VI6_RPFn_ALPH_SEL.ALPHA0 [7:0] value when the input 1-bit α value is 0 or by using the VI6_RPFn_ALPH_SEL.ALPHA1 [7:0] value when the input 1-bit α value is 1. When VI6_RPFn_ALPH_SEL.ASEL is set to 3, a packed α value that is included in RGB data is discarded.

1-bit mask α generator:

Generates 1-bit α data from the input 8-bit α data or pixel data. When the input α data is one bit, this generator outputs it without change.

When VI6_RPFn_ALPH_SEL.ASEL are set to 0 (8-, 4-, or 1-bit packed α) or 2 (plane α) and VI6_RPFn_MSKCTRL.MSK_EN is set to 0, the α plane read from the external memory to be used in IROP is converted to 1-bit α data when necessary. When the α plane data read from the external RAM is 8 bits (BSEL = 0), if the value is 0, a 1-bit α value of 0b is generated; if the value is not 0, a 1-bit α value of 1b is generated. When the α plane data is one bit (BSEL = 1), this generator outputs it without change.

When the value of the 1-bit α generated by the 1-bit mask α generator is 0b, the 8-bit α and pixel data specified in VI6_RPFn_MSKSET0 are output as the source. When the generated 1-bit α value is 1b, the 8-bit α and pixel data specified in VI6_RPFn_MSKSET1 are output as the source.

As shown in **Figure 9.4-14**, when VI6_RPFn_ALPH_SEL.ASEL are set to 1 (8-bit plane α) or 3 (1-bit plane α), the α plane read from the external RAM is sent to the 8-bit transparent α generator as transparency information. When VI6_RPFn_MSKCTRL.MSK_EN is set to 0, the 1-bit α for masking is generated according to the input α plane (refer to **(8) RPFn Mask Control Registers (LCDC_VSPD_VI6_RPFn_MSKCTRL)**), but the 1-bit mask α generator does not refer to the input α plane because it is input to the 8-bit transparent α generator as transparency information. Accordingly, the 1-bit mask α generator does not generate a 1-bit α for masking and the data on the source side becomes invalid; that is, IROP operation cannot be executed. Set the IROP bits to 0 in this case. In contrast, when VI6_RPFn_MSKCTRL.MSK_EN is set to 1, the 1-bit mask α generator creates α data for masking according to the pixel data instead of the input α plane data, and IROP operation can be executed in this case.

IROP operation unit:

Executes ROP operation according to the opcode specified in VI6_RPFn_ALPH_SEL.IROP. For ROP operation (other than NOP), valid values should be input both for the source and destination. As described in the above (description of the 1-bit mask α generator), when VI6_RPFn_ALPH_SEL.ASEL are set to 1 or 3 and VI6_RPFn_MSKCTRL.MSK_EN is set to 0, the source data for the IROP operation unit is treated as invalid; set VI6_RPFn_ALPH_SEL.IROP to 0 (NOP). When VI6_RPFn_ALPH_SEL.ASEL are set to 4, a fixed α value is output from the RPF and IROP operation is not available. In the same way as the above case, set VI6_RPFn_ALPH_SEL.IROP to 0 (NOP).

To specify a valid source value for the IROP operation unit and execute IROP operation (specify an opcode other than NOP in the IROP bits), specify register values as shown in **Table 9.4-15**. Where the source input state is indicated as “Valid” in the table, IROP operation can be executed. In the cases where IROP operation is not available, set the IROP bits to 0 (NOP).

Table 9.4-15 Source Input State in IROP Operation Unit

VI6_RPFn_ALPH_SEL.ASEL[2:0]		VI6_RPFn_MSKCTRL.MSK_EN		
		0 (Source data is generated according to input α plane)		1 (Source data is generated according to the destination-side pixel data)
000b	(1-, 4-, or 8-bit packed α + plane α)	Valid	(α plane input)	Valid
001b	(8-bit α plane)	Invalid	(IROP operation is not available; α plane is output to the subsequent modules behind RPF)	Valid
010b	(8-bit α generated from 1-bit packed α + plane α)	Valid	(α plane input)	Valid
011b	(8-bit α generated from 1-bit plane α)	Invalid	(IROP operation is not available; α plane is output to the subsequent modules behind RPF)	Valid
100b	(Fixed α)	Invalid (IROP operation is not available; fixed α is output to the subsequent modules behind RPF)		

For the handling of the α values shown in **Figure 9.4-14** and **Table 9.4-15**, the relationship between the RPF input format and RPF output α value is shown in **Table 9.4-16**. Where only bit names are shown in the table, the bits are in VI6_RPFn_ALPH_SEL described in this section.

Table 9.4-16 α Value Selected and Output according to ASEL Bits in Each Input Format

ASEL Setting		α Value Output for Each Input Format	
		RGB	YCbCr
000b	(8-, 4-, or 1-bit packed α is input)	1-, 4-, or 8-bit pixel α	FFh*1
001b	(8-bit plane α is input)	8-bit α plane	8-bit α plane
010b	(8-bit α is generated from the 1-bit packed α input)	ALPHA0 or ALPHA1 setting	FFh*1
011b	(8-bit α is generated from the 1-bit plane α input)	ALPHA0 or ALPHA1 setting	ALPHA0 or ALPHA1 setting
100b	(Fixed α is output)	VI6_RPFn_VRTCOL_SET.LAYA setting	

Note 1. Fixed value FFh is output because packed α is not included in YCbCr.

(7) RPFn Virtual Plane Color Information Registers (LCDC_VSPD_VI6_RPFn_VRTCOL_SET) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0318h (n = 0)
<LCDC_vspd_base> + 0418h (n = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	LAYA[7:0]	00h	RW	Virtual-Input Fixed α Value These bits specify the fixed α value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When the virtual input function is disabled (VI6_RPFn_INFMT.VIR = 0b), these bits are used to specify the fixed α value to be output from the RPF while VI6_RPFn_ALPH_SEL.ASEL are set to 4. A value from 0 to 255 can be specified.
23 to 16	LAYR[7:0]	00h	RW	Virtual-Input Fixed R/Cr Component Value These bits specify the fixed R or Cr value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When VI6_RPFn_INFMT.RDFMT is set to 19, the value specified in these bits is used as the R value. When VI6_RPFn_INFMT.RDFMT is set to 64, the value specified in these bits is used as the Cr value. A value from 0 to 255 can be specified.
15 to 8	LAYG[7:0]	00h	RW	Virtual-Input Fixed G/Y Component Value These bits specify the fixed G or Y value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When VI6_RPFn_INFMT.RDFMT is set to 19, the value specified in these bits is used as the G value. When VI6_RPFn_INFMT.RDFMT is set to 64, the value specified in these bits is used as the Y value. A value from 0 to 255 can be specified.
7 to 0	LAYB[7:0]	00h	RW	Virtual-Input Fixed B/Cb Component Value These bits specify the fixed B or Cb value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When VI6_RPFn_INFMT.RDFMT is set to 19, the value specified in these bits is used as the B value. When VI6_RPFn_INFMT.RDFMT is set to 64, the value specified in these bits is used as the Cb value. A value from 0 to 255 can be specified.

(8) RPFn Mask Control Registers (LCDC_VSPD_VI6_RPFn_MSKCTRL) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 031Ch (n = 0)
<LCDC_vspd_base> + 041Ch (n = 1)

Initial Value : 0000_0000h

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
24	MSK_EN	0h	RW	Mask Generation Specification Specifies the method of α value generation in the 1-bit mask α generator shown in **Figure 9.4-15**. 0b: A 1-bit mask value is generated according to the input α plane value. When the input α is in the 1-bit format (VI6_RPFn_ALPH_SEL.BSEL = 1b), the 1-bit mask value is output without change. When the input α is in the 8-bit format (VI6_RPFn_ALPH_SEL.BSEL = 0b), the 1-bit mask value is 0 if the α value is 00h; otherwise, the 1-bit mask value is 1. 1b: The R/Cr, G/Y, and B/Cb components of the image input to the destination side of the IROP operation unit are compared with the values specified in the MGR, MGG, and MGB bits, respectively. When all values match, 1 is output as the 1-bit mask value, and in other cases, 0 is output. When the generated 1-bit mask data is not used, set VI6_RPFn_ALPH_SEL.IROP to 0b.
23 to 16	MGR[7:0]	00h	RW	R/Cr Comparison Value for 1-Bit α Generation These bits specify the R/Cr value to be compared for 1-bit α generation by using the pixel data on the destination side. When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify an R value for comparison. When YCbCr is specified, specify a Cr value for comparison. This setting is ignored when the MSK_EN bit is set 0b. A value from 0 to 255 can be specified.
15 to 8	MGG[7:0]	00h	RW	G/Y Comparison Value for 1-Bit α Generation These bits specify the G/Y value to be compared for 1-bit α generation by using the pixel data on the destination side. When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a G value for comparison. When YCbCr is specified, specify a Y value for comparison. This setting is ignored when MSK_EN is set to 0b. A value from 0 to 255 can be specified.
7 to 0	MGB[7:0]	00h	RW	B/Cb Comparison Value for 1-Bit α Generation These bits specify the B/Cb value to be compared for 1-bit α generation by using the pixel data on the destination side. When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a B value for comparison. When YCbCr is specified, specify a Cb value for comparison. This setting is ignored when MSK_EN is set to 0b. A value from 0 to 255 can be specified.

(9) RPFn IROP-SRC Input Value Registers 0 (LCDC_VSPD_VI6_RPFn_MSKSET0) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0320h (n = 0)
<LCDC_vspd_base> + 0420h (n = 1)

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	MSA0[7:0]	00h	RW	IROP-Source Input α Value when 1-Bit α is 0 These bits specify the 8-bit α value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (**Figure 9.4-15**). A value from 0 to 255 can be specified.
23 to 16	MSR0[7:0]	00h	RW	IROP-Source Input R/Cr Value when 1-Bit α is 0 These bits specify the R/Cr value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (**Figure 9.4-15**). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify an R component value. When YCbCr is specified, specify a Cr component value. A value from 0 to 255 can be specified.
15 to 8	MSG0[7:0]	00h	RW	IROP-Source Input G/Y Value when 1-Bit α is 0 These bits specify the G/Y value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (**Figure 9.4-15**). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a G component value. When YCbCr is specified, specify a Y component value. A value from 0 to 255 can be specified.
7 to 0	MSB0[7:0]	00h	RW	IROP-Source Input B/Cb Value when 1-Bit α is 0 These bits specify the B/Cb value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (**Figure 9.4-15**). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a B component value. When YCbCr is specified, specify a Cb component value. A value from 0 to 255 can be specified.

(10) RPFn IROP-SRC Input Value Registers 1 (LCDC_VSPD_VI6_RPFn_MSKSET1) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0324h (n = 0)
<LCDC_vspd_base> + 0424h (n = 1)

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	MSA1[7:0]	00h	RW	IROP-Source Input α Value when 1-Bit α is 1 These bits specify the 8-bit α value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1. A value from 0 to 255 can be specified **(Figure 9.4-15)**.
23 to 16	MSR1[7:0]	00h	RW	IROP-Source Input R/Cr Value when 1-Bit α is 1 These bits specify the R/Cr value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (**Figure 9.4-15**). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify an R component value. When YCbCr is specified, specify a Cr component value. A value from 0 to 255 can be specified.
15 to 8	MSG1[7:0]	00h	RW	IROP-Source Input G/Y Value when 1-Bit α is 1 These bits specify the G/Y value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (**Figure 9.4-15**). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a G component value. When YCbCr is specified, specify a Y component value. A value from 0 to 255 can be specified.
7 to 0	MSB1[7:0]	00h	RW	IROP-Source Input B/Cb Value when 1-Bit α is 1 These bits specify the B/Cb value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (**Figure 9.4-15**). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a B component value. When YCbCr is specified, specify a Cb component value. A value from 0 to 255 can be specified.

(11) RPFn Color Keying Control Registers (LCDC_VSPD_VI6_RPFn_CKEY_CTRL) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0328h (n = 0)
<LCDC_vspd_base> + 0428h (n = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	LTH	0h	RW	Transparent color-luma Threshold Mode Enable/Disable This bit enables or disables transparent color-luma threshold mode for the color keying module. In transparent color-luma threshold mode, color information 0 (GY0) specified in VI6_RPFn_CKEY_SET0 register is compared with the input luma values. When the input data is in YCbCr format, and if input Y value is equal to or smaller than specified color information (VI6_RPFn_CKEY_SET0.GY0), the input α value is replaced with the value specified in VI6_RPFn_CKEY_SET0.AP0. This bit is available only when the input data is in YCbCr format. When the input data is in an RGB format, set this bit to 0b. This bit setting is valid only when the CV bit is set to 0b; it is ignored when the CV bit is set to 1b. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1b), set this bit to 0b. 0b: Luma threshold mode is disabled (Matched color mode) 1b: Luma threshold mode is enabled
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	CV	0h	RW	Color Replacement Control This bit controls the color replacement function in the color keying module shown in **Figure 9.4-3**. When an RGB format is specified as the color space of the RPFn input data through VI6_RPFn_INFMT.RDFMT, and if all components of an input pixel match the color components specified in VI6_RPFn_CKEY_SET0, the color replacement function replaces the values of the input α and all RGB components with the α and color components specified in VI6_RPFn_CKEY_SET1. When a YCbCr format is specified as the color space of the RPFn input data through VI6_RPFn_INFMT.RDFMT, only the Y data is compared; if the luminance component of an input pixel matches the value specified in VI6_RPFn_CKEY_SET0.GY0, the color replacement function replaces the values of the input α and all YCbCr components with the α and color components specified in VI6_RPFn_CKEY_SET1. When the CV bit is set to 1, the color replacement function is enabled. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), set this bit to 0. 0b: Color replacement function is disabled (transparent color mode). 1b: Color replacement function is enabled.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
1	SAPE1	0h	RW	Comparison Color Data Setting 1 Enable/Disable This bit enables or disables comparison color data setting 1 in the transparent color mode for the color keying module. This bit setting is valid only when the CV bit is set to 0; it is ignored when the CV bit is set to 1. In transparent color mode, color information 1 (VI6_RPFn_CKEY_SET1.R1/GY1/B1) specified in VI6_RPFn_CKEY_SET1 is compared with the input component values. When the input data is in an RGB format, and if all input values match the specified color information, the input α value is replaced with the value specified in VI6_RPFn_CKEY_SET1.AP. When the input data is in YCbCr format, only the Y data is compared. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), set this bit to 0. 0b: Comparison color data setting 1 is disabled. 1b: Comparison color data setting 1 is enabled.
0	SAPE0	0h	RW	Comparison Color Data Setting 0 Enable/Disable This bit enables or disables comparison color data setting 0 in the transparent color mode for the color keying module. This bit setting is valid only when the CV bit is set to 0b; it is ignored when the CV bit is set to 1b. In transparent color mode, color information 0 (VI6_RPFn_CKEY_SET0.R0/GY0/B0) specified in VI6_RPFn_CKEY_SET0 is compared with the input component values. When the input data is in an RGB format, and if all input values match the specified color information, the input α value is replaced with the value specified in VI6_RPFn_CKEY_SET0.AP. When the input data is in YCbCr format, only the Y data is compared. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1b), clear this bit to 0b. 0b: Comparison color data setting 0 is disabled. 1b: Comparison color data setting 0 is enabled.

(12) RPFn Color Keying Color Setting Registers-m (LCDC_VSPD_VI6_RPFn_CKEY_SETm) (n = 0, 1) (m = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 032Ch + m x 0004h (n = 0)
<LCDC_vspd_base> + 042Ch + m x 0004h (n = 1)

Initial Value : 0000_0000h

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	AP0[7:0]	00h	RW	α Data in Color Keying Color Information-1 - In transparent color-matched color mode for color keying When the input data matches color setting-0 (R0, GY0, and B0) for transparent color comparison in the color keying module, the input α value is replaced with the value specified in these bits. Specify the α value to replace the input value. - In transparent color-luma threshold mode for color keying When the input data is in YCbCr format, and if input Y value is equal to or smaller than GY0, the input α value is replaced with the value specified in this bit field (AP0). Specify the α value in this bit field (AP0) to replace the input value. - In color replacement mode for color keying These bits are not used in this mode. Clear them to 0. α value replacement through these bits in transparent color mode for color keying takes priority over the α value selected through the VI6_RPFn_ALPH_SEL.ASEL setting. A value from 0 to 255 can be specified.
23 to 16	R0[7:0]	00h	RW	R*[1]/Cr Component Data in Color Keying Color Information-1 - In transparent color-matched color mode for color keying Specify the R component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE0 setting. When the RPFn input is in YCbCr format, the color keying module does not compare the Cr component, and the setting of these bits is ignored. - In transparent color-luma threshold mode for color keying The color keying module does not refer this bit field, and the setting of these bits is ignored. - In color replacement mode for color keying Specify the R component value to be compared with the input data in the color replacement function of the color keying module. A value from 0 to 255 can be specified.
15 to 8	GY0[7:0]	00h	RW	G*[1]/Y Component Data in Color Keying Color Information-1 - In transparent color-matched color mode for color keying Specify the G/Y component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE0 setting. - In transparent color-luma threshold mode for color keying Specify the Y component value in the GY0 to be compared. - In color replacement mode for color keying Specify the G/Y component value to be compared with the input data in the color replacement function of the color keying module. A value from 0 to 255 can be specified.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	B0[7:0]	00h	RW	B*[1]/Cb Component Data in Color Keying Color Information-1 - In transparent color-matched color mode for color keying Specify the B component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE0 setting. When the RPFn input is in YCbCr format, the color keying module does not compare the Cb component, and the setting of these bits is ignored. - In transparent color-luma threshold mode for color keying The color keying module does not refer this bit field, and the setting of these bits is ignored. - In color replacement mode for color keying Specify the B component value to be compared with the input data in the color replacement function of the color keying module. A value from 0 to 255 can be specified.

Note 1. When comparison data is specified in an RGB format, if a packed format is selected for RGB input and each of the RGB components is not 8 bits, the lower-order bits of input data are extended as specified through VI6_RPFn_INFMT.CEXT before comparison. The RGB components to be compared with the input should also be extended in the same way and the extended values should be specified in this register.

(13) RPFn Source Picture Memory Stride Setting Registers (LCDC_VSPD_VI6_RPFn_SRCM_PSTRIDE) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 0334h (n = 0)
<LCDC_vspd_base> + 0434h (n = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PICT_STRD_Y [15:0]	0000h	RW	Memory Stride of Source Picture Y/RGB Plane These bits specify in 1-byte units the memory stride of the source picture Y/RGB plane read by the RPFn. A value from 0 to 65535 can be specified. Refer to **Figure 9.4-16** for settings.
15 to 0	PICT_STRD_C [15:0]	0000h	RW	Memory Stride of Source Picture C Plane These bits specify in 1-byte units the memory stride of the source picture C plane read by the RPFn. When an RGB-format picture is read, these bits do not need to be set. A value from 0 to 65535 can be specified. Refer to **Figure 9.4-16** for settings. In the YCbCr planar format, this setting is used as the memory stride of the Cb and Cr planes.

This register specifies the memory stride of the picture planes in the source area as shown in **Figure 9.4-15**. The memory stride of the α plane should be specified through VI6_RPFn_SRCM_ASTRIDE.ALPH_STRD. When the RPF input is in an RGB format, only the RGB plane is read; when the input is in YCbCr format, the Y and C planes are read as shown in **Figure 9.4-15**. When the α plane is used, the α plane is also read. According to the image format and the necessity of the α plane, specify the necessary addresses where the source image is stored (VI6_RPFn_SRCM_ADDR_Y, VI6_RPFn_SRCM_ADDR_C, and VI6_RPFn_SRCM_ADDR_AI).

Whether the α plane needs to be read is determined according to the α plane selection method and IROP operation type. For details, refer to **(6) RPFn α Plane Selection Control Registers (LCDC_VSPD_VI6_RPFn_ALPH_SEL)**.

9.4.3.2.7 WPF Control Registers

(1) WPF0-Source-RPF Register (LCDC_VSPD_VI6_WPF0_SRCRPF)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 1000h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	VIR_ACT2[1:0]		-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	RPF1_ACT [1:0]		RPF0_ACT [1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25, 24	VIR_ACT2[1:0]	0h	RW	Virtual RPF Start Enable in BRS These bits enable start of the virtual RPF in the BRS as the source RPF for the WPF0 when the WPF0 is started. For details of the virtual RPF, refer to the following. **9.4.3.2.10 (1) BRS Input Control Register (VI6_BRS_INCTRL)** **9.4.3.2.10 (2) Size Register of BRS Input Virtual RPF (VI6_BRS_VIRRPF_SIZE)** **9.4.3.2.10 (3) Display Location Register of BRS Input Virtual RPF (VI6_BRS_VIRRPF_LOC)** **9.4.3.2.10 (4) Color Information Register of BRS Input Virtual RPF (VI6_BRS_VIRRPF_COL)** Note that the virtual RPF is in the BRS as shown in **Figure 9.4-29** and there are no register bits for DPR setting related to the virtual RPF. 0h: The virtual RPF in the BRS is not started. 1h: The virtual RPF in the BRS is started as a sublayer source RPF for the WPF0. 2h: The virtual RPF in the BRS is started as the master-layer source RPF for the WPF0. 3h: Setting prohibited
23 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3, 2	RPF1_ACT[1:0]	0h	RW	RPF1 Start Enable These bits enable start of RPF1 as the source RPF for the WPF0 when the WPF0 is started. When RPF1 is not started by the WPF0, set the VI6_DPR_RPF1_ROUTE.RT_RPF1 bits to 63. 0h: RPF1 is not started. 1h: RPF1 is started as a sublayer source RPF for the WPF0. 2h: RPF1 is started as the master-layer source RPF for the WPF0. 3h: Setting prohibited
1, 0	RPF0_ACT[1:0]	0h	RW	RPF0 Start Enable These bits enable start of RPFn as the source RPF for the WPF0 when the WPF0 is started. When RPF0 is not started by the WPF0, set the VI6_DPR_RPF0_ROUTE.RT_RPF0 bits to 63. 0h: RPF0 is not started. 1h: RPF0 is started as a sublayer source RPF for the WPF0. 2h: RPF0 is started as the master-layer source RPF for the WPF0. 3h: Setting prohibited

When the WPFn is started through the VSPD start register n (VI6_CMDn: n = 0), the RPF and virtual RPF in the BRS specified as the source RPF in this register are also started to supply data to the VSPD internal modules.

Note the following when specifying the source RPF.

(1) When blending or ROP operation is applied to multiple images through the BRS, multiple source RPFs are necessary for one WPF. When multiple source RPFs are used, images should be classified into a master layer and sublayers; assign one of the source RPFs as the master-layer source RPF and other RPFs as sublayer source RPFs. Do not assign all RPFs as sublayer source RPFs (VI6_WPF1_SRCRPF = 00000005h) or two or more RPFs as the master-layer source RPF (VI6_WPF0_SRCRPF = 0000000Ah) (such settings are prohibited).

(2) When the BRS is not used, there should be only one source RPF for one WPF. In this case, the source RPF should be assigned as the master-layer source RPF.

(2) WPF0 Horizontal Input Size Clipping Register (LCDC_VSPD_VI6_WPF0_HSZCLIP)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 1004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	HCEN	-	-	-	-	HCL_OFST[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	HCL_SIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	HCEN	0h	RW	Horizontal Size Clipping Enable/Disable Enables or disables clipping of the horizontal size of the WPF0 input image. 0b: Horizontal size clipping is disabled 1b: Horizontal size clipping is enabled
27 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 16	HCL_OFST[7:0]	00h	RW	Horizontal Size Clipping Offset Value Setting These bits specify the offset size (pixels) from the left end of the image in horizontal size clipping when the HCEN bit is 1b (**Figure 9.4-17**). The left side of the image input to the WPF is cut off for the size specified in these bits. When the HCEN bit is 0b, this setting is ignored. A value from 0 to 255 can be specified. (HCL_OFST + HCL_SIZE) should not exceed the horizontal size of the WPF input. If the setting shown in the bottom example in **Figure 9.4-17** is made, VSPD does not operate correctly.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	HCL_SIZE [12:0]	0000h	RW	Horizontal Clipping Size Setting When the HCEN bit is 1b, these bits specify the clipping size for horizontal clipping processing. Through this processing, the area of the horizontal size specified through the HCL_SIZE bits starting from the offset position specified through the HCL_OFST bits is determined as the valid image area. Accordingly, the right-side pixels beyond the (HCL_OFST + HCL_SIZE) size in the WPF0 input image are discarded. When the HCEN bit is 0b, this setting is ignored. A value from 1 to 1920 can be specified. (HCL_OFST + HCL_SIZE) should not exceed the horizontal size of the WPF input. If the setting shown in the bottom example in **Figure 9.4-17** is made, VSPD does not operate correctly. When the WPF0 output format is YCbCr4:2:2 or YCbCr4:2:0, specify an even value in these bits.

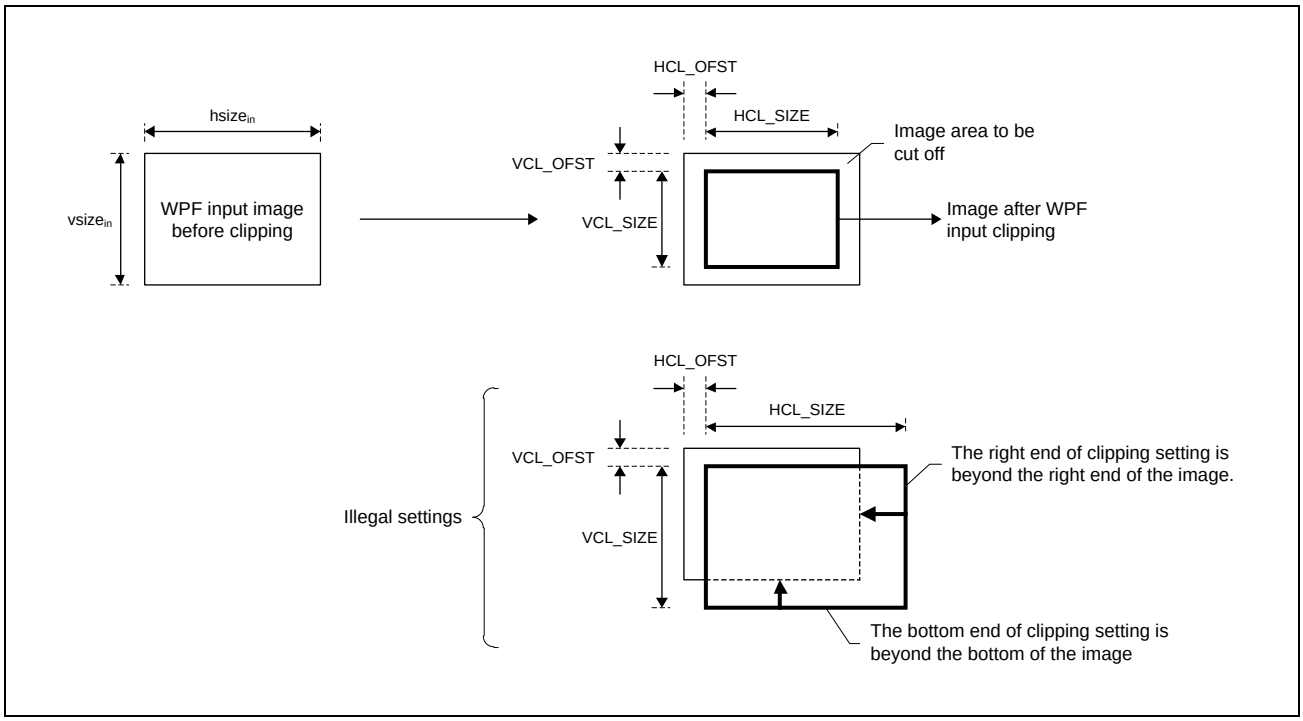

Figure 9.4-16 Image Clipping in WPF Input Section

(3) WPF0 Vertical Input Size Clipping Register (LCDC_VSPD_VI6_WPF0_VSZCLIP)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 1008h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	VCEN	-	-	-	-	VCL_OFST[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	VCL_SIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	VCEN	0h	RW	Vertical Size Clipping Enable/Disable Enables or disables clipping of the vertical size of the WPF0 input image. 0b: Vertical size clipping is disabled 1b: Vertical size clipping is enabled
27 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 16	VCL_OFST [7:0]	00h	RW	Vertical Size Clipping Offset Value Setting These bits specify the offset size (pixels) from the top end of the image in vertical size clipping when the VCEN bit is 1 (**Figure 9.4-17**). The top of the image input to the WPF is cut off for the size specified in these bits. When the VCEN bit is 0b, this setting is ignored. A value from 0 to 255 can be specified. (VCL_OFST + VCL_SIZE) should not exceed the vertical size of the WPF input. If the setting shown in the bottom example in **Figure 9.4-17** is made, VSPD does not operate correctly.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	VCL_SIZE [12:0]	0000h	RW	Vertical Clipping Size Setting When the VCEN bit is 1b, these bits specify the clipping size for vertical clipping processing. Through this processing, the area of the vertical size specified through the VCL_SIZE bits starting from the offset position specified through the VCL_OFST bits is determined as the valid image area. Accordingly, the bottom pixels beyond the (VCL_OFST + VCL_SIZE) size in the WPF0 input image are discarded. When the VCEN bit is 0b, this setting is ignored. A value from 1 to 1920 can be specified. (VCL_OFST + VCL_SIZE) should not exceed the vertical size of the WPF input. If the setting shown in the bottom example in **Figure 9.4-17** is made, VSPD does not operate correctly. When the WPF0 output format is YCbCr4:2:0, specify an even value in these bits.

(4) WPF0 Output Format Register (LCDC_VSPD_VI6_WPF0_OUTFMT)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 100Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PDV [7:0]								PXA	ODE	-	-	-	ROT[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPYCS	SPUVS	DITH[1:0]		WRTM[2:0]			CSC	-	WRFMT[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PDV [7:0]	00h	RW	PAD Value in Output Packed Data These bits specify the value to be stored in the bit field indicated as PAD or P in the output formats shown in **Table 9.4-18**. To store this value in PAD, specify 0 in the PXA bit. A value from 0 to 255 can be specified.
23	PXA	0h	RW	PAD Data Select Selects the value to be stored in the bit field indicated as PAD or P in the packed RGB output formats shown in **Table 9.4-19**. Both the value specified in the PDV bits and the α data input from the DPR to WPF are 8 bits, but some of the PAD and P bit fields shown in **Table 9.4-18** are four bits or one bit. When the target bit field is not 8 bits, the number of bits in the PDV value and the α data input from the DPR to WPF is reduced according to the VI6_WPF0_RNDCTRL.ABRM setting. For bit count reduction, refer to **Figure 9.4-18** and the description of VI6_WPF0_RNDCTRL.ABRM. 0b: The value specified in the PDV bits is stored in the PAD shown in **Table 9.4-18**. 1b: The α value output from DPR in pixel units is stored in the PAD shown in **Table 9.4-18**.
22	ODE	0h	RW	Ordered Dither (mode A) Enable/Disable 0b: Ordered dither (mode A) is disabled. 1b: Ordered dither (mode A) is enabled. When the output format specified through the WRFMT bits is YCbCr, specify 0b in this bit. And when VI6_WPF0_OUTFMT.CSC is set to 1b, specify 0b in this bit even in the case that the output format specified through the WRFMT bits is RGB. Ordered dither is available only for 18bpp. So, when ODE bit is equal to 1b, set WRFMT at 18bpp format. When ODE bit is equal to 0, WPF dither method is specified by DITH[1:0] in the register Ordered dither (mode A) is recommended rather than ordered dither (mode B) in case of 18bpp.
21 to 19	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18 to 16	ROT[2:0]	0h	RW	Rotation Processing Select These bits select the flipping processing to be applied to the WPF0 output image. **Figure 9.4-19** shows the correspondence between the original image and the flipping result according to each setting. 0b: No flipping 1b: Vertical flipping Note that the destination address setting should be changed according to the setting of these bits. For details, refer to **9.4.3.2.7 (9) WPFn Destination Y/RGB Address Registers (VI6_WPFn_DSTM_ADDR_Y)**. When the LIF module is used (VI6_LIF_CTRL.LIF_EN = 1b), set 0b to ROT[2:0].
15	SPYCS	0h	RW	WPF Output Mode Setting 1 When the output format is YUY2, set this bit to 1b and set the WRFMT bits to 71 (47h). When the output format is YVYU, set this bit and the SPUVS bit to 1b and set the WRFMT bits to 71 (47h). In other cases, set this bit to 0b.

Bit	Bit Name	Initial Value	R/W	Description
14	SPUVS	0h	RW	WPF Output Mode Setting 2 When the output format is NV61, set this bit to 1b and set the WRFMT bits to 65 (41h). When the output format is NV21, set this bit to 1b and set the WRFMT bits to 66 (42h). When the output format is YVYU, set this bit and the SPYCS bit to 1b and set the WRFMT bits to 71 (47h). In other cases, set this bit to 0b.
13, 12	DITH[1:0]	0h	RW	Ordered Dither (mode B) Enable/Disable When the output format specified through the WRFMT bits is RGB with 18 bpp (260000 colors) or less, the color reduction processing is applied to match the number of colors. The color reduction processing may generate the artifacts of pseudo gradation, which can be suppressed through dithering. The DITH bits enable or disable dithering during color reduction. When the output format specified through the WRFMT bits is YCbCr, specify 0 in these bits. And when VI6_WPF0_OUTFMT.CSC is set to 1, specify 0 in these bits even in the case that the output format specified through the WRFMT bits is RGB. 0h: Dithering (mode B) is disabled 3h: Dithering (mode B) is enabled 1, 2h: Setting prohibited When ODE bit in the register is 1b, set this bit to 0h.
11 to 9	WRTM[2:0]	0h	RW	CSC Conversion Expression Setting These bits select the expression for color space conversion. The conversion direction is RGB to YCbCr when the format specified in the WRFMT bits is RGB, or YCbCr to RGB when the format is YCbCr. 0h: BT.601 YCbCr [16,235/240] ↔ RGB [0,255] 1h: BT.601 YCbCr [0,255] ↔ RGB [0,255] 2h: BT.709 YCbCr [16,235/240] ↔ RGB [0,255] 3h: BT.709 YCbCr [16,235/240] ↔ RGB [16,235] 4h to 7h: Setting prohibited
8	CSC	0h	RW	Color Space Conversion Setting Enables or disables YCbCr ↔ RGB color space conversion to be executed in the WPF0. The characteristics of color space conversion are determined by the WRTM setting. There are some points to be noted about the relationship between the CSC setting and output format (WRFMT). For details refer to (*1) in **9.4.3.2.6 (3) RPFn Input Format Registers (VI6_RPFn_INFMT)**. 0b: Color space is not converted. 1b: Color space is converted.
7	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6 to 0	WRFMT[6:0]	00h	RW	WPF Output Image Format Setting These bits select the format of the image output from the WPF0 to the external memory from among those listed in **Table 9.4-18** and **Table 9.4-19**. [Note] Number of output pixels When YCbCr4:2:2 is specified through WRFMT, the horizontal size of the output image should be a multiple of 2 pixels. When YCbCr4:2:0 is specified, the vertical and horizontal sizes of the output image should be multiples of 2 pixels. Specify an appropriate data flow of the source RPF → DPR → target WPF so that the size of the image input to the target WPF satisfies the above restrictions. In particular, when the data flow includes a module or a function that modifies (up-scales, down-scales, or clips) the image size, take special care about the module or function settings. [Note] Output lines in YCbCr4:2:0 In the YCbCr4:2:0 output format, the number of chrominance lines in the vertical direction is one-half the number of luminance lines. For this reason, the WPF outputs only even-numbered chrominance lines (lines 0, 2, 4, 6, ...) (conversion from (A) to (B) in. When vertical flipping is also specified through the ROT bits, the flipping processing is executed last and the chrominance line locations are inverted (lines 1, 3, 5, 7, …) in the output image ((C) in **Figure 9.4-20**). [Note] Down sampling of CbCr in horizontal direction in YCbCr4:2:0 or YCbCr4:2:2 In the YCbCr4:2:2 or YCbCr4:2:0 output format, method of down sample of Cb/Cr in horizontal direction is average of neighbor two pixels.

Table 9.4-20 Packed YCbCr Formats for WPF Output

WRFMT[6:0]	Packed YCbCr Output Format	Reference
40h	YCbCr4:4:4 semi-planar	**Figure 9.4-9***4
41h	YCbCr4:2:2 semi-planar (NV16, NV61*1)	
42h	YCbCr4:2:0 semi-planar (NV12, NV21*1)	
43h to 45h	Reserved	—
46h	YCbCr4:4:4 interleaved	**Figure 9.4-10***4
47h	YCbCr4:2:2 interleaved type 0 (UYVY, YUY2*2, YVYU*3)	
48h	YCbCr4:2:2 interleaved type 1	
49h	YCbCr4:2:0 interleaved*5	
4Ah	YCbCr4:4:4 planar	**Figure 9.4-11***4
4Bh	YCbCr4:2:2 planar (YV16)	
4Ch	YCbCr4:2:0 planar (YV12, I420)	
4Dh to 7Fh	Reserved	—

Note 1. When the output format is NV61 or NV21, set SPUVS (bit 14) to 1.

Note 2. When the output format is YUY2, set SPYCS (bit 15) to 1.

Note 3. When the output format is YVYU, set SPUVS (bit 14) to 1 and SPYCS (bit 15) to 1.

Note 4. **Figure 9.4-12** shows the definition of memory address for each pixel in **Figure 9.4-9** to **Figure 9.4-11**.

Note 5. Each line of plane is written twice, so byte/pixel of YCbCr420ITL is 3 byte/pixel (same as YCbCr444ITL).

For details of each YCbCr format, refer to **Figure 9.4-9** to **Figure 9.4-12**. In these figures, registers for the RPF are indicated; read them as registers for the WPF as follows.

(RPF registers in the figures)	→	(Corresponding WPF registers)
VI6_RPFn_SRCM_ADDR_Y.SRCM_ADDR_Y	→	VI6_WPFn_DSTM_ADDR_Y.DSTM_ADDR_Y
VI6_RPFn_SRCM_ADDR_C0.SRCM_ADDR_C0	→	VI6_WPFn_DSTM_ADDR_C0.DSTM_ADDR_C0
VI6_RPFn_SRCM_ADDR_C1.SRCM_ADDR_C1	→	VI6_WPFn_DSTM_ADDR_C1.DSTM_ADDR_C1

(5) WPF0 Data Swapping Register (LCDC_VSPD_VI6_WPF0_DSWAP)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 1010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	P_LLS	P_LWS	P_WDS	P_BTS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	P_LLS	0h	RW	WPF Output Data Swapping in LONG LWORD Units The effect of this bit setting is the same as data swapping in the RPF; refer to **Table 9.4-13**. 0b: Data swapping in LONG LWORD (64-bit) units is disabled 1b: Data swapping in LONG LWORD (64-bit) units is enabled
2	P_LWS	0h	RW	WPF Output Data Swapping in long word Units The effect of this bit setting is the same as data swapping in the RPF; refer to **Table 9.4-13**. 0b: Data swapping in long word (32-bit) units is disabled 1b: Data swapping in long word (32-bit) units is enabled
1	P_WDS	0h	RW	WPF Output Data Swapping in Word Units The effect of this bit setting is the same as data swapping in the RPF; refer to **Table 9.4-13**. 0b: Data swapping in word (16-bit) units is disabled 1b: Data swapping in word (16-bit) units is enabled
0	P_BTS	0h	RW	WPF Output Data Swapping in Byte Units The effect of this bit setting is the same as data swapping in the RPF; refer to **Table 9.4-13**. 0b: Data swapping in byte (8-bit) units is disabled 1b: Data swapping in byte (8-bit) units is enabled

Table 9.4-14 shows the data order before and after swapping according to the long long word, long word, word, and byte swapping settings.

When data order in memory for each format is the same as in **Table 9.4-19** for RGB format and **Figure 9.4-9** to **Figure 9.4-12** for YCbCr format, set 1111b to {*_LLS, *_LWS, *_WDS, *_BTS}. If data order is not the same as the definition, change data order within 16byte unit by these bits as shown in **Table 9.4-14**.

(6) WPF0 Rounding Control Register (LCDC_VSPD_VI6_WPF0_RNDCTRL)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 1014h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	CBRM	-	-	ABRM[1:0]		ATHRESH[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	CLMD[1:0]		-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	CBRM	0h	RW	Bit Count Reduction Method Selection for Data Storage in Packed RGB This bit specifies the method for reducing the number of bits when data is stored in the bit fields indicated as R, G, and B in **Table 9.4-18** and the target bit fields are not 8 bits. 0b: Bit count conversion: The lower-order bits are truncated 1b: Bit count conversion: Rounding (rounding off)
27 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25, 24	ABRM[1:0]	0h	RW	Bit Count Reduction Method Selection for Data Storage in PAD These bits specify the method for reducing the number of bits when the data selected through VI6_WPF0_OUTFMT.PXA is stored in the bit fields indicated as PAD or P in **Table 9.4-18** and the target bit field is four bits or one bit. A value of 10b can be specified only when the packed RGB format specified through VI6_WPF0_OUTFMT.WRFMT includes a 1-bit P field. In this case, when the data selected through VI6_WPF0_OUTFMT.PXA is greater than the ATHRESH value, 1 is stored in the P field; when the selected data is not greater than the ATHRESH value, 0 is stored. 00b: Bit count conversion: The lower-order bits are truncated 01b: Bit count conversion: Rounding (rounding off) 10b: Bit count conversion: Comparison with the threshold value (this setting is allowed only when the storage field is one bit) 11b: Setting prohibited
23 to 16	ATHRESH[7:0]	00h	RW	Threshold for Conversion to 1-Bit α Data These bits specify the threshold value used for conversion from 8-bit α data to one bit when the ABRM bits are set to 10b. When the 8-bit α value before bit count reduction is equal to or smaller than the ATHRESH value, 0 is stored as the reduced 1-bit α data. In other cases, 1 is stored as the 1-bit α data. A value from 0 to 255 can be specified.
15 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13, 12	CLMD[1:0]	0h	RW	Color Data Clipping These bits specify the method for clipping the YCbCr color data output from the WPF. When RGB color data is output from the WPF, specify 0b in these bits. 00b: Output value is not clipped (0-255) 01b: Output value is clipped: YCbCr mode 1 (16-235 (Y), 16-240 (Cb/Cr)) 10b: Output value is clipped: YCbCr mode 2 (Y/Cb/Cr = 1-254) 11b: Setting prohibited
11 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(7) WPF0 Destination Y Plane Memory Stride Register (LCDC_VSPD_VI6_WPF0_DSTM_STRIDE_Y)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 101Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PICT_STRD_Y[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 0	PICT_STRD_Y [15:0]	0000h	RW	Memory Stride of Destination Picture Y/RGB Plane These bits specify in 1-byte units the memory stride of the destination picture in the external memory to be written to by the WPF0 as shown in **Figure 9.4-21**. A value from 0000h to FFFFh can be specified.

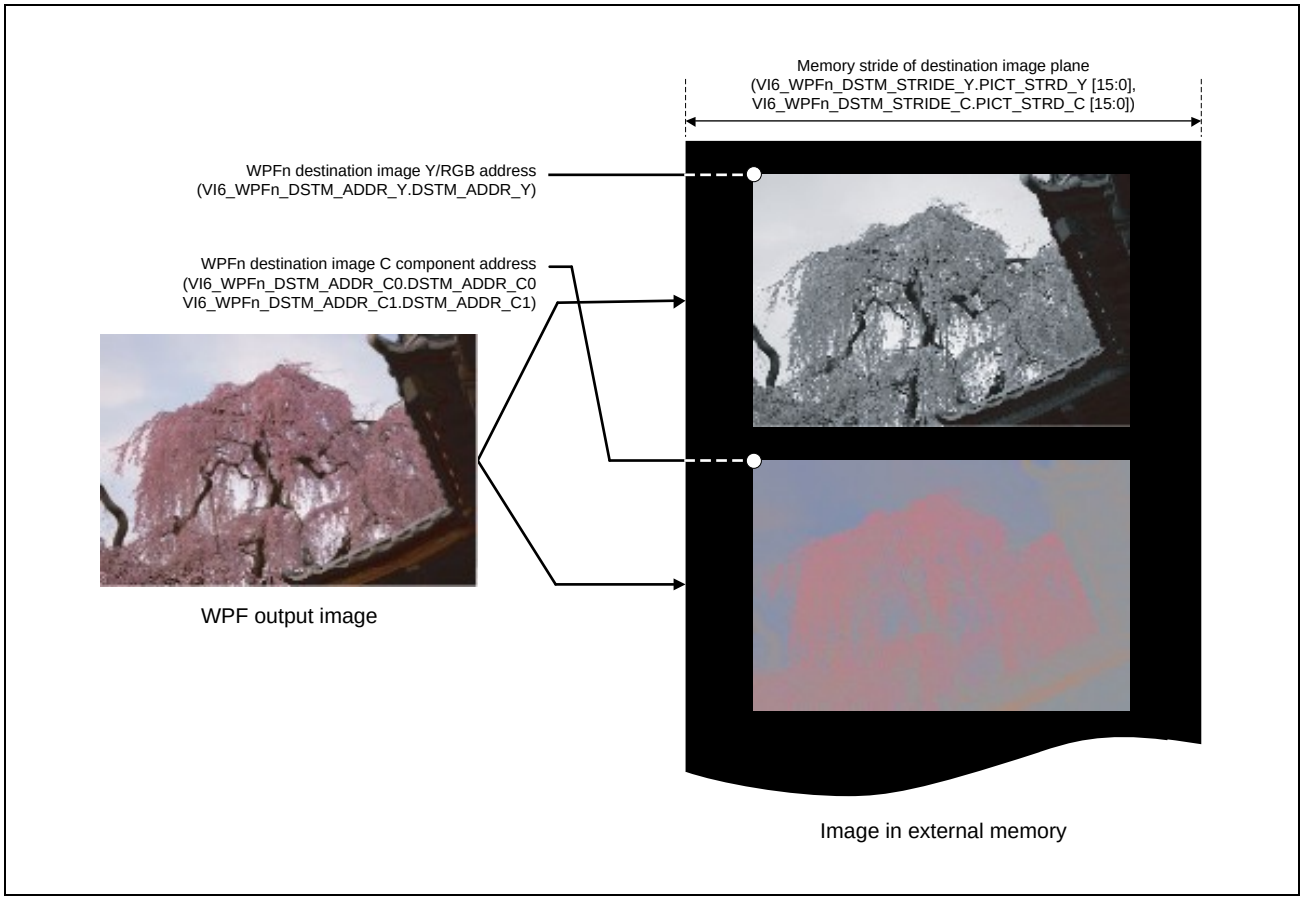

Figure 9.4-20 Writing Image Data to Destination Area in WPFn

(8) WPF0 Destination C Plane Memory Stride Register (LCDC_VSPD_VI6_WPF0_DSTM_STRIDE_C)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 1020h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 0	PICT_STRD_C [15:0]	0000h	RW	Memory Stride of Destination Picture C Plane These bits specify in 1-byte units the memory stride for the C plane of the destination picture in the external memory to be written to by the WPF0 as shown in **Figure 9.4-21**. When the WPF0 outputs images in an RGB format, this setting is not used. When the WPF0 outputs images in YCbCr planar format, this setting is applied to both the Cb and Cr planes. A value from 0000h to FFFFh can be specified.

(9) WPF0 Destination Y/RGB Address Register (LCDC_VSPD_VI6_WPF0_DSTM_ADDR_Y)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 1024h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DSTM_ADDR_Y[31:16]

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DSTM_ADDR_Y[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DSTM_ADDR_Y [31:0]	0000_0000h	RW	Destination Image Y/RGB Plane Storing Address These bits specify in 1-byte units the address for storing the destination-image Y plane or packed RGB plane to be written to by the WPF0 in the method described later. A value from 0000_0000h to FFFF_FFFFh can be specified.

[Destination Address Specification Method]

When flipping is not used, the start address of a frame (address FHA shown in **Figure 9.4-21**) should be specified as the destination address. When flipping is used, the destination address is not the frame start address (FHA); one of addresses A0 and A2 shown in **Figure 9.4-21** should be selected according to the combination of desired flipping (VI6_WPFn_OUTFMT.ROT setting).

To strictly define locations A0 and A2, let the horizontal size of the output image be H, the vertical size of the output image be V, and the memory stride (VI6_WPFn_DSTM_STRIDE_Y/C setting) be S as shown in **Figure 9.4-21**. Calculate the destination address (one of A0 and A2) using the formula shown in **Table 9.4-21** and specify it in the destination address storing register.

The values of variables L in **Table 9.4-21** depend on the other register settings and luminance and chrominance components. These values should be obtained by referring to **Table 9.4-22** when calculating the address to be specified in VI6_WPFn_DSTM_ADDR_Y, or **Table 9.4-23** when calculating the address to be specified in VI6_WPFn_DSTM_ADDR_C0 or VI6_WPFn_DSTM_ADDR_C1.

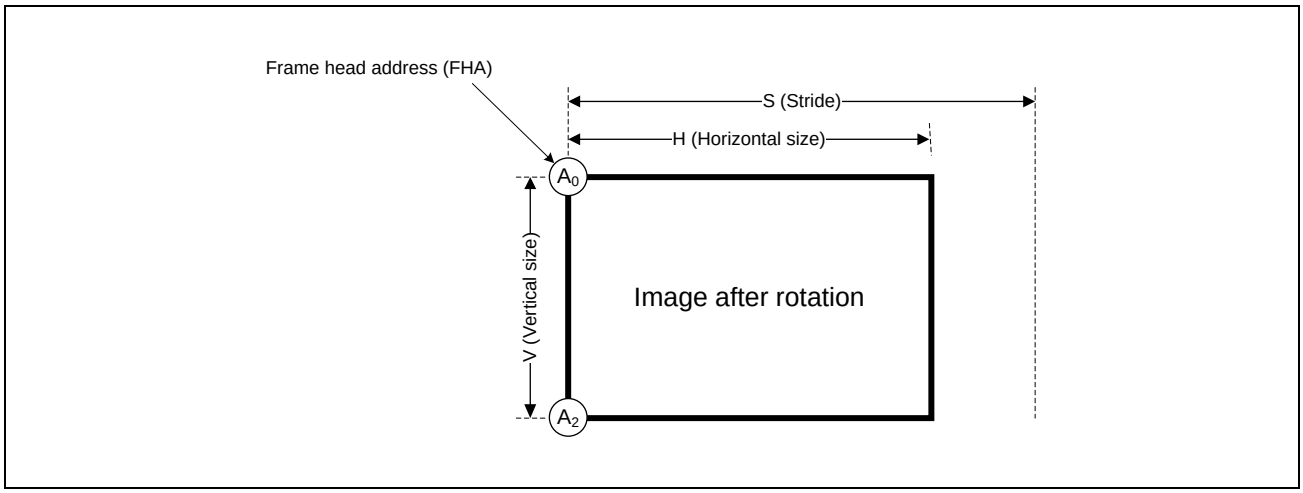

Figure 9.4-21 Location of Destination Address to be Specified for Flipping

Table 9.4-21 Destination Address A_0, A_1, A_2, and A3 Calculation Formulas

VI6_WPFn_OUTFMT.ROT Setting	Formula for Calculating Address to be Set in VI6_WPFn_DSTM_ADDR_Y, VI6_WPFn_DSTM_ADDR_C0, and VI6_WPFn_DSTM_ADDR_C1
0	A_0 = FHA
1	A_2 = FHA + (V×L – 1) × S

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DSTM_ADDR_C0[31:0]	0000_0000h	RW	Destination Image C Plane Storing Address 0 These bits specify in 1-byte units the address for storing the destination-image C plane to be written to by the WPF0. Refer to the description of VI6_WPF0_DSTM_ADDR_Y for settings. Here, the C plane indicates the combined CbCr plane when a semi-planar format is selected from the packed YCbCr formats shown in **Table 9.4-19** or the Cb plane when a planar format is selected. When an interleaved format is selected or the output is in an RGB format, this setting is not used. A value from 0000_0000h to FFFF_FFFFh can be specified. Refer to **Figure 9.4-22** in **9.4.3.2.7 (9) WPFn Destination Y/RGB Address Registers (VI6_WPFn_DSTM_ADDR_Y)** for settings.

(11) WPF0 Destination Chroma Address Register 1 (LCDC_VSPD_VI6_WPF0_DSTM_ADDR_C1)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 102Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DSTM_ADDR_C1[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DSTM_ADDR_C1[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DSTM_ADDR_C1[31:0]	0000_0000h	RW	Destination Image C Plane Storing Address 1 These bits specify in 1-byte units the address for storing the Cr plane when the WPF0 outputs images to the external memory in YCbCr planar format shown in **Table 9.4-19**. Refer to the description of VI6_WPF0_DSTM_ADDR_Y for settings. This setting is not used when the WPF outputs in YCbCr format that is not a planar format or in an RGB format. A value from 0000_0000h to FFFF_FFFFh can be specified. Refer to **Figure 9.4-22** in **9.4.3.2.7 (9) WPFn Destination Y/RGB Address Registers (VI6_WPFn_DSTM_ADDR_Y)** for settings.

(12) WPF0 LIF Write Back Control Register (LCDC_VSPD_VI6_WPF0_WRBCK_CTRL)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 1034h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WBMD[1:0]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1, 0	WBMD[1:0]	0h	RW	Display Data Write Back Control This bit is used for selecting the write back mode when the value of VI6_LIF0_CTRL.LIF_EN bit is set to 1b. 0b: Write Back Disabled 1b: Write Back Enabled

9.4.3.2.8 DPR Control Registers

(1) Concept of DPR Settings

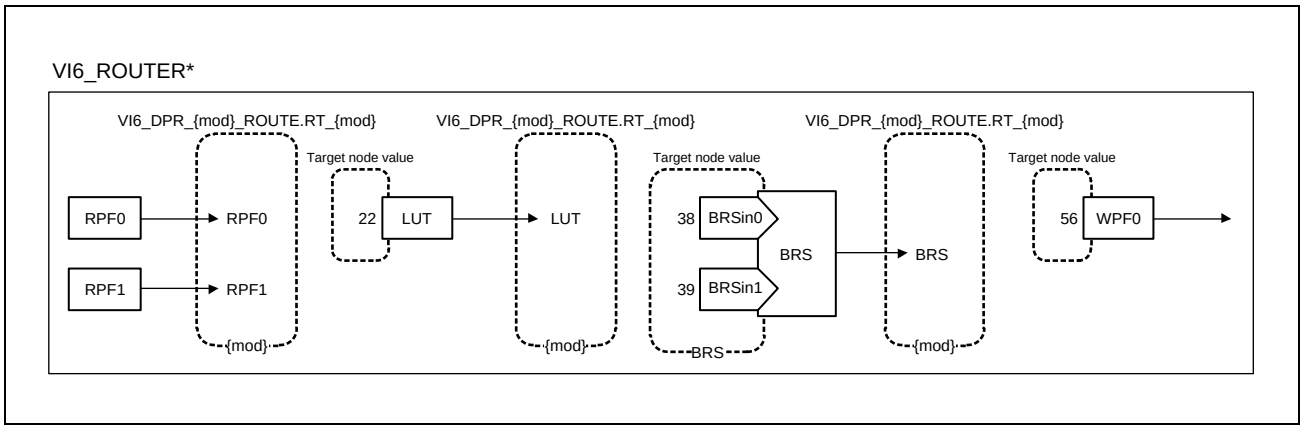

Figure 9.4-22 Node Register Names and Target Node Values on Data Path Router

In the VSPD internal data path, the order of processes can be specified as desired. The module for performing each process has a unique node value. Set each bit field in VI6_DPR_*_ROUTE to an appropriate node value shown in **Figure 9.4-22** to specify the target node to be connected behind each module.

For DPR settings, all of the following restrictions should be observed. If any of them is violated, even the WPF paths operating correctly at that time will be affected as well as the WPF paths connected through the DPR, and correct operation will not be guaranteed.

1. Specify 63 for the output node values of all RPFs and processing modules that are not used in the DPR. Here, make sure that no module is connected to a module for which 63 is specified as the node value. Note: VI6_DPR_{mod}_ROUTE.RT are not implemented in VSPD which doesn't have {mod}. See **Figure 9.4-1** whether VSPD has {mod} or not.
2. When specifying a value other than 63 for an output node value in the DPR, make sure that valid inputs (RPF0 to RPF1 or virtual RPF) and a target WPF are determined.
3. Only one module can be connected to each module; specifying the same target node value for two or more modules is prohibited.
4. Desired modules can be connected between each RPF and BRS input port, but all RPFs specified as the sources for a BRS input port should have the same target WPF.
5. Make appropriate routing or RPF register settings so that the color space formats (RGB/YCbCr) for all BRS input ports are the same.
6. Do not connect the output of any module as the input to the same module (in the BRS case, any input port) even when there is another module between the output and input (creating a loop is prohibited).
7. Each node can be used only once throughout all paths from RPFn to WPFn. When a module shown in **Figure 9.4-22** is assigned in one RPF to WPF path, it cannot be used in another RPF to WPF path.
8. While a WPF is operating, modifying the DPR connection settings in VI6_DPR_*_ROUTE is prohibited for modules used by the WPF but allowed for modules not used by the WPF. Be careful not to accidentally modify the settings of the modules included in the WPF path that is operating.
9. Be careful to do the following setting when BRS is used.
   VI6_DPR_BRS_ROUTE.BRSSEL = 1

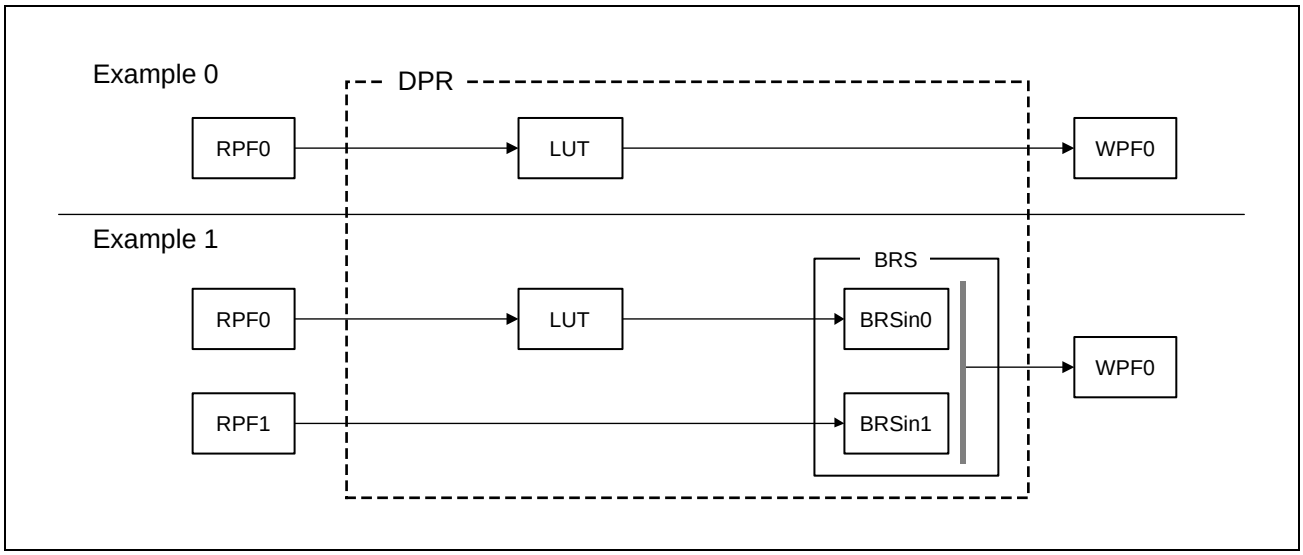

Figure 9.4-23 Examples of Internal Data Path Routing

Figure 9.4-23 shows examples of internal data path routing. Example 0 is WPF0 processing (RPF0 is the source RPF), and example 1 is also WPF0 (RPF0 to RPF1 are the source RPFs). Each example has the configuration shown in **Figure 9.4-23**. Example 0 performs LUT (e.g. γ correction) processing. Example 1 performs LUT processing (e.g. γ correction), for input 0 (RPF0) and then applies blending or raster operation between the resultant data and input data 1 (RPF1). The VI6_ DPR_*_ROUTE settings for these examples are shown in **Table 9.4-24**. The bit fields for the modules that are not used in the examples should be set to 63.

Table 9.4-24 VI6_DPR_*_ROUTE Register Settings in Connection Examples Shown in **Figure 9.4-23**. Although both examples show in **Figure 9.4-23** include operation in image processing modules, connect the RPF to the WPF directly when only image format conversion or packed format conversion is required.

Table 9.4-24 Examples of Internal Data Path Routing

	Register Name	Setting	
Example 0	VI6_DPR_RPF0_ROUTE.RT_RPF0	22	(To LUT)
	VI6_DPR_RPF1_ROUTE.RT_RPF1	63	(UNUSED)
	VI6_DPR_LUT_ROUTE.RT	56	(To WPF0)
	VI6_DPR_BRS_ROUTE.RT	63	(UNUSED)
Example 1	VI6_DPR_RPF0_ROUTE.RT_RPF0	22	(To LUT)
	VI6_DPR_RPF1_ROUTE.RT_RPF1	39	(To BRSin1)
	VI6_DPR_LUT_ROUTE.RT	38	(To BRSin0)
	VI6_DPR_BRS_ROUTE.RT	56	(To WPF0)

(2) RPFn Routing Register (LCDC_VSPD_VI6_DPR_RPFn_ROUTE) (n = 0, 1)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 2000h (n = 0)
<LCDC_vspd_base> + 2004h (n = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	-	-	FP_WPFn[5:0]						-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 8	FP_WPFn[5:0]	00h	RW	WPFn Internal Operation Timing Setting Specify 5.
7 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(4) LUT Routing Register (LCDC_VSPD_VI6_DPR_LUT_ROUTE)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 203Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	FXA[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	FP[5:0]						-	-	RT[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	R	R	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 16	FXA[7:0]	00h	RW	Fixed α Output Value for LUT The LUT does not support input/output of the α value. The α value input to the LUT is discarded, and the fixed α value specified in these bits is always output from the LUT. A value from 0 to 255 can be specified.
15, 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 8	FP[5:0]	00h	RW	LUT Internal Operation Timing Setting Specify 0.
7, 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5 to 0	RT[5:0]	00h	RW	LUT Target Node Value These bits specify the target node value for the LUT. When using the LUT, refer to **Figure 9.4-23** for settings. When not using the LUT, specify 63.

(5) BRS Routing Register (LCDC_VSPD_VI6_DPR_BRS_ROUTE)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 2050h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	BRSSEL	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	FP[5:0]						-	-	RT[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	R	R	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	BRSSEL	0h	RW	Always specify 1.
27 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 8	FP[5:0]	00h	RW	BRS Internal Operation Timing Setting Specify 0.
7, 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5 to 0	RT[5:0]	00h	RW	BRS Target Node Value These bits specify the target node value for the BRS. When using the BRS, refer to **Figure 9.4-23** for settings. When not using the BRS, specify 63.

9.4.3.2.9 LUT Control Register

(1) LUT Control Register (LCDC_VSPD_VI6_LUT_CTRL)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 2800h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	LUT_EN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	LUT_EN	0h	RW	1D-LUT Enable/Disable Enables or disables the 1D-LUT function by the LUT. When the 1D-LUT is used, the color component curve information needs to be set separately in the LUT table. For the LUT table settings, refer to **9.4.4.7.1 LUT**. 0b: 1D-LUT function is disabled 1b: 1D-LUT function is enabled

In the LUT, various image processing, such as curves with high operation load (e.g., γ correction), negative-positive conversion, and gain adjustment of images, can be achieved by the data replacement processing by the 1D-LUT. As shown in **Figure 9.4-24**, the LUT replaces each component of the input pixel data using the set replacement table of 256 entries. For example, if the LUT is set as in **Figure 9.4-25**, when there is an input of 150, the data stored in address 150 of the 1D-LUT is read and output as the LUT output. **Figure 9.4-25** shows a case in which the input and output become equal for convenience in explaining.

In the LUT settings shown in **Figure 9.4-26**, the input bits are reversed. This has the effect of negative-positive flipping. In **Figure 9.4-27**, γ correction (γ = 1.8 is shown as an example) is possible. As described above, information to be set in the LUT indicates LUT processing characteristics. If the same value is set for each component in the LUT, an equal effect can be obtained for each component of the input image when it is processed. If the LUT is set with different characteristics for each component, the processing characteristics can be changed for each component.

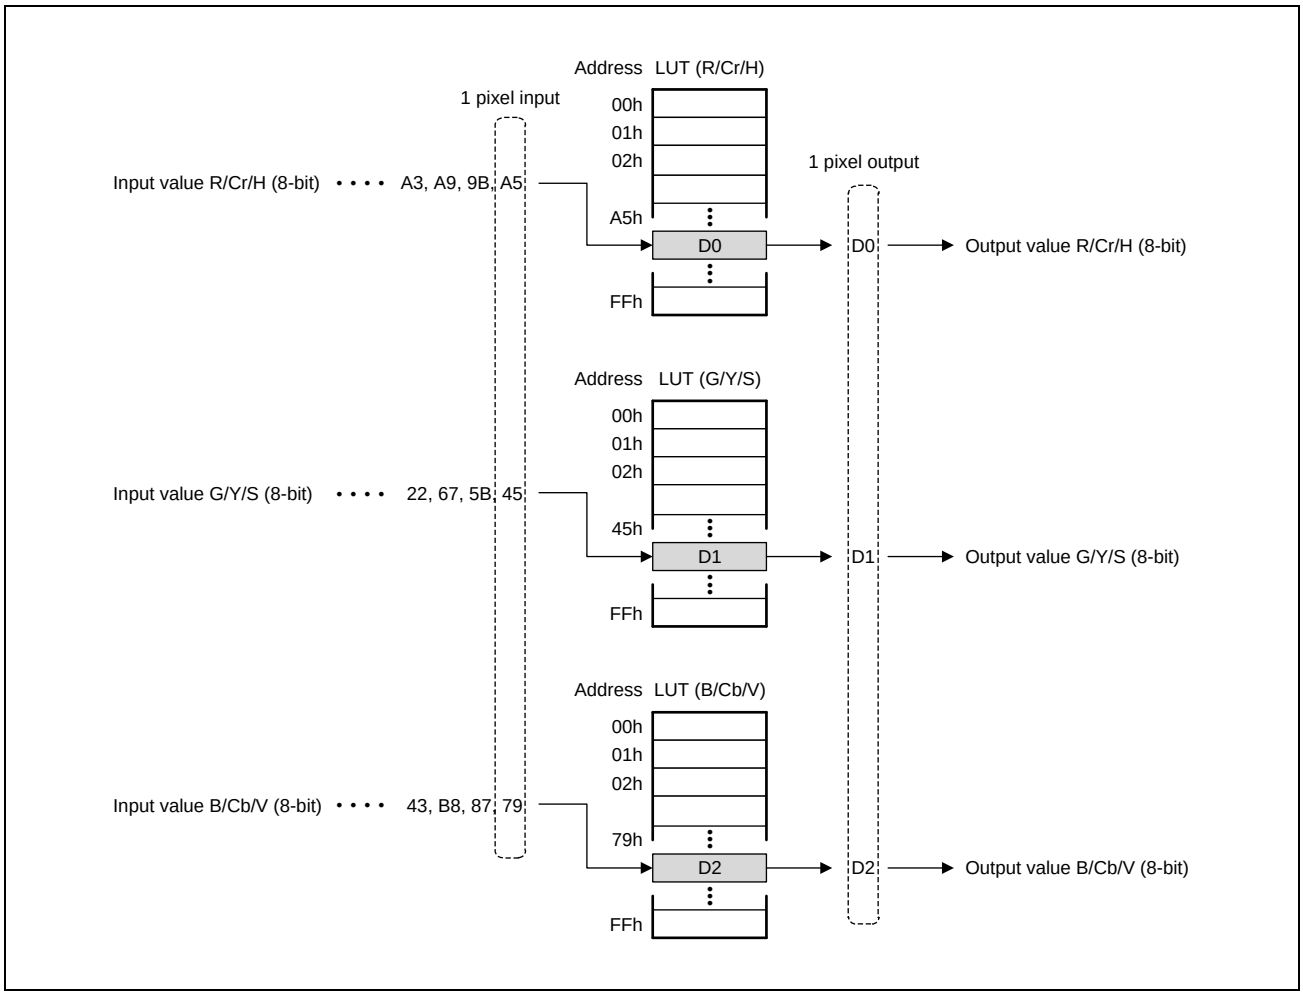

Figure 9.4-24 Relationship between Input and Output for 1D-LUT Table

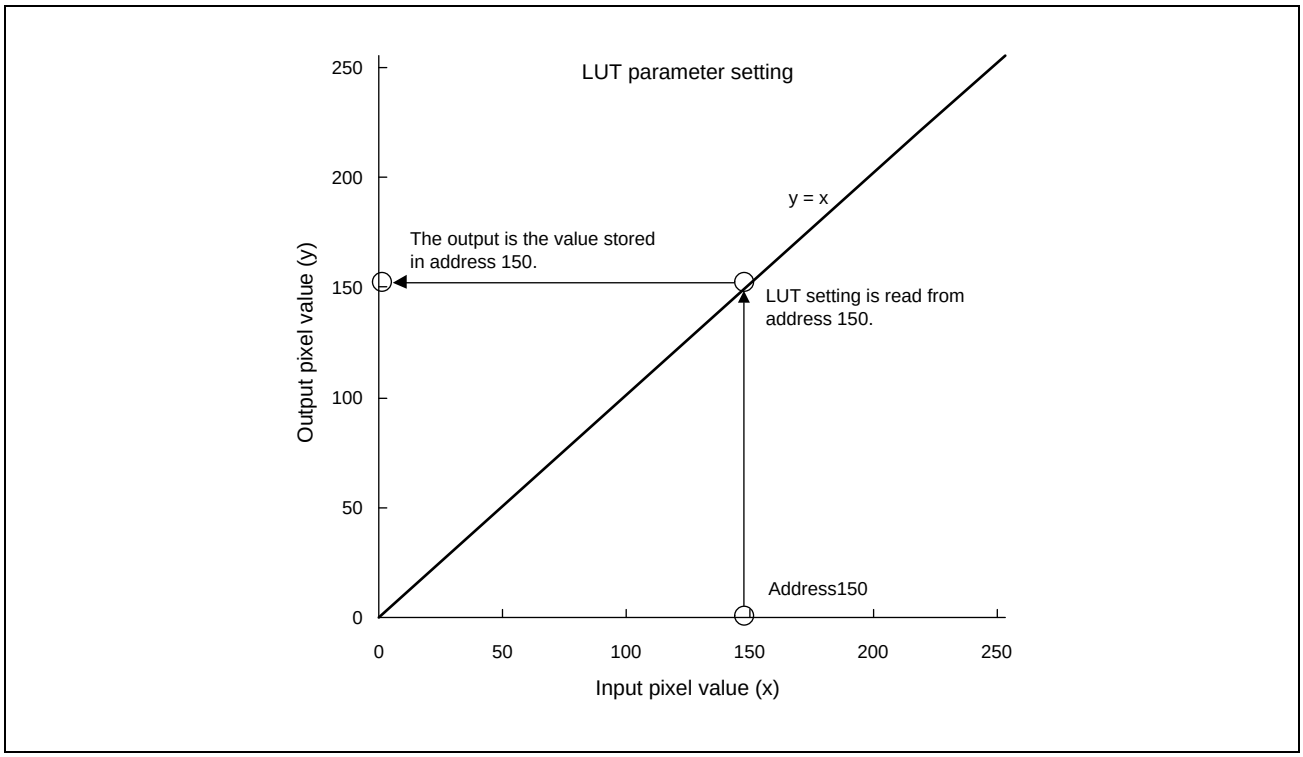

Figure 9.4-25 Setting Example in Which Output Becomes Equal to Input

R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	NRM	0h	RW	Color Data Normalization Enables or disables division by the α value of the color data in BRS blending operation. This is used when converting the RGB color data format to which the α value is multiplied (pre-multiplied color) into the RGB color data format to which the α value is not multiplied (non pre-multiplied color). Do not use this for the YCbCr format. 0b: Divider (DIV unit in **Figure 9.4-29**) does not divide the color value by α 1b: Divider (DIV unit in **Figure 9.4-29**) divides the color value by α
27 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	D1ON	0h	RW	Ordered dither (mode B) Enable of BRS Input 1 Enables or disables dithering (color reduction) of BRS input 1 (BRSin1 in **Figure 9.4-29**). 0b: Dithering (mode B) of BRSin1 is disabled 1b: Dithering (mode B) of BRSin1 is enabled When ODE1 in this bit is set to 1, set 0 to this bit.
16	D0ON	0h	RW	Ordered dither (mode B) Enable of BRS Input 0 Enables or disables dithering (color reduction) of BRS input 0 (BRSin0 in **Figure 9.4-29**). 0b: Dithering (mode B) of BRSin0 is disabled 1b: Dithering (mode B) of BRSin0 is enabled When ODE0 in this bit is set to 1, set 0 to this bit.
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7	ODE1	0h	RW	Ordered Dither (mode A) of CH1 Input to BRS Enable/Disable 0b: Ordered dither (mode A) of BRSin1 is disabled. 1b: Ordered dither (mode A) of BRSin1 is enabled. Ordered dither is available only for 18bpp. So, when ODE1 bit is equal to 1, set DITH1 = 1. When ODE1 bit is equal to 0, BRSin1 dither method is specified by D1ON in the register Ordered dither (mode A) is recommended rather than ordered dither (mode B) in case of 18bpp.
6 to 4	DITH1[2:0]	0h	RW	Dithering of CH1 Input to BRS These bits specify the number of colors for pixels after dithering (color reduction) when dithering (color reduction) for pixel information is enabled through the D1ON bit. When dithering (color reduction) for pixel information is disabled, specify 0h in these bits. 0h: Dithering of BRSin1 input image is disabled 1h: Dithering of BRSin1 input image at 18 bpp (RGB666: 260000 colors) 2h: Dithering of BRSin1 input image at 16 bpp (RGB565: 65535 colors) 3h: Dithering of BRSin1 input image at 15 bpp (RGB555: 32768 colors) 4h: Dithering of BRSin1 input image at 12 bpp (RGB444: 4096 colors) 5h: Dithering of BRSin1 input image at 8 bpp (RGB332: 256 colors) 6, 7h: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
3	ODE0	0h	RW	Ordered Dither (mode A) of CH0 Input to BRS Enable/Disable 0b: Ordered dither (mode A) of BRSin0 is disabled. 1b: Ordered dither (mode A) of BRSin0 is enabled. Ordered dither is available only for 18bpp. So, when ODE0 bit is equal to 1b, set DITH0 = 1b. When ODE0 bit is equal to 0, BRSin0 dither method is specified by D0ON in the register Ordered dither (mode A) is recommended rather than ordered dither (mode B) in case of 18bpp.
2 to 0	DITH0 [2:0]	0h	RW	Dithering of CH0 Input to BRS These bits specify how to perform dithering of the CH0 input to the BRS. The setting method is the same as that for the DITH1 bits. Read the description of the DITH1 bits with BRSin0 and D0ON replacing BRSin1 and D1ON, respectively.

Figure 9.4-28 shows the configuration of the BRS. For the BRS inputs, there are two inputs from the DPR and one internal input as a virtual RPF. BRSin0 to BRSin1 are input ports that have the target node values shown in **Figure 9.4-22**, and they can be connected to any module on the DPR. The same color space (YCbCr or RGB) has to be used for the two inputs from the DPR to the BRS.

The virtual RPF inside the BRS is an input unit not connected to the DPR. It is called the "virtual RPF" because it outputs images internally created by the BRS. Starting of the virtual RPF is controlled by VI6_WPFn_SRCRPF.VIR_ACT2, and the single-color data created at the virtual RPF can be used for blending or raster operation (ROP) with data from the other input units BRSin0 to BRSin1. The color space for the single color to be set for the virtual RPF needs to match the color space of the two inputs from the DPR to the BRS. For this setting method, see **(4) Color Information Register of BRS Input Virtual RPF (LCDC_VSPD_VI6_BRS_VIRRPF_COL)**.

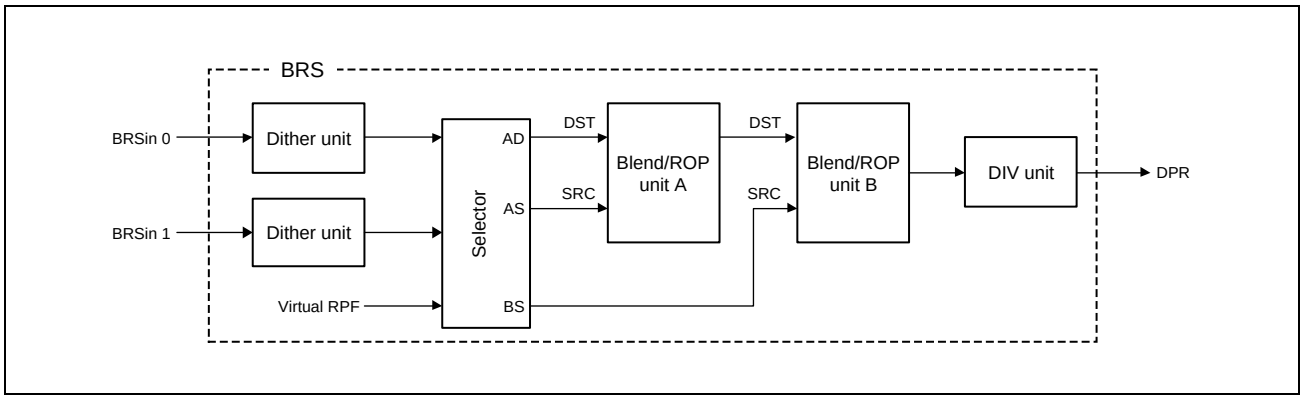

Figure 9.4-28 BRS Configuration

The selector in **Figure 9.4-28** is used to select the SRC and DST inputs to blending/ROP units A to B from BRSin0 to BRSin1 which are inputs from the DPR and the virtual RPF. The SRC and DST input sources for blending/ROP units A to B are either uniquely determined based on the configuration shown in **Figure 9.4-28** or selected as desired by registers. The input sources that can be arbitrarily selected by registers are AD, AS and BS, which correspond to the registers shown in **Table 9.4-25**.

Table 9.4-25 Correspondence between Selector Output Destinations and Register Bits for BRS

Selector Output	Output Destination	Register Bits
AD	Blending/ROP unit A - DST	VI6_BRSA_CTRL.DSTSEL
AS	Blending/ROP unit A - SRC	VI6_BRSA_CTRL.SRCSEL
BS	Blending/ROP unit B - SRC	VI6_BRSB_CTRL.SRCSEL

(2) Size Register of BRS Input Virtual RPF (LCDC_VSPD_VI6_BRS_VIRRPF_SIZE)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 3904h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	VIR_HSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	VIR_VSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	VIR_HSIZE [12:0]	0000h	RW	Virtual RPF Horizontal Size These bits set the horizontal size of an image from the virtual RPF shown in **Figure 9.4-29**. A value from 1 to 1920 can be specified.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	VIR_VSIZE [12:0]	0000h	RW	Virtual RPF Vertical Size These bits set the vertical size of an image from the virtual RPF shown in **Figure 9.4-29**. A value from 1 to 1920 can be specified.

The virtual RPF has only a function to output a fixed α value and a fixed pixel value. The virtual RPF can internally create a single-color image without accessing external memory via the MAU. Same as images from the other BRS input ports, a sublayer can be blended on an image created in this manner with the image used as the background (master layer). In turn, when using the image as a sublayer, it can be drawn on the master layer as a window.

(3) Display Location Register of BRS Input Virtual RPF (LCDC_VSPD_VI6_BRS_VIRRPF_LOC)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 3908h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	HCOORD[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	VCOORD[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	HCOORD [12:0]	0000h	RW	Horizontal Coordinate of Virtual RPF Location on Master Layer These bits specify the horizontal coordinate of where to locate the left-edge pixel of the virtual RPF's layer, with the left-edge pixel of the master layer set at coordinate 0. This setting should be made in pixel units. A value from 0 to 1919 can be specified. When the virtual RPF is specified as the master layer by VI6_WPF0_SRCRPF.VIR_ACT2, set these bits to 0b.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	VCOORD[12:0]	0000h	RW	Vertical Coordinate of Virtual RPF Location on Master Layer These bits specify the vertical coordinate of where to locate the top-edge pixel of the virtual RPF's layer, with the top-edge pixel of the master layer set at coordinate 0. This setting should be made in pixel units. A value from 0 to 1919 can be specified. When the virtual RPF is specified as the master layer by VI6_WPF0_SRCRPF.VIR_ACT2, set these bits to 0b.

(4) Color Information Register of BRS Input Virtual RPF (LCDC_VSPD_VI6_BRS_VIRRPF_COL)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 390Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	COL_A[7:0]								COL_RCR[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	COL_GY[7:0]								COL_BCB[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	COL_A[7:0]	00h	RW	Fixed α of Virtual RPF These bits set the fixed α value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.
23 to 16	COL_RCR[7:0]	00h	RW	Fixed R/Cr of Virtual RPF These bits set the fixed R/Cr value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.
15 to 8	COL_GY[7:0]	00h	RW	Fixed G/Y of Virtual RPF These bits set the fixed G/Y value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.
7 to 0	COL_BCB[7:0]	00h	RW	Fixed B/Cb of Virtual RPF These bits set the fixed B/Cb value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.

The transparency information and color information of the single color that is created by the virtual RPF are set in the bits of this register. As described earlier, the color information is set for the YCbCr or RGB color space. The color space to be set in this register depends on the register settings of the environment and other modules to which the BRS is connected by the DPR. Two cases can be considered. Since the α value (COL_A) is transparency information and irrelevant to the concept of color space, the same setting is made for either the YCbCr or RGB color space.

[Case 1: When an input other than the virtual RPF is used]

When the source RPF is connected to any one of the BRS input ports (BRSin0 to BRSin1) other than the virtual RPF and valid data is being supplied, the same color space data as the color space for the BRS inputs should be set in this register as the color space for the virtual RPF's color information. This is based on the restriction of "all BRS inputs must have the same color space", as described in **(1) Concept of DPR Settings** or **(1) BRS Input Control Register (LCDC_VSPD_VI6_BRS_INCTRL)**.

[Case 2: When only the virtual RPF is used]

When only the virtual RPF is used as the source RPF of WPFn, RPFn is not connected to the BRS, as shown in **Figure 9.4-29**. Thus, there is no color space for another input that the color space for the virtual RPF has to follow, as in case 1. This means that the color space of the data output by the BRS is determined by the WPF setting.

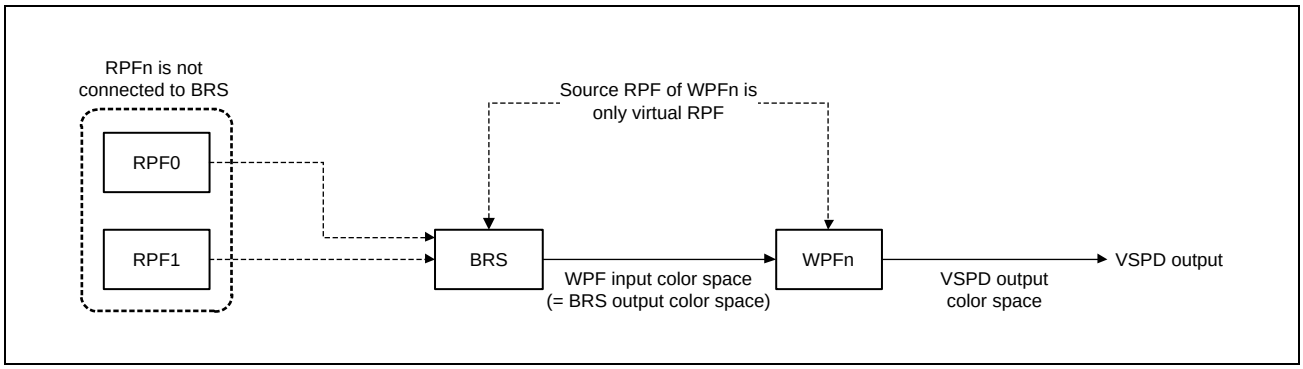

Figure 9.4-29 Relationship between DPR Connection and Color Space When Only Virtual RPF is Used

Figure 9.4-29, the output color space of the VSPD (= output color space of WPFn) is determined by VI6_WPFn_OUTFMT.WRFMT. When bit 6 in VI6_WPFn_OUTFMT.WRFMT (WRFMT [6]) is 0, the color space is RGB, while when it is 1, the color space is YCbCr. Next, the WPF input color space (= BRS output color space) is determined by the relationship between the WPF output color space and VI6_WPFn_OUTFMT.CSC. When VI6_WPFn_OUTFMT.CSC is 0, the WPF output color space and WPF input color space (= BRS output color space) are the same. When VI6_WPFn_OUTFMT.CSC is 1, the WPF output color space and WPF input color space (= BRS output color space) are the opposite. This relationship is summarized in **Table 9.4-26**.

The color space for the virtual RPF's color information should be set in this register according to the "BRS output color space" shown in **Table 9.4-26**.

Table 9.4-26 Relationship between WPF Output Color Space and BRS Output Color Space

VI6_WPFn_OUTFMT Register Bit Settings				BRS Output Color Space (= WPF Input Color Space)
Bit 6 in WRFMT		CSC		
0	(WPF output is RGB)	0	(YCbCr to RGB conversion is disabled)	RGB
0	(WPF output is RGB)	1	(YCbCr to RGB conversion is enabled)	YCbCr
1	(WPF output is YCbCr)	0	(RGB to YCbCr conversion is disabled)	YCbCr
1	(WPF output is YCbCr)	1	(RGB to YCbCr conversion is enabled)	RGB

(5) BRS Control Register A (LCDC_VSPD_VI6_BRSA_CTRL)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 3910h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RBC	-	-	-	-	-	-	-	-	DSTSEL[2:0]			-	SRCSEL[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	R	R	R	R	RW	RW	RW	R	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CROP[3:0]				AROP[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	RBC	0h	RW	Operation Type of Blending/ROP Unit A Specifies the operation type for blending/ROP unit A shown in **Figure 9.4-29**. 0b: ROP (raster operation) 1b: Blending operation
30 to 23	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
22 to 20	DSTSEL[2:0]	0h	RW	Input Selection for DST Side of Blending/ROP Unit A These bits select the input for the DST side of blending/ROP unit A shown in **Figure 9.4-29**. These bits specify the connection between the BRS input port and the DST separately from the setting of connections between other modules and the BRS input port through the DPR. 000b: BRS input 0 (BRSin0) is input to DST 001b: BRS input 1 (BRSin1) is input to DST 100b: Virtual RPF is input to DST 010b, 011b, 101b to 111b: Setting prohibited [Note] The DSTSEL bits for blending/ROP unit B are reserved. The write value should always be 0b.
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18 to 16	SRCSEL[2:0]	0h	RW	Input Selection for SRC Side of Blending/ROP Unit A These bits select the input for the SRC side of blending/ROP unit A shown in **Figure 9.4-29**. These bits specify the connection between the BRS input port and the SRC separately from the setting of connections between other modules and the BRS input port through the DPR. 000b: BRS input 0 (BRSin0) is input to SRC 001b: BRS input 1 (BRSin1) is input to SRC 100b: Virtual RPF is input to SRC 010b, 011b, 101b to 111b: Setting prohibited
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7 to 4	CROP[3:0]	0h	RW	Color Data ROP Operator These bits select the ROP operator of the color data in blending/ROP unit A. Select the opcode for ROP operation from **Table 9.4-26**.
3 to 0	AROP[3:0]	0h	RW	α Data ROP Operator These bits select the ROP operator of the α data in blending/ROP unit A. Select the opcode for ROP operation from **Table 9.4-26**.

Table 9.4-27 ROP Operator of Blending/ROP Unit m (m = A, B)

Opcode	Operator
0000b	NOP(D)
0001b	AND(S & D)
0010b	AND_REVERSE(S & ~D)
0011b	COPY(S)
0100b	AND_INVERTED(~S & D)
0101b	CLEAR(0)
0110b	XOR(S ^ D)
0111b	OR(S | D)
1000b	NOR(~(S | D))
1001b	EQUIV(~(S ^ D))
1010b	INVERT(~D)
1011b	OR_REVERSE(S | ~D)
1100b	COPY_INVERTED(~S)
1101b	OR_INVERTED(~S | D)
1110b	NAND(~(S & D))
1111b	SET(all1)

(6) BRS Blend Control Register A (LCDC_VSPD_VI6_BRSA_BLD)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 3914h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CBES	CCMDX[2:0]			-	CCMDY[2:0]			ABES	ACMDX[2:0]			-	ACMDY[2:0]

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	CBES	0h	RW	Blending Expression Selection Selects the blending expression of the color data in the BRS (VI6_BRSA_CTRL.RBC = 1b). Blending coefficients are specified by the CCMDX and CCMDY bits. 0b: CCMDX × (DST color data) + CCMDY × (SRC color data) 1b: CCMDX × (DST color data) - CCMDY × (SRC color data)
30 to 28	CCMDX[2:0]	0h	RW	Blending Coefficient X Selection These bits specify coefficient X used in the blending expression determined by the CBES bit. 000b: DST α data is used as blending coefficient X 001b: 255 - (DST α data) is used as blending coefficient X 010b: SRC α data is used as blending coefficient X 011b: 255 - (SRC α data) is used as blending coefficient X 100b: Fixed α value 0 (COEFX setting)
27	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26 to 24	CCMDY[2:0]	0h	RW	Blending Coefficient Y Selection These bits specify coefficient Y used in the blending expression determined by the CBES bit. 000b: DST α data is used as blending coefficient Y 001b: 255 - (DST α data) is used as blending coefficient Y 010b: SRC α data is used as blending coefficient Y 011b: 255 - (SRC α data) is used as blending coefficient Y 100b: Fixed α value 1 (COEFY setting)
23	ABES	0h	RW	Blending α Creation Expression Specifies the expression for creating α data after blending by blending/ROP unit m (m = A, B, C, D, E). α creation coefficients are specified by the ACMDX and ACMDY bits. 0b: ACMDX × (DST α data) + ACMDY × (SRC α data) 1b: ACMDX × (DST α data) - ACMDY × (SRC α data)
22 to 20	ACMDX[2:0]	0h	RW	α Creation Coefficient X These bits specify α creation coefficient X used in the α creation expression determined by the ABES bit. 000b: (α creation coefficient X) = (DST α data) 001b: (α creation coefficient X) = 255 - (DST α data) 010b: (α creation coefficient X) = (SRC α data) 011b: (α creation coefficient X) = 255 - (SRC α data) 100b: (α creation coefficient X) = Fixed α value 0 (COEFX setting) 101b to 111b: Setting prohibited
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	ACMDY[2:0]	0h	RW	α Creation Coefficient Y These bits specify α creation coefficient Y used in the α creation expression determined by the ABES bit. 000b: (α creation coefficient Y) = (DST α data) 001b: (α creation coefficient Y) = 255 - (DST α data) 010b: (α creation coefficient Y) = (SRC α data) 011b: (α creation coefficient Y) = 255 - (SRC α data) 100b: (α creation coefficient Y) = Fixed α value 1 (COEFY setting) 101b to 111b: Setting prohibited
15 to 8	COEFX[7:0]	00h	RW	Fixed α Value 0 These bits specify fixed α value 0 used when the CCMDX or ACMDX bits are set to 100b. A value from 00h to FFh can be specified.
7 to 0	COEFY[7:0]	00h	RW	Fixed α Value 1 These bits specify fixed α value 1 used when the CCMDY or ACMDY bits are set to 100b. A value from 00h to FFh can be specified.

(7) BRS Control Register B (LCDC_VSPD_VI6_BRSB_CTRL)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 3918h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	CBES	0h	RW	Blending Expression Selection Selects the blending expression of the color data in the BRS (VI6_BRSB_CTRL.RBC = 1). Blending coefficients are specified by the CCMDX and CCMDY bits. 0b: CCMDX × (DST color data) + CCMDY × (SRC color data) 1b: CCMDX × (DST color data) - CCMDY × (SRC color data)
30 to 28	CCMDX[2:0]	0h	RW	Blending Coefficient X Selection These bits specify coefficient X used in the blending expression determined by the CBES bit. 000b: DST α data is used as blending coefficient X 001b: 255 - (DST α data) is used as blending coefficient X 010b: SRC α data is used as blending coefficient X 011b: 255 - (SRC α data) is used as blending coefficient X 100b: Fixed α value 0 (COEFX setting)
27	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26 to 24	CCMDY[2:0]	0h	RW	Blending Coefficient Y Selection These bits specify coefficient Y used in the blending expression determined by the CBES bit. 000b: DST α data is used as blending coefficient Y 001b: 255 - (DST α data) is used as blending coefficient Y 010b: SRC α data is used as blending coefficient Y 011b: 255 - (SRC α data) is used as blending coefficient Y 100b: Fixed α value 1 (COEFY setting)
23	ABES	0h	RW	Blending α Creation Expression Specifies the expression for creating α data after blending by blending/ROP unit m (m = A, B, C, D, E). α creation coefficients are specified by the ACMDX and ACMDY bits. 0b: ACMDX × (DST α data) + ACMDY × (SRC α data) 1b: ACMDX × (DST α data) - ACMDY × (SRC α data)
22 to 20	ACMDX[2:0]	0h	RW	α Creation Coefficient X These bits specify α creation coefficient X used in the α creation expression determined by the ABES bit. 000b: (α creation coefficient X) = (DST α data) 001b: (α creation coefficient X) = 255 - (DST α data) 010b: (α creation coefficient X) = (SRC α data) 011b: (α creation coefficient X) = 255 - (SRC α data) 100b: (α creation coefficient X) = Fixed α value 0 (COEFX setting) 101b to 111b: Setting prohibited
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	ACMDY[2:0]	0h	RW	α Creation Coefficient Y These bits specify α creation coefficient Y used in the α creation expression determined by the ABES bit. 000b: (α creation coefficient Y) = (DST α data) 001b: (α creation coefficient Y) = 255 - (DST α data) 010b: (α creation coefficient Y) = (SRC α data) 011b: (α creation coefficient Y) = 255 - (SRC α data) 100b: (α creation coefficient Y) = Fixed α value 1 (COEFY setting) 101b to 111b: Setting prohibited
15 to 8	COEFX[7:0]	00h	RW	Fixed α Value 0 These bits specify fixed α value 0 used when the CCMDX or ACMDX bits are set to 100b. A value from 00h to FFh can be specified.
7 to 0	COEFY[7:0]	00h	RW	Fixed α Value 1 These bits specify fixed α value 1 used when the CCMDY or ACMDY bits are set to 100b. A value from 00h to FFh can be specified.

9.4.3.2.11 LIF Control Registers

(1) LIF0 Control Register (LCDC_VSPD_VI6_LIF0_CTRL)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 3B00h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	OBTH [11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	PADL	-	-	-	CFMT	-	-	REQSEL	LIF_EN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 16	OBTH [11:0]	000h	RW	Buffer Threshold for Start Ready Notification to Display Module Always specify 1500, when LIF_EN is set to 1b.
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	PADL	0h	RW	Enable/Disable of padding with dummy lines to output-image to the DU. Enables or disables of padding with dummy lines to output-image to the DU. 0b: Padding with dummy lines to output image to DU is disabled. 1b: Padding with dummy lines to output image to DU is enabled.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	CFMT	0h	RW	Chroma Format This bit selects the output format from the LIF module to the display module. When RGB format is used, this bit shall be set to 0b. 0b: YCbCr444 or RGB Format 1b: YCbCr422 Format [Note] The DU cannot receive YCbCr422 format. Therefore, when CFMT is 1, YCbCr444 data which information contents is equal to YCbCr422 is output to DU as shown in **Figure 9.4-31**.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	REQSEL	0h	RW	External Display Module Selection 0b: This value is setting prohibited when 1b is set to LIF_EN 1b: DU is selected as the destination external display module.
0	LIF_EN	0h	RW	Enable/Disable of Data Output to External Display Module Enables or disables data output from the LIF to the external display module (DU). 0b: Data output to the external display module is disabled. 1b: Data output to the external display module is enabled.

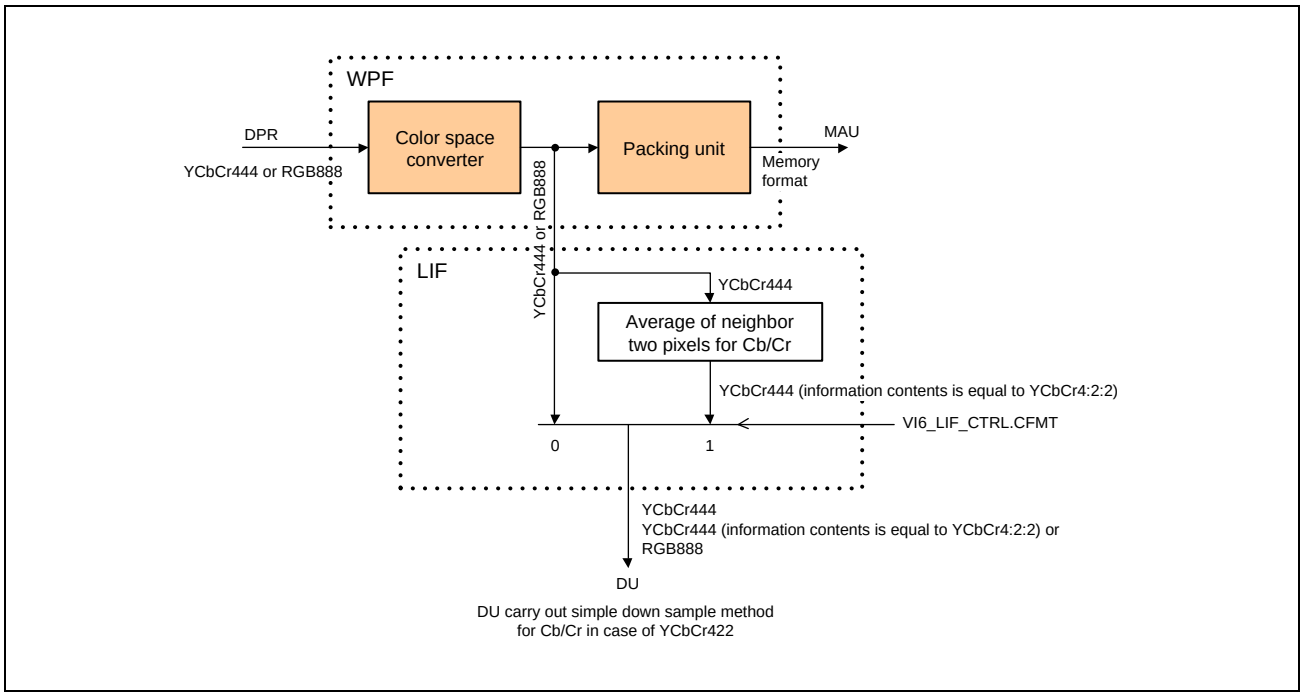

Figure 9.4-30 Data flow between LIF and DU

(2) LIF0 Clock Stop Buffer Control Register (LCDC_VI6_LIF0_CSBTH)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 3B04h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	HBTH[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	LBTH[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 16	HBTH[11:0]	000h	RW	Buffer Threshold for Clock Stop in Dynamic Clock Control Set HBTH[11:0] = 0 (fixed value)
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	LBTH[11:0]	000h	RW	Buffer Threshold for Clock Start in Dynamic Clock Control Set LBTH[11:0] = 0 (fixed value)

(3) LIF0 Buffer Attribute Register (LCDC_VI6_LIF0_LBA)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 3B0Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LBA0	-	-	-	LBA1[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	LBA2[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	LBA0	0h	RW	LIF Buffer Attribute Register0 Always specify 1b, when LIF_EN is set to 1b
30 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 16	LBA1[11:0]	000h	RW	LIF Buffer Attribute Register1 Always specify 1536, when LIF_EN is set to 1b
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	LBA2[11:0]	000h	R	LIF Buffer Attribute Register2 These bits are internal status for purpose of h/w debugging.

(4) LIF0 Padding Line Cycle Register (LCDC_VI6_LIF0_PADLN_CYC)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 3B30h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	PADLN_CYC[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW

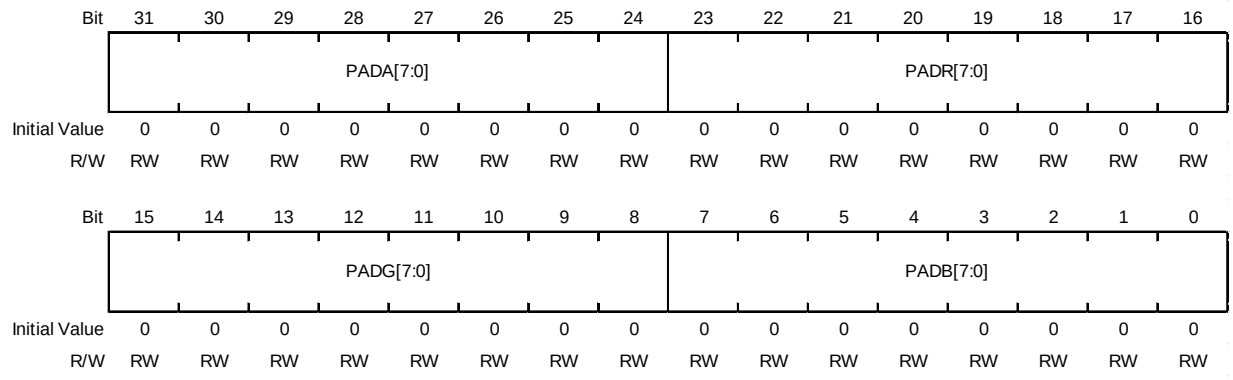
Bit	Bit Name	Initial Value	R/W	Description
31 to 6	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
5 to 0	PADLN_CYC [5:0]	00h	RW	Cycle of padding pattern. These bits specify the minimum number of cycles of the padding pattern of valid lines and dummy lines. For example, if PADLN_CYC[5:0] is 4, lower 4 bits of PADLN_PATTERN[3:0] indicates padding pattern. A value from 1 to 32 can be specified.

(5) LIF0 Padding Line Pattern Register (LCDC_VI6_LIF0_PADLN_PT)

Access Size : 32 bits

Address : <LCDC_vspd_base> + 3B34h

Initial Value : 0000_0000h



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PADLN_PATTERN[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PADLN_PATTERN[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PADLN_PATTERN[31:0]	0000_0000h	RW	Pattern of padding with dummy lines These bits specify the padding pattern of valid lines and dummy lines. In each bit, 0b indicates an active line, 1b indicates a dummy line. It starts from the lower bit (Bit 0). First line should be valid line (Always set 0 to PADLN_PATTERN[0]).

(6) LIF0 Padding Line Value Register (LCDC_VI6_LIF0_PADLN_VAL)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 3B38h
Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PADA[7:0]	00h	RW	Padding data of EDC code for dummy line.
23 to 16	PADR[7:0]	00h	RW	Padding data of R/Cr for dummy line.
15 to 8	PADG[7:0]	00h	RW	Padding data of G/Y for dummy line.
7 to 0	PADB[7:0]	00h	RW	Padding data of B/Cb for dummy line.

Note: Set the register to 24FF_FFFFh when the output format is YUV422.
Otherwise, set it 2EFF_FFFFh.

(7) LIF0 Padding Line Size Register (LCDC_VI6_LIF0_PADLN_SIZE)

Access Size : 32 bits
Address : <LCDC_vspd_base> + 3B3Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	PADLN_VSIZE[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	PADLN_VSIZE [12:0]	0000h	RW	Vertical Size of LIF output in case of enabling Padding line When VI6_LIF0_CTRL.PADL is 1b, dummy lines are included in the output data from LIF, so set the LIF output VSIZE including dummy lines to these bits. If the number of output lines does not reach the value of PADLN_VSIZE[12:0] even if all valid lines are output according to padding pattern, dummy lines are inserted until the number of output lines reaches PADLN_VSIZE[12:0]. - Output vsize of LIF is same with input vsize to LIF when VI6_LIF0_CTRL.PADL is 0b - Output vsize of LIF is PADLN_VSIZE[12:0] when VI6_LIF0_CTRL.PADL is 1b

9.4.4 DU Registers

The DU contains the registers which can directly be read and written to by the host CPU. The host can access any long word (32 bits), word (16 bits), and byte (8 bits) in the registers. Therefore, read-modify-write is needed to change partial bits not more than 8 bits in the 32-bit register.

Never access the registers when the DU is in the module standby mode (with the operation clock placed in hold status).

Table 9.4-28 DU Register Base Address

Base Register Name	LCDC Ch.	Base Address
<LCDC_du_base>	LCDC	0_1089_0000h (5089_0000h*1, 4089_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.4.4.1 List of DU Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
DU Module Control Register 0	LCDC_DU_MCR0	0000_0000h	0000h	32, 16, 8
DU Module Status Register 0	LCDC_DU_MSR0	0054_0000h	0004h	32, 16, 8
DU Module Status Register 1	LCDC_DU_MSR1	0000_0000h	0008h	32, 16, 8
DU Interrupt Mask Register 0	LCDC_DU_IMR0	0000_0000h	000Ch	32, 16, 8
DU Display I/F Timing Register 0	LCDC_DU_DITR0	0003_0300h	0010h	32, 16, 8
DU Display I/F Timing Register 1	LCDC_DU_DITR1	0000_0000h	0014h	32, 16, 8
DU Display I/F Timing Register 2	LCDC_DU_DITR2	0000_0000h	0018h	32, 16, 8
DU Display I/F Timing Register 3	LCDC_DU_DITR3	0000_0000h	001Ch	32, 16, 8
DU Display I/F Timing Register 4	LCDC_DU_DITR4	0000_0000h	0020h	32, 16, 8
Reserve	-	-	0024h to 003Fh	-
DU Module Control Register 1	LCDC_DU_MCR1	0000_0000h	0040h	32, 16, 8
Reserve	-	-	0044h to 004Bh	-
DU PBUF Control Register 0	LCDC_DU_PBCR0	0000_001Fh	004Ch	32, 16, 8
DU PBUF Control Register 1	LCDC_DU_PBCR1	0000_0000h	0050h	32, 16, 8
DU PBUF Control Register 2	LCDC_DU_PBCR2	0000_0000h	0054h	32, 16, 8

9.4.4.2 DU Register Description

The prefix (LCDC_) of the register names is omitted in this and subsequent sections.

9.4.4.2.1 DU Module Control Register 0 (LCDC_DU_MCR0)

Access Size : 32, 16, 8 bits
Address : <LCDC_du_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	PB_CLR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	DI_EN	-	-	-	-	-	-	-	DPI_OE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	PB_CLR	0h	RW	Clear PBUF pointers. This parameter must be changed while VSPD is not running and DU_MSR0.ST_DIF_BSY is '0b'. Writing '1b' to this parameter starts clearing the PBUF pointers. After clearing the PBUF pointers is completed, DU_MSR0.ST_PB_WINIT and DU_MSR0.ST_PB_RINIT are read as 1b, this parameter must be written back to '0b'.
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	DI_EN	0h	RW	Display enable. 1b: Enabled 0b: Disabled
7 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	DPI_OE	0h	RW	Display parallel interface output enable. This parameter is directly connected to duo_dpi_oe port. If duo_dpi_oe port is not used, this parameter is invalid. This parameter must be changed while VSPD is not running and DU_MSR0.ST_DIF_BSY is 0b. 0b: Disabled 1b: Enabled

9.4.4.2.2 DU Module Status Register 0 (LCDC_DU_MSR0)

Access Size : 32, 16, 8 bits

Address : <LCDC_du_base> + 0004h

Initial Value : 0054_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	ST_PB_RINIT	ST_PB_RUF	ST_PB_REMPTY	-	ST_PB_WINIT	-	ST_PB_WFULL
Initial Value	0	0	0	0	0	0	0	0	0	1	0	1	0	1	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	ST_DI_BSY	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
22	ST_PB_RINIT	1h	R	PBUF FIFO read pointer cleared status. 1b: Cleared (initial value) 0b: Not cleared
21	ST_PB_RUF	0h	R	PBUF read underflow status. This parameter clears when PBUF pointers are cleared. 1b: Occur PBUF underflow 0b: Not occur PBUF underflow
20	ST_PB_REMPTY	1h	R	PBUF read empty status. 1b: Empty 0b: Not empty
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	ST_PB_WINIT	1h	R	PBUF FIFO write pointer cleared status. 1b: Cleared (initial value) 0b: Not cleared
17	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	ST_PB_WFULL	0h	R	PBUF write full status. 1b: Full 0b: Not full
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	ST_DI_BSY	0h	R	Display I/F status. 1b: Busy 0b: Idle
7 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.4.4.2.3 DU Module Status Register 1 (LCDC_DU_MSR1)

Access Size : 32, 16, 8 bits

Address : <LCDC_du_base> + 0008h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	UF_VACT[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	UF_HACT[12:0]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	UF_VACT[12:0]	0000h	R	Vactive counter when the PBUF underflow occurs. This parameter is value latched the down counter starting from VACTIVE. This parameter is cleared when DU_MSR0.ST_PB_RUF is cleared.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	UF_HACT[12:0]	0000h	R	Hactive counter when the PBUF underflow occurs. This parameter is value latched the down counter starting from HACTIVE. This parameter is cleared when DU_MSR0.ST_PB_RUF is cleared.

9.4.4.2.4 DU Interrupt Mask Register 0 (LCDC_DU_IMR0)

Access Size : 32, 16, 8 bits

Address : <LCDC_du_base> + 000Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	PB_RUFOP	0h	RW	Specify behavior when the PBUF underflow occurs. 0b: Continue outputting invalid data 1b: Output DU_PBCR2.PB_RUFDAT

9.4.4.2.13 DU PBUF Control Register 2 (LCDC_DU_PBCR2)

Access Size : 32, 16, 8 bits

Address : <LCDC_du_base> + 0054h

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 0	PB_RUFDAT [23:0]	00_0000h	RW	Read data when the PBUF underflow occurs.

9.4.5 Operation

9.4.5.1 Operation Control Setting

(a) To start image process

FCPVD registers do not need to be set when starting an image process. Therefore, refer **9.4.5.4 Concept of VSPD Operation Starting and Stopping** for the guidance of starting an image process.

9.4.5.2 Reset Operation

This unit can be reset by hardware reset. The hardware reset is controlled by LCDC_n_RESET_N (n = 0, 1) of CPG, and this reset initializes the whole this unit immediately.

9.4.5.3 Registers to Set Fixed Value

Set fixed value to following registers in any case.

[1] Always set 0000 0808h to VI6_CLK_DCSWT

[2] Always set 256 to VI6_DL_CTRL.AR_WAIT [7:0] in case of using display list.

[3] Always set 2 to VI6_DL_EXT_CTRLn.POLINT [5:0] in case of using extended display list of WPFn.

[4] Always set 1 to VI6_DL_EXT_CTRLn.DLPRI in case of using extended display list of WPFn.

[5] Always set 0 to VI6_DL_EXT_CTRLn.EXPRI in case of using extended display list of WPFn.

[6] Always set 0000 0500h toVI6_DPR_WPFn_FPORCH (n = 0, 1) in case of using WPFn.

[7] Always set 1500 to VI6_LIF0_CTRL.OBTH [11:0] in case of using LIF (VI6_LIF0_CTRL.LIF_EN = 1).

[8] Always set 8600 0000h to VI6_LIF0_LBA in case of using LIF0 (VI6_LIF0_CTRL.LIF_EN = 1).

[9] Always set 1 to VI6_LIFn_CTRL.REQSEL in case of using LIFn (VI6_LIFn_CTRL.LIF_EN = 1).

[10] Always set 0 to VI6_LIFn_CSBTH in case of using LIFn (VI6_LIFn_CTRL.LIF_EN = 1).

[11] Always set 1Fh to DU_PBCR0 in case of using DU (DU_MCR0.DI_EN = 1).

9.4.5.4 Concept of VSPD Operation Starting and Stopping

The VSPD provides one channel of image processing. Each channel is started by setting the corresponding start register. Here, starting a processing channel means starting one of WPF0, which are output modules of the VSPD. Use the start registers shown in **Table 9.4-29** to start WPF modules.

After a WPF module is started and specified processing is completed, the corresponding channel stops operation and notifies the end of processing through an end interrupt. End interrupts are generated through the end interrupt source registers shown in **Table 9.4-29**; clearing a source register cancels the corresponding interrupt signal. Each of the operating status registers shown in the table indicates the busy state after the corresponding channel is started through the start register until processing is completed and operation stops. **Figure 9.4-33** shows these operation timings.

Table 9.4-29 Target Module and Corresponding Registers for Starting and Stopping Operation

Target Module	Start Register	End Interrupt Source Register	Operating Status Register
WPF0	VI6_CMD0.STRCMD	VI6_WPF0_IRQ_STA. FRE	VI6_STATUS.SYS0_ACT

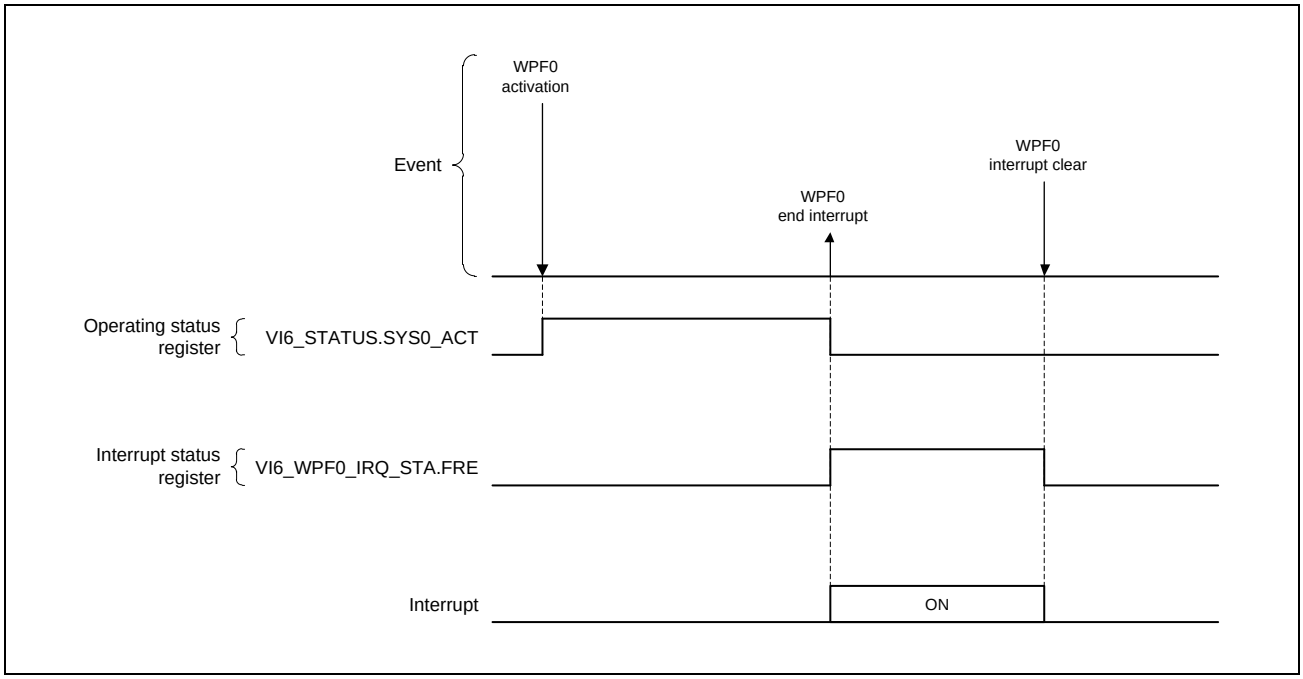

Figure 9.4-32 VSPD Startup and Status of Each Register and Interrupt

The following describes the operating states (operating or stopped) of VSPD internal modules. As described in **9.4.3.2 VSPD Register Description**, the VSPD has several image processing modules and the connections between modules are determined by the DPR. Accordingly, the operating state of a module is the same as that of the target WPF for that module. For example, when the target WPF for the BRS is WPF0, the BRS operating state is the same as that of WPF0; that is, the BRS operating state is indicated by the VI6_STATUS.SYS0_ACT as shown in **Table 9.4-29** and the status change timing is shown as VI6_STATUS. SYS0_ACT in **Figure 9.4-32**. Likewise, the operating states of all modules connected to WPF0 is indicated by VI6_STATUS. SYS0_ACT.

Connections should be changed through the DPR-related registers (described later) while all modules to be affected by any change in connections are stopped. If connections through the DPR are changed during operation, the VSPD will hang.

Figure 9.4-33 shows relation between start reservation and operating status. When start is reserved while VSPD is operating, the reservation is accepted after VSPD status is moved from “operating” into “idle” as shown in **Figure 9.4-33**.

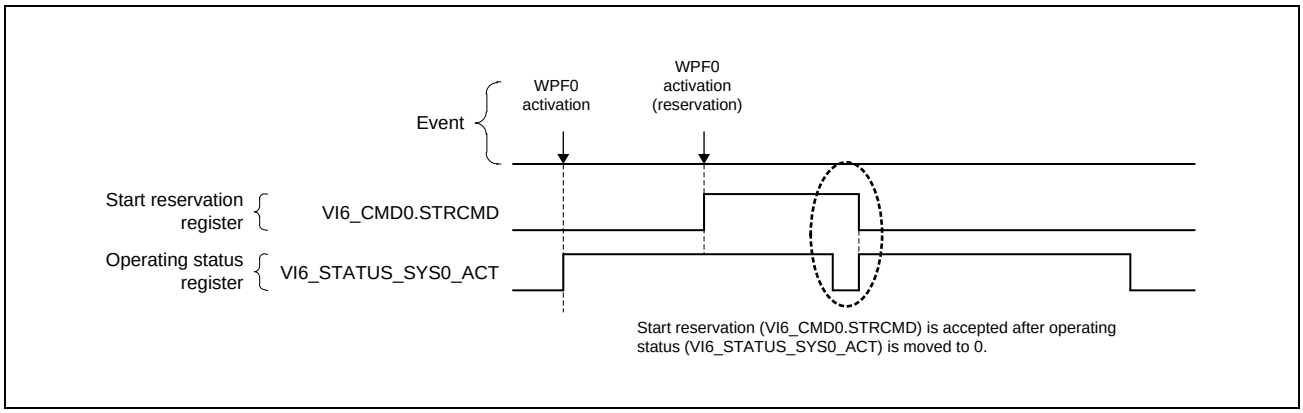

Figure 9.4-33 VSPD Start Reservation and Operating Status

9.4.5.5 Display List

9.4.5.5.1 Functional description

The VSPD provides the display list function. As a display list, the VSPD automatically downloads the register settings except for the control registers (**9.4.3.2.4 General Control Registers** and **9.4.3.2.5 Display List Control Registers**) from external memory and stores the settings in the VSPD registers. This function is advantageous in that the interrupt processing or register setting modification processing can be executed without CPU intervention during multiple-frame processing because the register settings used for VSPD processing are prepared in advance in external memory such as SDRAM.

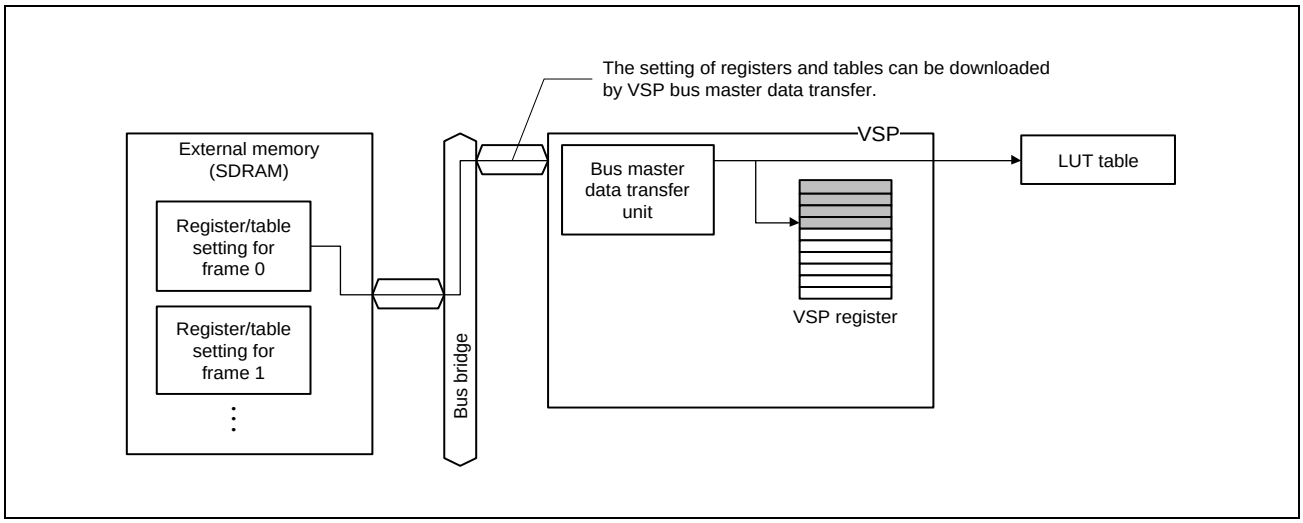

Figure 9.4-34 Concept of Display List

To use display lists, specify the external memory addresses to the display list control registers described in **9.4.3.2.5 Display List Control Registers**. The register settings or various types of information should be stored in external memory in the format described in **9.4.5.5.2 Normal display list mode**. **Figure 9.4-35** shows the difference between VSPD operation through normal register settings and through display lists.

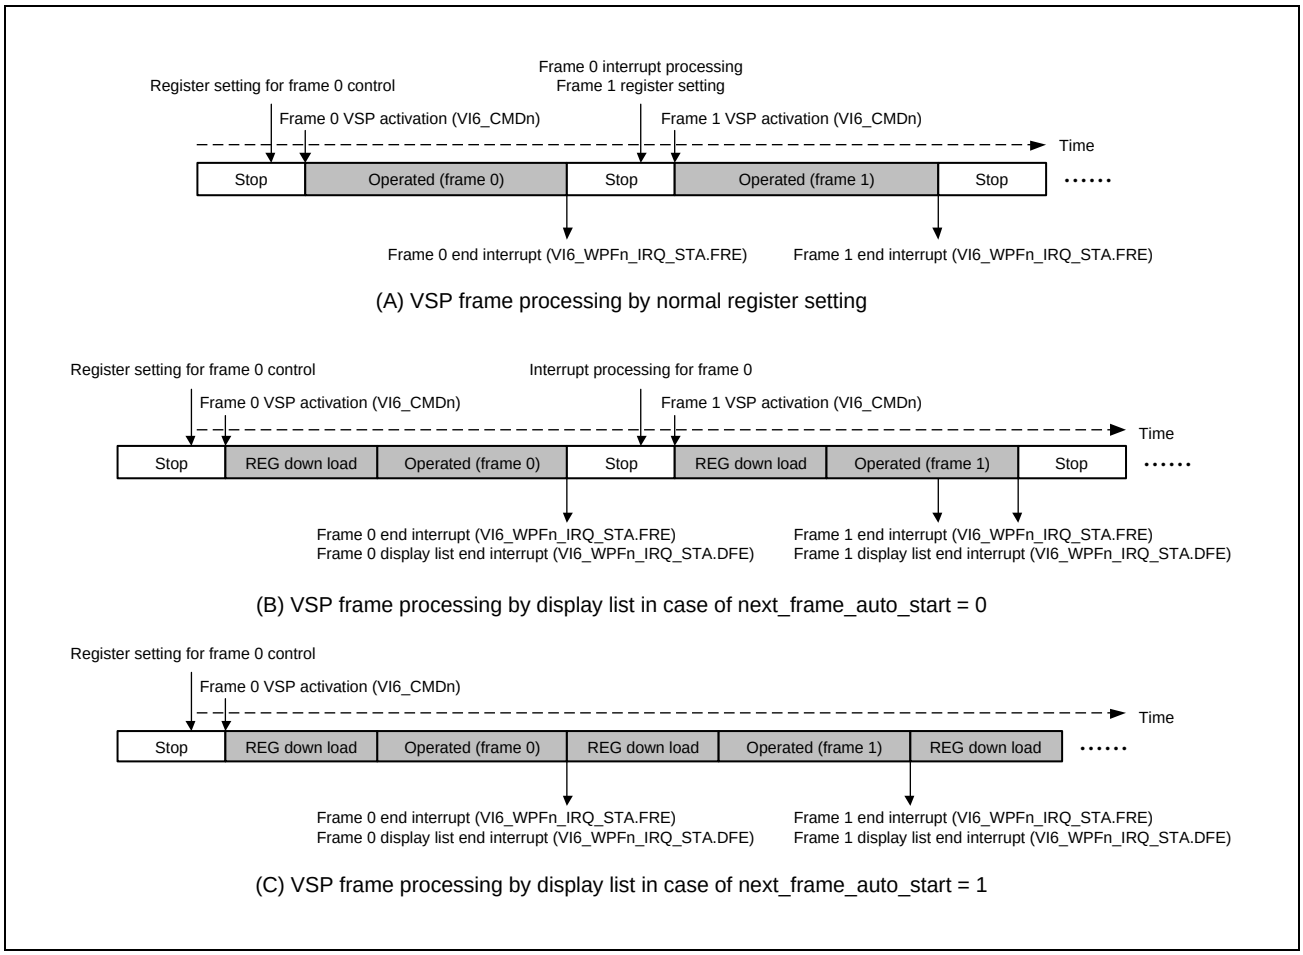

Figure 9.4-35 Comparison of VSPD Operation between Normal Register Settings and Display Lists

As shown in **Figure 9.4-35** (A), in the VSPD processing through normal register settings, all registers should be set up before the VSPD is started for each frame. After the VSPD processing is completed, the VSPD outputs a frame end interrupt (VI6_WPFn_IRQ_STA.FRE). This method requires a certain amount of time for register settings or interrupt processing by the CPU between frames. In contrast, when display lists are used, the VSPD automatically downloads register settings from external memory as shown in **Figure 9.4-35** (B) and (C), which reduces the load on the CPU between frames.

Figure 9.4-35 (B) shows the display list usage where the VSPD stops at the end of every frame; only the VSPD start processing for each frame is done by the CPU. This is suitable for the cases when the CPU controls synchronization of frame processing in frame buffer management or when the amount of register values or table data to be set in the VSPD is large. In the case shown in **Figure 9.4-35** (C), as soon as the frame processing ends, the VSPD automatically begins next frame operation and starts downloading new register settings. This is the fastest operation using display lists.

Table 9.4-30 shows the modes of the display list and the supported functions for each mode. The detail of each mode is described in the following sections.

Table 9.4-30 Display list mode and supported functions

Mode	Extended Display List	Continuous Frames
Normal Display List Mode	Supported	Controlled by “next frame auto start” in the header of the display list.
Header-less Display List Mode	Not Supported	Controlled by VI6_DL_CTRL.CFM0 bit.

9.4.5.5.2 Normal display list mode

The VSPD display lists include control information as well as simple register settings in order to control multiple-frame processing in an optimum way for each application. **Figure 9.4-36** shows the display list structure.

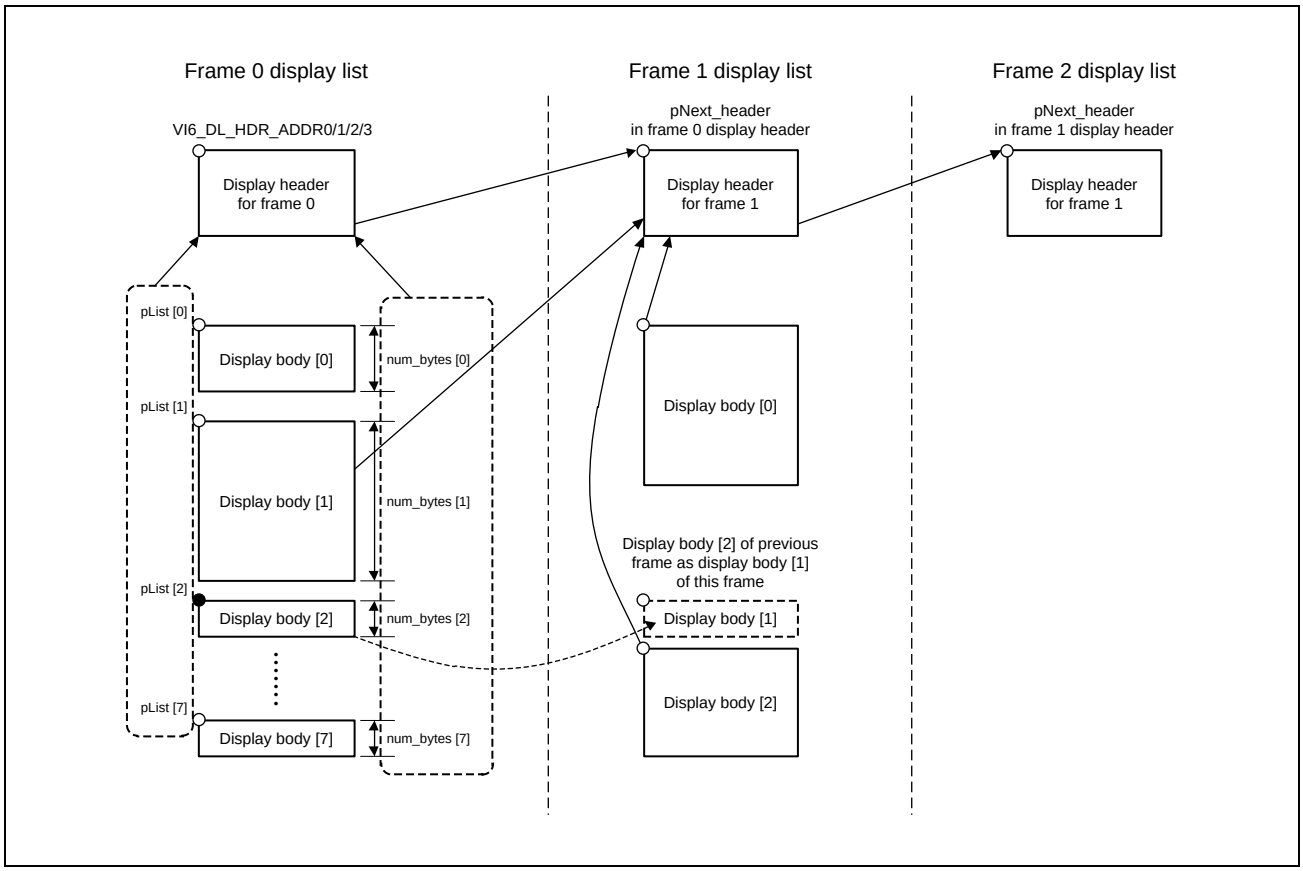

Figure 9.4-36 Structure and Concept of VSPD Display List

A VSPD display list consists of two sections; a header section for storing various information and control flags and a body section for storing register and table settings. A combination of these two sections is defined as a display list for a frame. The register and table settings can be divided and stored in up to eight separate bodies allocated in memory. Therefore, the separate bodies storing the register settings for one frame (for example, frame 0) can have non-sequential start addresses; that is, the bodies for one frame can be allocated to areas distant from each other in memory. To gather these bodies and configure the register settings for one frame, a header is used. A display header stores the number of bodies linked with the header and the start address and size of each body.

The VSPD analyzes the header to gather register and table settings stored in separate memory areas and reconfigures the complete register settings.

The addresses of display headers should be specified in the VSPD registers described in **9.4.3.2.5 Display List Control Registers**. When activated in a mode that uses display lists, the VSPD downloads display headers from the

addresses specified in VI6_DL_HDR_ADDR0 (number 0 correspond to the WPF channel index numbers), analyzes the numbers of bodies and the address and data size of each body, downloads the bodies, and completes register and table settings. After display list downloading is completed, the VSPD becomes ready for frame image processing; the VSPD then starts the actual frame processing.

After processing of a frame ends, the VSPD proceeds to the next frame processing. Here, there are two modes for starting the next frame processing as shown in **Figure 9.4-35**. In one mode, the VSPD stops operation and waits for the next activation by the CPU in the same way as when display lists are not used. In this mode, the address used for downloading the display header of the next frame is kept by the internal hardware. Therefore, if valid address information is not stored in the display header for the previous frame, a correct value should be specified in VI6_DL_HDR_ADDR0 while the VSPD is stopped. When the VSPD is started after a correct value is specified, the VSPD starts next frame processing with the same procedure for the previous frame. In contrast to this mode, which stops the VSPD after the end of one-frame processing, there is another mode for automatically starting next frame processing. In automatic start mode, the VSPD downloads the next display header as soon as the previous frame processing ends. After downloading ends, the VSPD starts image processing. The information regarding mode selection, that is, whether to automatically start next frame processing, should be stored in the display header downloaded for the previous frame.

To strictly define the display list format described above, the following shows the grammatical structure of a display list using pseudo-code. First, to simplify the description of the display list format in the following pages, **Table 9.4-31** defines a function. Function zero bits (num bits) generates a string of one-bit 0s for the number of bits specified by the parameter for the function. By using this function, **Table 9.4-32** defines the header section format of a display list and **Table 9.4-33** defines the body section format and **Table 9.4-34** defines the extended display list body section format.

Data order of Display List Header Section, Display List Body Section and Extended Display List Body Section are assumed as the data is stored in SDRAM by big endian. **Table 9.4-35** shows an example of data order. If data order is not same as the definition, data order within 8byte unit can be adjusted by setting VI6_DL_SWAP (see **(3) Display List-0 Data Swapping Register (LCDC_VSPD_VI6_DL_SWAP0)**).

Table 9.4-31 Definition of a Function for Simple Description

Syntax	Bit Count
zero_bits (num_bits)	
{	
for (i = 0; i<num_bits; i++) {	
zero_bit	1
}	
}	

Bit String	Contents
zero_bit	zero_bit indicates a 1-bit integer having a value of 0.

Table 9.4-32 Format of Display List Header Section

Syntax	Bit Count
display_header () /* Fixed length */	
{	
zero_bits (29)	
num_list_minus1	3
for (i=0; i<8; i++)	
zero_bits (15)	
num_bytes [i]	17
pList [i]	32
}	
pNext_header	32

wait_wup	1
zero_bits (3)	
ignore_upd_dl	1
zero_bits (2)	
current_frame_int_enable	1
next_frame_auto_start /* 76 bytes from the beginning of this header*/	1
if (VI6_DL_EXT_CTRL.EXT) {	
zero_bits (32) /* padding zero 4 bytes for alignment */	
zero_bits (6)	
pre_ext_dl_exec	1
post_ext_dl_exec	1
zero_bits (8)	
pre_ext_dl_num_cmd	16
pre_ext_dl_pList	32
zero_bits (16)	
post_ext_dl_num_cmd	16
post_ext_dl_pList /* 96 bytes from the beginning of this header*/	32
}	
}	

Bit String	Contents
num_list_minus1	Specifies the value obtained by subtracting 1 from the total number of display list bodies linked with the display header. For example, when this bit field is set to 0, this display list uses one body.
num_bytes [i]	Specifies the number of bytes in the i-th display list body (indicated by index i). Be sure to specify a multiple of eight bytes. For the bodies that are not defined in num_list_minus1 (for example, i = 5 to 7 when num_list_minus1 is set to 4), specify 0.
pList [i]	Specifies the start address of the i-th display list body (indicated by index i). Be sure to specify an address aligned with an 8-byte boundary (the lower-order three bits are 0). For the bodies that are not defined in num_list_minus1 (for example, i = 5 to 7 when num_list_minus1 is set to 4), specify 0.
pNext_header	Specifies the address of the display list header for the next frame. After display list downloading ends, the VSPD keeps its value in the internal memory and uses it in the next display list header downloading. Be sure to specify an address aligned with an 8-byte boundary (the lower-order three bits are 0).
wait_wup	When this bit is 1, VSPD starts reading image data from external memory after WUP (Wake Up) signal from any channel of VIN asserts. This bit is available for WPF0.
ignore_upd_dl	If this bit is set to 1, new display list pointed by VI6_DL_HDR_ADDR0 is not downloaded in VSPD H/W for the next frame, even if S/W sets VI6_DL_HDR_ADDR0 during the frame. New display list is downloaded in VSPD H/W at next frame of the processing which this bit is 0. This bit is available for WPF0.
current_frame_int_enable	This is a flag that indicates whether to set the display list end interrupt source (VI6_WPFn_IRQ_STA.DFE) to 1 when the current frame processing ends. If this flag is set to 0, the display list end interrupt source (VI6_WPFn_IRQ_STA.DFE) is not set to 1 when one-frame processing by this display header ends. In this state, even if the display list end interrupt is enabled (VI6_WPFn_IRQ_ENB.DFEE is set to 1), no interrupt will be generated. If this flag is set to 1, the display list end interrupt source (VI6_WPFn_IRQ_STA.DFE) is set to 1 when one-frame processing by this display header ends. In this state, if the display list end interrupt is enabled (VI6_WPFn_IRQ_ENB.DFEE is set to 1), the VSPD generates an interrupt.
Next_frame_auto_start	Enables or disables automatic start of next frame processing when one-frame processing by this display header ends. If this bit is set to 1, the VSPD starts next frame processing as soon as one-frame processing by this display header ends, and starts downloading the next frame display header from the pNext_header address specified in this display header. If this bit is set to 0, the VSPD stops operation when one-frame processing by this display header ends. In this case, start the VSPD through VI6_CMDn to process the next frame.
pre_ext_dl_exec	Enables execution of the extended display list for frame preprocessing when VI6_DL_EXT_CTRL.EXT is 1. If this bit is set to 1, the VSPD executes the extended display list for frame preprocessing. The VSPD does not execute it if this bit is set to 0. This bit setting is ignored when VI6_DL_EXT_CTRL.EXT is 0.
post_ext_dl_exec	Set 0 to this bit.
pre_ext_dl_num_cmd	Specifies the number of commands in the extended display list body section for frame preprocessing when VI6_DL_EXT_CTRL.EXT is 1. The number of commands that can be specified is 1, and a command is 16 bytes. When pre_ext_dl_exec is set to 0, the extended display list for frame preprocessing is not executed; specify 0 in this bit. This bit setting is ignored when VI6_DL_EXT_CTRL.EXT is 0.
pre_ext_dl_pList	Specifies the start address of the area where the extended display list body section for frame preprocessing is stored when VI6_DL_EXT_CTRL.EXT is 1. Be sure to specify an address aligned with a 16-byte boundary (lower-order four bits are 0). When pre_ext_dl_exec is set to 0, the extended display list for frame preprocessing is not executed; specify 0 in this bit. This bit setting is ignored when VI6_DL_EXT_CTRL.EXT is 0.
post_ext_dl_num_cmd	Set 0 to this bit.
post_ext_dl_pList	Set 0 to this bit.

Table 9.4-33 Format of Display List Body Section

Syntax	Bit Count
display_list (num_bytes) /* Variable length (num_bytes) */	
{	
for (i=0; i<num_bytes; i+=8) {	
set_address	32
set_data	32
}	
}	

Bit String	Contents
set_address	Specifies the address where the value specified by set_data is to be stored. Specify a register address. *Note*: Register space of VSPD is 32 Kbyte (0000h - 7FFCh). So, set 0 to upper 17-bit of set_address in Display List Body Section.
set_data	Specifies the value to be stored in the address specified by set_address. Specify a value to be set in a register.

Table 9.4-34 Format of Extended Display List Body Section

pList + 15	set_data [1] (bit7-0)
~~	~~~

9.4.5.5.3 Header-less display list mode

The header-less display list does not have the display header listed in **Table 9.4-32**, and it has the simplest structure that has only single body. The extended display list function is not available in case of the header-less display list mode. Set the value 1 to VI6_DL_CTRL.NH0 (see **(1) Display List Control Register (LCDC_VSPD_VI6_DL_CTRL)**) to use the header-less display list. The start address downloaded by the header-less display list should be set to VI6_DL_HDR_ADDR0. And the size of the display body which is originally defined in the display header should be set to VI6_DL_BODY_SIZE0. The header-less display list is available only in WPF0.

9.4.5.5.4 Restrictions on display list usage

Access to the general control registers and display list control registers through a display list is prohibited. When using display lists, be sure to observe the following restrictions on register access by the CPU.

1. Do not execute write access to the same register (same address) from the CPU and through a display list at the same time. If such a conflict occurs, correct operation of the VSPD is not guaranteed.
2. Do not execute write access to the same LUT lookup table from the CPU and through a display list at the same time. If such a conflict occurs, correct operation of the VSPD is not guaranteed. Here, the same lookup table means the address space having the same space name shown in **Table 9.4-36**.
3. When read access by the CPU and write access through a display list to the same register (same address) occur at the same time, the read value returned to the CPU is not guaranteed.
4. When read access by the CPU and write access through a display list to the same LUT lookup table occur at the same time, the read value returned to the CPU is not guaranteed. Here, the same lookup table means the address space having the same space name shown in **Table 9.4-36**.
5. For other restrictions on values and timing of register setting through display lists, refer to the restrictions on normal register settings described in **9.4.3.2.3 Restrictions on Access to Registers and Lookup Tables**.
6. Manipulation and setting of the registers described in **9.4.3.2.4 General Control Registers** and **9.4.3.2.5 Display List Control Registers** through a display list is prohibited.
7. Do not use extended display lists.

9.4.5.6 Interrupt Processing

9.4.5.6.1 vs1o_intreq_n

When a WPF module generates an internal source that should be notified, an interrupt signal is output. As internal sources are generated in WPF independently, the VSPD has the following registers to control interrupts in WPF.

- WPFn Interrupt Enable Registers (VI6_WPFn_IRQ_ENB: n = 0) (refer to **(12) WPF0 Interrupt Enable Register (LCDC_VSPD_VI6_WPF0_IRQ_ENB)**)
- WPFn Interrupt Status Registers (VI6_WPFn_IRQ_STA: n = 0) (refer to **(13) WPF0 Interrupt Status Register (LCDC_VSPD_VI6_WPF0_IRQ_STA)**)

CAUTION

To use interrupts, enable them through WPF interrupt enable registers. If an interrupt source register has already been set to 1 for some reason, an unintended interrupt will occur as soon as the corresponding interrupt enable register is set as enabled. To avoid this, before enabling interrupts through WPF interrupt enable registers, be sure to clear all WPF interrupt sources to be enabled to 0. Be careful about this procedure when setting up registers before starting the VSPD.

9.4.5.6.2 duo_intr_n

When the PBUF will detect a FIFO underflow, an interrupt signal is output. The DU has the following registers to control the interrupt.

- DU Module Status Register 0 (DU_MSR0) (refer to **9.4.4.2.2 DU Module Status Register 0 (LCDC_DU_MSR0)**)
- DU Interrupt Mask Register 0 (DU_IMR0) (refer to **9.4.4.2.4 DU Interrupt Mask Register 0 (LCDC_DU_IMR0)**)

CAUTION

To use interrupts, enable them through DU Interrupt Mask Register. If an interrupt is asserted, the PBUF is underflowing and invalid display data is being output. When an interrupt occurs, the interrupt can only be cleared by DU_MCR0.PB_CLR register.

If DU_MCR1.PB_AUTOCLR is set a value other than 0, an interrupt is cleared according to the DU_MCR1.OPMD register.

9.4.5.7 Lookup Table Settings

9.4.5.7.1 LUT

For a single entry to the LUT space (see **Table 9.4-36**) of the VSPD, the LUT data is set by a write access in the format shown in **Figure 9.4-37**.

The entry address of each space is (start address of the space) + (entry number counting from the base point 0 × 4). For example, the address of entry 7 to the LUT space is (offset address) + 7000h + 7 × 4 = (offset address) + 701Ch.

Table 9.4-36 shows the spaces for which entries can be made. Note that if the module that references that space is operating, write accesses to the relevant space are prohibited. So, while LUT is operating, accesses to the entire space of VI6_LUT_TBL are prohibited. When a read access is made to the relevant space during operation of the referencing module, undefined values will be read out.

The operating/stopped state of each module in **Table 9.4-36** is the operating state of the WPF to which each module is connected. Determine whether the module is operating or stopped using each WPF operating status bit in the VI6_STATUS register.

Table 9.4-36 LUT Space Addresses

Space Name	Space Addresses	Entry Count	Module that References the Space in the Left Column
VI6_LUT_TBL	(offset address) + 7000h to (offset address) + 73FCh	256	LUT

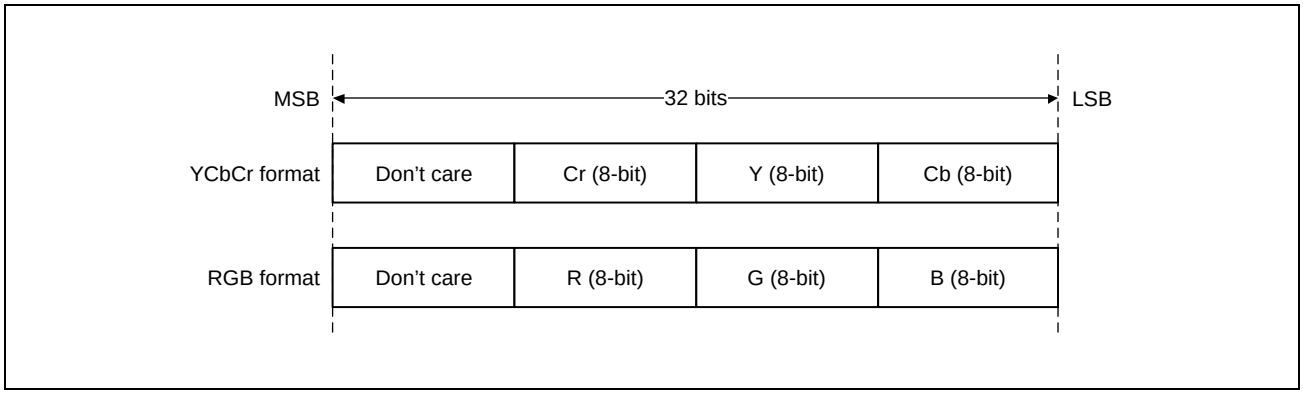

Figure 9.4-37 VI6_LUT_TBL Formats

9.4.5.8 Linked with DU

9.4.5.8.1 Operation flow of VSPD and DU

This section shows operation flow of VSPD by using Normal Display List Mode. For details of Normal Display List Mode, refer to **9.4.5.5.2 Normal display list mode**.

Figure 9.4-38 and **Figure 9.4-39** shows a procedure (register setting flow) to display image data to display panel.

Figure 9.4-38 shows setting flow to start VSPD/LIF0 linked with DU. **Figure 9.4-39** shows setting flow to update display image.

Using display list with enabling next_frame_auto_start shown in **9.4.5.5 Display List** is required to take the flow from **Figure 9.4-38** and **Figure 9.4-39**.

NOTE

If display sync operation ([1-7] step in **Figure 9.4-38**) is set before activating the VSPD, invalid data is displayed until image data read from external memory is ready to be transferred to DU. In this case, image data from external memory is displayed late by one vsync or more.

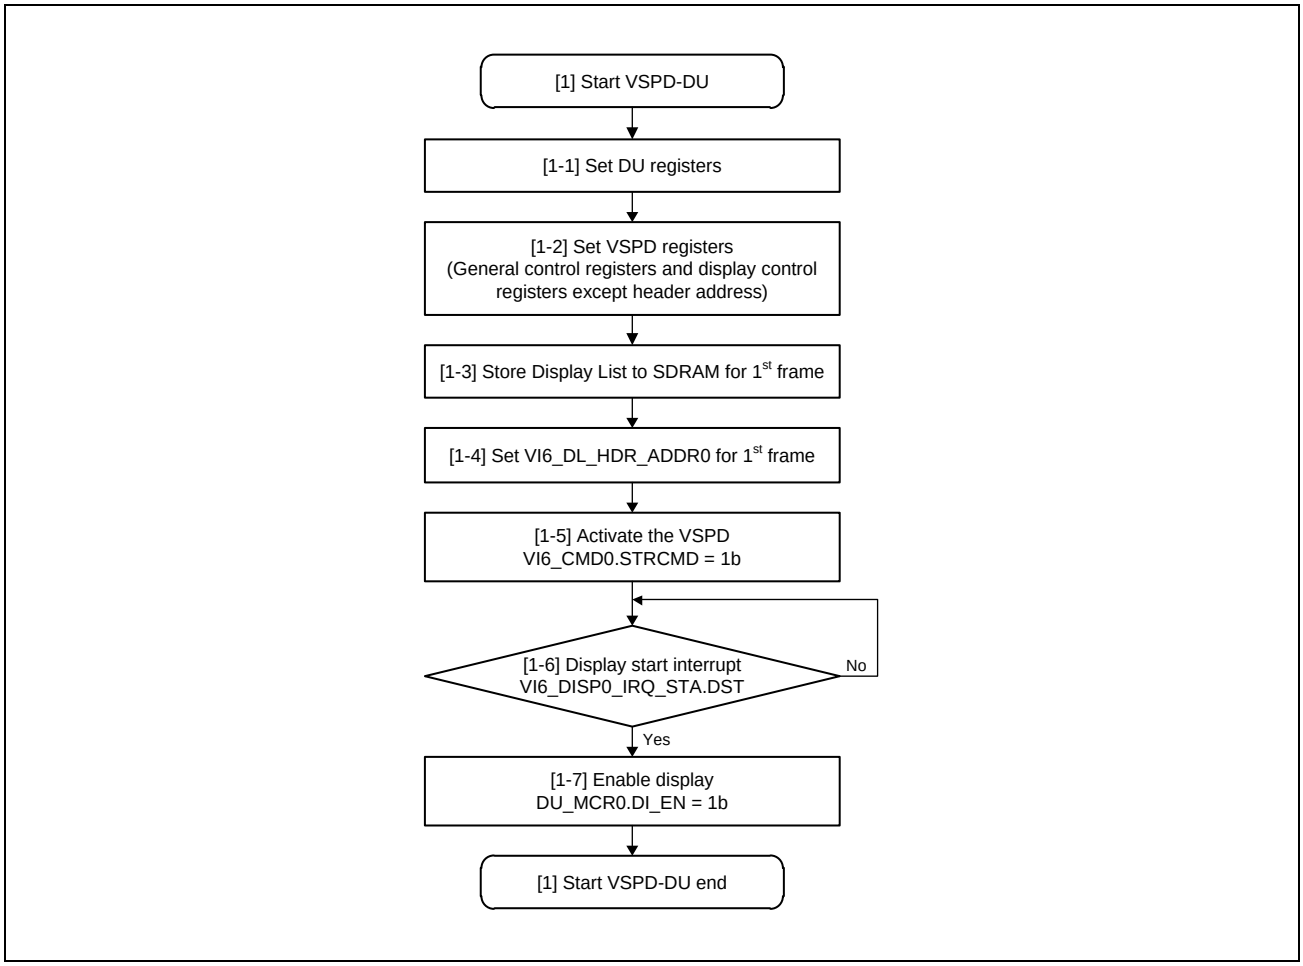

Figure 9.4-38 Setting Flow to Start VSPD Linked with DU

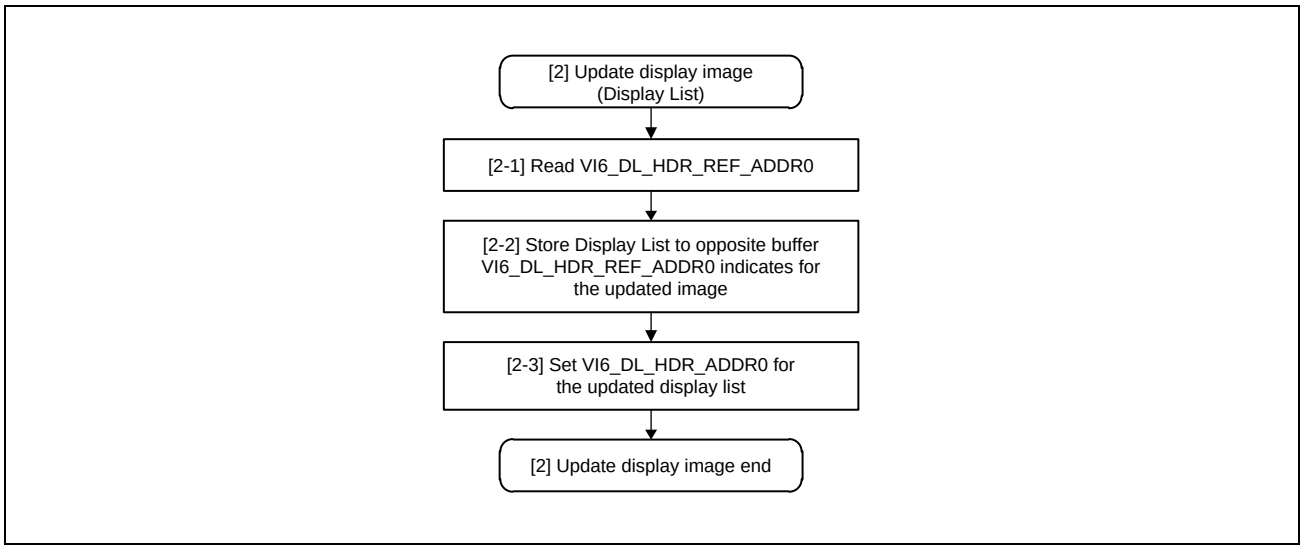

Figure 9.4-39 Setting flow to update display image

It is possible to update display list at any time (arbitrary timing) as shown in **Figure 9.4-39**. Don't overwrite display list in external memory pointed by VI6_DL_HDR_REF_ADDR. It is because VSPD is reading the display list pointed by VI6_DL_HDR_REF_ADDR or will be reading the display list soon.

Detail explanation is shown below.

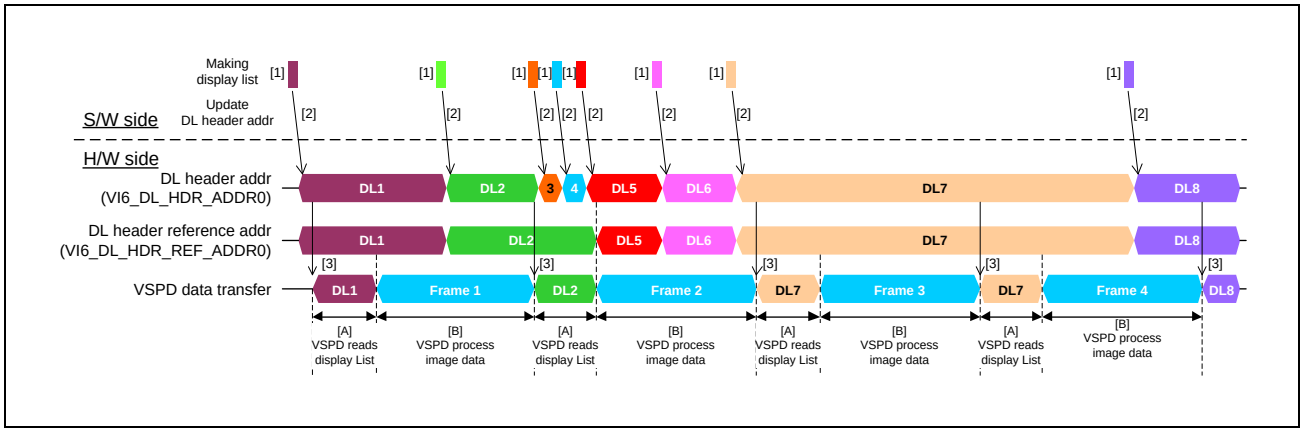
As shown in **(6) Display List-0 Header Reference Address Register (LCDC_VSPD_VI6_DL_HDR_REF_ADDR0)**, when VSPD is reading display list from external memory (Period [A] in **Figure 9.4-40**), VI6_DL_HDR_REF_ADDRn indicates header address of the display list referred by VSPD. When VSPD is not reading display list from external memory (Period [B] in **Figure 9.4-40**), VI6_DL_HDR_REF_ADDRn indicates the value of VI6_DL_HDR_ADDRn, and there is possibility that the display list is being read soon by VSPD at next frame start timing. Therefore, keep display list in external memory pointed by VI6_DL_HDR_REF_ADDR. Detail software sequence to update display list and VSPD -H/W behavior are shown below.

[1] Store latest display list in external memory area different from the area pointed by VI6_DL_HDR_REF_ADDR, because the area pointed by VI6_DL_HDR_REF_ADDR is being read or is being read soon by VSPD.

[2] Set header address of new display list into VI6_DL_HDR_ADDRn.

[3] VSPD reads display list from the external memory area pointed by VI6_DL_HDR_ADDRn at frame start timing.

Refer also to **(2) Display List-0 Header Address Register (LCDC_VSPD_VI6_DL_HDR_ADDR0)** and **(6) Display List-0 Header Reference Address Register (LCDC_VSPD_VI6_DL_HDR_REF_ADDR0)**.



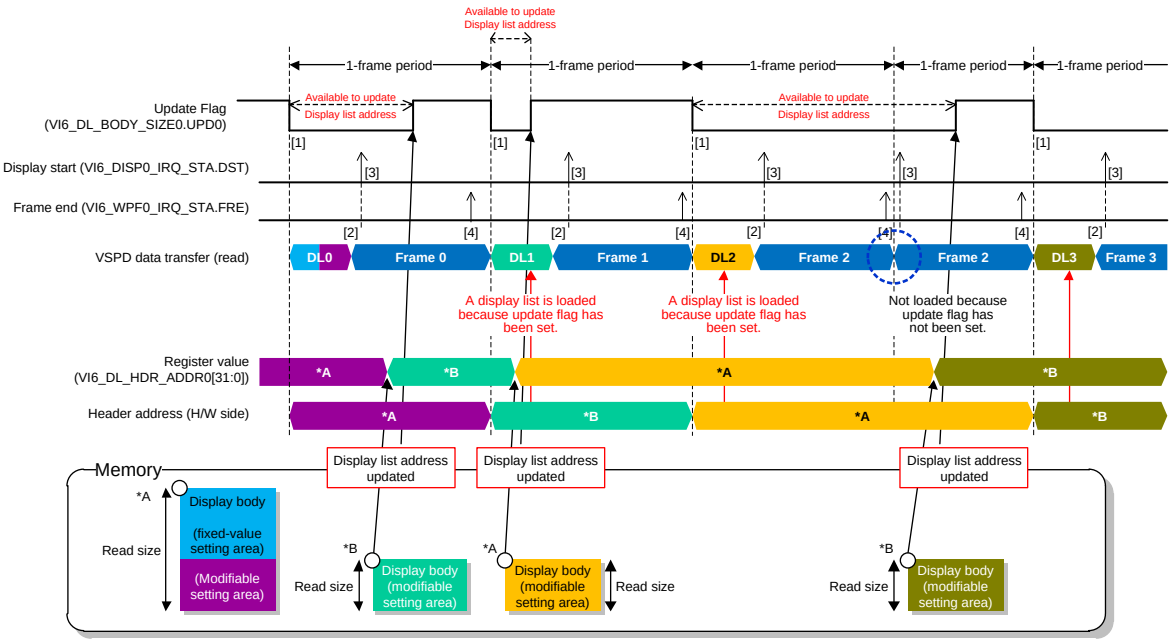


Figure 9.4-40 Updating Display List at Arbitrary Timing

9.4.5.8.2 Controlling two register planes using display lists

This section shows operation flow of VSPD by using Header-less Display List Mode. Start procedure and stop procedure are same with Normal Display List Mode in **9.4.5.8.1 Operation flow of VSPD and DU** except for the point that VI6_DL_BODY_SIZE0 should be set before step [1-5] in start procedure shown in **Figure 9.4-38**. The procedure to update display list is different with Normal Display List Mode, and is described later. **Figure 9.4-41** shows the control of two register planes using header-less display lists (see **9.4.5.5.3 Header-less display list mode**) and its timing. In the description hereafter, the use of header-less display lists is always assumed and they are simply called display lists.

Display list plane A: “Fixed-value settings” and “modifiable settings” are stored as a set in contiguous area A.
Display list plane B: Only the “modifiable settings” are stored in area B, which is separate from display list A.

To switch settings for every frame, modify two display list planes alternately. After every modification, update the display list address register (VI6_DL_HDR_ADDR0[31:0]) and writing 1 to update flag (VI6_DL_BODY_SIZE0.UPD0) in the VSPD.
Update flag (VI6_DL_BODY_SIZE0.UPD0) is negated automatically after Header Address is loaded into H/W side.

Figure 9.4-41 Controlling Two Register Planes Using a Display List

The VSPD downloads a display list immediately after activation. In the start frame, download the display list that contains all necessary settings. From the next frame on, only the necessary register or table values should be specified in a display list.

When the update flag of VI6_DL_BODY_SIZE0.UPD0 is set to 1, VSPD downloads a new display list at the start of the next frame. When the update flag of VI6_DL_BODY_SIZE0.UPD0 is set to 0, the register settings acquired from the display list previously downloaded are retained and used for the next operation without downloading a new display list.

Order of each VSPD -H/W Events mentioned as [1], [2], [3] and [4] in **Figure 9.4-41** are shown below.

[1] VI6_DL_BODY_SIZE0.BS0 and VI6_DL_HDR_ADDR0 are downloaded in H/W side. And Update Flag (VI6_DL_BODY_SIZE0.UPD0) is negated automatically.

[2] Reading DisplayList from external memory into VSPD -H/W is finished through master access.

[3] Display start interrupt status (VI6_DISP_IRQ_STA.DST) asserts.

[4] Frame end interrupt status (VI6_WPF0_IRQ_STA.FRE) asserts.

Don’t overwrite the display list in external memory for a period from “[4] VI6_WPF0_IRQ_STA.FRE” to next “[3] VI6_DISP_IRQ_STA.DST”, because VSPD is reading the display list for the period.

9.4.6 Usage Note

9.4.6.1 Assignment in Memory Space

Make sure that VSPD memory space shall be mapped to Non-Cache region.

9.4.6.2 Limitations on Software Reset and Module Standby

Stop LCDC with the software reset sequence following to the guidance in **9.4.5.1 Operation Control Setting**.

9.4.6.3 Input Image Size

Table 9.4-37 is a list of input size specifications.

Table 9.4-37 List of Input Size Specifications

Module	Min. Input Size (horizontal × vertical)	Max. Input Size (horizontal × vertical)	Restriction on Setting Unit
RPF	1 × 1 pixel	1920 × 1200 pixels 1200 × 1920 pixels	YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. YCbCr420: 2-pixel units both horizontally and vertically. Other formats: 1-pixel units both horizontally and vertically. *Note 1.* When the 1-bpp alpha plane*1 is input, the size can always be specified in 8-pixel units both horizontally and vertically regardless of the input format. *Note 2.* These restrictions including note 1 are applied to the following. VI6_RPFn_SRC_BSIZE VI6_RPFn_SRC_ESIZE
LUT	1 × 1 pixel	1920 × 1200 pixels 1200 × 1920 pixels	1-pixel units both horizontally and vertically.
BRS	1 × 1 pixel	1920 × 1200 pixels 1200 × 1920 pixels	1-pixel units both horizontally and vertically.
LIF	1 × 1 pixel	1920 × 1200 pixels 1200 × 1920 pixels	1-pixel units both horizontally and vertically.
WPF	1 × 1 pixel	1920 × 1200 pixels 1200 × 1920 pixels	YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. YCbCr420: 2-pixel units both horizontally and vertically. Other formats: 1-pixel units both horizontally and vertically. *Note 1.* This restriction on the WPF only applies to the WPF output size. The WPF input size should be specified in 1-pixel units.

Note 1. When VI6_RPFn_ALPH_SEL.ASEL is set to 011b.

The most important restriction shown in **Table 9.4-37** is the setting unit. Make appropriate register settings so that the size of the image input to each module does comply with setting units and does not exceed the limits shown in **Table 9.4-37**.

9.4.6.4 Output Image Size

The size of the output from each WPF is determined by the results of processing in the modules connected with the DPR. As shown in **Figure 9.4-1**, the data input to the VSPD is sent to the WPF output modules through the RPF and the modules connected with the DPR. When there is no processing that changes the image size through this data path, the WPF output size is the same as the RPF input size. **Table 9.4-38** is a list of the processing that changes image size.

Table 9.4-38 Image Processing that changes image size

Module	Function*1	Related Register	Size of Output from Module
WPF	Input size clipping	VI6_WPFn_HSZCLIP VI6_WPFn_VSZCLIP	When this function is disabled, the input size and the output size are the same. When this function is enabled, the output is in the following size. Horizontal output size: VI6_WPFn_HSZCLIP.HCL_SIZE × 2 setting Vertical output size: VI6_WPFn_VSZCLIP.VCL_SIZE × 2 setting
LIF	Padding line	VI6_LIFn_CTRL	When padding with dummy lines is disabled, output size is same with Input size. When padding with dummy lines is enabled: Horizontal output size: input size Vertical output size: VI6_LIF0_PADLN_SIZE setting

Note 1. For details of each function, refer to the descriptions of the related registers.

Note 2. Refer to **9.4.3.2.1 Notational Conventions for Registers and Bit Fields** for explanation of register bit field.

The input image size can be changed only with the modules and functions shown in **Table 9.4-38**. With the other modules and functions, the input size and output size are the same. Accordingly, after module connections with the DPR are determined, the VSPD output size can also be determined through the following steps.

1. The image size (VI6_RPFn_SRC_ESIZE) read from the external memory and sent to the DPR by the RPFn is the initial value.
2. When the module connected with the DPR is not a module (function) shown in **Table 9.4-38**, the output size from the module is the same as the input size; the image size does not need to be updated.
3. When a module connected with the DPR is a module (function) shown in **Table 9.4-38**, the output image size should be updated to the size shown in the table, which should be used as the input image size for the module connected behind it.
4. When the final image size at the WPFn is determined, this size is the VSPD output size for that WPFn path.

Figure 9.4-42 shows how to determine the image size in a sample DPR connection through the above steps. The related conditions that determine the image size are also shown.

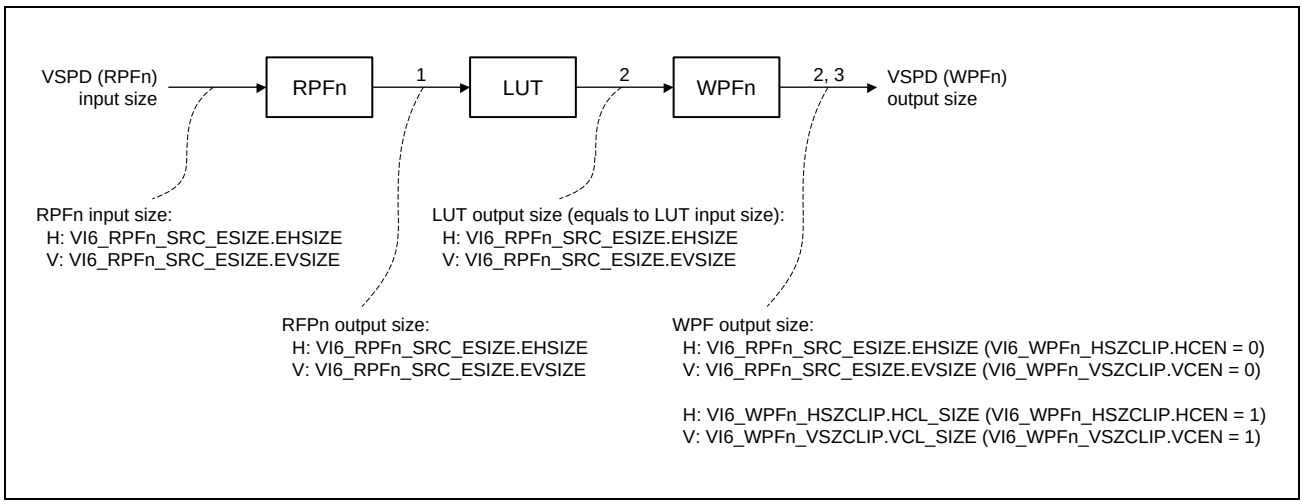

Figure 9.4-42 Input/output Size for Each Module in a Sample DPR Connection

Make appropriate register settings in each module so that the VSPD output image size determined as shown in the figure does not violate the restrictions shown in **Table 9.4-38**.

9.4.6.5 Restriction

When the data output from this unit is written back to the same memory area where the input data for this unit has been read, this unit has the following restrictions.

1. The access order and format on the frame memory are the same between the input pixels and output pixels.
2. Specifying a larger output image size than the input image size, either vertically or horizontally or both vertically and horizontally, is prohibited.
3. When the YCbCr4:2:0 format is input, operation between color components is prohibited.

These restrictions are summarized in. Refer to the descriptions of the registers related to each restriction. In the table, RPFm indicates the RPFn that inputs the master layer, and WPFwb indicates the WPFn that writes back the output image to the source image area for the master layer.

Table 9.4-39 Restrictions on Use when Output Data is Written Back to Input Data Area

No.	Restriction	Related Registers
Restriction 1	The RPFm input format and the WPFwb output format should be the same.	VI6_RPFn_INFMT.RDFMT VI6_RPFn_INFMT.VIR
	The RPFm source image storing address and the WPFwb destination address should be the same.	VI6_RPFn_SRCM_ADDR_*
	The RPFm source picture memory stride and the WPFwb destination memory stride should be the same.	VI6_RPFn_SRCM_PSTRIDE VI6_RPFn_SRCM_ASTRIDE
	The RPFm and WPFwb data swapping settings should be the same.	VI6_WPFn_DSWAP
Restriction 2	The RPFm basic read size and extended read size should be the same.	VI6_RPFn_SRC_BSIZE VI6_RPFn_SRC_ESIZE
	Color space conversion is prohibited in RPFm and WPFwb.	VI6_RPFn_INFMT.CSC VI6_WPFn_OUTFMT.CSC
Restriction 3*1	NOP should be specified for IROP operation.	VI6_RPFn_ALPH_SEL.IROP
	Color keying is prohibited.	VI6_RPFn_CKEY_CTRL.CV

Note 1. When the input format is not YCbCr4:2:0, restriction 3 in not applied.

SECTION 9 IMAGE

9.5 MIPI DSI Interface (DSI)

9.5.1 Overview

This section describes the features of the MIPI-DSI unit of this LSI.
If MIPI-DSI is used, change the LVDS to the reset state.

This module cannot be used at the same time as LVDS.

This unit is the MIPI-DSI Tx Module; it is composed of the MIPI DSI-2 host controller (LINK) and the MIPI D-PHY Tx (D-PHY).

This unit supports the MIPI Alliance Specification for Display Serial Interface (DSI) Specification. This unit provides a solution for transmitting MIPI DSI compliant digital video and packets. The normative references are listed below.

- MIPI Alliance Specification for Display Serial Interface Version 1.3.1
- MIPI Alliance Specification for D-PHY Version 2.1

9.5.1.1 Features

The following is key features of this unit.

In this document the word “DSI” means “Display Serial Interface Version 1.3.1”.

Overview

- 1 channel
- The number of lanes: 4 lanes
- Supports up to 1920 × 1200, 60 fps (RGB888)
- Maximum bandwidth: 1.5 Gbps per lane
- Supports the output data format: RGB666 / RGB888

Protocol Interface

- PPI interface (8 bits)
- Packet generation from Video Input signal for Video Mode (Video-Input Operation)
  - Supports the RGB format (18-bit, 18-bit loosely and 24-bit)
  - Not supports the RGB format (30-bit and 36-bit)
  - Not supports the YCbCr 4:2:2 format (16-bit, 20-bit loosely and 24-bit)
  - Not supports the YCbCr 4:2:0 format (12-bit)
  - Not supports Compressed Pixel Stream
  - Supports Blanking Packet or LP-11 selection during each of HSA, HBP, and HFP blanking interval
  - Supports “Non-Burst Mode with Sync Pulse”, “Non-Burst Mode with Sync Event”, and “Burst Mode”

- Not supports interlaced video
- Not supports deskew pattern insertion after vertical video data timing

- LP only packet generation and LP packet reception from descriptor list (Sequence Operation channel 0)
  - Supports one sequence input channel
- HS or LP packet generation and LP packet reception from descriptor list (Sequence Operation channel 1)
  - Supports one sequence input channel

Link Layer

- Supports 1, 2, 3, and 4 lane configurations
- Supports unidirectional high-speed mode Tx
- Supports bidirectional LP mode Tx/Rx (Only Lane0)
- Supports ECC/Checksum generation for Tx packet
- Supports ECC/Checksum verification and ECC error correction for Rx packet
- Supports automated insertion of EoTp in HS mode
- Supports ULPS (Tx)
- Supports automated power change to LP mode and return to HS mode
- Supports automated clock stop and resume (non-continuous clock mode)
- Supports assignment for Virtual Channel for video input channel in Video-Input Operation
- Supports assignment for individual Virtual Channel for each packet in Sequence Operation
- Supports detection for PHY contention error and timeout error
- Supports generation of scrambled packets
- Not supports input of TE signal

PHY Layer

- Number of Lanes
  Data Lane (DL): 4 Lanes
  Clock Lane (CL): 1 Lane
  - Transfer Rate
  - High Speed (HS) Mode: 80 – 1500Mbps
- Lane Module Functions
  - DL: CIL-MFAA (HS-TX, LP-TX, LP-RX, LP-CD)
  - CL: CIL-MCNN (HS-TX, LP-TX)

  <Number of Lanes>
  - Escape Mode
    - LPDT
      - LP Transmit: Supported
      - LP Receive: Supported
      - ULPS: Supported
      - Reset Trigger: Supported

- Bi-Direction
  - Bus Turn-Around: Supported
  - Contention Detection: Supported
- Calibration
  - Deskew Calibration / Preamble: Not-Supported
  - Pre/De-Emphasis: Not-Supported
  - Equalization: Not-Supported
- Others
  - HS-IDLE: Not-Supported
  - 16bit, 32bit width of Tx Data: Not-Supported

- Power Supply Voltage
  - VDD: In this section, replace it with VDD10_ISO.
  - VCCQLV18: In this section, replace it with VAA18_DSI.

9.5.1.2 Block Diagram

Figure 9.5-1 shows a block diagram.

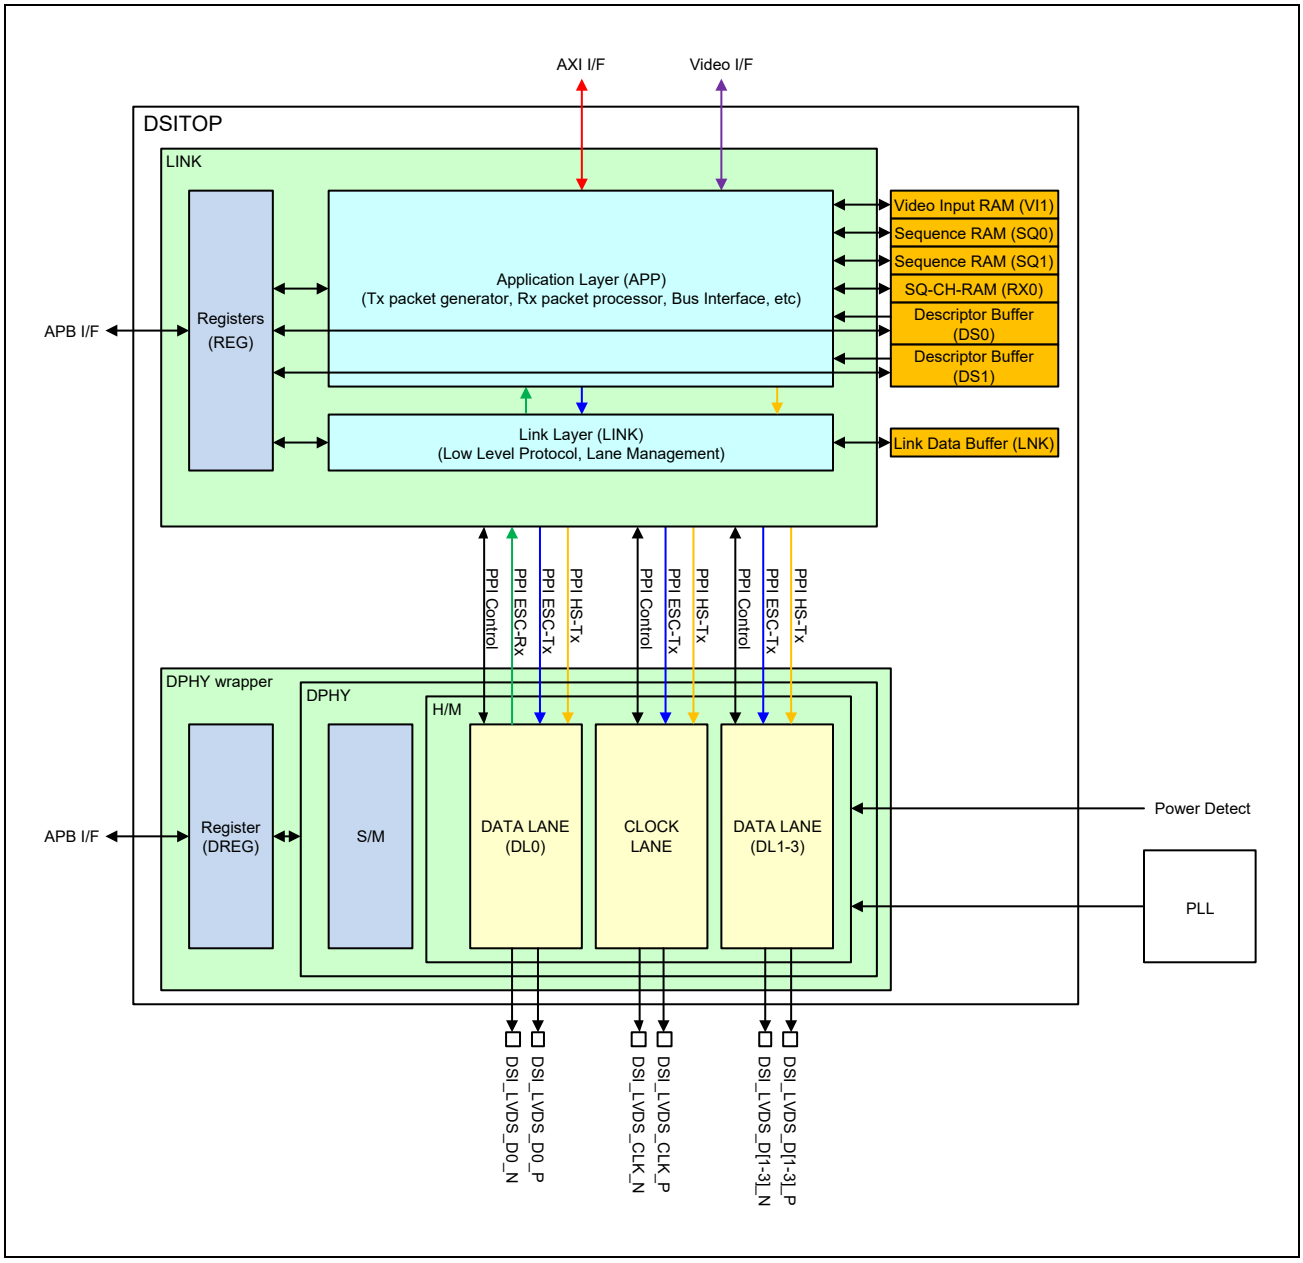

Figure 9.5-1 Block Diagram

9.5.1.3 External Pins

Table 9.5-1 shows the pin configuration.

Table 9.5-1 External Pins

Pin Name	Input/Output	Function
DSI_LVDS_CLK_P	Output	MIPI DSI Tx clock lane (pos)
DSI_LVDS_CLK_N	Output	MIPI DSI Tx clock lane (neg)
DSI_LVDS_D0_P	Output	MIPI DSI Tx data 0 lane (pos)
DSI_LVDS_D0_N	Output	MIPI DSI Tx data 0 lane (neg)
DSI_LVDS_D1_P	Output	MIPI DSI Tx data 1 lane (pos)
DSI_LVDS_D1_N	Output	MIPI DSI Tx data 1 lane (neg)
DSI_LVDS_D2_P	Output	MIPI DSI Tx data 2 lane (pos)
DSI_LVDS_D2_N	Output	MIPI DSI Tx data 2 lane (neg)
DSI_LVDS_D3_P	Output	MIPI DSI Tx data 3 lane (pos)
DSI_LVDS_D3_N	Output	MIPI DSI Tx data 3 lane (neg)

9.5.1.4 Clocks

The following shows a list of clocks for this unit.

- T_{LPX}: Transmitted length of any low-power state period (Min: 50 ns)
- $T_{LPX(H)}$: TLPX of the host processor (the DSI-2 TX module)
- $T_{LPX(P)}$: TLPX of the peripheral device (connected device)

Table 9.5-2 Clocks and the Frequency Range

Clock Name	CPG Clock Name	Input/ Output	Description	Frequency (MHz)
pclk	MIPI_DSI_PCLK	Input	APB clock	100 / 50
aclk	MIPI_DSI_ACLK	Input	AXI clock	200 / 100
vclk1	MIPI_DSI_VCLK	Input	Video clock	5.44 to 187.5
lpclk	MIPI_DSI_LPCLK	Input	DSI Escape mode Transmit Clock (TxClkEsc) Set D-PHY TxClkEsc ($1/T_{LPX(H)}$) frequency. $T_{LPX(H)}/T_{LPX(P)}$ needs to set between 2/3 to 3/2.	16.667 / 8.333 / 4.167 / 2.083
—	MIPI_DSI_SYSCLK	Input	System clock for D-PHY.	133.333
—	MIPI_DSI_PLLCLK	Input	PLL Multiplied clock. {Transfer rate x 2} MHz	160~3000
hsclk	—	—	DSI High-Speed Transmit Word Clock (TxWordClkHS) Upper limit for D-PHY 1.5 Gbps Lower limit for D-PHY 80 Mbps This clock is supplied from D-PHY directly, and its frequency is 1/16 for MIPI_DSI_PLLCLK.	10 to 187.5
lppclk	—	—	DSI Escape mode Receive Clock (RxClkEsc) This clock is supplied from D-PHY directly, and its frequency is ($1/T_{LPX(P)}$). This clock is generated dividing in D-PHY.	2 to 20

Video clock and DSI HS Byte clock must follow the relationship.

Video clock Frequency [Hz] × Video Pixel Bit Depth [bit]
<= DSI HS Byte clock Frequency [Hz] × 8 [bit] × Number of DSI HS Data Lane

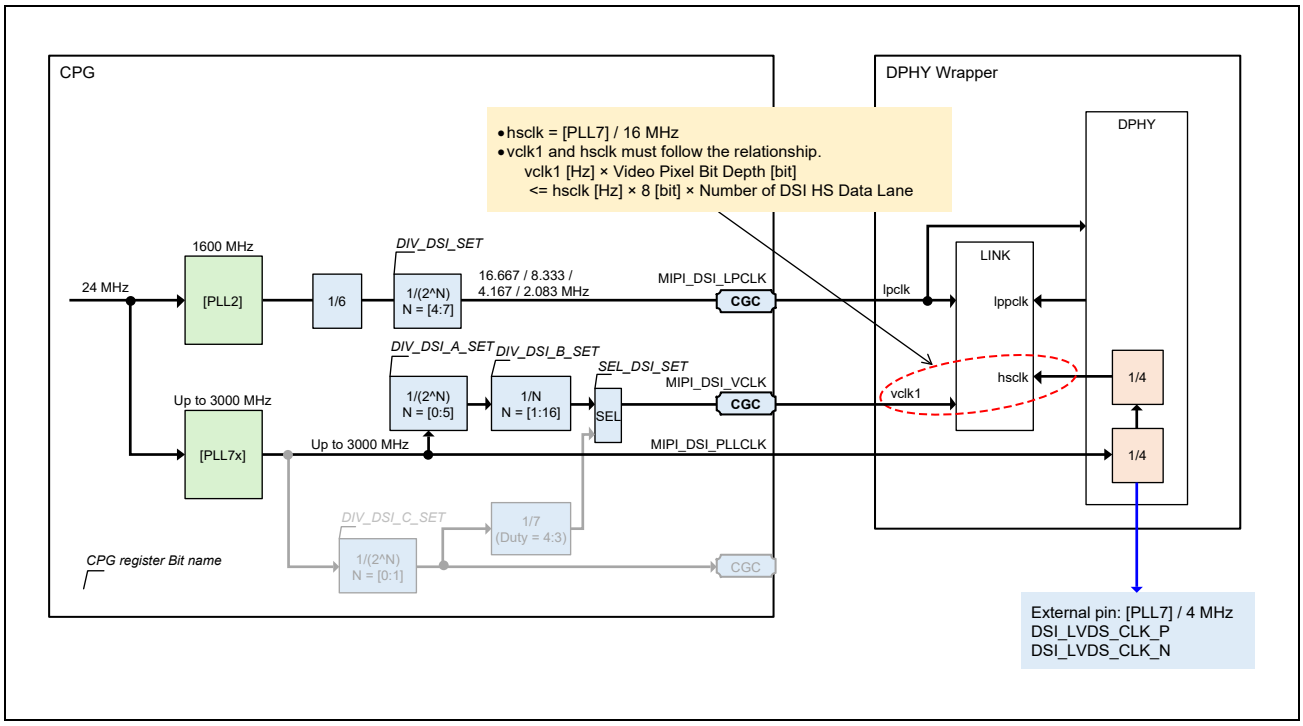

Figure 9.5-2 Clock Diagram

9.5.2 DSI Registers

The base addresses for the DSI are as follows.

Table 9.5-3 Register Base Addresses

Base Register Name	Unit Name	Base Address
<DSI_LINK_base>	DSI (LINK)	0_1086_0000h (5086_0000h*1, 4086_0000h*2)
<DSI_DPHY_base>	DSI (DPHY)	0_1085_0000h (5085_0000h*1, 4085_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.5.2.1 List of Registers

9.5.2.1.1 Registers in LINK

This section describes the registers in LINK. All registers can be accessed in 8/16/32 bits.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Interrupt Status Register	DSI_LINK_ISR	0000_0000h	0000h	8, 16, 32
Reserve	-	-	0004h to 000Fh	-
Link Status Register	DSI_LINK_LINKSR	0000_0000h	0010h	8, 16, 32
Reserve	-	-	0014h to 00FFh	-
Tx Set Register	DSI_LINK_TXSETR	0003_0003h	0100h	8, 16, 32
HS Clock Set Register	DSI_LINK_HSCLKSETR	0000_0000h	0104h	8, 16, 32
ULPS Set Register	DSI_LINK_ULPSSETR	0000_00A0h	0108h	8, 16, 32
ULPS Control Register	DSI_LINK_ULPSCR	0000_0000h	010Ch	8, 16, 32
Reset Control Register	DSI_LINK_RSTCR	0000_0000h	0110h	8, 16, 32
Reset Status Register	DSI_LINK_RSTSR	0000_0000h	0114h	8, 16, 32
Reserve	-	-	0118h to 011Fh	-
DSI Set Register	DSI_LINK_DSISETR	80F1_0001h	0120h	8, 16, 32
Receive Buffer Size Register	DSI_LINK_RXBUFSZR	0000_0000h	0124h	8, 16, 32
Reserve	-	-	0128h to 015Fh	-
Tx Packet Payload Data 0 Register	DSI_LINK_TXPPD0R	0000_0000h	0160h	8, 16, 32
Tx Packet Payload Data 1 Register	DSI_LINK_TXPPD1R	0000_0000h	0164h	8, 16, 32
Tx Packet Payload Data 2 Register	DSI_LINK_TXPPD2R	0000_0000h	0168h	8, 16, 32
Tx Packet Payload Data 3 Register	DSI_LINK_TXPPD3R	0000_0000h	016Ch	8, 16, 32
Reserve	-	-	0170h to 01FFh	-
Rx Status Register	DSI_LINK_RXSR	0000_0000h	0200h	8, 16, 32
Rx Status Clear Register	DSI_LINK_RXSCR	0000_0000h	0204h	8, 16, 32
Rx Interrupt Enable Register	DSI_LINK_RXIER	0000_0000h	0208h	8, 16, 32
Reserve	-	-	020Ch to 020Fh	-
Peripheral Response Timeout BTA Set Register	DSI_LINK_PRESPTOBTASETR	0000_0000h	0210h	8, 16, 32
Peripheral Response Timeout LP Set Register	DSI_LINK_PRESPTOLPSETR	0000_0000h	0214h	8, 16, 32
Peripheral Response Timeout HS Set Register	DSI_LINK_PRESPTOHSSETR	0000_0000h	0218h	8, 16, 32
Reserve	-	-	021Ch to 021Fh	-
Acknowledge and Error Report Packet Parameter Latest Info Register	DSI_LINK_AKEPLATIR	0000_0000h	0220h	8, 16, 32
Acknowledge and Error Report Packet Parameter Accumulate Status Register	DSI_LINK_AKEPACMSR	0000_0000h	0224h	8, 16, 32
Acknowledge and Error Report Packet Parameter Status Clear Register	DSI_LINK_AKEPSCR	0000_0000h	0228h	8, 16, 32
Reserve	-	-	022Ch to 022Fh	-

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Rx Result Saved Status Register	DSI_LINK_RXRSSR	0000_0000h	0230h	8, 16, 32
Rx Result Saved Status Clear Register	DSI_LINK_RXRSSCR	0000_0000h	0234h	8, 16, 32
Rx Result Info Overwrite Status Register	DSI_LINK_RXRINFOOWSR	0000_0000h	0238h	8, 16, 32
Rx Result Info Overwrite Status Clear Register	DSI_LINK_RXRINFOOWSCR	0000_0000h	023Ch	8, 16, 32
Rx Result Save Slot 0 Register	DSI_LINK_RXRSS0R	0000_0000h	0240h	8, 16, 32
Rx Result Save Slot 1 Register	DSI_LINK_RXRSS1R	0000_0000h	0244h	8, 16, 32
Rx Result Save Slot 2 Register	DSI_LINK_RXRSS2R	0000_0000h	0248h	8, 16, 32
Rx Result Save Slot 3 Register	DSI_LINK_RXRSS3R	0000_0000h	024Ch	8, 16, 32
Reserve	-	-	0250h to 02BFh	-
Rx Packet Payload Data 0 Register	DSI_LINK_RXPPD0R	0000_0000h	02C0h	8, 16, 32
Rx Packet Payload Data 1 Register	DSI_LINK_RXPPD1R	0000_0000h	02C4h	8, 16, 32
Rx Packet Payload Data 2 Register	DSI_LINK_RXPPD2R	0000_0000h	02C8h	8, 16, 32
Rx Packet Payload Data 3 Register	DSI_LINK_RXPPD3R	0000_0000h	02CCh	8, 16, 32
Reserve	-	-	02D0h to 02DFh	-
HSTX Timeout Set Register	DSI_LINK_HSTXTOSETR	0000_0000h	02E0h	8, 16, 32
LRX-H Timeout Set Register	DSI_LINK_LRXHTOSETR	0000_0000h	02E4h	8, 16, 32
TA Timeout Set Register	DSI_LINK_TATOSETR	0000_0000h	02E8h	8, 16, 32
Reserve	-	-	02ECh to 02FFh	-
Fatal Error Status Register	DSI_LINK_FERRSR	0000_0000h	0300h	8, 16, 32
Fatal Error Status Clear Register	DSI_LINK_FERRSCR	0000_0000h	0304h	8, 16, 32
Fatal Error Interrupt Enable Register	DSI_LINK_FERRIER	0000_0000h	0308h	8, 16, 32
Reserve	-	-	030Ch to 0313h	-
Clock Lane Stop Time Set Register	DSI_LINK_CLSTPTSETR	0000_0000h	0314h	8, 16, 32
LP Transition Time Set Register	DSI_LINK_LPTRNSTSETR	0000_0000h	0318h	8, 16, 32
Reserve	-	-	031Ch to 031Fh	-
Physical Lane Status Register	DSI_LINK_PLSR	0000_00F1h	0320h	8, 16, 32
Physical Lane Status Clear Register	DSI_LINK_PLSCR	0000_0000h	0324h	8, 16, 32
Physical Lane Interrupt Enable Register	DSI_LINK_PLIER	0000_0000h	0328h	8, 16, 32
Reserve	-	-	032Ch to 03FFh	-
Video-Input Channel 1 Set 0 Register	DSI_LINK_VICH1SET0R	0000_0000h	0400h	8, 16, 32
Video-Input Channel 1 Set 1 Register	DSI_LINK_VICH1SET1R	1063_0000h	0404h	8, 16, 32
Reserve	-	-	0408h to 040Fh	-
Video-Input Channel 1 Status Register	DSI_LINK_VICH1SR	0000_0000h	0410h	8, 16, 32
Video-Input Channel 1 Status Clear Register	DSI_LINK_VICH1SCR	0000_0000h	0414h	8, 16, 32
Video-Input Channel 1 Interrupt Enable Register	DSI_LINK_VICH1IER	0000_0000h	0418h	8, 16, 32
Reserve	-	-	041Ch to 041Fh	-
Video-Input Channel 1 Pixel Packet Set Register	DSI_LINK_VICH1PPSETR	000E_0000h	0420h	8, 16, 32
Reserve	-	-	0424h to 0427h	-
Video-Input Channel 1 Vertical Size Set Register	DSI_LINK_VICH1VSSETR	0000_0000h	0428h	8, 16, 32

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Video-Input Channel 1 Vertical Porch Set Register	DSI_LINK_VICH1VPSETR	0000_0000h	042Ch	8, 16, 32
Video-Input Channel 1 Horizontal Size Set Register	DSI_LINK_VICH1HSSETR	0000_0000h	0430h	8, 16, 32
Video-Input Channel 1 Horizontal Porch Set Register	DSI_LINK_VICH1HPSETR	0000_0000h	0434h	8, 16, 32
Reserve	-	-	0438h to 05BFh	-
Sequence Channel 0 Set 0 Register	DSI_LINK_SQCH0SET0R	0080_0000h	05C0h	8, 16, 32
Sequence Channel 0 Set 1 Register	DSI_LINK_SQCH0SET1R	0800_0000h	05C4h	8, 16, 32
Reserve	-	-	05C8h to 05CFh	-
Sequence Channel 0 Status Register	DSI_LINK_SQCH0SR	0000_0000h	05D0h	8, 16, 32
Sequence Channel 0 Status Clear Register	DSI_LINK_SQCH0SCR	0000_0000h	05D4h	8, 16, 32
Sequence Channel 0 Interrupt Enable Register	DSI_LINK_SQCH0IER	0000_0000h	05D8h	8, 16, 32
Reserve	-	-	05DCh to 05FFh	-
Sequence Channel 1 Set 0 Register	DSI_LINK_SQCH1SET0R	0080_0000h	0600h	8, 16, 32
Sequence Channel 1 Set 1 Register	DSI_LINK_SQCH1SET1R	0830_0000h	0604h	8, 16, 32
Reserve	-	-	0608h to 060Fh	-
Sequence Channel 1 Status Register	DSI_LINK_SQCH1SR	0000_0000h	0610h	8, 16, 32
Sequence Channel 1 Status Clear Register	DSI_LINK_SQCH1SCR	0000_0000h	0614h	8, 16, 32
Sequence Channel 1 Interrupt Enable Register	DSI_LINK_SQCH1IER	0000_0000h	0618h	8, 16, 32
Reserve	-	-	061Ch to 077Fh	-

Sequence Channel 1 Descriptor 07-C Register	DSI_LINK_SQCH1DSC07CR	xxxx_xxxxh	0878h	32
Sequence Channel 1 Descriptor 07-D Register	DSI_LINK_SQCH1DSC07DR	xxxx_xxxxh	087Ch	32

9.5.2.1.2 Registers in D-PHY

This section describes the registers in D-PHY. All registers can be accessed in 8/16/32 bits.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
DSI D-PHY Control Resister 0	DSI_DPHY_CTRL0	0000_0104h	0000h	8, 16, 32
DSI D-PHY Timing Resister 0	DSI_DPHY_TIM0	0100_2710h	0004h	8, 16, 32
DSI D-PHY Timing Resister 1	DSI_DPHY_TIM1	0403_0909h	0008h	8, 16, 32
DSI D-PHY Timing Resister 2	DSI_DPHY_TIM2	0510_0119h	000Ch	8, 16, 32
DSI D-PHY Timing Resister 3	DSI_DPHY_TIM3	0409_060Bh	0010h	8, 16, 32

9.5.2.2 MIPI DSI Register Descriptions

The prefix (DSI_LINK_, DSI_DPHY_) of the register names is omitted in this and subsequent sections.

9.5.2.2.1 Interrupt Status Register (DSI_LINK_ISR)

Access Size : 8, 16, 32 bits
Address : <DSI_LINK_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	PPI	-	-	-	FERR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	RCV	-	-	-	VIN1	-	-	-	SQ1	-	-	-	SQ0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	PPI	0h	R	PPI Interrupt When this value is 1b, a DSI D-PHY PPI related interrupt exists. Refer to the description of the PLSR register for more information.
19 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	FERR	0h	R	FERR Interrupt When this value is 1b, a DSI Fatal Error interrupt exists. Refer to the description of the FERRSR register for more information.
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12	RCV	0h	R	RCV Interrupt When this value is 1b, a DSI Packet Receive interrupt exists. Refer to the description of the RXSR register for more information.
11 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	VIN1	0h	R	VIN1 Interrupt When this value is 1b, a Video Input-Operation channel 1 interrupt exists. Refer to the description of the VICH1SR register for more information.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	SQ1	0h	R	SQ1 Interrupt When this value is 1b, a Sequence Operation channel 1 interrupt exists. Refer to the description of the SQCH1SR register for more information.
3 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	SQ0	0h	R	SQ1 Interrupt When this value is 1b, a Sequence Operation channel 0 interrupt exists. Refer to the description of the SQCH0SR register for more information.

9.5.2.2.2 Link Status Register (DSI_LINK_LINKSR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0010h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	LPBUSY	HSBUSY	-	-	-	VICHRUN1	-	-	-	SQCHRUN1	-	-	-	SQCHRUN0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13	LPBUSY	0h	R	LP Operation Busy The setting 1b indicates that an operation related to LP is in progress.
12	HSBUSY	0h	R	HS Operation Busy The setting 1b indicates that an operation related to HS is in progress.
11 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	VICHRUN1	0h	R	Video-Input Channel 1 Running This bit is a copy of VICH1SR.RUNNING.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	SQCHRUN1	0h	R	Sequence Channel 1 Running This bit is a copy of SQCH1SR.RUNNING.
3 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	SQCHRUN0	0h	R	Sequence Channel 0 Running This bit is a copy of SQCH0SR.RUNNING.

9.5.2.2.3 Tx Set Register (DSI_LINK_TXSETR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0100h

Initial Value : 0003_0003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	NUMLANECAP [1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	DLEN	CLEN	-	-	-	-	-	-	NUMLANEUSE [1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	RW	RW	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17, 16	NUMLANECAP [1:0]	3h	R	Number of Lanes Capability 3h: The maximum Lane count is 4 (Lanes 0 to 3 can be used)
15 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
9	DLEN	0h	RW	Data Lane Enable When this bit is 1b, Data Lanes are enabled by the PHY interface. Lanes to be enabled are determined by NUMLANEUSE.
8	CLEN	0h	RW	Clock Lane Enable When this bit is 1b, Clock Lane is enabled by the PHY interface.
7 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1, 0	NUMLANEUSE [1:0]	3h	RW	Number of Lanes for Use Set the Lane count for use. Selected Data Lanes are enabled if DLEN is “1”. 0h: 1 Lane (use of Lane 0) 1h: 2 Lane (use of Lanes 0 and 1) 2h: 3 Lane (use of Lanes 0 to 2) 3h: 4 Lane (use of Lanes 0 to 3) Setting a value over NUMLANECAP is prohibited.

9.5.2.2.4 HS Clock Set Register (DSI_LINK_HSCLKSETR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0104h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	HSCLK MODE	HSCLK RUN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	HSCLKMODE	0h	RW	HS Clock running Mode 0b: Requests Clock Lane HS transmission when HS transmission is scheduled (non-continuous clock mode). 1b: Keeps Clock Lane HS transmission (continuous clock mode). If HSCLKRUN = 0, this field has no meaning. Changing the value of this bit while HSCLKRUN = 1 is prohibited.
0	HSCLKRUN	0h	RW	Start HS Clock running on Clock Lane 0b: No HS transmission (keep LP) 1b: Allows HS transmission according to HSCLKMODE Confirm stable TxWordClkHS (hsclk) before setting this field to 1. Setting this field to “1” while TXSETR.CLEN = 0 is prohibited.

9.5.2.2.5 ULPS Set Register (DSI_LINK_ULPSSETR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0108h

Initial Value : 0000_00A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	ULPSWKUP[7:0]							
Initial Value	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7 to 0	ULPSWKUP [7:0]	A0h	RW	Twakeup period of ULPS This period is specified by the count value of lpclk *128. This period should be longer than 1 ms. For example, - In the case lpclk is 4/3 MHz and lpclk*128 = 96 µs, set ULPSWKUP = 0Bh and Twakeup period = 1.06 ms (11*96 µs) - In the case lpclk is 20 MHz and lpclk*128 = 6.4 µs, set ULPSWKUP = A0h and Twakeup period = 1.02 ms (160*6.4 µs)

9.5.2.2.6 ULPS Control Register (DSI_LINK_ULPSCR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 010Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	DLULPSEXT	DLULPSENT	-	-	CLULPSEXT	CLULPSENT	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R0W	R0W	R	R	R0W	R0W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29	DLULPSEXT	0h	R0W	The read value is always 0b. DL ULPS Exit Writing 1b to this bit issues a request for all enabled Data Lanes to exit the Ultra-Low Power State (ULPS). Writing 1b while enabled Data Lanes are not in ULPS is prohibited. Writing 0b has no effect.
28	DLULPSENT	0h	R0W	The read value is always 0b. DL ULPS Enter Writing 1b to this bit issues a request for enabled Data Lanes to enter the Ultra- Low Power State (ULPS). Writing 1b while the enabled Data Lanes are in ULPS is prohibited. Writing 0b has no effect.
27, 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25	CLULPSEXT	0h	R0W	The read value is always 0b. CL ULPS Exit Writing 1b to this bit issues a request for Clock Lane to exit the Ultra-Low Power State (ULPS). Writing 1b while Clock Lane is not in ULPS is prohibited. Writing 0b has no effect.
24	CLULPSENT	0h	R0W	The read value is always 0b. CL ULPS Enter Writing 1b to this bit issues a request for Clock Lane to enter the Ultra-Low Power State (ULPS). Before setting this field, HSCLKSETR.HSCLKRUN must be set to 0b. Writing 1b while Clock Lane is in ULPS is prohibited. Writing 0b has no effect.
23 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.7 Reset Control Register (DSI_LINK_RSTCR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0110h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	FCETXSTP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SWRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
23 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	FCETXSTP	0h	RW	Force Tx Stop Mode When this bit is 1b, change to Transmit mode and Stop State is forced by ForceTxStopmode on all PPI Data Lanes. Setting this bit to 1b when SWRST = 0 is prohibited.
15 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	SWRST	0h	RW	Request for Software Reset Set this bit to 1b to request a software reset. Then, wait until you confirm the completion of the Reset procedure by RSTSR.SWRSTx=1. And set to 0b after that.

9.5.2.2.8 Reset Status Register (DSI_LINK_RSTSR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0114h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DL0DIR	-	-	-	DLSTPST[3:0]				-	-	-	SWRS TV1	SWRS TIB	SWRS TAPB	SWRS TLP	SWRS THS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15	DL0DIR	0h	R	Direction (Tx or Rx) of PPI Data Lane 0 0b: PHY is in Tx Mode 1b: PHY is in Rx Mode This field is a copy of PLSR.DL0DIR.
14 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 8	DLSTPST[3:0]	All 0	R	Status of Stop State on Data Lane Bit 3: Stop State of Data Lane 3 Bit 2: Stop State of Data Lane 2 Bit 1: Stop State of Data Lane 1 Bit 0: Stop State of Data Lane 0 This field is a copy of PLSR.DLSTPST.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	SWRSTV1	0h	R	Status of Software Reset by RSTCR.SWRST at MIPI_DSI_VCLK 0b: Reset procedure is not underway at MIPI_DSI_VCLK. 1b: Reset procedure is underway MIPI_DSI_VCLK.
3	SWRSTIB	0h	R	Status of Software Reset by RSTCR.SWRST at MIPI_DSI_ACLK 0b: Reset procedure is not underway at MIPI_DSI_ACLK. 1b: Reset procedure is underway at MIPI_DSI_ACLK.
2	SWRSTAPB	0h	R	Status of Software Reset by RSTCR.SWRST at MIPI_DSI_PCLK 0b: Reset procedure is not underway at MIPI_DSI_PCLK. 1b: Reset procedure is underway at MIPI_DSI_PCLK.
1	SWRSTLP	0h	R	Status of Software Reset by RSTCR.SWRST at MIPI_DSI_LPCLK 0b: Reset procedure is not underway at MIPI_DSI_LPCLK. 1b: Reset procedure is underway at MIPI_DSI_LPCLK.
0	SWRSTHS	0h	R	Status of Software Reset by RSTCR.SWRST at hsclk 0b: Reset procedure is not underway at hsclk. 1b: Reset procedure is underway at hsclk.

9.5.2.2.9 DSI Set Register (DSI_LINK_DSISETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0120h

Initial Value : 80F1_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EOTPEN	TEIDIR	SCREN	-	-	-	-	-	CRCEN[3:0]				-	-	-	ECCEN
Initial Value	1	0	0	0	0	0	0	0	1	1	1	1	0	0	0	1
R/W	RW	RW	RW	R	R	R	R	R	RW	RW	RW	RW	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MRPSZ[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	EOTPEN	1h	RW	HS Transfer EoTp Enable 0b: Transfer of EoTp is disabled. 1b: Transfer of EoTp is enabled. EoTp is always disabled in LP Transfer.
30	TEIDIR	0h	RW	Tearing Effect Input Direction External Tearing Effect Setting 0b: Rise edge detection. 1b: Fall edge detection.
29	SCREN	0h	RW	Scramble Enable 0b: Scrambling data is disabled. 1b: Scrambling data is enabled. This bit should not be set to “1” if the peer-device does not support a data scrambling function.
28 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 20	CRCEN[3:0]	Fh	RW	Enable Received CRC check for Virtual Channel Bit 3: Enable Received CRC check for Virtual Channel 3 (0b: Disabled, 1b: Enabled). Bit 2: Enable Received CRC check for Virtual Channel 2 (0b: Disabled, 1b: Enabled). Bit 1: Enable Received CRC check for Virtual Channel 1 (0b: Disabled, 1b: Enabled). Bit 0: Enable Received CRC check for Virtual Channel 0 (0b: Disabled, 1b: Enabled).
19 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	ECCEN	1h	RW	Enable Received ECC Check 0b: Received ECC check is disabled. 1b: Received ECC check is enabled.
15 to 0	MRPSZ[15:0]	1h	RW	Maximum Return Packet Size If the returned Long Packet’s WC is over this value, the DSI-Tx module asserts the RXSR.MAXRPSZERR error. In that case, data will not be saved to the memory space. Setting this field to 0b is prohibited. Set this field to a value greater than or equal to the peripheral setting.

9.5.2.2.10 Receive Buffer Size Register (DSI_LINK_RXBUFSZR)

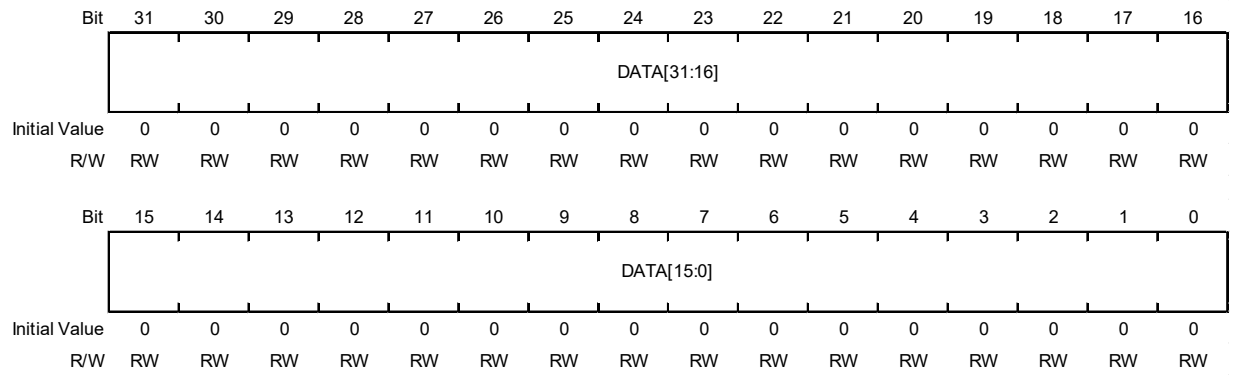
Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0124h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	RXBUFSZ[3:0]				-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



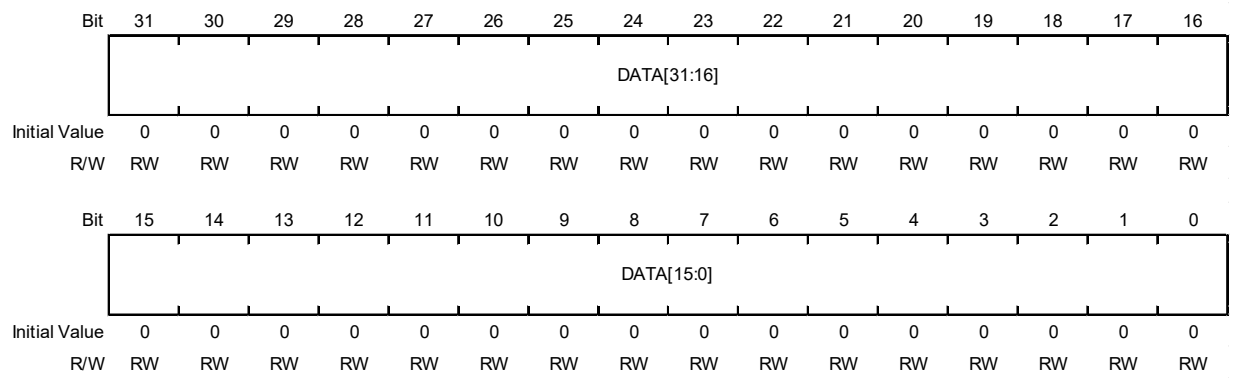
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 20	RXBUFSZ[3:0]	0h	R	Receive Buffer Size 0h: 128 B Buffer size = 128 * 2 RXBUFSZ
19 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.11 Tx Packet Payload Data 0 Register (DSI_LINK_TXPPD0R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0160h

Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	0h	RW	Tx Packet Payload Data 0 When Sequence Operation Long Packet is set (SQCHxDSCyAR.FMT = 1) and the Packet Payload Data register is selected (SQCHxDSCyBR.DTSEL = 0h) for payload data access, the values in this register are used for Long Packet Payload. [7:0]: Data 0 [15:8]: Data 1 [23:16]: Data 2 [31:24]: Data 3

9.5.2.2.12 Tx Packet Payload Data 1 Register (DSI_LINK_TXPPD1R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0164h

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	0h	RW	Tx Packet Payload Data 1 When Sequence Operation Long Packet is set (SQCHxDSCyAR.FMT = 1) and the Packet Payload Data register is selected (SQCHxDSCyBR.DTSEL = 0h) for payload data access, the values in this register are used for Long Packet Payload. [7:0]: Data 4 [15:8]: Data 5 [23:16]: Data 6 [31:24]: Data 7

9.5.2.2.13 Tx Packet Payload Data 2 Register (DSI_LINK_TXPPD2R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0168h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9.5.2.2.15 Rx Status Register (DSI_LINK_RXSR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0200h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	RXAKE	-	ECCERR1B	-	MAXRPSZERR	NORETERR	PRESPTOERR	RXOVFERR	IBERR	CRCERR	WCERR	-	UEXPKTERR	ECCERR	MLFERR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EXTTEDET	RXACK	-	RXRTRG	RXUK5TRG	RXEOTP	-	RXRESP	-	-	-	-	-	TATO	LRXHTO	BTAREQEND
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30	RXAKE	0h	R	Rx Acknowledge and Error Report When this value is 1b, the Acknowledge and Error Report Packet is received. Write 1b to the RXSCR.RXAKE register to clear this field.
29	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	ECCERR1B	0h	R	ECC Error (1 bit) When this value is 1b, the Rx ECC Error (1 bit) is detected. Write 1b to the RXSCR.ECCERR1B register to clear this field.
27	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26	MAXRPSZERR	0h	R	Maximum Return Packet Size Error When this value is 1b, the WC value of Rx Long Packet is larger than DSISETR.MRPSZ. Write 1b to the RXSCR.MAXRPSZERR register to clear this field.
25	NORETERR	0h	R	Nothing Return Error When this value is 1b, no trigger or packet is returned in BTA period. Write 1b to the RXSCR.NORETERR register to clear this field.
24	PRESPTOERR	0h	R	Peripheral Response Timeout Error When this value is 1b, the Rx Peripheral Response Timeout is detected after the transition to Rx mode along with Bus Turn-Around and within the time specified by PRESPTOBTASETR.PRESPTOBTA, PRESPTOLPSETR.PRESPTOLPR, PRESPTOLPSETR.PRESPTOLPW, PRESPTOLPSETR.PRESPTOHSR or PRESPTOLPSETR.PRESPTOHSW. The value is selected from kind of BTA. Write 1b to the RXSCR.PRESPTOERR register to clear this field.
23	RXOVFERR	0h	R	Receive Buffer Overflow Error When this value is 1b, the Buffer Overflow Error is detected at Rx Long Packet. Write 1b to the RXSCR.RXOVFERR register to clear this field.
22	IBERR	0h	R	Internal Bus Error When this value is 1b, the Internal Bus Write had failed to respond. Write 1b to the RXSCR.IBERR register to clear this field.
21	CRCERR	0h	R	CRC Error When this value is 1b, the Rx CRC Error is detected. Write 1b to the RXSCR.CRCERR register to clear this field.
20	WCERR	0h	R	Word Count Error When this value is 1b, the Rx packet's actual WC length is shorter than the packet header's WC. Write 1b the to RXSCR.WCERR register to clear this field.
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	UEXPKTERR	0h	R	Unexpected Packet Error When this value is 1b, an unexpected packet is received. "Unexpected Packet" means unexpected DT for receive or an unexpected response for receive. Write 1b to the RXSCR.UEXPKTERR register to clear this field.

Bit	Bit Name	Initial Value	R/W	Description
17	ECCERR	0h	R	ECC Error (over 1 bit) When this value is 1b, the Rx ECC Error (over 1 bit) is detected. Write 1b to the RXSCR.ECCERR register to clear this field.
16	MLFERR	0h	R	Malform Error When this value is 1b, the Rx packet shorter than 4 bytes is received. Write 1b to the RXSCR.MLFERR register to clear this field.
15	EXTTEDET	0h	R	External Tearing Effect Detect When this value is 1b, External Tearing Effect is detected. Write 1b to the RXSCR.EXTTEDET register to clear this field.
14	RXACK	0h	R	Rx ACK Trigger When this value is 1b, the ACK trigger is received. Write 1b to the RXSCR.RXACK register to clear this field.
13	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12	RXRTRG	0h	R	Rx Reset Trigger When this value is 1b, Reset Trigger is received. Normally, the DSI-Tx module does not receive Reset Trigger. Write 1b to the RXSCR.RXRTRG register to clear this field.
11	RXUK5TRG	0h	R	Rx Unknown-5 Trigger When this value is 1b, Unknown-5 Trigger is received. Normally, the DSI-Tx module does not receive Unknown-5 Trigger. Write 1b to the RXSCR.RXUK5TRG register to clear this field.
10	RXEOTP	0h	R	Rx EoTp When this value is 1b, the EoTp is received. Write 1b to the RXSCR.RXEOTP register to clear this field.
9	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	RXRESP	0h	R	Rx Response Packet When this value is 1b, the Response Packet is received. Write 1b to the RXSCR.RXRESP register to clear this field.
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	TATO	0h	R	Turnaround Acknowledge Timeout When this value is 1b, the Turnaround Acknowledge Timeout (TA_TO) is detected. Write 1b to the RXSCR.TATO register to clear this field.
1	LRXHTO	0h	R	LP-RX Host Processor Timeout When this value is 1b, the LP-RX Host Processor Timeout (LRX-H_TO) is detected. Write 1b to RXSCR.LRXHTO register to clear this field.
0	BTAREQEND	0h	R	BTA Request End When this value is 1b, the completion of the transmission request which includes Rx is detected. This bit is set if all BTA requests are finished including error. The BTA request status is indicated by RXSR[31:1]. Write 1b to the RXSCR.BTAREQEND register to clear this field.

9.5.2.2.16 Rx Status Clear Register (DSI_LINK_RXSCR)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0204h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R0W	R0W	R0W	R0W	R0W	R0W	R	R0W	R	R	R	R	R	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30	RXAKE	0h	R0W	The read value is always 0b. RXSR.RXAKE Clear Set to 1b to clear RXSR.RXAKE. Writing 0b has no effect.
29	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	ECCERR1B	0h	R0W	The read value is always 0b. RXSR.ECCERR1B Clear Set to 1b to clear RXSR.ECCERR1B. Writing 0b has no effect.
27	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26	MAXRPSZERR	0h	R0W	The read value is always 0b. RXSR.MAXRPSZERR Clear Set to 1b to clear RXSR.MAXRPSZERR. Writing 0b has no effect.
25	NORETERR	0h	R0W	The read value is always 0b. RXSR.NORETERR Clear Set to 1b to clear RXSR.NORETERR. Writing 0b has no effect.
24	PRESPTOERR	0h	R0W	The read value is always 0b. RXSR.PRESPTOERR Clear Set to 1b to clear RXSR.PRESPTOERR. Writing 0b has no effect.
23	RXOVFERR	0h	R0W	The read value is always 0b. RXSR.RXOVFERR Clear Set to 1b to clear RXSR.RXOVFERR. Writing 0b has no effect.
22	IBERR	0h	R0W	The read value is always 0b. RXSR.IBERR Clear Set to 1b to clear RXSR.IBERR. Writing 0b has no effect.
21	CRCERR	0h	R0W	The read value is always 0b. RXSR.CRCERR Clear Set to 1b to clear RXSR.CRCERR. Writing 0b has no effect.
20	WCERR	0h	R0W	The read value is always 0b. RXSR.WCERR Clear Set to 1b to clear RXSR.WCERR. Writing 0b has no effect.

Bit	Bit Name	Initial Value	R/W	Description
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	UEXPKTERR	0h	R0W	The read value is always 0b. RXSR.UEXPKTERR Clear Set to 1b to clear RXSR.UEXPKTERR. Writing 0b has no effect.
17	ECCERR	0h	R0W	The read value is always 0b. RXSR.ECCERR Clear Set to 1b to clear RXSR.ECCERR. Writing 0b has no effect.
16	MLFERR	0h	R0W	The read value is always 0b. RXSR.MLFERR Clear Set to 1b to clear RXSR.MLFERR. Writing 0b has no effect.
15	EXTTEDET	0h	R0W	The read value is always 0b. RXSR.EXTTTEDET Clear Set to 1b to clear RXSR.EXTTTEDET. Writing 0b has no effect.
14	RXACK	0h	R0W	The read value is always 0b. RXSR.RXACK Clear Set to 1b to clear RXSR.RXACK. Writing 0b has no effect.
13	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
12	RXRTRG	0h	R0W	The read value is always 0b. RXSR.RXRTRG Clear Set to 1b to clear RXSR.RXRTRG. Writing 0b has no effect.
11	RXUK5TRG	0h	R0W	The read value is always 0b. RXSR.RXUK5TRG Clear Set to 1b to clear RXSR.RXUK5TRG. Writing 0b has no effect.
10	RXEOTP	0h	R0W	The read value is always 0b. RXSR.RXEOTP Clear Set to 1b to clear RXSR.RXEOTP. Writing 0b has no effect.
9	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	RXRESP	0h	R0W	The read value is always 0b. RXSR.RXRESP Clear Set to 1b to clear RXSR.RXRESP. Writing 0b has no effect.
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	TATO	0h	R0W	The read value is always 0b. RXSR.TATO Clear Set to 1b to clear RXSR.TATO. Writing 0b has no effect.
1	LRXHTO	0h	R0W	The read value is always 0b. RXSR.LRXHTO Clear Set to 1b to clear RXSR.LRXHTO. Writing 0b has no effect.
0	BTAREQEND	0h	R0W	The read value is always 0b. RXSR.BTAREQEND Clear Set to 1b to clear RXSR.BTAREQEND. Writing 0b has no effect.

9.5.2.2.17 Rx Interrupt Enable Register (DSI_LINK_RXIER)

Access Size : 8, 16, 32 bits

Address : <DSI_LINK_base> + 0208h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

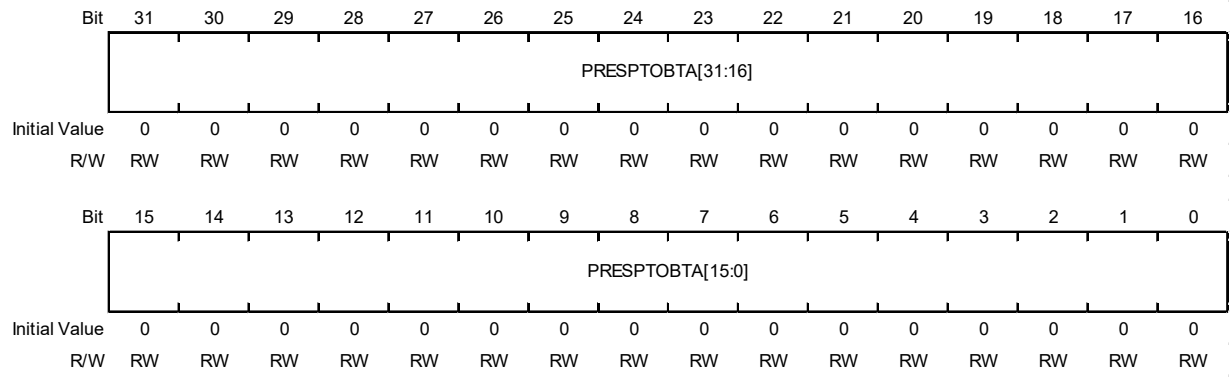
R/W	RW	RW	RW	RW	RW	RW	R	RW	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30	RXAKE	0h	RW	Interrupt enable for RXSR.RXAKE 0b: Disables interrupt dsi_int_rcv when RXSR.RXAKE = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXAKE = 1.
29	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	ECCERR1B	0h	RW	Interrupt enable for RXSR.ECCERR1B 0b: Disables interrupt dsi_int_rcv when RXSR.ECCERR1B = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.ECCERR1B = 1.
27	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26	MAXRPSZERR	0h	RW	Interrupt enable for RXSR.MAXRPSZERR 0b: Disables interrupt dsi_int_rcv when RXSR.MAXRPSZERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.MAXRPSZERR = 1.
25	NORETERR	0h	RW	Interrupt enable for RXSR.NORETERR 0b: Disables interrupt dsi_int_rcv when RXSR.NORETERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.NORETERR = 1.
24	PRESPTOERR	0h	RW	Interrupt enable for RXSR.PRESPTOERR 0b: Disables interrupt dsi_int_rcv when RXSR.PRESPTOERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.PRESPTOERR = 1.
23	RXOVFERR	0h	RW	Interrupt enable for RXSR.RXOVFERR 0b: Disables interrupt dsi_int_rcv when RXSR.RXOVFERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXOVFERR = 1.
22	IBERR	0h	RW	Interrupt enable for RXSR.IBERR 0b: Disables interrupt dsi_int_rcv when RXSR.IBERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.IBERR = 1.
21	CRCERR	0h	RW	Interrupt enable for RXSR. CRCERR 0b: Disables interrupt dsi_int_rcv when RXSR.CRCERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.CRCERR = 1.
20	WCERR	0h	RW	Interrupt enable for RXSR. WCERR 0b: Disables interrupt dsi_int_rcv when RXSR.WCERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.WCERR = 1.
19	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	UEXPKTERR	0h	RW	Interrupt enable for RXSR.UEXPKTERR 0b: Disables interrupt dsi_int_rcv when RXSR.UEXPKTERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.UEXPKTERR = 1.
17	ECCERR	0h	RW	Interrupt enable for RXSR.ECCERR 0b: Disables interrupt dsi_int_rcv when RXSR.ECCERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.ECCERR = 1.



Bit	Bit Name	Initial Value	R/W	Description
16	MLFERR	0h	RW	Interrupt enable for RXSR.MLFERR 0b: Disables interrupt dsi_int_rcv when RXSR.MLFERR = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.MLFERR = 1.
15	EXTTEDET	0h	RW	Interrupt enable for RXSR.EXTTEDET 0b: Disables interrupt dsi_int_rcv when RXSR.EXTTEDET = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.EXTTEDET = 1.
14	RXACK	0h	RW	Interrupt enable for RXSR.RXACK 0b: Disables interrupt dsi_int_rcv when RXSR.RXACK = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXACK = 1.
13	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
12	RXRTRG	0h	RW	Interrupt enable for RXSR.RXRTRG 0b: Disables interrupt dsi_int_rcv when RXSR.RXRTRG = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXRTRG = 1.
11	RXUK5TRG	0h	RW	Interrupt enable for RXSR.RXUK5TRG 0b: Disables interrupt dsi_int_rcv when RXSR.RXUK5TRG = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXUK5TRG = 1.
10	RXEOTP	0h	RW	Interrupt enable for RXSR.RXEOTP 0b: Disables interrupt dsi_int_rcv when RXSR.RXEOTP = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXEOTP = 1.
9	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	RXRESP	0h	RW	Interrupt enable for RXSR.RXRESP 0b: Disables interrupt dsi_int_rcv when RXSR.RXRESP = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.RXRESP = 1.
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	TATO	0h	RW	Interrupt enable for RXSR.TATO 0b: Disables interrupt dsi_int_rcv when RXSR.TATO = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.TATO = 1.
1	LRXHTO	0h	RW	Interrupt enable for RXSR.LRXHTO 0b: Disables interrupt dsi_int_rcv when RXSR.LRXHTO = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.LRXHTO = 1.
0	BTAREQEND	0h	RW	Interrupt enable for RXSR.BTAREQEND 0b: Disables interrupt dsi_int_rcv when RXSR.BTAREQEND = 1. 1b: Enables interrupt dsi_int_rcv when RXSR.BTAREQEND = 1.

9.5.2.2.18 Peripheral Response Timeout BTA Set Register (DSI_LINK_PRESPTOBTASETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0210h

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PRESPTOBTA [31:0]	0h	RW	Peripheral Response Timeout (Bus Turn Around) Count Set the timeout value to measure the interval between the start of Rx mode and the start of packet reception along with Bus Turn-Around while SQCHxDSCyAR.BTA = 3h. The limit time for timeout is calculated by the formula of PRESPTOBTA * (the period of MIPI_DSI_LPCLK). When RXSR.PRESPTOERR is 1b, a timeout is detected. Note that no timeout is detected when PRESPTOBTA = 0. Since the counting clock is asynchronous with packet reception, there is some jitter in the timeout.

9.5.2.2.19 Peripheral Response Timeout LP Set Register (DSI_LINK_PRESPTOLPSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0214h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PRESPTOLPR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PRESPTOLPW[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PRESPTOLPR [15:0]	0h	RW	Peripheral Response Timeout (LPDT READ Request) Count Set the timeout value to measure the interval between the start of Rx mode and the start of packet reception along with Bus Turn-Around while SQCHxDSCyAR.BTA = 2h and SQCHxDSCyAR.SPD = 1b. The limit time for timeout is calculated by the formula of PRESPTOLPR * (the period of MIPI_DSI_LPCLK). When RXSR.PRESPTOERR is 1b, a timeout is detected. Note that no timeout is detected when PRESPTOLPR = 0. Since the counting clock is asynchronous with packet reception, there is some jitter in the timeout.
15 to 0	PRESPTOLPW [15:0]	0h	RW	Peripheral Response Timeout (LPDT WRITE Request) Count Set the timeout value to measure the interval between the start of Rx mode and the start of packet reception along with Bus Turn-Around while SQCHxDSCyAR.BTA = 01b and SQCHxDSCyAR.SPD = 1b. The limit time for timeout is calculated by the formula of PRESPTOLPW * (the period of MIPI_DSI_LPCLK). When RXSR.PRESPTOERR is 1b, a timeout is detected. Note that no timeout is detected when PRESPTOLPW = 0. Since the counting clock is asynchronous with packet reception, there is some jitter in the timeout.

9.5.2.2.20 Peripheral Response Timeout HS Set Register (DSI_LINK_PRESPTOHSSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0218h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PRESPTOHSR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PRESPTOHSW[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PRESPTOHSR [15:0]	0h	RW	Peripheral Response Timeout (HS READ Request) Count Set the timeout value to measure the interval between the start of Rx mode and the start of packet reception along with Bus Turn-Around while SQCHxDSCyAR.BTA = 2h and SQCHxDSCyAR.SPD = 0b. The limit time for timeout is calculated by the formula of PRESPTOHSR * (the period of MIPI_DSI_LPCLK). When RXSR.PRESPTOERR is 1b, a timeout is detected. Note that no timeout is detected when PRESPTOHSR = 0. Since the counting clock is asynchronous with packet reception, there is some jitter in the timeout.
15 to 0	PRESPTOHSW [15:0]	0h	RW	Peripheral Response Timeout (HS WRITE Request) Count Set the timeout value to measure the interval between the start of Rx mode and the start of packet reception along with Bus Turn-Around while SQCHxDSCyAR.BTA = 1h and SQCHxDSCyAR.SPD = 0b. The limit time for timeout is calculated by the formula of PRESPTOHSW * (the period of MIPI_DSI_LPCLK). When RXSR.PRESPTOERR is 1b, a timeout is detected. Note that no timeout is detected when PRESPTOHSW = 0. Since the counting clock is asynchronous with packet reception, there is some jitter in the timeout.

9.5.2.2.21 Acknowledge and Error Report Packet Parameter Latest Info Register (DSI_LINK_AKEPLATIR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0220h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	VC3	VC2	VC1	VC0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRRPTLAT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	VC3	0h	R	Virtual Channel Identifier 3 Latest This field indicates the Virtual Channel identifier of a received Acknowledge and Error Report Packet. 0b: Virtual Channel identifier is not 3. 1b: Virtual Channel identifier is 3. This field indicates the latest information. Whenever an Acknowledge and Error Report Packet is received, this field is updated.
18	VC2	0h	R	Virtual Channel Identifier 2 Latest This field indicates the Virtual Channel identifier of a received Acknowledge and Error Report Packet. 0b: Virtual Channel identifier is not 2. 1b: Virtual Channel identifier is 2. This field indicates the latest information. Whenever an Acknowledge and Error Report Packet is received, this field is updated.
17	VC1	0h	R	Virtual Channel Identifier 1 Latest This field indicates the Virtual Channel identifier of a received Acknowledge and Error Report Packet. 0b: Virtual Channel identifier is not 1. 1b: Virtual Channel identifier is 1. This field indicates the latest information. Whenever an Acknowledge and Error Report Packet is received, this field is updated.
16	VC0	0h	R	Virtual Channel Identifier 0 Latest This field indicates the Virtual Channel identifier of a received Acknowledge and Error Report Packet. 0b: Virtual Channel identifier is not 0. 1b: Virtual Channel identifier is 0. This field indicates the latest information. Whenever an Acknowledge and Error Report Packet is received, this field is updated.
15 to 0	ERRRPTLAT [15:0]	0h	R	Error Report Latest This field indicates the Error Report of a received Acknowledge and Error Report Packet. This field indicates the latest information. Whenever an Acknowledge and Error Report Packet is received, this field is updated.

9.5.2.2.22 Acknowledge and Error Report Packet Parameter Accumulate Status Register (DSI_LINK_AKEPACMSR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0224h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	VC3	VC2	VC1	VC0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRRPTACM[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	VC3	0h	R	Virtual Channel Identifier 3 Accumulate This field is set to 1b when an Acknowledge and Error Report Packet whose Virtual Channel identifier = 3 is received. This field indicates accumulated information. This bit is cleared by AKEPSCR.VC3.
18	VC2	0h	R	Virtual Channel Identifier 2 Accumulate This field is set to 1b when an Acknowledge and Error Report Packet whose Virtual Channel identifier = 2 is received. This field indicates accumulated information. This bit is cleared by AKEPSCR.VC2.
17	VC1	0h	R	Virtual Channel Identifier 1 Accumulate This field is set to 1b when an Acknowledge and Error Report Packet whose Virtual Channel identifier = 1 is received. This field indicates accumulated information. This bit is cleared by AKEPSCR.VC1.
16	VC0	0h	R	Virtual Channel Identifier 0 Accumulate This field is set to 1b when an Acknowledge and Error Report Packet whose Virtual Channel identifier = 0 is received. This field indicates accumulated information. This bit is cleared by AKEPSCR.VC0.
15 to 0	ERRRPTACM [15:0]	0h	R	Error Report Accumulate Each bit of this field is set to 1b, when an Acknowledge and Error Report Packet whose each Error Report bit = 1 is received. This field indicates accumulated information. Each bit is cleared by the corresponding AKESCR.ERRRPTACM.

9.5.2.2.23 Acknowledge and Error Report Packet Parameter Status Clear Register (DSI_LINK_AKEPSCR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0228h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	VC3	VC2	VC1	VC0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R0W	R0W	R0W	R0W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRRPTACM[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	VC3	0h	R0W	The read value is always 0b. AKEPACMSR.VC3 Clear Set to 1b to clear AKEPACMSR.VC3. Writing 0b has no effect.
18	VC2	0h	R0W	The read value is always 0b. AKEPACMSR.VC2 Clear Set to 1b to clear AKEPACMSR.VC2. Writing 0b has no effect.
17	VC1	0h	R0W	The read value is always 0b. AKEPACMSR.VC1 Clear Set to 1b to clear AKEPACMSR.VC1. Writing 0b has no effect.
16	VC0	0h	R0W	The read value is always 0b. AKEPACMSR.VC0 Clear Set to 1b to clear AKEPACMSR.VC0. Writing 0b has no effect.
15 to 0	ERRRPTACM[15:0]	0h	R0W	The read value is always 0b. Error Report Accumulate Clear Set to 1b to clear each AKEPACMSR.ERRRPTACM. Writing 0b has no effect.

9.5.2.2.24 Rx Result Saved Status Register (DSI_LINK_RXRSSR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0230h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	SLT3VLD	SLT2VLD	SLT1VLD	SLT0VLD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	SLT3VLD	0h	R	Slot 3 Valid Response packet is received, or information is saved to RXRSS3R. Write 1b to RXRSSCR.SLT3C to clear this bit. This bit and RXRSS3R are set if the next receive action is caused with SQCHxDSCyCR.ACTCODE = 03 again.
2	SLT2VLD	0h	R	Slot 2 Valid Response packet is received, or information is saved to RXRSS2R. Write 1b to RXRSSCR.SLT2C to clear this bit. This bit and RXRSS2R are set if the next receive action is caused with SQCHxDSCyCR.ACTCODE = 02 again.
1	SLT1VLD	0h	R	Slot 1 Valid Response packet is received, or information is saved to RXRSS1R. Write 1b to RXRSSCR.SLT1C to clear this bit. This bit and RXRSS1R are set if the next receive action is caused with SQCHxDSCyCR.ACTCODE = 01 again.
0	SLT0VLD	0h	R	Slot 0 Valid Response packet is received, or information is saved to RXRSS0R. Write 1b to RXRSSCR.SLT0C to clear this bit. This bit and RXRSS0R are set if the next receive action is caused with SQCHxDSCyCR.ACTCODE = 00 again.

9.5.2.2.25 Rx Result Saved Status Clear Register (DSI_LINK_RXRSSCR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0234h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	SLT3C	SLT2C	SLT1C	SLT0C
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R0W	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	SLT3C	0h	R0W	The read value is always 0b. RXRSSR.SLT3VLD Clear Write 1b to clear RXRSSR.SLT3VLD. Writing 0b has no effect.
2	SLT2C	0h	R0W	The read value is always 0b. RXRSSR.SLT2VLD Clear Write 1b to clear RXRSSR.SLT2VLD. Writing 0b has no effect.
1	SLT1C	0h	R0W	The read value is always 0b. RXRSSR.SLT1VLD Clear Write 1b to clear RXRSSR.SLT1VLD. Writing 0b has no effect.
0	SLT0C	0h	R0W	The read value is always 0b. RXRSSR.SLT0VLD Clear Write 1b to clear RXRSSR.SLT0VLD. Writing 0b has no effect.

9.5.2.2.26 Rx Result Info Overwrite Status Register (DSI_LINK_RXRINFOOWSR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0238h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	SLT3INFOOWC	0h	R0W	The read value is always 0b. RXRSS3R.INFOOW Clear Write 1b to clear RXRSS3R.INFOOW. Writing 0b has no effect. To prevent missing of RXRSS3R.INFOOW, clear RXRSS3R.INFOOW before clearing RXRSSR.SLT3VLD.
2	SLT2INFOOWC	0h	R0W	The read value is always 0b. RXRSS2R.INFOOW Clear Write 1b to clear RXRSS2R.INFOOW. Writing 0b has no effect. To prevent missing of RXRSS2R.INFOOW, clear RXRSS2R.INFOOW before clearing RXRSSR.SLT2VLD.
1	SLT1INFOOWC	0h	R0W	The read value is always 0b. RXRSS1R.INFOOW Clear Write 1b to clear RXRSS1R.INFOOW. Writing 0b has no effect. To prevent missing of RXRSS1R.INFOOW, clear RXRSS1R.INFOOW before clearing RXRSSR.SLT1VLD.
0	SLT0INFOOWC	0h	R0W	The read value is always 0b. RXRSS0R.INFOOW Clear Write 1b to clear RXRSS0R.INFOOW. Writing 0b has no effect. To prevent missing of RXRSS0R.INFOOW, clear RXRSS0R.INFOOW before clearing RXRSSR.SLT0VLD.

9.5.2.2.28 Rx Result Save Slot x Register (DSI_LINK_RXRSSxR) (x = 0, 1, 2, 3)

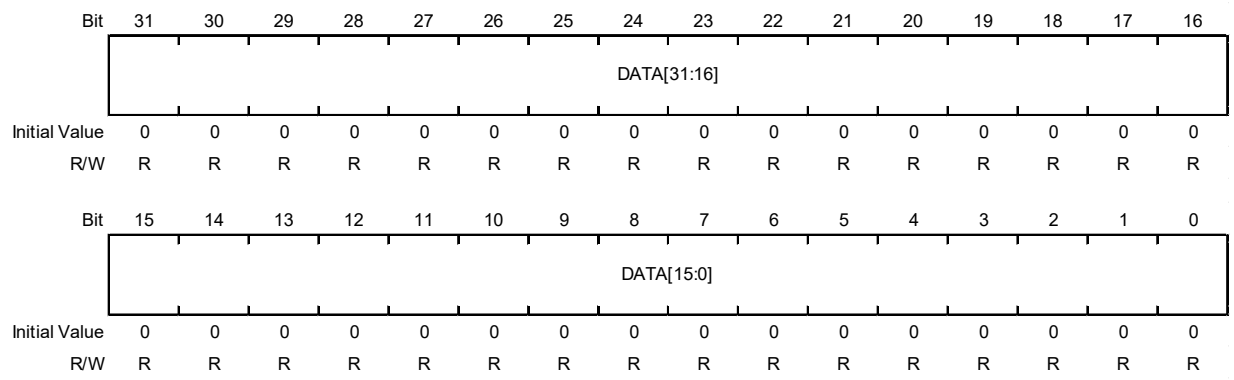
Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0240h + 0004h × (x)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INFOOW	RXAKE	RXCORERR	RXPKTDFAIL	RXFAIL	RXFATALERR	RXSUC	FMT	VC[1:0]		DT[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA1[7:0]								DATA0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



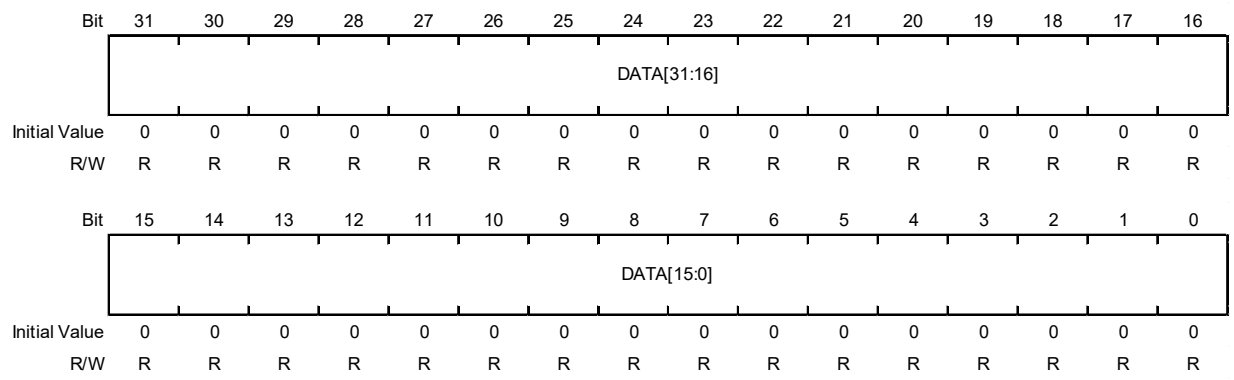
Bit	Bit Name	Initial Value	R/W	Description
31	INFOOW	0h	R	Information Overwrite This bit is set if the information of RXRSSxR is updated when RXRSSR.SLTxVLD is 1b. Write 1b to RXRINFOOWSCR.SLTxINFOOWC to clear this bit.
30	RXAKE	0h	R	Receive Acknowledge and Error Report Packet RXSR.RXAKE is also reported.
29	RXCORERR	0h	R	Receive Correctable Error The received packet has a correctable error. RXSR.ECCERR1B is also reported.
28	RXPKTDFAIL	0h	R	Receive Packet Data Fail The packet header was saved correctly but data were not. One or more of the following bits are also reported. RXSR.CRCERR, RXSR.WCERR, RXSR.MAXRPSZERR, RXSR.UEXPKTERR, RXSR.RXOVFERR and RXSR.IBERR. When both of this bit and RXRESP are asserted, it means a redundant packet was received in BTA.
27	RXFAIL	0h	R	Receive Fail Expected reception did not proceed. One or more of the following bits are also reported. RXSR.PRESPTOERR, RXSR.ECCERR, RXSR.MLFERR and RXSR.NORETERR.
26	RXFATALERR	0h	R	Fatal Error A fatal timeout occurred during BTA. One or more of the following bits are also reported. FERRSR.TATO and FERRSR.LRXHTO.
25	RXSUC	0h	R	Receive Success When this value is 1b, the Response Packet or ACK trigger is received. One or more of the following bits are also reported. RXSR.RXRESP and RXSR.RXACK.
24	FMT	0h	R	Packet format of Rx Packet Header 0b: Short Packet 1b: Long Packet This field is valid when RXPKTDFAIL = 1 or (RXSUC = 1 and DT != 0).
23, 22	VC[1:0]	0h	R	Identifier of Virtual Channel of Rx Packet Header This field is valid when (RXSUC = 1 and DT != 0).
21 to 16	DT[5:0]	0h	R	Data Type of Rx Packet Header 00h: ACK trigger received 01h to 3Fh: Data Type This field is valid when RXSUC = 1.
15 to 8	DATA1[7:0]	0h	R	Data1 of Rx Packet Header When the Rx packet format is Long Packet, this value is the upper 8 bits of the word count. This field is valid when (RXSUC = 1 and DT != 0).
7 to 0	DATA0[7:0]	0h	R	Data0 of Rx Packet Header When Rx packet format is Long Packet, this value is the lower 8 bits of the word count. This field is valid when (RXSUC = 1 and DT != 0).

9.5.2.2.29 Rx Packet Payload Data 0 Register (DSI_LINK_RXPPD0R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 02C0h

Initial Value : 0000_0000h



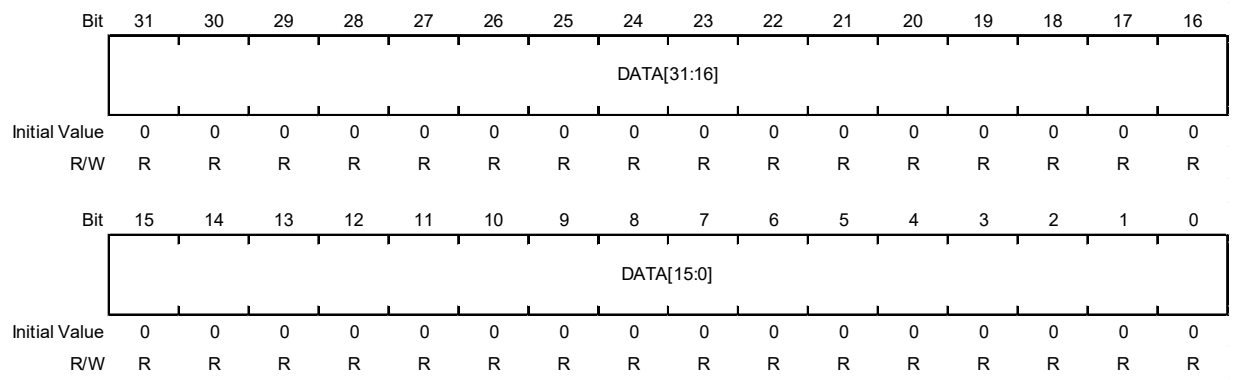
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	0h	R	Rx Packet Payload Data 0 When a Long Packet is received with SQCHxDSCyBR.DTSEL = 0h, the received packet payload is saved. [7:0]: Data 0 [15:8]: Data 1 [23:16]: Data 2 [31:24]: Data 3

9.5.2.2.30 Rx Packet Payload Data 1 Register (DSI_LINK_RXPPD1R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 02C4h

Initial Value : 0000_0000h



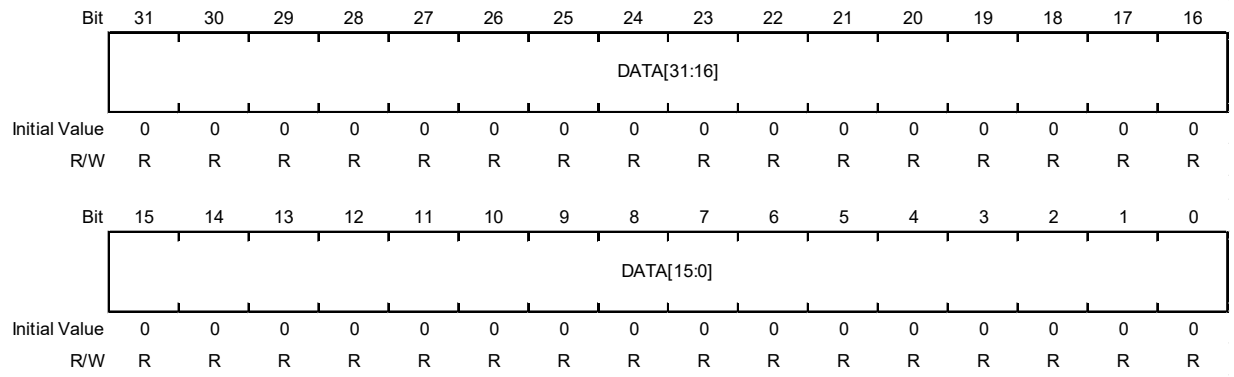
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	0h	R	Rx Packet Payload Data 1 When a Long Packet is received with SQCHxDSCyBR.DTSEL = 0h, the received packet payload is saved. [7:0]: Data 4 [15:8]: Data 5 [23:16]: Data 6 [31:24]: Data 7

9.5.2.2.31 Rx Packet Payload Data 2 Register (DSI_LINK_RXPPD2R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 02C8h

Initial Value : 0000_0000h



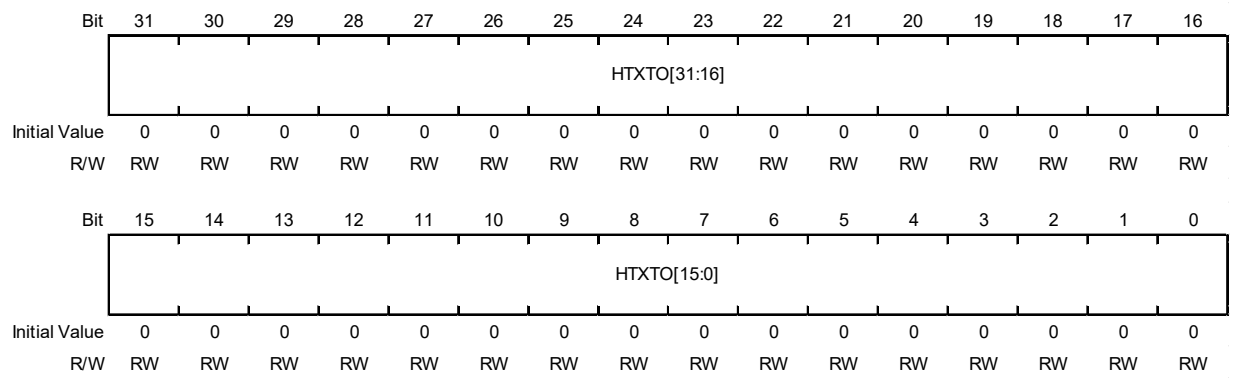
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	0h	R	Rx Packet Payload Data 2 When a Long Packet is received with SQCHxDSCyBR.DTSEL = 0h, the received packet payload is saved. [7:0]: Data 8 [15:8]: Data 9 [23:16]: Data 10 [31:24]: Data 11

9.5.2.2.32 Rx Packet Payload Data 3 Register (DSI_LINK_RXPPD3R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 02CCh

Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	0h	R	Rx Packet Payload Data 3 When a Long Packet is received with SQCHxDSCyBR.DTSEL = 0h, the received packet payload is saved. [7:0]: Data 12 [15:8]: Data 13 [23:16]: Data 14 [31:24]: Data 15

9.5.2.2.33 HSTX Timeout Set Register (DSI_LINK_HSTXTOSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 02E0h

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	HTXTO[31:0]	0h	RW	HS TX Timeout Count (HTX_TO) The limit time for timeout is calculated by the formula of HTXTO * (the period of high-speed serial UI * 32). When FERRSR.HTXTO is 1b, a timeout is detected. Note that no timeout is detected when HTXTO = 0.

9.5.2.2.34 LRX-H Timeout Set Register (DSI_LINK_LRXHTOSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 02E4h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LRXHTO[31:16]

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28	ERRCLP1S	0h	R	Status of Contention Error of LP1 (ErrContentionLP1)
27	ERRCLP0S	0h	R	Status of Contention Error of LP0 (ErrContentionLP0)
26 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	ERRCLP1	0h	R	Contention Error of LP1 (ErrContentionLP1) When this value is 1b, the Contention Error of LP1 (ErrContentionLP1) is detected on PPI Data Lane 0. Write 1b to the FERRSCR.ERRCLP1 register to clear this field.
19	ERRCLP0	0h	R	Contention Error of LP0 (ErrContentionLP0) When this value is 1b, the Contention Error of LP0 (ErrContentionLP0) is detected on PPI Data Lane 0. Write 1b to the FERRSCR.ERRCLP0 register to clear this field.
18	ERRCTRL	0h	R	Control Error (ErrControl) When this value is 1b, the Control Error (ErrControl) is detected on PPI Data Lane 0. Write 1b to the FERRSCR.ERRCTRL register to clear this field.
17	ERRSYNESC	0h	R	Sync Error of LPDT (ErrSyncEsc) When this value is 1b, the Sync Error of LPDT (ErrSyncEsc) is detected on PPI Data Lane 0. Write 1b to the FERRSCR.ERRSYNESC register to clear this field.
16	ERRESC	0h	R	Escape mode Entry Error (ErrEsc) When this value is 1b, the Escape mode Entry Error (ErrEsc) is detected on PPI Data Lane 0. Write 1b to the FERRSCR.ERRESC register to clear this field.
15 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	TATO	0h	R	Turnaround Acknowledge Timeout (TA_TO) When this value is 1b, the Turnaround Acknowledge Timeout (TA_TO) is detected. Write 1b to the FERRSCR.TATO register to clear this field.
1	LRXHTO	0h	R	LP-RX Host Processor Timeout (LRX-H_TO) When this value is 1b, the LP-RX Host Processor Timeout (LRX-H_TO) is detected. Write 1b to the FERRSCR.LRXHTO register to clear this field.
0	HTXTO	0h	R	HS TX Timeout (HTX_TO) When this value is 1b, the HS TX Timeout (HTX_TO) is detected. Write 1b to the FERRSCR.HTXTO register to clear this field.

9.5.2.2.37 Fatal Error Status Clear Register (DSI_LINK_FERRSCR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0304h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	ERRCLP1	ERRCLP0	ERRCTRL	ERRSYNESC	ERRESC
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R0W	R0W	R0W	R0W	R0W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	ERRCLP1	0h	RW	Interrupt enable for the Contention Error of LP1 on PPI Data Lane 0 (ErrContentionLP1) 0b: Disables interrupt dsi_int_ferr when FERRSR.ERRCLP1 = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.ERRCLP1 = 1
19	ERRCLP0	0h	RW	Interrupt enable for the Contention Error of LP0 on PPI Data Lane 0 (ErrContentionLP0) 0b: Disables interrupt dsi_int_ferr when FERRSR.ERRCLP0 = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.ERRCLP0 = 1
18	ERRCTRL	0h	RW	Interrupt enable for the Control Error on PPI Data Lane 0 (ErrControl) 0b: Disables interrupt dsi_int_ferr when FERRSR.ERRCTRL = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.ERRCTRL = 1
17	ERRSYNESC	0h	RW	Interrupt enable for the LPDT Sync Error on PPI Data Lane 0 (ErrSyncEsc) 0b: Disables interrupt dsi_int_ferr when FERRSR.ERRSYNESC = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.ERRSYNESC = 1
16	ERRESC	0h	RW	Interrupt enable for the Escape mode Error on PPI Data Lane 0 (ErrEsc) 0b: Disables interrupt dsi_int_ferr when FERRSR.ERRESC = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.ERRESC = 1
15 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	TATO	0h	RW	Interrupt enable for Turnaround Acknowledge Timeout (TA_TO) 0b: Disables interrupt dsi_int_ferr when FERRSR.TATO = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.TATO = 1
1	LRXHTO	0h	RW	Interrupt enable for LP-RX Host Processor Timeout (LRX_H_TO) 0b: Disables interrupt dsi_int_ferr when FERRSR.LRXHTO = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.LRXHTO = 1
0	HTXTO	0h	RW	Interrupt enable for HS TX Timeout (HTX_TO) 0b: Disables interrupt dsi_int_ferr when FERRSR.HTXTO = 1 1b: Enables interrupt dsi_int_ferr when FERRSR.HTXTO = 1

9.5.2.2.39 Clock Lane Stop Time Set Register (DSI_LINK_CLSTPTSETR)

Access Size : 8, 16, 32 bits
Offset Address : <DSI_LINK_base> + 0314h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLKKPT[7:0]								CLKBFHT[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	CLKSTPT[9:0]										-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CLKKPT[7:0]	0h	RW	Clock Keep Time The time period over which the HS Clock Lane keeps active after HS packet transfer. The time is calculated by the formula of CLKKPT * (the period of high-speed serial UI * 32). This time corresponds to the D-PHY specification's ($T_{HS-TRAIL}$ + $T_{CLK-POST}$). The value must be greater than the one calculated. For information about each parameter, see **Table 9.5-4**. Set an appropriate value (other than 0) before HSCLKSETR.HSCLKRUN is set to "1".
23 to 16	CLKBFHT[7:0]	0h	RW	Clock Beforehand Time The time period over which Clock Lane is changed back to HS before HS packet transfer. If HS transfers are scheduled in LP, Clock Lane will start before HS transfer by this setting. The time is calculated by the formula of CLKBFHT * (the period of high-speed serial UI * 32). This time corresponds to the D-PHY specification's (T_{LPX}(For Clock Lane HS Entry) + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$). The value must be greater than the one calculated. For information about each parameter, see **Table 9.5-4**. Set an appropriate value (other than 0) before HSCLKSETR.HSCLKRUN is set to "1". The "T_{LPX}(For Clock Lane HS Entry)" means the period of LP-01 in HS entry sequence of Clock Lane. If this period is not same as normal T_{LPX} value of host device (in the range of 67% to 150% of the T_{LPX} value of peripheral device), use the actual period for this calculation.
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 2	CLKSTPT[9:0]	0h	RW	Clock Stop Time The time period over which the HS Clock Lane is changed to LP and back to HS. If Data Lanes exit HS and the time of CLKKPT expires, and the scheduled time till the next HS transfer is more than this setting, Clock Lane will be changed to LP. This setting has no meaning if HSCLKSETR.HSCLKMODE is 1b or if HSCLKSETR.HSCLKRUN is 0b. The time is calculated by the formula of CLKSTPT * (the period of high-speed serial UI * 32) This time corresponds to the D-PHY specification's ($T_{HS-TRAIL}$ + $T_{CLK-POST}$ + $T_{CLK-TRAIL}$ + $T_{HS-EXIT}$ + T_{LPX} * 2 + T_{LPX}(For Clock Lane HS Entry) + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$ + T_{LPX}(For Data Lane HS Entry) + $T_{HS-PREPARE}$ + $T_{HS-ZERO}$ + $T_{HS-SYNC}$). For information about each parameter, see **Figure 9.5-2** and **Table 9.5-4**. Of these parameters, it is necessary to set the time actually set in CLKKPT for ($T_{HS-TRAIL}$ + $T_{CLK-POST}$) and that actually set in CLKBFHT for (T_{LPX}(For Clock Lane HS Entry) + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$). Set the rounded-up value plus at least 3. Setting this field to "0" is prohibited. The "T_{LPX}(For Clock Lane HS Entry)" means the period of LP-01 in HS entry sequence of Clock Lane. And the "T_{LPX}(For Data Lane HS Entry)" means the period of LP-01 in HS entry sequence of Data Lane. If these periods are not same as normal T_{LPX} value of host device (in the range of 67% to 150% of the T_{LPX} value of peripheral device), use the actual periods for this calculation.
1, 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

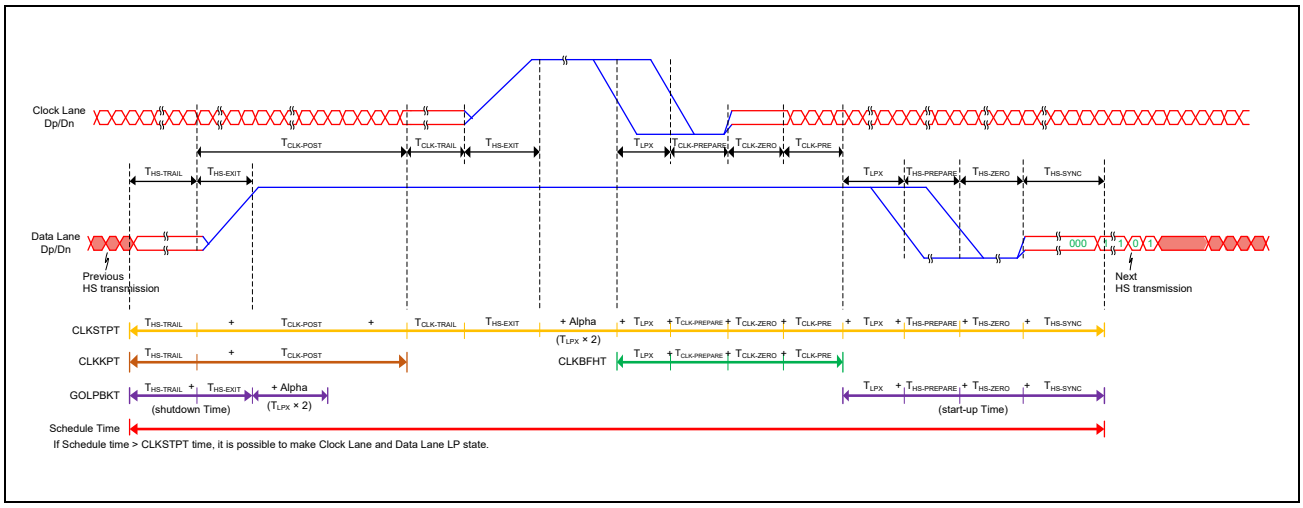

Figure 9.5-3 Switching the Clock Lane between Clock Transmission and Low-Power Mode

9.5.2.2.40 LP Transition Time Set Register (DSI_LINK_LPTRNSTSETR)

Access Size : 8, 16, 32 bits
Offset Address : <DSI_LINK_base> + 0318h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	GOLPBKT[9:0]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
9 to 0	GOLPBKT[9:0]	0h	RW	Go LP and Back Time The time period over which the HS Data Lanes are changed to LP and back to HS. If the scheduled time between HS transfers is more than this setting, Data Lanes will be changed to LP. The time is calculated by the formula of GOLPBKT * (the period of high-speed serial 8 * UI). This time corresponds to D-PHY specification's ($T_{HS-TRAIL}$ + $T_{HS-EXIT}$ + T_{LPX} * 2 + T_{LPX}(For Data Lane HS Entry) + $T_{HS-PREPARE}$ + $T_{HS-ZERO}$ + $T_{HS-SYNC}$). For information about each parameter, see **Figure 9.5-3** and **Table 9.5-4**. The unit of this setting is 8 UIs, so if the result of this formula contains a fraction of less than 8 UIs, round it up. Set the rounded-up value plus at least 3. The "T_{LPX}(For Data Lane HS Entry)" means the period of LP-01 in HS entry sequence of Data Lane. If this period is not same as normal T_{LPX} value of host device (in the range of 67% to 150% of the T_{LPX} value of peripheral device), use the actual period for this calculation.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29	DLFROMULPS	0h	R	From ULPS (Data Lane) When this value is 1b, all PPI Data Lanes enabled by TXSETR.NUMLANEUSE were changed from ULPS to Stop State by exiting ULPS. Write 1b to the PLSCR.DLFROMULPS register to clear this field.
28	DLTOULPS	0h	R	To ULPS (Data Lane) When this value is 1b, all PPI Data Lanes enabled by TXSETR.NUMLANEUSE were changed from Stop State to ULPS by entering ULPS. Write 1b to the PLSCR.DLTOULPS register to clear this field.
27	CLHS2LP	0h	R	HS to LP (Clock Lane) When this value is 1b, a transition of Clock Lane from HS to LP is detected. Checking this bit during non-continuous clock mode operation has no meaning. Therefore, ignore this bit when HSCLKSETR.HSCLKMODE = 0b. Write 1b to the PLSCR.CLHS2LP register to clear this field.
26	CLLP2HS	0h	R	LP to HS (Clock Lane) When this value is 1b, a transition of Clock Lane from LP to HS is detected. Checking this bit during non-continuous clock mode operation has no meaning. Therefore, ignore this bit when HSCLKSETR.HSCLKMODE = 0b. Write 1b to the PLSCR.CLLP2HS register to clear this field.
25	CLFROMULPS	0h	R	From ULPS (Clock Lane) When this value is 1b, Clock Lane exiting ULPS is detected. Write 1b to the PLSCR.CLFROMULPS register to clear this field.
24	CLTOULPS	0h	R	To ULPS (Clock Lane) When this value is 1b, Clock Lane entering ULPS is detected. Write 1b to the PLSCR.CLTOULPS register to clear this field.
23 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15	DL0DIR	0h	R	Direction (Tx or Rx) of Data Lane 0 0b: PHY is in Tx Mode 1b: PHY is in Rx Mode This field indicates Direction of PPI Data Lane 0 after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.
14	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13	DL0TX2RX	0h	R	Tx to Rx on Data Lane 0 When this value is 1b, a transition of Direction from 0 (Tx) to 1 (Rx) is detected on Data Lane 0. Write 1b to the PLSCR.DL0TX2RX register to clear this field.
12	DL0RX2TX	0h	R	Rx to Tx on Data Lane 0 When this value is 1b, a transition of Direction from 1 (Rx) to 0 (Tx) is detected on Data Lane 0. Write 1b to the PLSCR.DL0RX2TX register to clear this field.

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	DLSTPST[3:0]	All 0	R	Stop State of Data Lane bit 3: Stop State of Data Lane 3 bit 2: Stop State of Data Lane 2 bit 1: Stop State of Data Lane 1 bit 0: Stop State of Data Lane 0 This field indicates Stop State of a PPI Data Lane after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.
7 to 4	DLULPSACTN [3:0]	Fh	R	UlpsActiveNot of Data Lane bit 3: UlpsActiveNot of Data Lane 3 bit 2: UlpsActiveNot of Data Lane 2 bit 1: UlpsActiveNot of Data Lane 1 bit 0: UlpsActiveNot of Data Lane 0 This field indicates UlpsActiveNot of a PPI Data Lane after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.
3	DL0RXULPSESC	0h	R	RxUlpsEsc of Data Lane 0 This field indicates RxUlpsEsc of PPI Data Lane 0 after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.
2	DL0RXLPDTESC	0h	R	RxLpdtEsc of Data Lane 0 This field indicates RxLpdtEsc of PPI Data Lane 0 after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.
1	CLSTPST	0h	R	Stop State of PPI Clock Lane This field indicates Stop State of the PPI Clock Lane after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.
0	CLULPSACTN	1h	R	UlpsActiveNot of PPI Clock Lane This field indicates UlpsActiveNot of the PPI Clock Lane after synchronization to lpclk. This field does not indicate the current status while lpclk is not running.

9.5.2.2.42 Physical Lane Status Clear Register (DSI_LINK_PLSCR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0324h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	DLFROMULPS	DLTOULPS	CLHS2LP	CLLP2HS	CLFROMULPS	CLTOULPS	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R0W	R0W	R0W	R0W	R0W	R0W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	DL0TX2RX	DL0RX2TX	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R0W	R0W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29	DLFROMULPS	0h	R0W	The read value is always 0b. PLSR.DLFROMULPS Clear Set to 1b to clear PLSR.DLFROMULPS. Writing 0b has no effect.
28	DLTOULPS	0h	R0W	The read value is always 0b. PLSR.DLTOULPS Clear Set to 1b to clear PLSR.DLTOULPS. Writing 0b has no effect.
27	CLHS2LP	0h	R0W	The read value is always 0b. PLSR.CLHS2LP Clear Set to 1b to clear PLSR.CLHS2LP. Writing 0b has no effect.
26	CLLP2HS	0h	R0W	The read value is always 0b. PLSR.CLLP2HS Clear Set to 1b to clear PLSR.CLLP2HS. Writing 0b has no effect.
25	CLFROMULPS	0h	R0W	The read value is always 0b. PLSR.CLFROMULPS Clear Set to 1b to clear PLSR.CLFROMULPS. Writing 0b has no effect.
24	CLTOULPS	0h	R0W	The read value is always 0b. PLSR.CLTOULPS Clear Set to 1b to clear PLSR.CLTOULPS. Writing 0b has no effect.
23 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13	DL0TX2RX	0h	R0W	The read value is always 0b. PLSR.DL0TX2RX Clear Set to 1b to clear PLSR.DL0TX2RX. Writing 0b has no effect.
12	DL0RX2TX	0h	R0W	The read value is always 0b. PLSR.DL0RX2TX Clear Set to 1b to clear PLSR.DL0RX2TX. Writing 0b has no effect.
11 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.43 Physical Lane Interrupt Enable Register (DSI_LINK_PLIER)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0328h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	DLFROMULPS	DLTOULPS	CLHS2LP	CLLP2HS	CLFROMULPS	CLTOULPS	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	DL0TX2RX	DL0RX2TX	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29	DLFROMULPS	0h	RW	Interrupt enable for all Data Lane transition from ULPS 0b: Disables interrupt dsi_int_ppi when PLSR.DLFROMULPS = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.DLFROMULPS = 1.
28	DLTOULPS	0h	RW	Interrupt enable for all Data Lane transition to ULPS 0b: Disables interrupt dsi_int_ppi when PLSR.DLTOULPS = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.DLTOULPS = 1.
27	CLHS2LP	0h	RW	Interrupt enable for Clock Lane transition to LP from HS 0b: Disables interrupt dsi_int_ppi when PLSR.CLHS2LP = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.CLHS2LP = 1.
26	CLLP2HS	0h	RW	Interrupt enable for Clock Lane transition to HS from LP 0b: Disables interrupt dsi_int_ppi when PLSR.CLLP2HS = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.CLLP2HS = 1.
25	CLFROMULPS	0h	RW	Interrupt enable for Clock Lane transition from ULPS 0b: Disables interrupt dsi_int_ppi when PLSR.CLFROMULPS = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.CLFROMULPS = 1.
24	CLTOULPS	0h	RW	Interrupt enable for Clock Lane transition to ULPS 0b: Disables interrupt dsi_int_ppi when PLSR.CLTOULPS = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.CLTOULPS = 1.
23 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13	DL0TX2RX	0h	RW	Interrupt enable for Data Lane 0 direction change from Tx to Rx 0b: Disables interrupt dsi_int_ppi when PLSR.DL0TX2RX = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.DL0TX2RX = 1.
12	DL0RX2TX	0h	RW	Interrupt enable for Data Lane 0 direction change from Rx to Tx 0b: Disables interrupt dsi_int_ppi when PLSR.DL0RX2TX = 1. 1b: Enables interrupt dsi_int_ppi when PLSR.DL0RX2TX = 1.
11 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.44 Video-Input Channel 1 Set 0 Register (DSI_LINK_VICH1SET0R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0400h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	VSEN	-	HFPNOLP	HBPNOLP	HSANOLP	-	-	-	-	-	-	VSTPAFT	VSTART
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
12	VSEN	0h	RW	Video Skew Calibration Enable 0b: No skew calibration is issued by this channel. 1b: Periodic skew calibration is issued in the first line of VBP. When periodic skew calibration is enabled, set HSCLKSETR.HSCLKMODE = 1.
11	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
10	HFPNOLP	0h	RW	HFP period No LP Specifies whether suppress to transition to LP during the HFP period. 0b: Does not suppress transition to LP during the period 1b: Suppresses transition to LP during the period and keeps HS. HS is kept by sending a blanking packet.
9	HBPNOLP	0h	RW	HBP period No LP Specifies whether suppress transition to LP during the HBP period. 0b: Does not suppress transition to LP during the period 1b: Suppresses transition to LP during the period and keeps HS. HS is kept by sending a blanking packet.
8	HSANOLP	0h	RW	HSA period No LP Specifies whether suppress transition to LP during the HSA period. When TXESYNC=0, this field has no meaning. 0b: Does not suppress transition to LP during the period 1b: Suppresses transition to LP during the period and keeps HS. HS is kept by sending a blanking packet.
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
1	VSTPAFT	0h	R0W	The read value is always 0b. Video-Input signals stop after Video-Input Operation stop Stop Video-Input Operation. Video-Input Operation will end at the end of video-frame. After Video-Input Operation end, stop Video-Input signals. If Video-Input Operation is stopped, VICH1SR.RUNNING bit will change to 0b. Set 1b to both VSTPAFT and VSTART is prohibited. Set 1b during VICH1SR.RUNNING=0 is prohibited. Writing 0b has no effect.

Bit	Bit Name	Initial Value	R/W	Description
0	VSTART	0h	R0W	The read value is always 0b. Video-Input Operation Start Write 1b to start Video-Input Operation. Setting both VSTART and VSTPAFT to 1b is prohibited. Setting this bit to 1b while VICH1SR.RUNNING = 1 is prohibited. Writing 0b has no effect.

9.5.2.2.45 Video-Input Channel 1 Set 1 Register (DSI_LINK_VICH1SET1R)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0404h

Initial Value : 1063_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSPC	-	BPP[5:0]						CHBUFSZ[3:0]				-	-	-	-
Initial Value	0	0	0	1	0	0	0	0	0	1	1	0	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	DLY[11:0]												-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CSPC	0h	R	Color Space of Input Video Pixel This field reflects the color space of Data Type selected by VICH1PPSETR.DT. 0h: RGB 1h: Reserved
30	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
29 to 24	BPP[5:0]	10h	R	Bit Per Pixel of Input Video Pixel This field reflects bits per pixel of Data Type selected by VICH1PPSETR.DT. 10h: 16 bpp 12h: 18 bpp 18h: 24 bpp, 18 bpp (Loosely Packed) (RGB)
23 to 20	CHBUFSZ [3:0]	6h	R	Channel Buffer Size 6h: 8 kB Buffer size = 128×2^{CHBUFSZ}
19, 18	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17, 16	-	3h	R	Reserved Whenever it is read, 1b is read. The written value will be ignored.
15, 14	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
13 to 2	DLY[11:0]	0h	RW	Delay Value The delay time is calculated by the formula of DLY * (the period of high-speed serial UI * 32). Setting to this field to 0b is prohibited. If VICH1SET0R.HFPNOLP = 1, set this field to a value greater than the HFP period. If VICH1SET0R.HBPNOLP = 1, set this field to a value greater than the HBP period. If VICH1SET0R.HSANOLP = 1, set this field to a value greater than the HSA period.
1, 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.46 Video-Input Channel 1 Status Register (DSI_LINK_VICH1SR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0410h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	VBUFOVF	VBUFUDF	-	TIMERR	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23	VBUFOVF	0h	R	Video-Input Buffer Overflow Error A data overflow has occurred in Video-Input Buffer. Write 1b to the VICH1SCR.VBUFOVF register to clear this field.
22	VBUFUDF	0h	R	Video-Input Buffer Underflow Error A data underflow has occurred in Video-Input Buffer. Write 1b to the VICH1SCR.VBUFUDF register to clear this field.
21	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	TIMERR	0h	R	Timing Error A timing error has occurred during Video-Input Operation. Write 1b to the VICH1SCR.TIMERR register to clear this field.
19 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	VIRDY	0h	R	Video-Input Signal Accept Ready The value will be set to 1b when the input signal can be accepted by Video-Input Operation channel 1 ready.
2	RUNNING	0h	R	Video-Input Operation channel 1 Transfer Running The value will be set to 1b while Video-Input Operation channel 1 transfer is in progress. Changing the values of the VICH1SET0R, VICH1SET1R, VICH1PPSETR, VICH1VSSETR, VICH1VPSETR, VICH1HSSETR and VICH1HPSETR is prohibited while the transfer is in progress (VICH1SR.RUNNING = 1).
1	STOP	0h	R	Video Input Operation channel 1 Transfer Stop Write 1b to the VICH1SCR.STOP register to clear this field.
0	START	0h	R	Video Input Operation channel 1 Transfer Start. Write 1b to the VICH1SCR.START register to clear this field.

9.5.2.2.47 Video-Input Channel 1 Status Clear Register (DSI_LINK_VICH1SCR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0414h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	VBUFOVF	VBUFUDF	-	TIMERR	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	-	-	-	-	-	-	-	-	-	-	-	-	VIRDY	-	STOP	START
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R0W	R	R	R	R	R	R	R	R	R	R	R0W	R	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30 to 26	-	All 0	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
25, 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23	VBUFOVF	0h	R0W	The read value is always 0b. VICH1SR.VBUFOVF Clear Set to 1b to clear VICH1SR.VBUFOVF. Writing 0b has no effect.
22	VBUFUDF	0h	R0W	The read value is always 0b. VICH1SR.VBUFUDF Clear Set to 1b to clear VICH1SR.VBUFUDF. Writing 0b has no effect.
21	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
20	TIMERR	0h	R0W	The read value is always 0b. VICH1SR.TIMERR Clear Set to 1b to clear VICH1SR.TIMERR. Writing 0b has no effect.
19 to 15	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
14	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
13 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	VIRDY	0h	R0W	The read value is always 0b. VICH1SR.VIRDY Clear Set to 1b to clear VICH1SR.VIRDY. Writing 0b has no effect.
2	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	STOP	0h	R0W	The read value is always 0b. VICH1SR.STOP Clear Set to 1b to clear VICH1SR.STOP. Writing 0b has no effect.
0	START	0h	R0W	The read value is always 0b. VICH1SR.START Clear Set to 1b to clear VICH1SR.START. Writing 0b has no effect.

9.5.2.2.48 Video-Input Channel 1 Interrupt Enable Register (DSI_LINK_VICH1IER)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0418h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

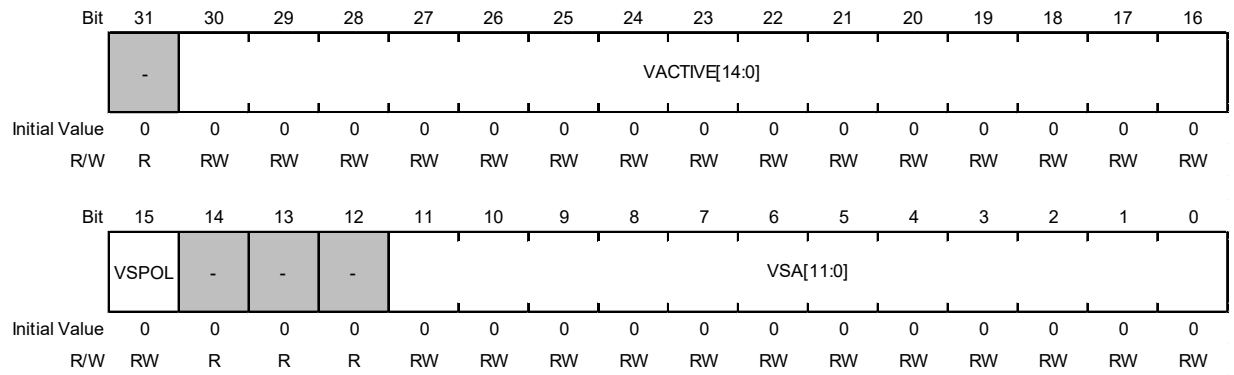
R/W	RW	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW



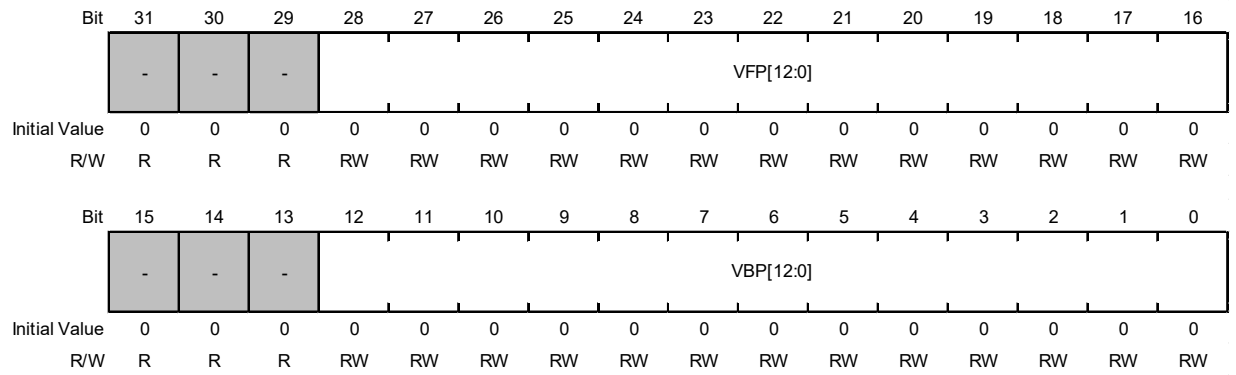
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23, 22	VC[1:0]	0h	RW	Video-Input Operation Channel 1 Pixel Stream Packet Header Virtual Channel Identifier
21 to 16	DT[5:0]	Eh	RW	Video-Input Operation Channel 1 Pixel Stream Packet Header Data Type The following values can be set. 0Eh: Packed Pixel Stream, 16-bit RGB 1Eh: Packed Pixel Stream, 18-bit RGB 2Eh: Loosely Packed Pixel Stream, 18-bit RGB 3Eh: Packed Pixel Stream, 24-bit RGB Setting any other values is prohibited.
15	TXESYNC	0h	RW	Transmit End of Sync Pulse 0b: HSE and VSE are NOT transmitted 1b: HSE and VSE are transmitted The setting 0b is used for “Burst Mode” sequence or “Non-Burst Mode with Sync Events” sequence. The setting 1b is used for “Non-Burst Mode with Sync Pulse” sequence.
14 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	-	All 0	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.

9.5.2.2.50 Video-Input Channel 1 Vertical Size Set Register (DSI_LINK_VICH1VSSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0428h

Initial Value : 0000_0000h



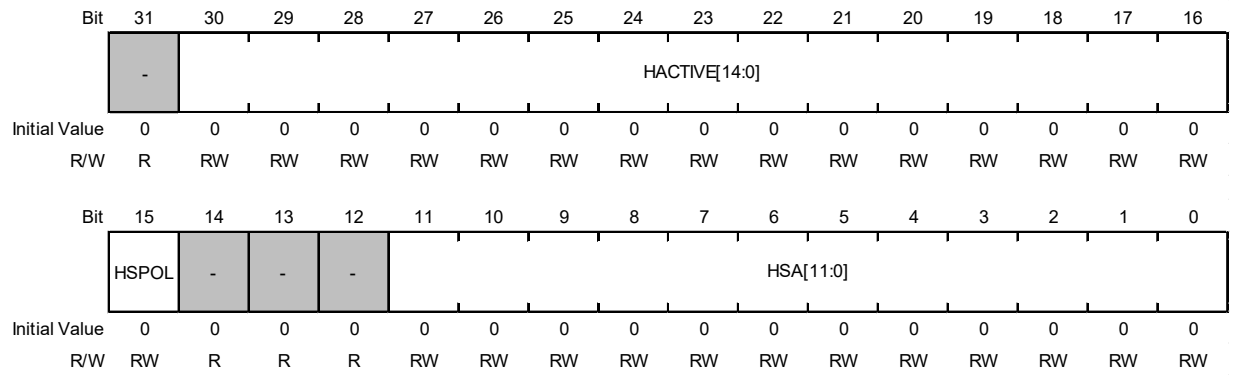
Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30 to 16	VACTIVE[14:0]	0h	RW	Sets the Line count of VACTIVE (Vertical Active lines)
15	VSPOL	0h	RW	Polarity of VSYNC Sets the polarity (active state) of the VSYNC signal. 0b: Active high 1b: Active low
14 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	VSA[11:0]	0h	RW	VSA Count Sets the Line count of VSA (Vertical Sync Active)

9.5.2.2.51 Video-Input Channel 1 Vertical Porch Set Register (DSI_LINK_VICH1VPSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 042Ch

Initial Value : 0000_0000h



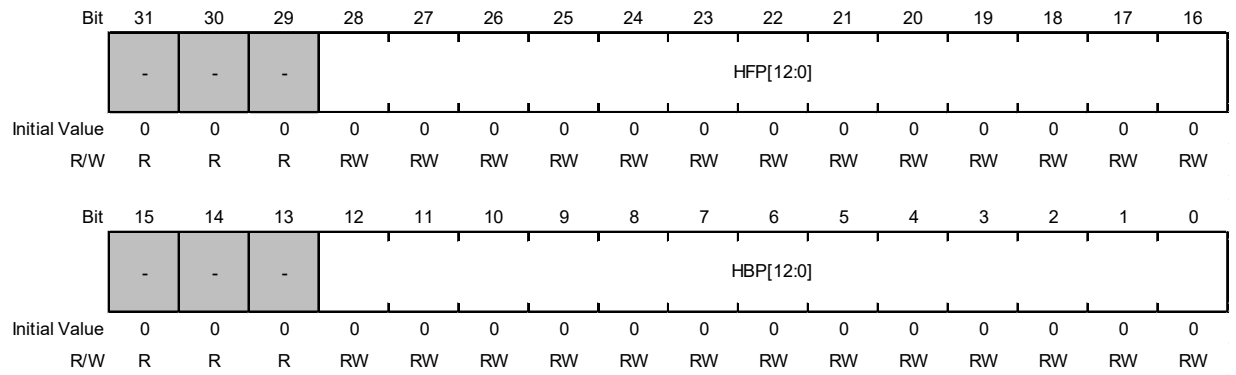
Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	VFP[12:0]	0h	RW	VFP Count Sets the Line count of VFP (Vertical Front Porch)
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	VBP[12:0]	0h	RW	VBP Count Sets the Line count of VBP (Vertical Back Porch)

9.5.2.2.52 Video-Input Channel 1 Horizontal Size Set Register (DSI_LINK_VICH1HSSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0430h

Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30 to 16	HACTIVE [14:0]	0h	RW	HACTIVE Count Sets the pixel count of HACTIVE (Horizontal Active pixels)
15	HSPOL	0h	RW	Polarity of HSYNC Sets the polarity (active state) of the HSYNC signal. 0b: Active high 1b: Active low
14 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	HSA[11:0]	0h	RW	HSA Count Sets the pixel count of HSA (Horizontal Sync Active)

9.5.2.2.53 Video-Input Channel 1 Horizontal Porch Set Register (DSI_LINK_VICH1HPSETR)

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 0434h

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 16	HFP[12:0]	0h	RW	HFP Count Sets the pixel count of HFP (Horizontal Front Porch)
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 0	HBP[12:0]	0h	RW	HBP Count Sets the pixel count of HBP (Horizontal Back Porch)

9.5.2.2.54 Sequence Channel x Set 0 Register (DSI_LINK_SQCHxSET0R)

"x" indicates the channel number.

Note: "x" is 0 or 1.

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 05C0h (x = 0)
<DSI_LINK_base> + 0600h (x = 1)

Initial Value : 0080_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0
R/W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R0W	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	START
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	R	R	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
23	-	1h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
22 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8 to 4	-	All 0	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
3, 2	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
0	START	0h	R0W	The read value is always 0b. Sequence Operation Start Write 1b to start running from Descriptor #0. Setting it to 1b while RUNNING = 1 is prohibited. Writing 0b has no effect.

9.5.2.2.55 Sequence Channel x Set 1 Register (DSI_LINK_SQCHxSET1R)

"x" indicates the channel number.

Note: "x" is 0 or 1.

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 05C4h (x = 0)
<DSI_LINK_base> + 0604h (x = 1)

Initial Value : 0800_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MAXDESNUM[7:0]								CHBUFSZ[3:0]				-	-	-	-
Initial Value	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	MAXDESNUM [7:0]	8h	RW	Max Descriptor Number This field indicates the maximum number of descriptors, with the descriptor numbers starting from zero (e.g. the setting 8 means #0 to #7 can be used as descriptors). Writing a value other than the initial value is prohibited.
23 to 20	CHBUFSZ [3:0]	0h	R	Sequence Channel x Buffer Size 0h: 128 B 1h: 256 B 2h: 512 B 3h: 1 kB 4h: 2 kB 5h: 4 kB 6h: 8 kB 7h: 16 kB 8h: 32 kB 9h: 64 kB Buffer size = 128 x 2 CHBUFSZ Setting a transfer packet size larger than this field is prohibited.
19 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.56 Sequence Channel x Status Register (DSI_LINK_SQCHxSR)

"x" indicates the channel number.

Note: "x" is 0 or 1.

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 05D0h (x = 0)
<DSI_LINK_base> + 0610h (x = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	RXAKE	RXCORERR	RXPKTDFAIL	RXFAIL	RXFATALERR	-	TXIBERR	-	-	-	-	PKTBIGERR	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	-	-	-	-	-	-	-	ADESFIN	-	-	-	AACTFIN	-	RUNNING	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30	RXAKE	0h	R	Receive Acknowledge and Error Report Packet RXSR.RXAKE is also reported. Write 1b to the SQCHxSCR.RXAKE register to clear this field.
29	RXCORERR	0h	R	Receive Correctable Error The received packet has a correctable error. RXSR.ECCERR1B is also reported. Write 1b to the SQCHxSCR.RXCORERR register to clear this field.
28	RXPKTDFAIL	0h	R	Receive Packet Data Fail The packet Header was saved correctly but data were not. One or more of the following bits are also reported. RXSR.CRCERR, RXSR.WCERR, RXSR.UEXPKTERR, RXSR.MAXRPSZERR, RXSR.RXOVFERR and RXSR.IBERR. Write 1b to the SQCHxSCR.RXPKTDFAIL register to clear this field.
27	RXFAIL	0h	R	Receive Fail Expected reception did not proceed. One or more of the following bits are also reported. RXSR.PRESPTOERR, RXSR.ECCERR, RXSR.MLFERR and RXSR.NORETERR. Write 1b to the SQCHxSCR.RXFAIL register to clear this field.
26	RXFATALERR	0h	R	Receive Fatal Error A fatal timeout occurred during BTA. One or more of the following bits are also reported. FERRSR.TATO and FERRSR.LRXHTO. Write 1b to the SQCHxSCR.RXFATALERR register to clear this field.
25	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	TXIBERR	0h	R	Tx Internal Bus Error When this value is 1b, the Internal Bus Read had failed to respond. Write 1b to the SQCHxSCR.TXIBERR register to clear this field.
23 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	PKTBIGERR	0h	R	Packet is too big Error Sequence Operation channel 0: Hard wired to 0b. Sequence Operation channel 1: This bit is set when the length of a sequence packet is bigger than Video-Input channel's BLLP. Write 1b to the SQCHxSCR.PKTBIGERR register to clear this field.
18 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
8	ADESFIN	0h	R	All Descriptor Finished by Setting The descriptor is finished by setting SQCHxDSCyAR.NXACT = 0h for the descriptor. Write 1b to the SQCHxSCR.ADESFIN register to clear this field.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	AACTFIN	0h	R	Descriptor's All Action Finished This bit is set if this descriptor's all actions are finished with SQCHxDSCyCR.FINACT[0] =1b. Write 1b to the SQCHxSCR.AACTFIN register to clear this field.
3	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	RUNNING	0h	R	Sequence Operation Running The value will be set to "1" during Sequence Operation. Do not change descriptor values while this bit is 1b. Do not change the values in SQCHxSET0R and SQCHxSET1R.
1, 0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.57 Sequence Channel x Status Clear Register (DSI_LINK_SQCHxSCR)

"x" indicates the channel number.

Note: "x" is 0 or 1.

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 05D4h (x = 0)
<DSI_LINK_base> + 0614h (x = 1)

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	RXAKE	RXCORERR	RXPKTDFAIL	RXFAIL	RXFATALERR	-	TXIBERR	-	-	-	-	PKTBIGERR	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R0W	R0W	R0W	R0W	R0W	R	R0W	R	R0W	R	R	R0W	R	R	R0W

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0W	R	R	R	R	R	R	R0W	R	R	R	R0W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30	RXAKE	0h	R0W	The read value is always 0b. SQCHxSR.RXAKE Clear Set to 1b to clear SQCHxSR.RXAKE. Writing 0b has no effect.
29	RXCORERR	0h	R0W	The read value is always 0b. SQCHxSR.RXCORERR Clear Set to 1b to clear SQCHxSR.RXCORERR. Writing 0b has no effect.
28	RXPKTDFAIL	0h	R0W	The read value is always 0b. SQCHxSR.RXPKTDFAIL Clear Set to 1b to clear SQCHxSR.RXPKTDFAIL. Writing 0b has no effect.
27	RXFAIL	0h	R0W	The read value is always 0b. SQCHxSR.RXFAIL Clear Set to 1b to clear SQCHxSR.RXFAIL. Writing 0b has no effect.
26	RXFATALERR	0h	R0W	The read value is always 0b. SQCHxSR.RXFATALERR Clear Set to 1b to clear SQCHxSR.RXFATALERR. Writing 0b has no effect.
25	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	TXIBERR	0h	R0W	The read value is always 0b. SQCHxSR.TXIBERR Clear Set to 1b to clear SQCHxSR.TXIBERR. Writing 0b has no effect.
23	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
22	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
21, 20		0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	PKTBIGERR	0h	R0W	The read value is always 0b. SQCHxSR.PKTBIGERR Clear Set to 1b to clear SQCHxSR.PKTBIGERR. Writing 0b has no effect.

Bit	Bit Name	Initial Value	R/W	Description
18, 17	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16, 15	-	0h	R0W	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
14 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	ADESFIN	0h	R0W	The read value is always 0b. SQCHxSR.ADESFIN Clear Set to 1b to clear SQCHxSR.ADESFIN. Writing 0b has no effect.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	AACTFIN	0h	R0W	The read value is always 0b. SQCHxSR.AACTFIN Clear Set to 1b to clear SQCHxSR.AACTFIN. Writing 0b has no effect.
3 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.58 Sequence Channel x Interrupt Enable Register (DSI_LINK_SQCHxIER)

"x" indicates the channel number.

Note: "x" is 0 or 1.

Access Size : 8, 16, 32 bits

Offset Address : <DSI_LINK_base> + 05D8h (x = 0)
<DSI_LINK_base> + 0618h (x = 1)

Initial Value : 0000_0000h

R/W	RW	R	R	R	R	R	R	RW	R	R	R	RW	R	R	R	R

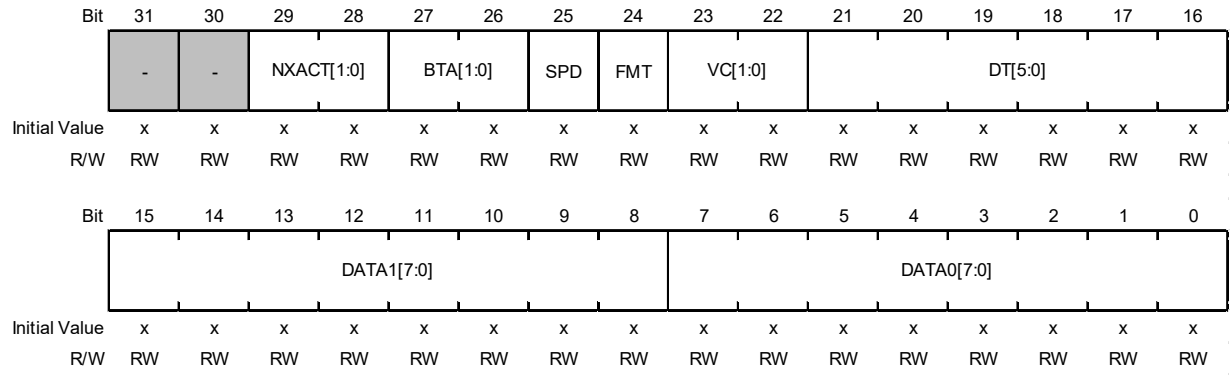
Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
30	RXAKE	0h	RW	Interrupt enable for the Receive Acknowledge and Error Report Packet 0b: Disables interrupt dsi_int_sqx when SQCHxSR.RXAKE = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.RXAKE = 1.
29	RXCORERR	0h	RW	Interrupt enable for the Receive Correctable Error 0b: Disables interrupt dsi_int_sqx when SQCHxSR.RXCORERR = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.RXCORERR = 1.
28	RXPKTDFAIL	0h	RW	Interrupt enable for the Receive Packet Data Fail 0b: Disables interrupt dsi_int_sqx when SQCHxSR.RXPKTDFAIL = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.RXPKTDFAIL = 1.
27	RXFAIL	0h	RW	Interrupt enable for the Receive Fail 0b: Disables interrupt dsi_int_sqx when SQCHxSR.RXFAIL = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.RXFAIL = 1.
26	RXFATALERR	0h	RW	Interrupt enable for the Receive Fatal Error 0b: Disables interrupt dsi_int_sqx when SQCHxSR.RXFATALERR = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.RXFATALERR = 1.
25	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	TXIBERR	0h	RW	Interrupt enable for the Tx Internal Bus Error 0b: Disables interrupt dsi_int_sqx when SQCHxSR.TXIBERR = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.TXIBERR = 1.
23	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
22	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
21, 20		0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19	PKTBIGERR	0h	RW	Interrupt enable for the Packet is too big Error Sequence Operation channel 0: This field has no meaning. Sequence Operation channel 1: 0b: Disables interrupt dsi_int_sqx when SQCHxSR.PKTBIGERR = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.PKTBIGERR = 1.
18, 17	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16, 15	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.

Bit	Bit Name	Initial Value	R/W	Description
14 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	ADESFIN	0h	RW	Interrupt enable for the Descriptor Finished by Setting 0b: Disables interrupt dsi_int_sqx when SQCHxSR.ADESFIN = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.ADESFIN = 1.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	AACTFIN	0h	RW	Interrupt enable for the Descriptor's All Action Finished 0b: Disables interrupt dsi_int_sqx when SQCHxSR.AACTFIN = 1. 1b: Enables interrupt dsi_int_sqx when SQCHxSR.AACTFIN = 1.
3 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.5.2.2.59 Sequence Channel x Descriptor y-A Register (DSI_LINK_SQCHxDSCyAR)

"x" indicates the channel number.

Note: "x" is 0 or 1.



"y" indicates the descriptor number.

Note: "y" is 00 to 07.

Access Size : 32 bits

Offset Address : <DSI_LINK_base> + 0780h + 0010h × (y) (x = 0)
<DSI_LINK_base> + 0800h + 0010h × (y) (x = 1)

Initial Value : xxxx_xxxxh

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	xh*2	RW	Reserved When read, the last written value is read. When writing, be sure to write 0b. Operation is not guaranteed if a value other than 0b is written.
29, 28	NXACT[1:0]	xh*2	RW	Next Action 0h: Terminates operation after this descriptor is finished. 1h: Operates the next descriptor after this descriptor is finished. 2h: Reserved 3h: Reserved
27, 26	BTA[1:0]	xh*2	RW	Bus Turn Around Sets Tx Request without either Bus Turn-Around (BTA) or no-operation. Or else, sets Tx Request with BTA. 0h: Tx Request without BTA or no-operation. 1h: Tx non-Read Request with BTA. 2h: Tx Read Request with BTA. 3h: BTA only
25	SPD	xh*2	RW	Speed Sets the speed type in Tx Request. 0b: High Speed 1b: Low Power Setting this bit to "1" during Video-Input Operation is prohibited.
24	FMT	xh*2	RW	Format Packet format of Tx Packet Header. This field should be set by Data Type. 0b: Short Packet 1b: Long Packet
23, 22	VC[1:0]	xh*2	RW	Virtual Channel Identifier of Virtual Channel of Tx Packet Header.
21 to 16	DT[5:0]	xh*2	RW	Data Type Data Type of Tx Packet Header.
15 to 8	DATA1[7:0]	xh*2	RW	Data 1 Data 1 of Tx Packet Header*1. When Tx Packet format is Long Packet, this value is the upper 8 bits of the word count. The maximum Long Packet size in Command Transfer mode which uses registers is 16 bytes. (SQCHxDSCyBR.DTSEL = 0h and SQCHxDSCyAR.FMT = 1) The maximum Long Packet size in Command Transfer mode which uses the internal bus memory is the number of bytes indicated by SQCHxSET1R.CHBUFSZ. (SQCHxDSCyBR.DTSEL = 1h and SQCHxDSCyAR.FMT = 1)

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	DATA0[7:0]	xh*2	RW	Data 0 Data 0 of Tx Packet Header*1. When Tx Packet format is Long Packet, this value is the lower 8 bits of the word count. The maximum Long Packet size in Command Transfer mode which uses registers is 16 bytes. (SQCHxDSCyBR.DTSEL = 0h and SQCHxDSCyAR.FMT = 1) The maximum Long Packet size in Command Transfer mode which uses the internal bus memory is the number of bytes indicated by SQCHxSET1R.CHBUFSZ. (SQCHxDSCyBR.DTSEL = 1h and SQCHxDSCyAR.FMT = 1)

x = Undefined

Note 1. The maximum size for Command Transfer mode Long Packet by using the register is 16 bytes. (SQCHxDSCyBR.DTSEL = 0h and SQCHxDSCyAR.FMT = 1h)
The maximum size for Command Transfer mode Long Packet by using the internal bus memory is SQCHxSET1R.CHBUFSZ bytes. (SQCHxDSCyBR.DTSEL = 1h and SQCHxDSCyAR.FMT = 1h)

Note 2. The initial values are determined by the initial value of Descriptor RAM.

9.5.2.2.60 Sequence Channel x Descriptor y-B Register (DSI_LINK_SQCHxDSCyBR)

"x" indicates the channel number.

Note: "x" is 0 or 1.

"y" indicates the descriptor number.

Note: "y" is 00 to 07.

Access Size : 32 bits

Offset Address : <DSI_LINK_base> + 0784h + 0010h × (y) (x = 0)
<DSI_LINK_base> + 0804h + 0010h × (y) (x = 1)

Initial Value : xxxx_xxxxh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	DTSEL[1:0]		-	-	-	-	-	-	-	-
Initial Value	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	xh*1	RW	Reserved When read, the last written value is read. When writing, be sure to write 0b. Operation is not guaranteed if a value other than 0b is written.
25, 24	DTSEL[1:0]	xh*1	RW	Data Select 0h: Packet Payload Data register 1h: Long Packet data use memory space. In the case of writing, internal read causes reading from the SQCHxDSCyDR address. In the case of reading, internal write causes writing to the SQCHxDSCyDR address. Note: Read Header is always saved to the RXRSSxR register. 2h, 3h: Reserved If a write request with Short packet, then set 0h. When DTSEL = 0h, Long packet write request data size shall be equal to or smaller than 16 bytes. If read request data to save exceeds 16 bytes, this is reported as an error.
23 to 0	-	xh*1	RW	Reserved When read, the last written value is read. When writing, be sure to write 0b. Operation is not guaranteed if a value other than 0b is written.

x = Undefined

Note 1. The initial values are determined by the initial value of Descriptor RAM.

9.5.2.2.61 Sequence Channel x Descriptor y-C Register (DSI_LINK_SQCHxDSCyCR)

"x" indicates the channel number.

Note: "x" is 0 or 1.

"y" indicates the descriptor number.

Note: "y" is 00 to 07.

Access Size : 32 bits

Offset Address : <DSI_LINK_base> + 0788h + 0010h × (y) (x = 0)
<DSI_LINK_base> + 0808h + 0010h × (y) (x = 1)

Initial Value : xxxx_xxxxh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ACTCODE[7:0]								-	AUXOP	-	-	-	-	-	-

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ACTCODE[7:0]	xh*1	RW	Action Code Indicates the rx result same slot number for BTA action. Setting a value greater than or equal to 4 is prohibited. Setting the same rx result save slot number to a different descriptor is prohibited. When AUXOP is 1. 00h: Sends Reset-Trigger. 04h: Sends initial skew calibration Prohibited to use in channel 0 (LP only). 05h: Sends periodic skew calibration Prohibited to use in channel 0 (LP only). 08h: No-operation Other: Reserved Set 00h in other cases.
23	-	xh*1	RW	Reserved When read, the last written value is read. When writing, be sure to write 0b. Operation is not guaranteed if a value other than 0b is written.
22	AUXOP	xh*1	RW	Auxiliary Operation Used for auxiliary operation execution. When this bit is set to 1b, SQCHxDSCyBR.BTA should be set to 0h. Set this bit to 1b with BTA = 0h. Setting this bit to 1b during Video-Input Operation is prohibited.
21 to 3	-	xh*1	RW	Reserved When read, the last written value is read. When writing, be sure to write 0b. Operation is not guaranteed if a value other than 0b is written.
2 to 0	FINACT[2:0]	xh*1	RW	Finish Action Bit 2: Set to 0b. Bit 1: Set to 0b. Bit 0: Sets SQCHxSR.AACTFIN if this descriptor's all actions have finished. (0b: Disabled, 1b: Enabled). Since each descriptor's operation is not the same, descriptors may finish out of order. For example, Descriptor#1 may finish before Descriptor#0.

x = Undefined

Note 1. The initial values are determined by the initial value of Descriptor RAM.

9.5.2.2.62 Sequence Channel x Descriptor y-D Register (DSI_LINK_SQCHxDSCyDR)

"x" indicates the channel number.

Note: "x" is 0 or 1.

"y" indicates the descriptor number.

Note: "y" is 00 to 07.

Access Size : 32 bits

Offset Address : <DSI_LINK_base> + 078Ch + 0010h × (y) (x = 0)
<DSI_LINK_base> + 080Ch + 0010h × (y) (x = 1)

Initial Value : xxxx_xxxxh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

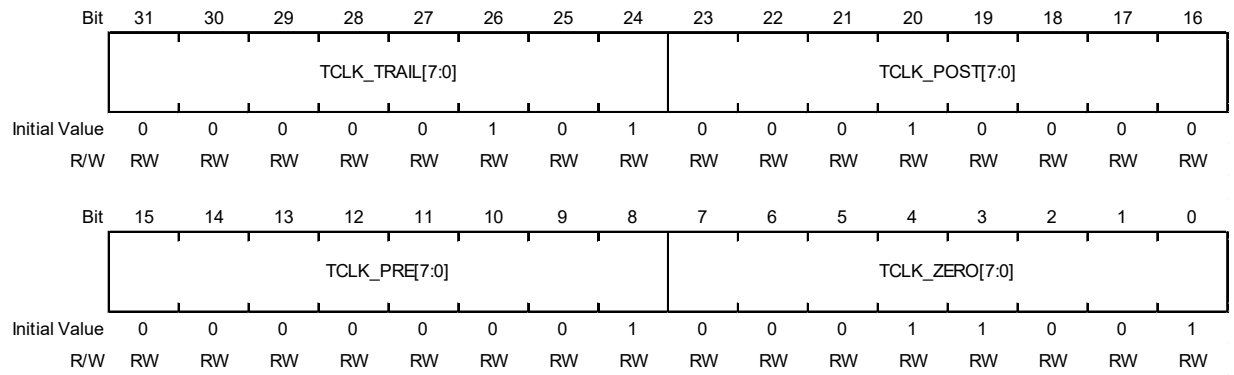
9.5.2.3.3 DSI D-PHY Timing Register 1 (DSI_DPHY_TIM1)

Access Size : 8, 16, 32 bits

Address : <DSI_DPHY_base> + 0008h

Initial Value : 0403_0909h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	THS_PREPARE [7:0]	4h	RW	Timing parameter*1
23 to 16	TCLK_PREPAR E[7:0]	3h	RW	Timing parameter*1
15 to 8	THS_SETTLE [7:0]	9h	RW	Timing parameter Set 0.
7 to 0	TCLK_SETTLE [7:0]	9h	RW	Timing parameter Set 0.



Note 1. **Table 9.5-4** lists the recommended setting values.

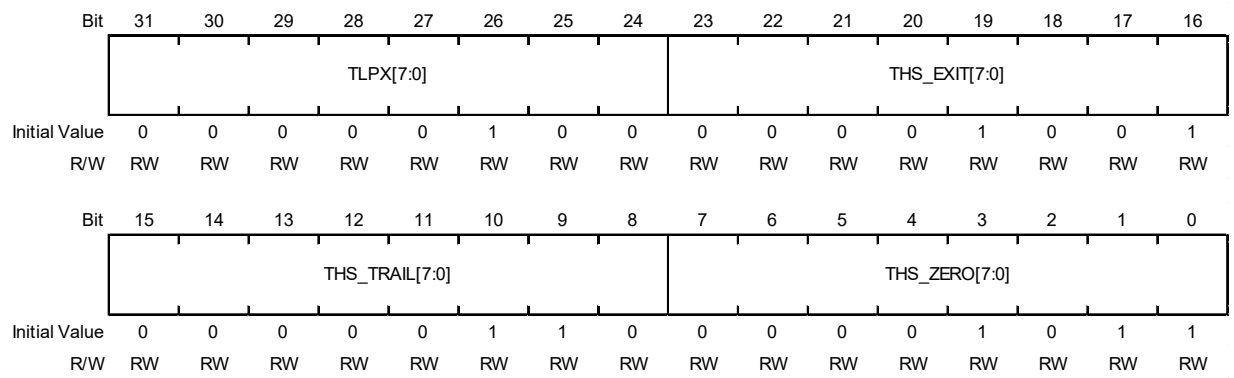
9.5.2.3.4 DSI D-PHY Timing Register 2 (DSI_DPHY_TIM2)

Access Size : 8, 16, 32 bits

Address : <DSI_DPHY_base> + 000Ch

Initial Value : 0510_0119h

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TCLK_TRAIL [7:0]	5h	RW	Timing parameter*1
23 to 16	TCLK_POST [7:0]	10h	RW	Timing parameter*1
15 to 8	TCLK_PRE[7:0]	1h	RW	Timing parameter*1
7 to 0	TCLK_ZERO [7:0]	19h	RW	Timing parameter*1



Note 1. **Table 9.5-4** lists the recommended setting values.

9.5.2.3.5 DSI D-PHY Timing Register 3 (DSI_DPHY_TIM3)

Access Size : 8, 16, 32 bits

Address : <DSI_DPHY_base> + 0010h

Initial Value : 0409_060Bh

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TLPX[7:0]	4h	RW	Timing parameter*1
23 to 16	THS_EXIT[7:0]	9h	RW	Timing parameter*1
15 to 8	THS_TRAIL[7:0]	6h	RW	Timing parameter*1
7 to 0	THS_ZERO[7:0]	Bh	RW	Timing parameter*1

Note 1. **Table 9.5-4** lists the recommended setting values.

9.5.3 Operation

9.5.3.1 Interrupts

Interrupts can be divided into the following categories:

Table 9.5-5 Interrupt Signals (1/2)

Interrupt Signal	Category	Interrupt Condition	Interrupt Source Register
dsi_int_sq0	Sequence operation channel 0 interrupt	Receive Acknowledge and Error Report Packet in Sequence Operation BTA	SQCH0SR.RXAKE
		Receive Correctable Error in Sequence Operation BTA	SQCH0SR.RXCORERR
		Receive Packet Data Error in Sequence Operation BTA	SQCH0SR.RXPKTDFAIL
		Receive Fail Error in Sequence Operation BTA	SQCH0SR.RXFAIL
		Receive Fatal Error in Sequence Operation BTA	SQCH0SR.RXFATALERR
		Transmit Internal Bus Error in Sequence Operation	SQCH0SR.TXIBERR
		Descriptor Finished by Setting in Sequence Operation	SQCH0SR.ADESFIN
		Descriptor's All Action Finished in Sequence Operation	SQCH0SR.AACTFIN
dsi_int_sq1	Sequence operation channel 1 interrupt	Receive Acknowledge and Error Report Packet in Sequence Operation BTA	SQCH1SR.RXAKE
		Receive Correctable Error in Sequence Operation BTA	SQCH1SR.RXCORERR
		Receive Packet Data Error in Sequence Operation BTA	SQCH1SR.RXPKTDFAIL
		Receive Fail Error in Sequence Operation BTA	SQCH1SR.RXFAIL
		Receive Fatal Error in Sequence Operation BTA	SQCH1SR.RXFATALERR
		Transmit Internal Bus Error in Sequence Operation	SQCH1SR.TXIBERR
		Transmit Packet is too big Error in Sequence Operation	SQCH1SR.PKTBIGERR
		Descriptor Finished by Setting in Sequence Operation	SQCH1SR.ADESFIN
		Descriptor's All Action Finished in Sequence Operation	SQCH1SR.AACTFIN
dsi_int_vin1	Video-Input operation channel 1 interrupt	Transmit Buffer Overflow in Video-Input Operation	VICH1SR.VBUFOVF
		Transmit Buffer Underflow in Video-Input Operation	VICH1SR.VBUFUDF
		Transmit Timing Error in Video-Input Operation	VICH1SR.TIMERR
		Video-Input Signal Accept Ready	VICH1SR.VIRDY
		Video-Input Operation Stopped	VICH1SR.STOP
		Video-Input Operation Started	VICH1SR.START

Table 9.5-5 Interrupt Signals (2/2)

Interrupt Signal	Category	Interrupt Condition	Interrupt Source Register
dsi_int_rcv	DSI Packet Receive interrupt	Receive Acknowledge and Error Report Packet	RXSR.RXAKE
		ECC 1bit Error	RXSR.ECCERR1B
		Maximum Return Packet Size Error	RXSR.MAXRPSZERR
		No Return Error	RXSR.NORETERR
		Peripheral Response timeout	RXSR.PRESPTOERR
		Receive Buffer overflow error	RXSR.RXOVFERR
		Internal Bus Error detect on data save	RXSR.IBERR
		CRC Error	RXSR.CRCERR
		Word Count Error	RXSR.WCERR
		Unexpected Packet Error	RXSR.UEXPKTERR
		ECC Error	RXSR.ECCERR
		Malformed Error	RXSR.MLFERR
		External Tearing Effect	RXSR.EXTTEDET
		Receive ACK trigger	RXSR.RXACK
		Receive Reset trigger	RXSR.RXRTRG
		Receive Unknown-5 trigger	RXSR.RXUK5TRG
		Receive EoTp	RXSR.RXEOTP
		Receive Response packet	RXSR.RXRESP
		Turnaround Acknowledge Timeout	RXSR.TATO
		LP-RX Host Processor Timeout	RXSR.LRXHTO
		BTA request End	RXSR.BTAREQEND
dsi_int_ferr	DSI Fatal Error interrupt	Contention Error LP1	FERRSR.ERRCLP1
		Contention Error LP0	FERRSR.ERRCLP0
		Control Error	FERRSR.ERRCTRL
		Sync Escape Error	FERRSR.ERRSYNESC
		Error Escape	FERRSR.ERRESC
		Turnaround Acknowledge Timeout	FERRSR.TATO
		LP-RX Host Processor Timeout	FERRSR.LRXHTO
		HS TX Timeout	FERRSR.HTXTO
dsi_int_ppi	DSI D-PHY PPI interrupt	Data Lanes return from ULPS	PLSR.DLFROMULPS
		Data Lanes go to ULPS	PLSR.DLTOULPS
		Clock Lane change HS to LP	PLSR.CLHS2LP
		Clock Lane change LP to HS	PLSR.CLLP2HS
		Clock Lanes return from ULPS	PLSR.CLFROMULPS
		Clock Lanes go to ULPS	PLSR.CLTOULPS
		Data Lane 0 change TX to RX	PLSR.DL0TX2RX
		Data Lane 0 change RX to TX	PLSR.DL0RX2TX

The interrupt signal consists of combination logic. The interrupt signal from a Status Register is enabled by the signal related Interrupt Enable Register. These interrupt signals are bound by OR logic.

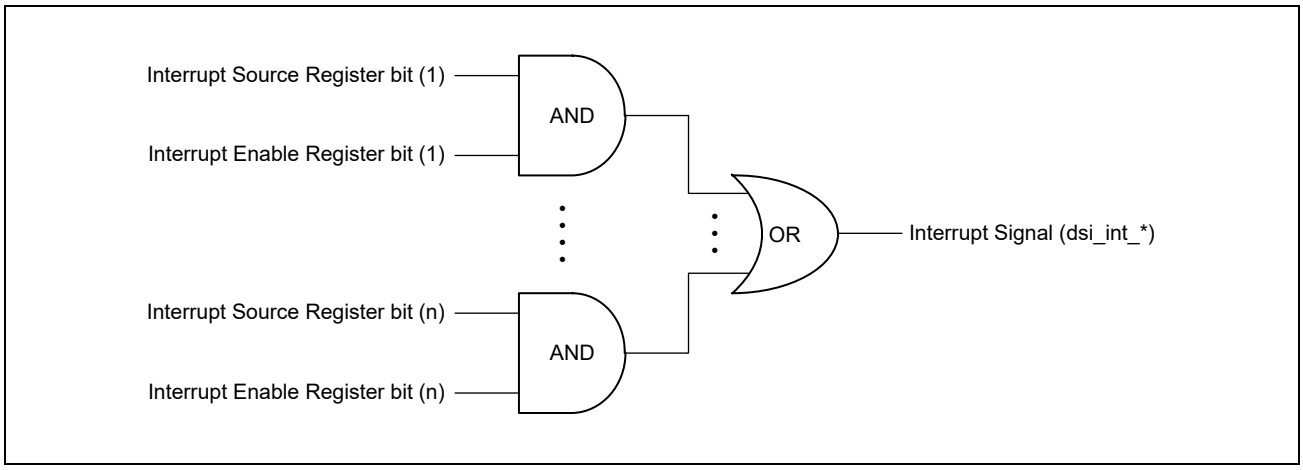


Figure 9.5-5 Interrupt Signal Output

9.5.3.2 Operation Flow

This chapter shows various operation procedures for using the DSI-Tx Module. As for the interrupt operation, Interrupt Enable bit of each interrupt source is enabled (set to 1) before use, and after confirming the interrupt, the interrupt source is cleared. And more, previous action's interrupt source must be cleared before setting the interrupt enable. Flows in this chapter indicate only interrupt bit. The DSI-Tx Module does not care whether firmware use the bits by interrupt action or flag polling action. These descriptions are omitted in each flow in this chapter unless otherwise specified. Error checks are also omitted in normal flow.

9.5.3.2.1 Reset

(1) Power on Reset and Initial Settings for All Operations

The power on sequence of the DSI-Tx Module is shown **Figure 9.5-6**

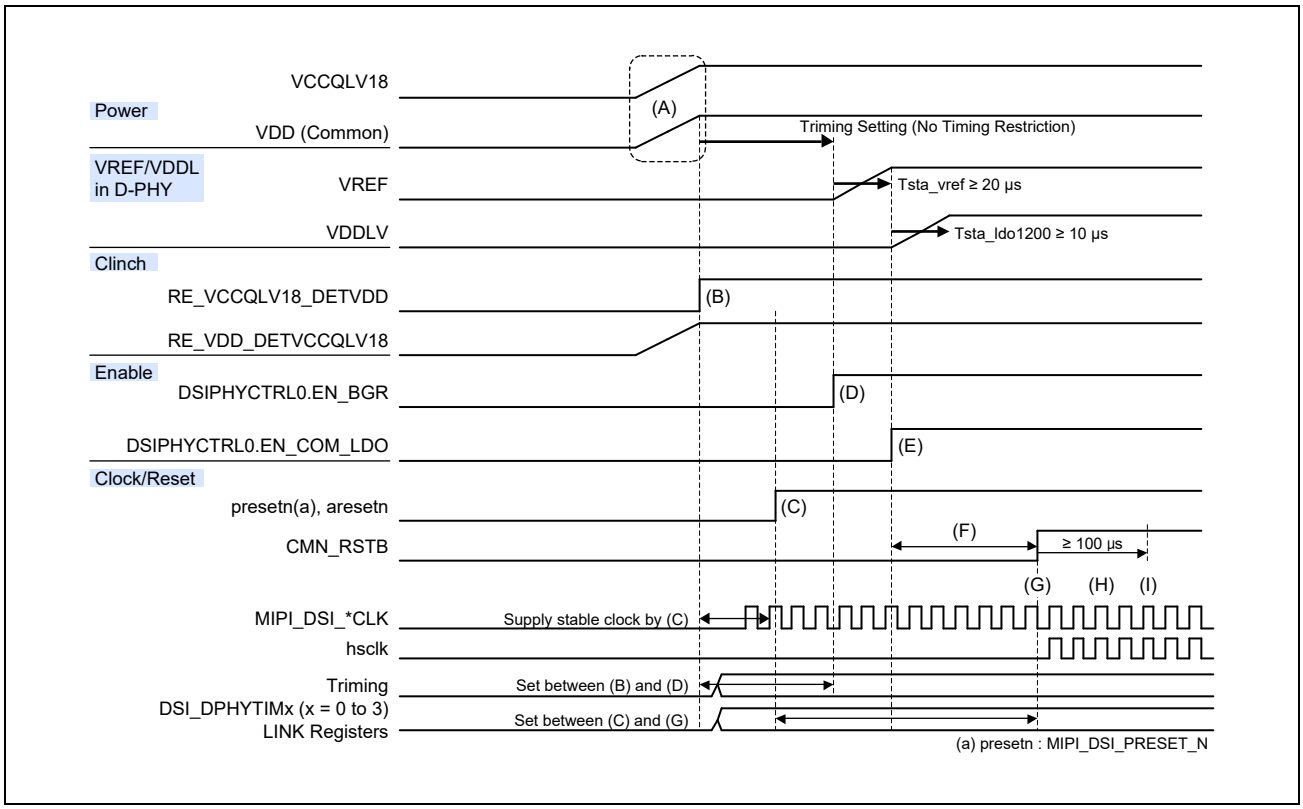

Figure 9.5-6 Power on Sequence

(A) Bring up VDD and VCCQLV18. There are no restrictions on the order to bring up VDD and VCCQLV18.

(B) Set 1 to RE_VCCQLV18_DETVDD and RE_VDD_DETVCCQLV18. (Both signals will detect their respective power supply and will automatically become "1").

(C) De-assert preestn and aresetn after after MIPI_DSI_*CLK is stable.

(D) Write 1 to DSIDPHYCTRL0.EN_BGR.

(E) Write 1 to DSIDPHYCTRL0.EN_COM_LDO after waiting for more than 20 usec.

(F) Write DSIDPHYTIMx (x = 0 to 3) registers and LINK registers after waiting for more than 10 usec.

(G) De-assert CMN_RSTB.

(H) Wait for more than 100 usec.

(I) The DSI-Tx Module is ready.

At power-on reset, all registers of the DSI-Tx Module are initialized.

Perform the initial settings of the register after canceling the power-on reset. It is not necessary to set the register that is used with the default value.

The registers that need to be initialized are as follows.

- Common Settings
  - TXSETR
  - ULPSSETR
  - DSISETR
  - CLSTPTSETR
  - LPTRNSTSETR
- Timeout Settings
  - PRESPTOBTASETR
  - PRESPTOLPSETR
  - PRESPTOHSSETR
  - HSTXTOSETR
  - LRXHTOSETR
  - TATOSETR

These registers can only be changed during the initial setup after a power-on reset and during a software reset in **9.5.3.2.1(2)**. It is prohibited to change at any other time.

(2) Software Reset

Figure 9.5-7 shows the operation during software reset. Make sure that APB clock (MIPI_DSI_PCLK), Internal Bus clock (MIPI_DSI_ACLK), Video clock (MIPI_DSI_VCLK), PLL Multiplied clock (MIPI_DSI_PLLCLK), Escape mode Transmit clock (MIPI_DSI_LPCLK) are running and CMN_RSTB is High before starting software reset.

Writing 1 to RSTCR.SWRST will issue a software reset. After issuing the software reset, check the start of the software reset process with RSTSR.SWRSTxx = 1. Then write 1 to RSTCR.FCETXSTP to transition the valid data lane of the D-PHY to the Tx Stop State. By checking RSTSR.DL0DIR = 0 and RSTSR.DLSTPST [x] = 1 of the valid data lane, it is possible to confirm that the valid data lane of D-PHY has transitioned to Tx Stop State. After confirming that the valid data lane of the D-PHY has transitioned to the Tx Stop State, write 0 to RSTCR.FCETXSTP. Then write 0 to RSTCR.SWRST and check the completion of the software reset process with RSTSR.SWRSTx = 0. Since all registers are synchronously reset except for some registers*[1], the software reset process is not completed even if a software reset is issued while the clock is stopped.

Registers that require initial settings as described in **9.5.3.2.1(1)**, RSTCR register, RSTSR register, and SQCHxDSCyAR – SQCHxDSCyDR register are not initialized by software reset.

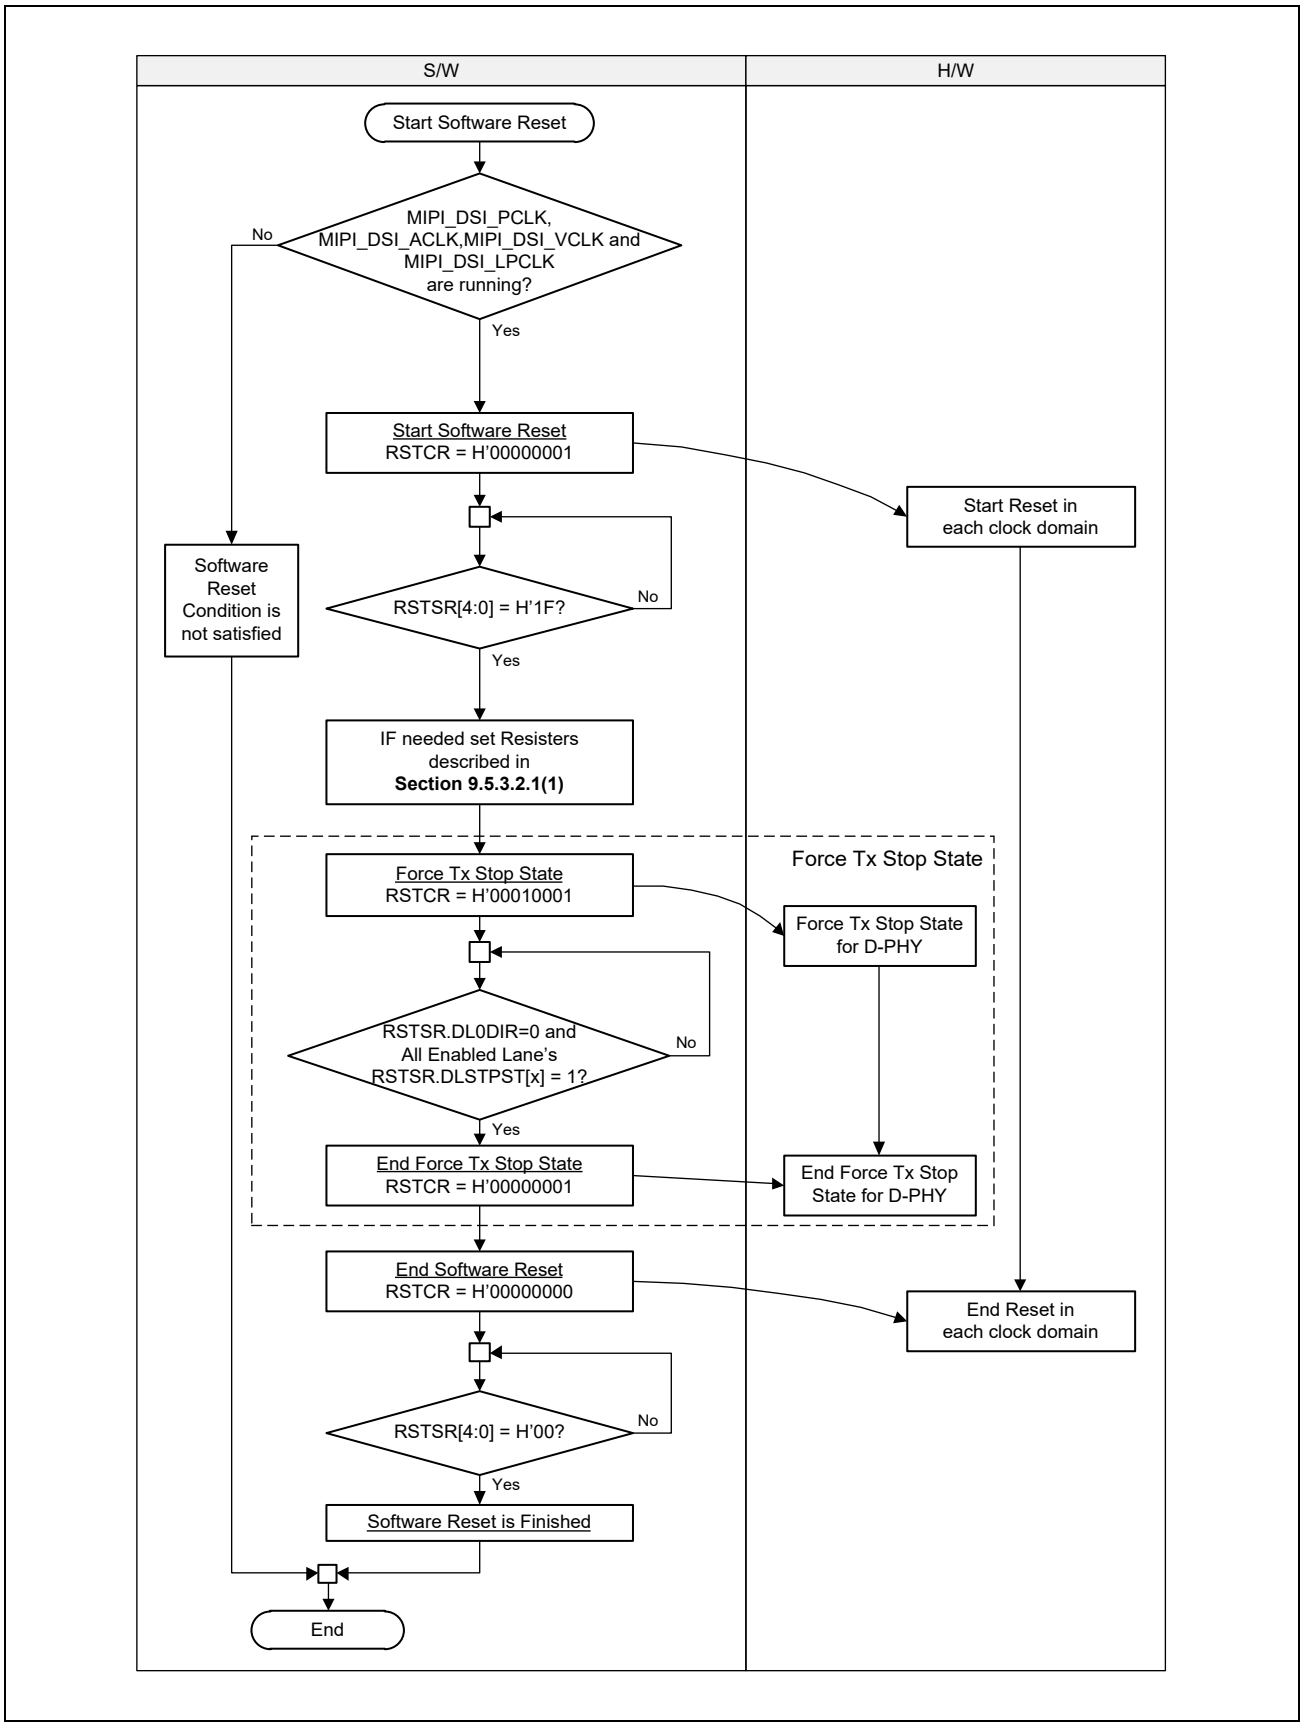

Figure 9.5-7 Software Reset

9.5.3.2.2 Start/Stop of HS Clock

The following describes the HS Clock Start/Stop sequence. HS Clock Start / Stop is controlled by Software.

Figure 9.5-8 shows the operation at HS Clock Start.

Write 1 to TXSETR.CLEN to enable DPHY clock lanes before starting Video-Input Operation or Sequence Operation channel 1 operation.

After the clock lane is enabled and the source clock of the clock lane is stable, write 1 to HSCLKSETR.HSCLKRUN to set the clock lane to HS. It is forbidden to change HSCLKRUN while Sequence Channel is in operation.

At the same time as writing 1 to HSCLKSETR.HSCLKRUN, set continuous clock mode and non-continuous clock mode with HSCLKSETR.HSCLKMODE.

In continuous clock mode, always set the clock lane to HS. PLSR.CLLP2HS is set to 1 when the clock lane transitions from LP to HS. After checking, perform the following operations.

In non-continuous clock mode, the DSI-Tx Module automatically transitions the clock lane from LP to HS depending on the presence or absence of HS Transmission. PLSR.CLLP2HS and PLSR.CLHS2LP are set for each transition, but confirmation is not required.

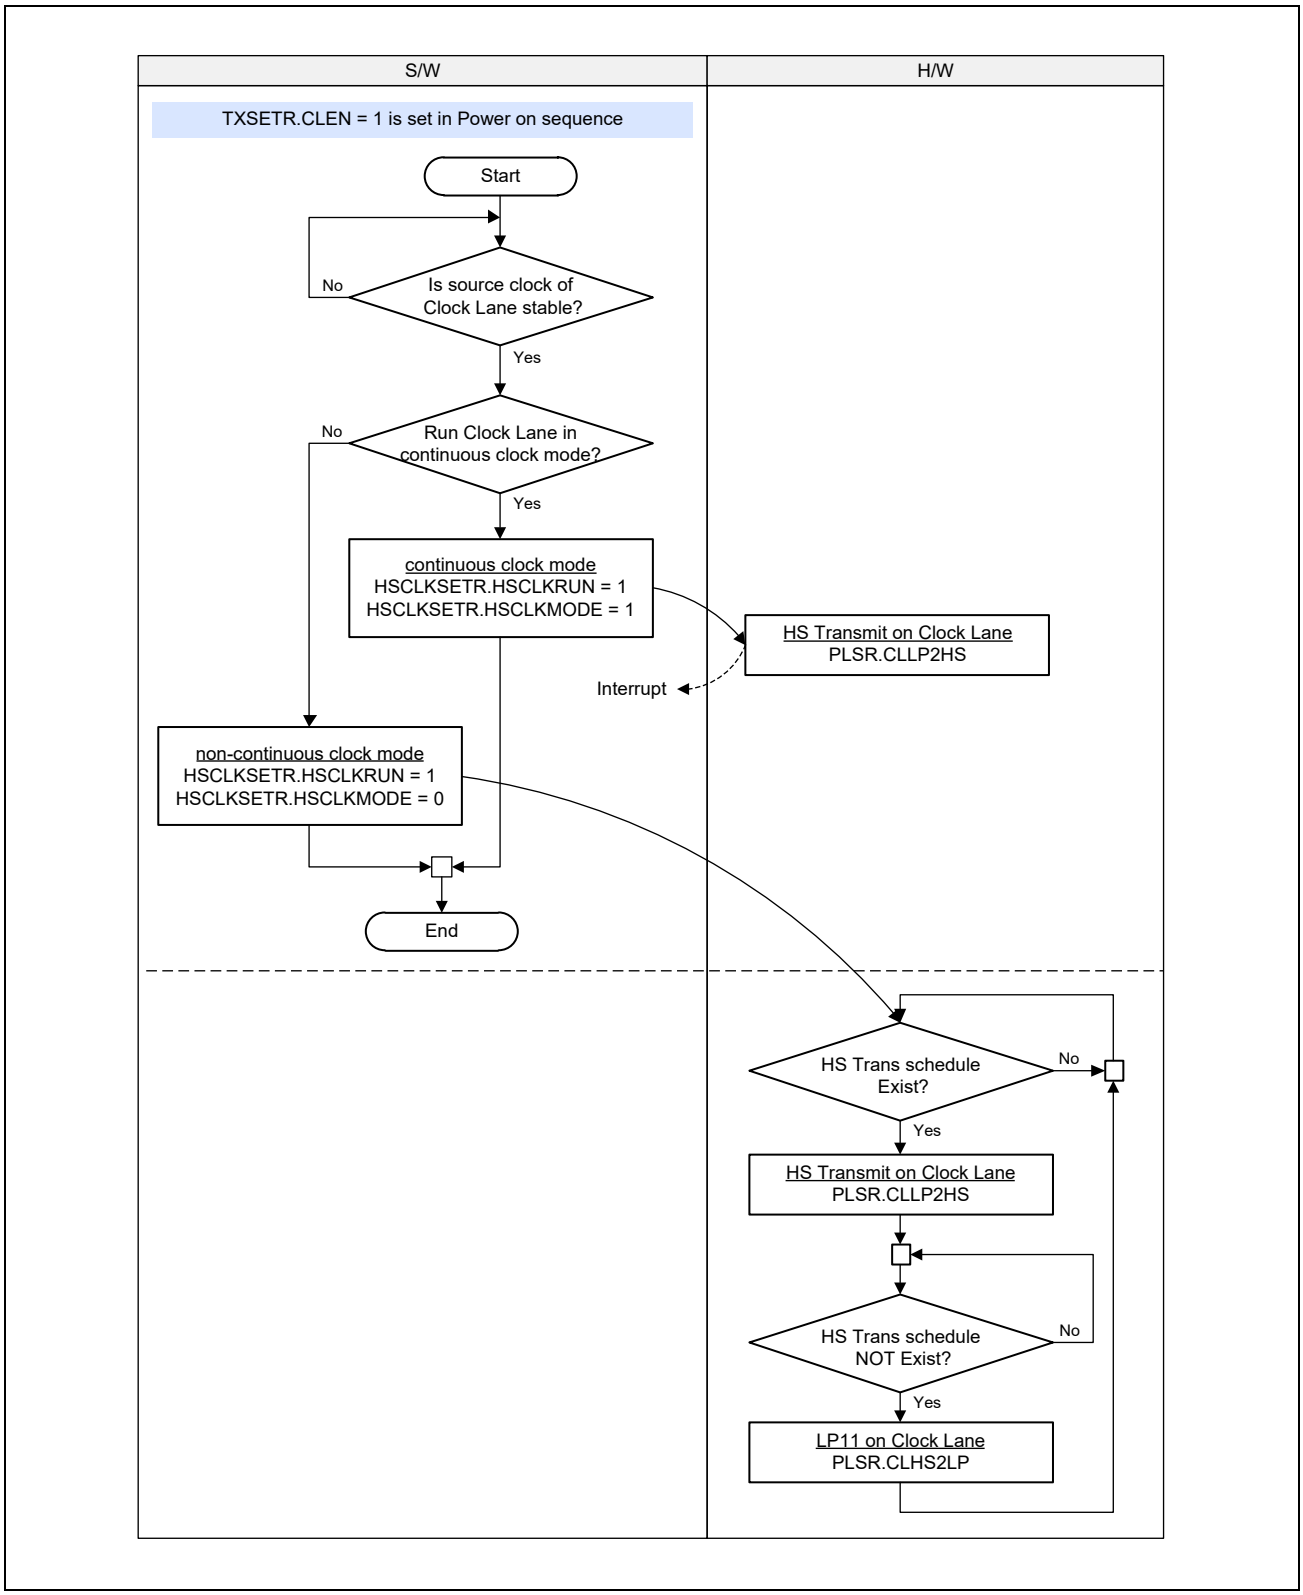

Figure 9.5-8 Start of HS Clock

Figure 9.5-9 shows the operation when HS Clock Stop. After confirming that Video-Input Operation and Sequence Operation channel 1 are not running, write 0 to HSCLKSETR.HSCLKRUN to make the clock lane LP. PLSR.CLHS2LP is set to 1 when the clock lane transitions from HS to LP. In non-continuous clock mode, you do not need to check PLSR.CLHS2LP because the clock lane is likely to be LP already when you write 0 to HSCLKSETR.HSCLKRUN. It is possible to check the clock lane status by reading PLSR.CLSTPST.

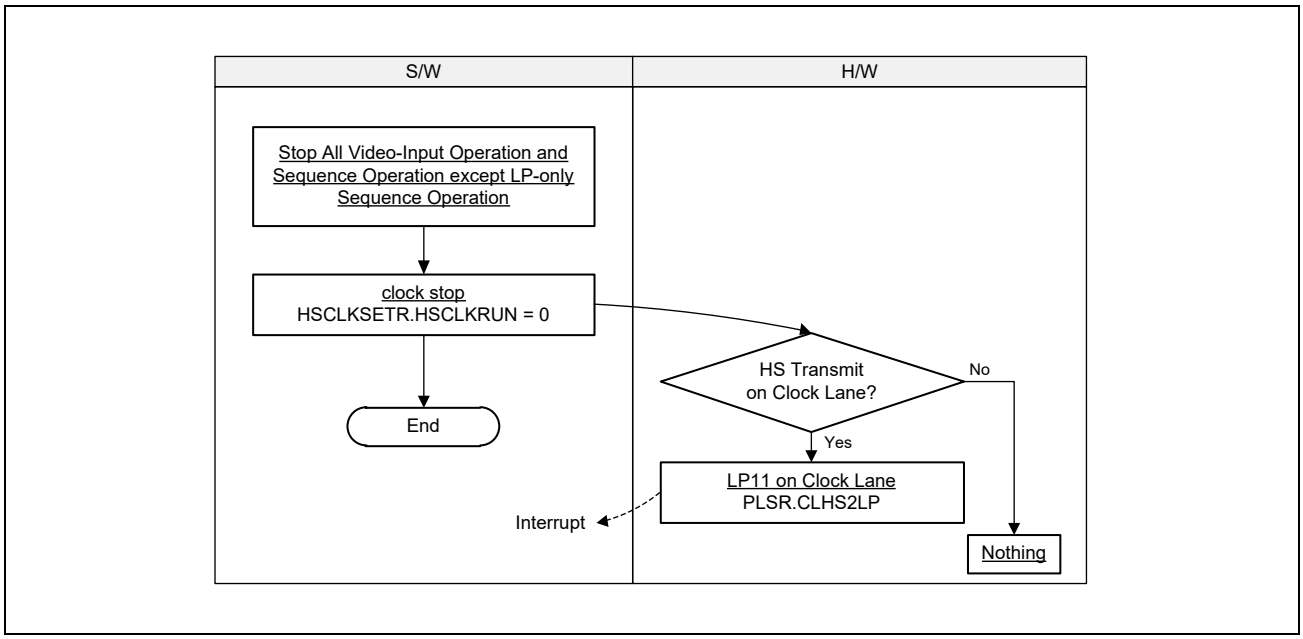

Figure 9.5-9 Stop of HS Clock

9.5.3.2.3 Sequence Operation

(1) Basic Running Sequence

Sequence Operation requires initial settings before the operation starts.

- Channel Register Setting
  - Set SQCHxSET1R, SQCHxIER
- Prepare Write Data
  - Prepare Write Data to Memory Area
  - Prepare Write Data to TXPPDxR Registers
- Allocate Read Data Area
  - Clear RXRSSR Register if previous valid flag remains.
  - Allocate each read action's Memory area.
- Write all Descriptors
- Confirm running HSCLK if Sequence channel 1 is targeted to run.

When "1" is written to SQCHxSET0R.START, Sequence Operation channel x starts the processing of Descriptor, and when the processing of Descriptor of SQCHxDSCyAR.NXACT = "00b" is completed, the processing of Descriptor ends.

Since Descriptor consists of SRAM, the initial value is indefinite. When the user sets the Descriptor, set all the bits.

After writing 1 to SQCHxSET0R.START on Sequence Operation channel x and SQCHxSR.RUNNING becomes 1, It is prohibited to change the settings of SQCHxSET1R, SQCHxDSCyAR, SQCHxDSCyBR, SQCHxDSCyCR, and SQCHxDSCyDR until SQCHxSR.RUNNING becomes 0.

HS-related operations are prohibited on Sequence Operation channel 0.

(2) Single Packet Transmission

The following describes sending non-read packets using the Sequence Operation channel.

For non-read packet transmission, set the following registers before packet transmission.

SQCHxDSCyAR.NXACT: "00b"

SQCHxDSCyAR.FMT: "0b" Short Packet or "1b" Long Packet

SQCHxDSCyAR.SPD: "0b" High Speed or "1b" Low Speed

SQCHxDSCyAR.BTA: "00b" without BTA or "01b" with BTA

SQCHxDSCyAR.VC, DT, DATA0, DATA1

SQCHxDSCyBR.DTSEL: Specify payload data storage location for non-read packets

"00b" TXPPD0R – TXPPD3R. Payloads size is limited up to 16 Bytes.

"01b" Memory space. Payloads size is limited up to SQCHxSET1R.CHBUFSZ Bytes.

SQCHxDSCyCR.AUXOP "0b"

When setting a Long Packet with SQCHxDSCyAR.FMT, prepare the payload data in the location specified by SQCHxDSCyBR.DTSEL in the form of little endian.

No payload data is required when configuring Short Packets with SQCHxDSCyAR.FMT.

After the above settings, write “1” to SQCHxSET0R.START to send non-read packets.

The user can know the completion of Single Packet Transmission by asserting SQCHxSR.ADESFIN.

If “01b” is set in SQCHxDSCyAR.BTA, BTA is performed after sending a non-read packet.

An ACK trigger or Acknowledge and Error Report Packet may be received when the bus rights are transferred to the peripheral.

The user can get an overview of the reception result by reading the RXRSSxR register with the number specified by SQCHxDSCyCR.ACTCODE. Also, by reading the RXSR register, the user can know the details of the reception result.

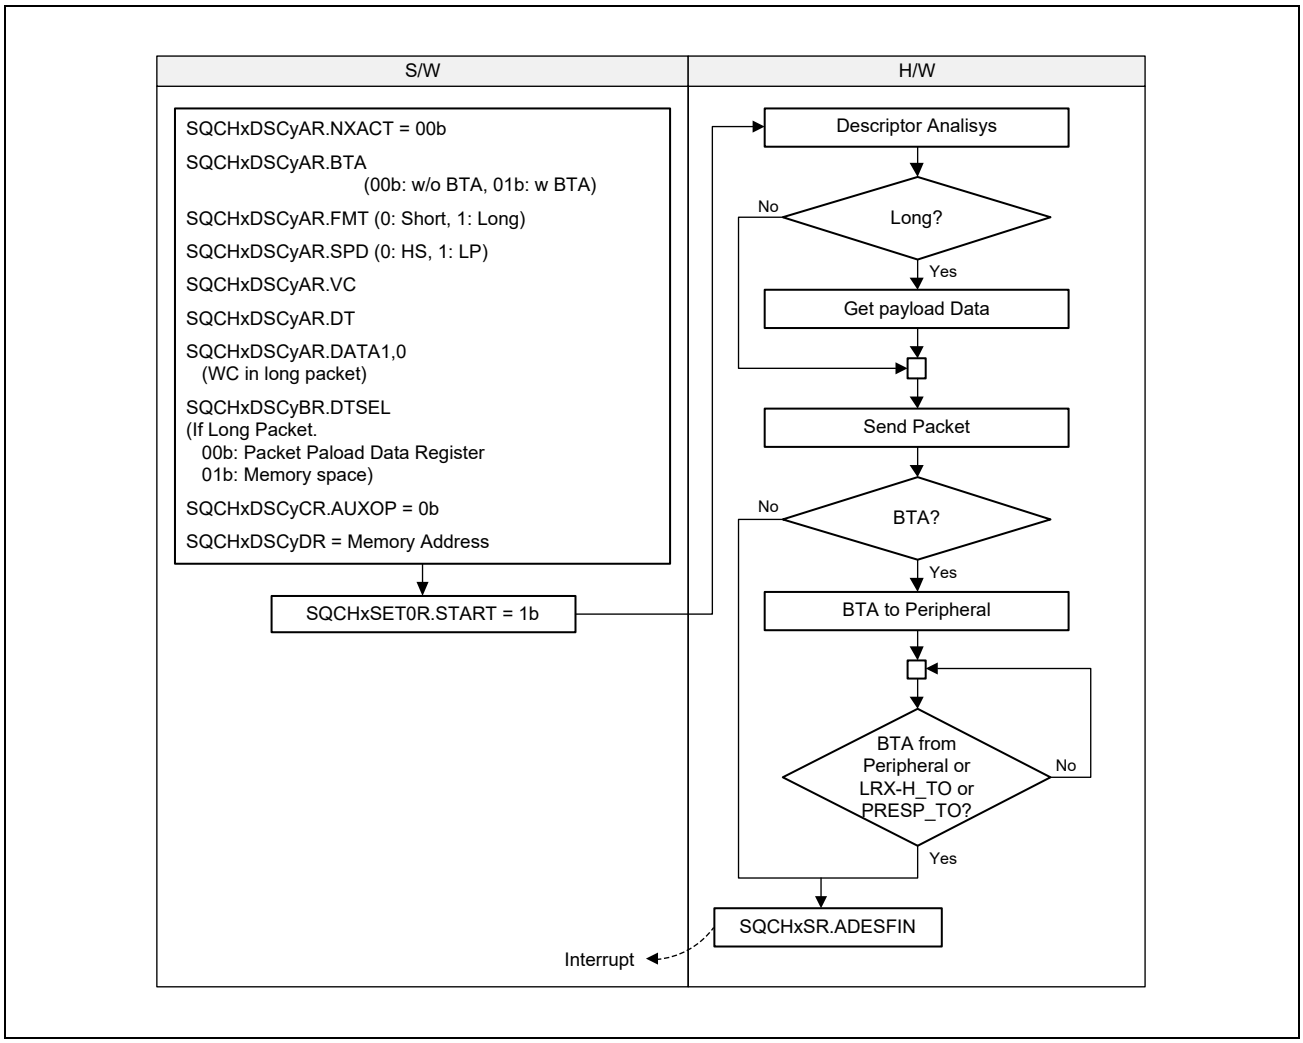

Figure 9.5-10 Single Packet Transfer

(3) Single Packet Reception

This section describes sending read packets and receiving response packets using the Sequence Operation channel.

Since the read packet is a short packet, set the following registers before sending the packet.

SQCHxDSCyAR.NXACT: “00b”

SQCHxDSCyAR.FMT: “0b” Short Packet

SQCHxDSCyAR.SPD: “0b” High Speed or “1b” Low Speed

SQCHxDSCyAR.BTA: “10b” Read Request with BTA

SQCHxDSCyAR.VC, DT, DATA0, DATA1

SQCHxDSCyBR.DTSEL: Specify the payload data storage location of the response packet

“00b” RXPPD0R – RXPPD3R. Payloads size is limited up to 16 Bytes.

“01b” Memory space. Payloads size is limited up to RXBUFSZR.RXBUFSZ Bytes.

SQCHxDSCyCR.AUXOP: “0b”

SQCHxDSCyCR.ACTCODE: Rx Result Save Slot number

When SQCHxDSC00BR.DTSEL = “00b” is set, receiving payload data of 17 bytes or more is not supported. Therefore, if there is a possibility of receiving payload data of 17 bytes or more, please set SQCHxDSC00BR.DTSEL = “01b”.

After the above settings, write “1” to SQCHxSET0R.START to send the read packet.

BTA is performed after sending the read packet. When the bus right is transferred to the peripheral, the response packet is received. At this time, the Acknowledge and Error Report Packet may also be received at the same time.

The user can know the completion of Single Packet Reception by asserting SQCHxSR.ADESFIN.

The user can get an overview of the reception result by reading the RXRSSxR register with the number specified by SQCHxDSCyCR.ACTCODE, and can know the details of the previous reception result by reading the RXSR register.

If the received response packet is a Short Packet or a Long Packet with WC = 0, the setting value of SQCHxDSC00BR.DTSEL is meaningless.

Figure 9.5-11 shows the flow of Single Packet Reception.

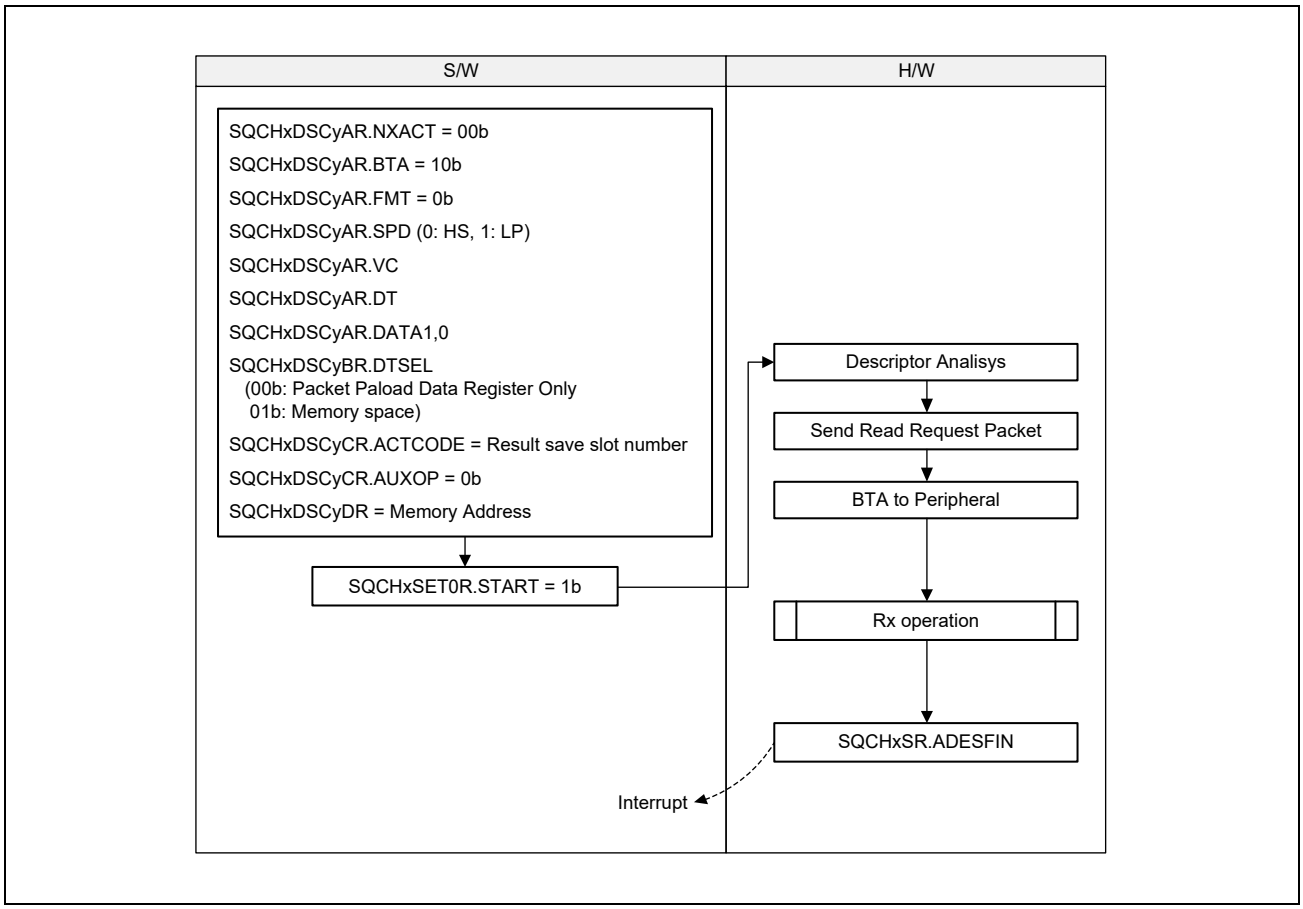

Figure 9.5-11 Single Packet Receive

(4) Reset Trigger Transmission

The DSI-Tx Module can send triggers using the Sequence Operation channel.

Since the DSI-Tx Module is a host, the only trigger that can be sent is a reset trigger.

After setting SQCHxDSCyAR.NXACT = “00b”, SQCHxDSCyCR.AUXOP = “1b”, and SQCHxDSCyCR.ACTCODE = “H’00”, write “1” to SQCHxSET0R.START to send a reset trigger.

The user can know the completion of reset trigger transmission by asserting SQCHxSR.ADESFIN.

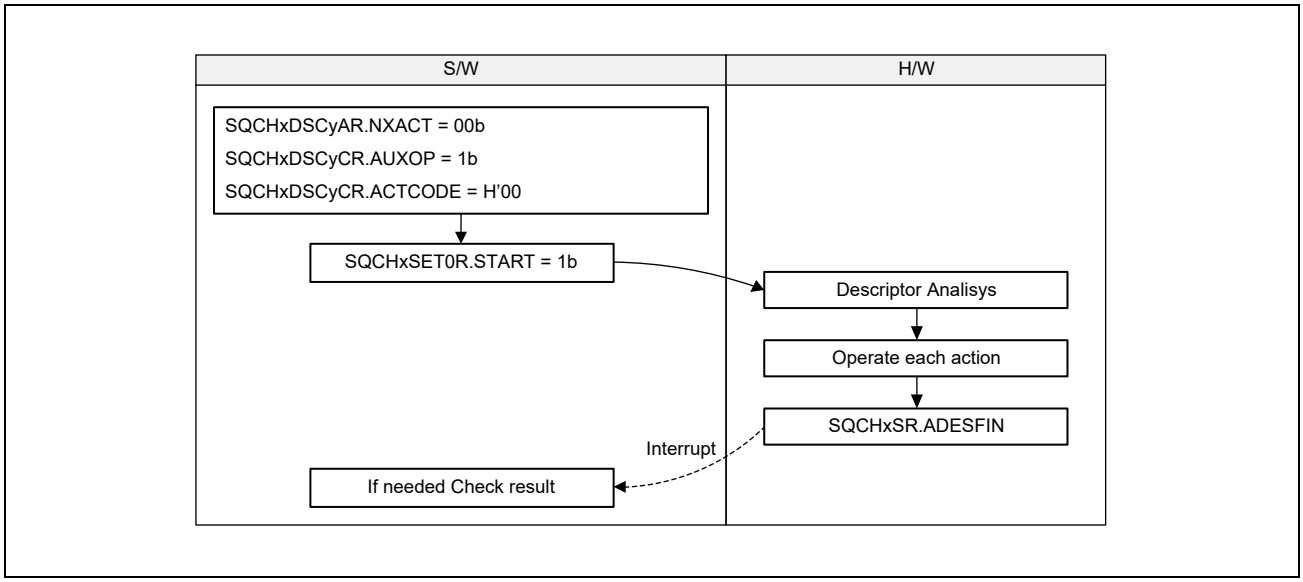

Figure 9.5-12 Trigger transmission

(5) Execute Operation in Sequence

The following describes the descriptor in Sequence Operation.

By writing “1” to SQCHxSET0R.START, Sequence Operation channel x will be enabled and processing will be performed from descriptor # 0.

When the processing of the corresponding descriptor is completed, the next processing follows SQCHxDSCyAR.NXACT.

SQCHxDSCyAR.NXACT= “00b”: Sequence Operation channel x stop after the processing of the corresponding descriptor is completed

SQCHxDSCyAR.NXACT= “01b”: After the processing of the corresponding descriptor is completed, the next descriptor is executed. The next descriptor after descriptor # N is descriptor # (N + 1).

(6) Receiving EoTp

The DSI-Tx Module can receive End of Transmission Packets (EoTp).

The DSI-Tx Module notifies the reception of EoTp by setting RXSR.RXEOTP to “1”.

(7) Acknowledge and Error Reporting Mechanism

The user can know the reliability of the serial bus by using “Acknowledge and Error Reporting Mechanism”.

If Peripheral detects an error on the serial bus during the period from the previous Peripheral to Host communication to this Peripheral to Host communication, Peripheral will send an “Acknowledge and Error Report” packet.

When the DSI-Tx Module receives the "Acknowledge and Error Report” packet, it sets “1” to RXRSSxR.RXAKE, RXSR.RXAKE, and SQCHxSR.RXAKE. The Virtual Channel Identifier and Error Report of the latest “Acknowledge and Error Report” packet received are stored in the AKEPLATIR register, and the integrated value is displayed in the AKEPACMSR register.

Figure 9.5-13 shows the operation when HS Clock Stop. After confirming that Video-Input Operation and Sequence Operation channel 1 are not running, write 0b to HSCLKSETR.HSCLKRUN to make the clock lane LP. PLSR.CLHS2LP is set to 1b when the clock lane transitions from HS to LP. In non-continuous clock mode, you do not need to check PLSR.CLHS2LP because the clock lane is likely to be LP already when you write 0b to HSCLKSETR.HSCLKRUN. It is possible to check the clock lane status by reading PLSR.CLSTPST.

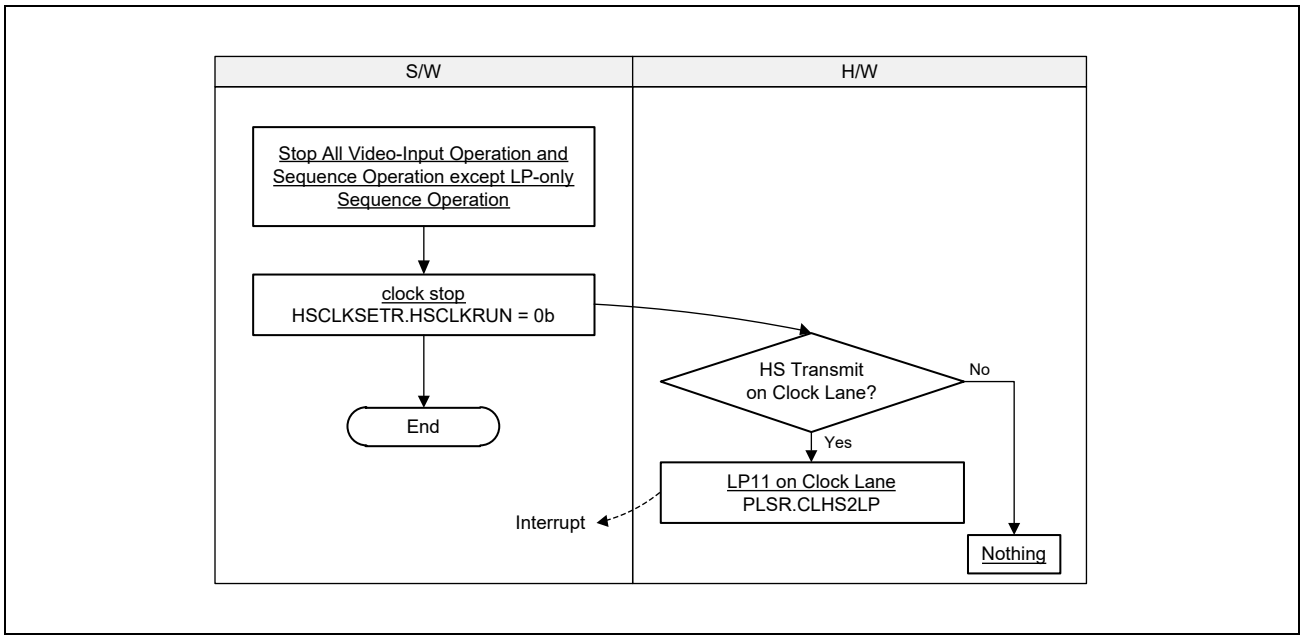

Figure 9.5-13 Stop of HS Clock

9.5.3.2.4 Video-Input Operation

(1) Video-Input Timing

Video-Input Timing and Video-Input Parameters are described in **Figure 9.5-14** and **Table 9.5-6**.

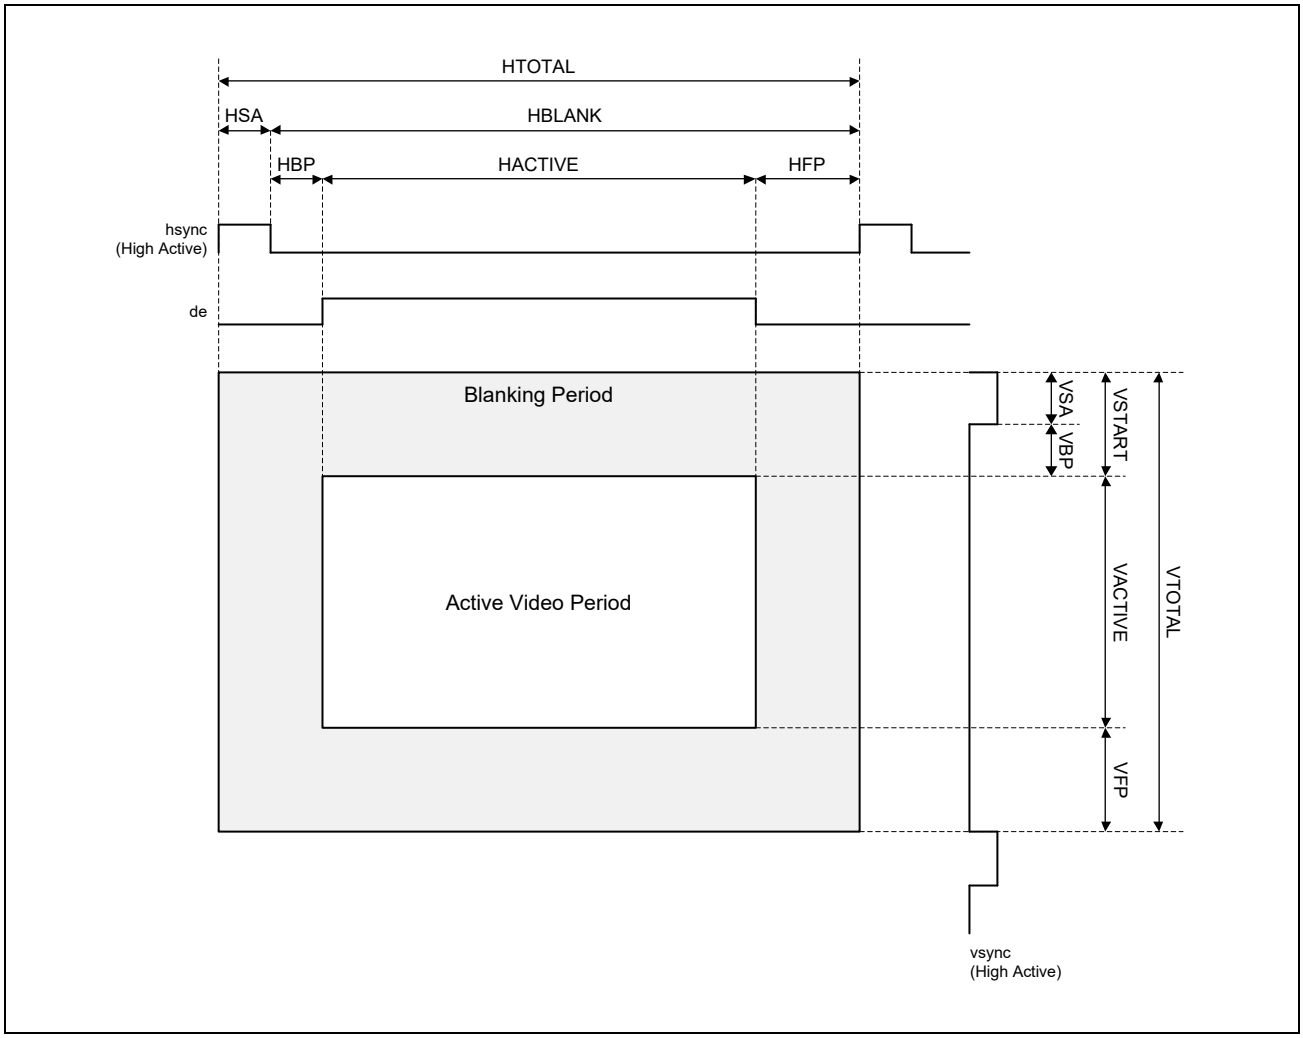

Figure 9.5-14 Video Input Timing

Table 9.5-6 Configurations for Video Input Interface (1/2)

- Common Rules for all mode

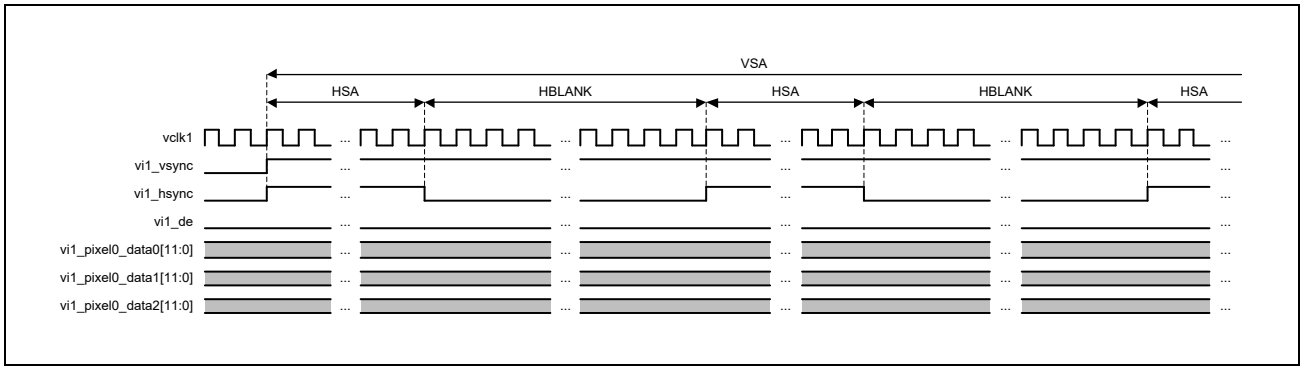
Parameter	Description
All	All parameters related to Input Video should be set to the value of not less than 1. Example for “All parameters”: HSA, HBP, HACTIVE, HFP, VSA, VBP, VACTIVE, VFP
HACTIVE	

VICH1PPSETR.DT	VICH1HSSETR.HACTIVE
H’1E: Packed Pixel Stream, 18bit RGB	This value should be the multiple of 4.
H’2E: Loosely Packed Pixel Stream, 18bit RGB H’3E: Packed Pixel Stream, 24bit RGB	No Limitation

Parameter	Description
HFP	Rounddown (HFP*BPP/ 8, 0) >= 12, (12 = means Pixel Packet Header & footer 6 + Blanking Packet Header & footer 6)
HTOTAL	

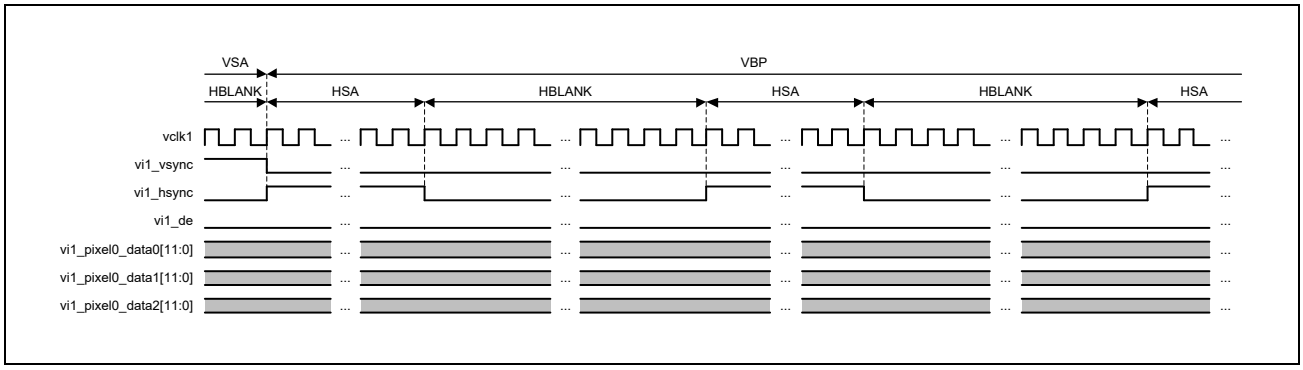
VICH1PPSETR.DT	VICH1HSSETR.HSA + VICH1HPSETR.HBP + VICH1HSSETR.HACTIVE + VICH1HPSETR.HFP
H’1E: Packed Pixel Stream, 18bit RGB	This value should be the multiple of 4.
H’2E: Loosely Packed Pixel Stream, 18bit RGB H’3E: Packed Pixel Stream, 24bit RGB	No Limitation

- Additional Rules for non-burst Sync Pulse mode



Parameter	Description
Sequence Operation Packet	When a packet by sequence operation is transmitted during Video Opearation (VICH1SR.RUNNING=1), the period of (HBP+HACTIVE+HFP) should be set the value longer than sum of below periods. • Period for the Tx Sync Event packet (4 Byte) • Period for the packet by sequence operation • Period for the Header and CRC of a Blanking Packet (6 Byte)
HBP+HACTIVE+HFP	Transition of HS-LP-HS is caused within the period between current Sync Event Packet and next Sync Event Packet, the period of (HBP+HACTIVE+HFP) should be set to the value within the range described below. (HBP+HACTIVE+HFP) > (period for the Tx Sync Event Packet) + (period for transition time as HS-LP-HS)
HSA	Transmission of Blanking Packet is caused within the period between current Sync Event Packet and next Sync Event Packet, the period of HSA should be set to the value within the range described below. (HSA*BPP)/8 >= 10 Notice, HSA should be set to the value not less than minimum value of (period for the Tx Sync Event Packet) + (period for the Tx Blanking Packet).
HBP	Transmission of Blanking Packet is caused within the period between current Sync Event Packet and next Sync Event Packet, the period of HPB should be set to the value within the range described below. (HBP*BPP)/8 >= 10 Notice, HPB should be set to the value not less than minimum value of (period for the Tx Sync Event Packet) + (period for the Tx Blanking Packet).

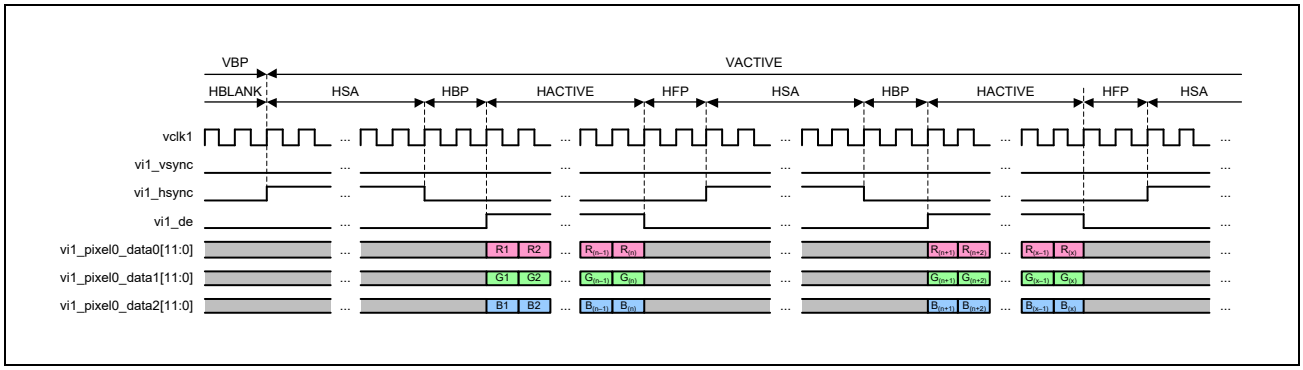
Table 9.5-6 Configurations for Video Input Interface (2/2)



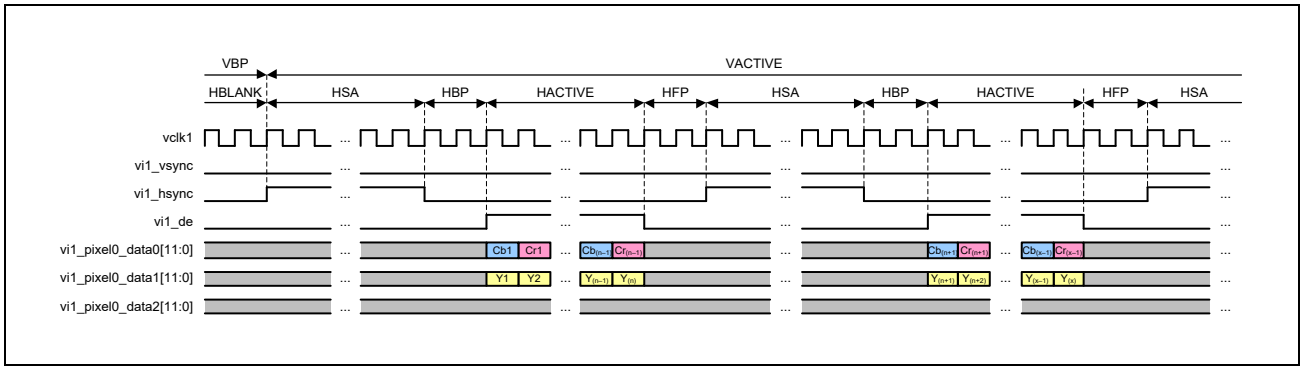
- Additional Rules for non-burst Sync-Event mode and Burst mode

Parameter	Description
Sequence Operation Packet	When a packet by sequence operation is transmitted during Video Operation (VICH1SR.RUNNING=1), the period of HTOTAL should be set the value longer than sum of below periods. • Period for the Tx Sync Event packet (4 Byte) • Period for the packet by sequence operation • Period for the Header and CRC of a Blanking Packet (6 Byte)
HTOTAL	Transition of HS-LP-HS is caused within the period between current Sync Event Packet and next Sync Event Packet, the period of HTOTAL should be set to the value within the range described below. HTOTAL > (period for the Tx Sync Event Packet) +(period for transition time as HS-LPHS)
HSA+HBP	Transmission of Blanking Packet is caused within the period between current Sync Event Packet and next Sync Event Packet, the period of (HSA+HBP) should be set to the value within the range described below. ((HSA+HBP)*BPP)/8 >= 10 Notice, HSA+HBP should be set to the value not less than minimum value of (period for the Tx Sync Event Packet) + (period for the Tx Blanking Packet).

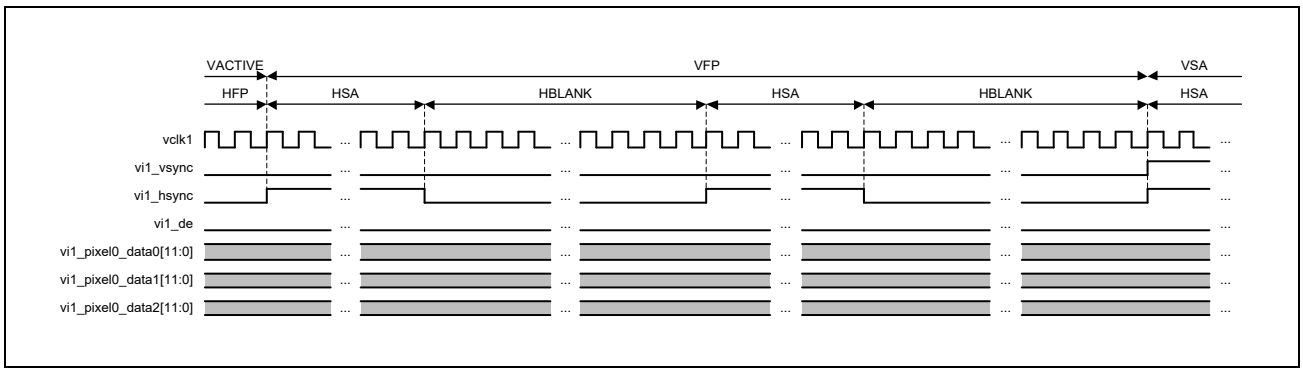
(a) VSA Start (and VFP End)



(b) VSA End and VBP Start



(c) VBP End and VACTIVE Start



a) RGB

b) YCbCr 4: 2: 2

(d) VACTIVE End and VFP Start

(2) Video-Input Start, End, Change Setting

1) Video Input Start

Video input must be started after Video-Input Operation Start sequence. It must be start from V-Sync start edge.

2) Video Input End

End of Video Input must follow sequence of **9.5.3.2.4(4)**.

3) Change of Video Input Setting

Changing of Video-Input setting must be done during Video-Input operation is not running.

(3) Start of Video-Input Operation

The procedure for Start of Video-Input Operation is shown in **Figure 9.5-15**.

1. Initialize common settings. Refer **9.5.3.2.1(1)**.
2. Some peripheral setting may be done by Sequence operation. Since it is differed from peripheral devices, it is out of this document.
3. Confirm Video-Input clock and hsclk stable and set HS clock. Refer **9.5.3.2.2**.
4. Set Video-Input Operation channel parameters (VICH1PPSETR, VICH1VSSETR, VICH1VPSETR,VICH1HSSETR, VICH1HPSETR)
5. Calculate VICH1SET1R.DLY value and set. Refer **9.5.3.2.4(9)**.
6. Set “1” to VICH1SET0R.VSTART with other VICH1SET0R setting values.
7. Wait until VICH1SR.VIRDY=1.
8. Start Video signal input

VICH1SET0R, VICH1SET1R, VICH1PPSETR, VICH1VSSETR, VICH1VPSETR, VICH1HSSETR and VICH1HPSETR are prohibited to change value between VICH1SET0R.VSTART=1 and VICH1SR.RUNNING=0 after VICH1SET0R.STOP=1.

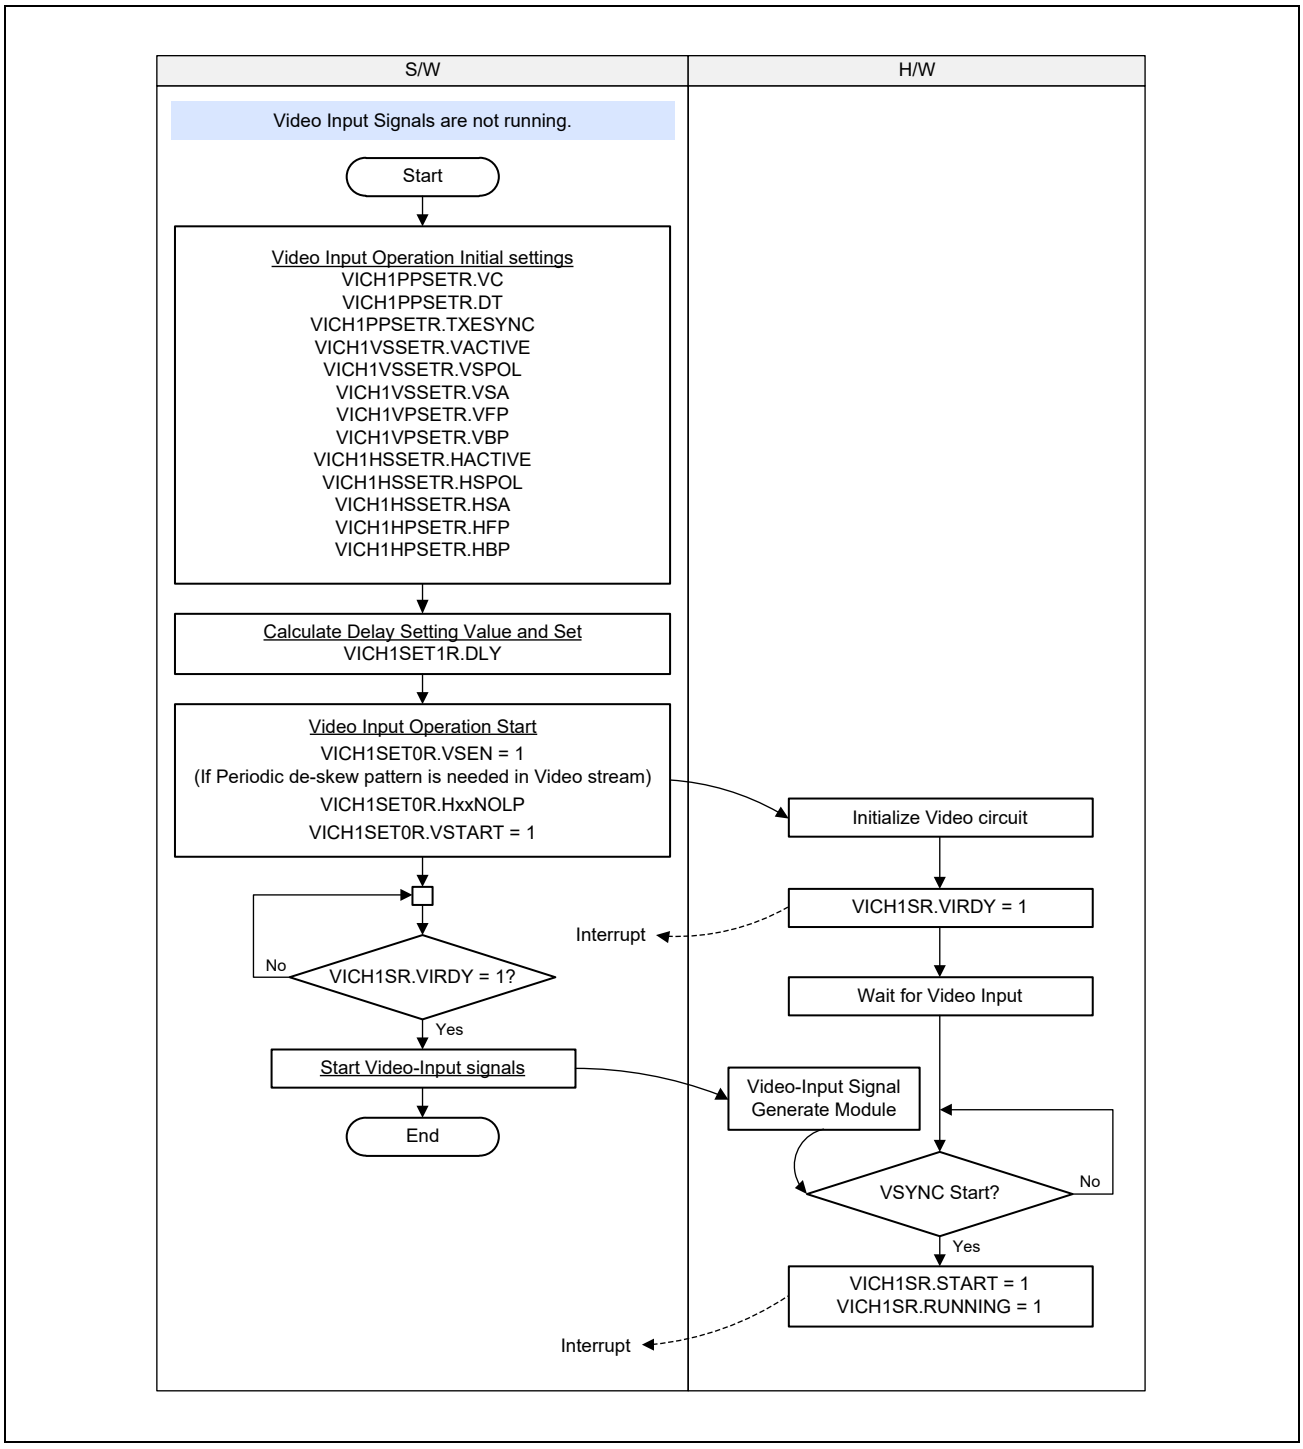


Figure 9.5-15 Video-Input Channel Start

(4) End of Video-Input Operation

The video-input operation stop flow is shown in **Figure 9.5-16**. Execute the flow when VICH1SR.RUNNING = 1.

(1) VICH1SET0R.VSTPAFT (**Figure 9.5-16**)

Write 1 to VICH1SET0R.VSTPAFT to request the Video-Input Operation to stop. When the DSI-Tx Module detects the start of one frame (assertion of VSYNC), it stops sending video mode packets and sets VICH1SR.STOP to 1.

After checking VICH1SR.STOP, stop the video input. The video input can be stopped at any time after VICH1SR.STOP becomes 1.

After stopping the video input, wait for LINKSR.HSBUSY to become 0.

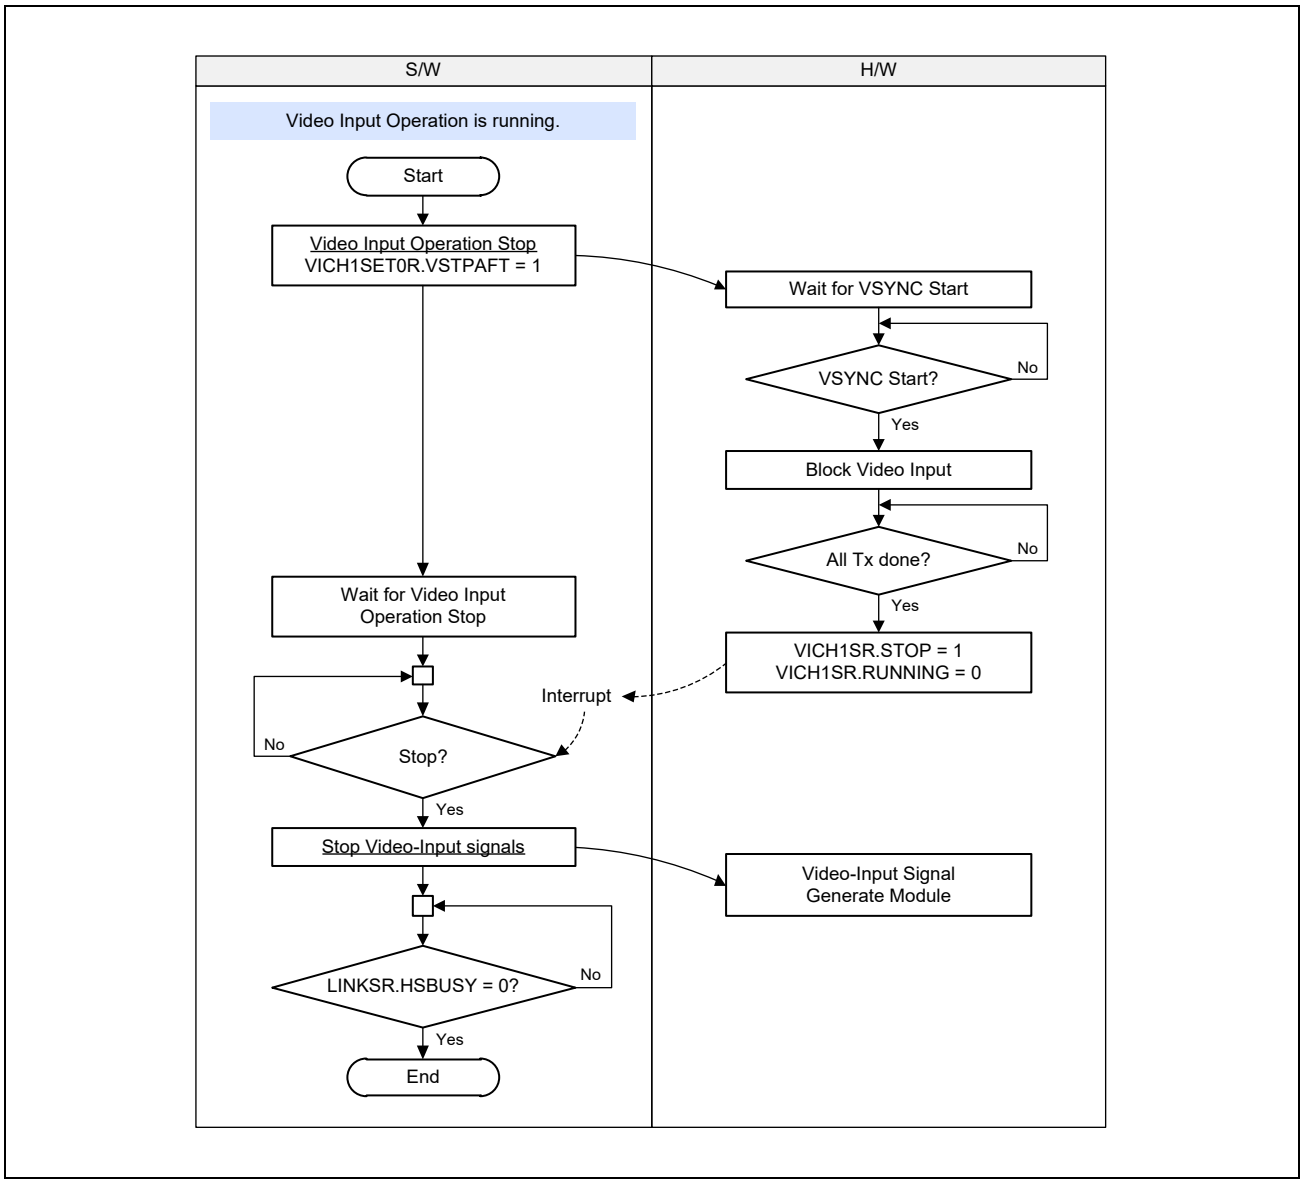

Figure 9.5-16 End of Video-Input Operation (VICH1SET0R.VSTPAFT)

(5) Burst Mode

The DSI-Tx Module supports Burst Mode.

Burst Mode is a mode that time-compresses pixel data.

Make the D-PHY bandwidth wider than the Video-Input bandwidth for time compression of pixel data. Video transmissions with a 1-line pixel data size (VICH1HSSETR.HACTIVE × VICH1SET1R.BPP / 8) greater than 65,535 Bytes are not supported.

Video clock Frequency [Hz] × Video Pixel Bit Depth (BPP) [bit]

<= DSI HS Byte clock Frequency[Hz] × 8[bit] × Number of DSI HS Data Lane

In the case of Video-Input bandwidth equals DSI output bandwidth, it will be indistinguishable from non-burst sync-event mode.

(6) Non-Burst Mode

The DSI-Tx Module supports Non-Burst Mode.

Make the D-PHY bandwidth the same as the Video-Input bandwidth. Video transmissions with a 1-line pixel data size (VICH1HSSETR.HACTIVE × VICH1SET1R.BPP / 8) greater than 65,535 Bytes are not supported.

Video clock Frequency [Hz] × Video Pixel Bit Depth (BPP) [bit]

= DSI HS Byte clock Frequency[Hz] × 8[bit] × Number of DSI HS Data Lane

(7) LP Transition and Blanking

The DSI-Tx Module automatically transitions the Data Lane from HS to LP if both of the following two conditions are met:

If it does not transition from HS to LP, it sends a Blanking Packet with the same VC as the VC in the previous packet to maintain the HS.

- There is time to make an HS => LP => HS transition before the next HS transfer starts.
- The period is not prohibited by VICH1SET0R.xxxNOLP to transition to LP.

(8) Non video packet action during Video-Input Operation Running

1) Packet Transmission/Reception by Sequence operation

The DSI-Tx Module can send and receive packets (see **9.5.3.2.3(2)** and **9.5.3.2.3(3)**) using Sequence Operation while Video-Input Operation is operating*[1].

Make sure that all Sequence Operations are finished before starting the Video-Input Operation operation.

While Video-Input Operation is operating*[1], packet transmission / reception using Sequence Operation is performed only immediately after the HSE packet (VICH1PPSETR.TXESYNC = 1b) or VSS packet (VICH1PPSETR.TXESYNC = 0b) on the first horizontal line. Also, sending packets using Sequence Operation is possible only with HS (SQCHxDSCyAR.SPD = 0b). Sending with LP (SQCHxDSCyAR.SPD = 1b) is not supported. Send and receive packets that are completed within the BLLP period of the first horizontal line.

Execution of Sequence Operation processing is prohibited except for sending and receiving HS packets.

Note 1. ""while Video-Input Operation is operating" here is different from VICH1SR.RUNNING. It means the period from setting VICH1SET0R.VSTART to 0 in the flow of **Figure 9.5-15** until VICH1SR.RUNNING becomes 0 in the flow of **Figure 9.5-16**. Also, please note that there is some latency from executing VICH1SET0R.VSTART to being transmitted to the inside of the module for clock transfer.

(9) Delay about Video-Input Operation

Video-Input Operation run in some latency which call in the DSI-Tx Module "Delay". "Delay" value must set to VICH1SET1R.DLY before operation.

"Delay" value is defined by calculation using below parameters.
Refer to attached excel file for the "MIPI-DSI_Calculated_register_table" about some calculation results of DLY.
(Please double-click the icon on the right side) 

- Clock frequencies
  - Video channel 1 clock (MIPI_DSI_VCLK) frequency
  - DSI High-Speed Transmit Word Clock (TxWordClkHS, hsclk) frequency
- Video parameters
  - HSA period, set by VICH1HSSETR.HSA
  - HACTIVE period, set by VICH1HSSETR.HACTIVE
  - HBP period, set by VICH1HPSETR.HBP
  - HFP period, set by VICH1HPSETR.HFP
  - BPP value, shown in VICH1SET1R.BPP and derived from VICH1PPSETR.DT
- Video transmit settings
  - The number of active lanes, set by TXSETR.NUMLANEUSE
  - Transmit mode, set by VICH1PPSETR.TXESYNC
  - No LP, set by VICH1SET0R.HSANOLP, HBPNOLP, HFPNOLP
  - Clock mode, set by HSCLKSETR.HSCLKMODE
  - Clock stop time, set by CLSTPTSETR.CLKSTPT
  - Go LP and back time, set by LPTRNSTSETR.GOLPBKT
- Other parameters
  - Video-Input channel buffer size, shown in VICH1SET1R.CHBUFSZ

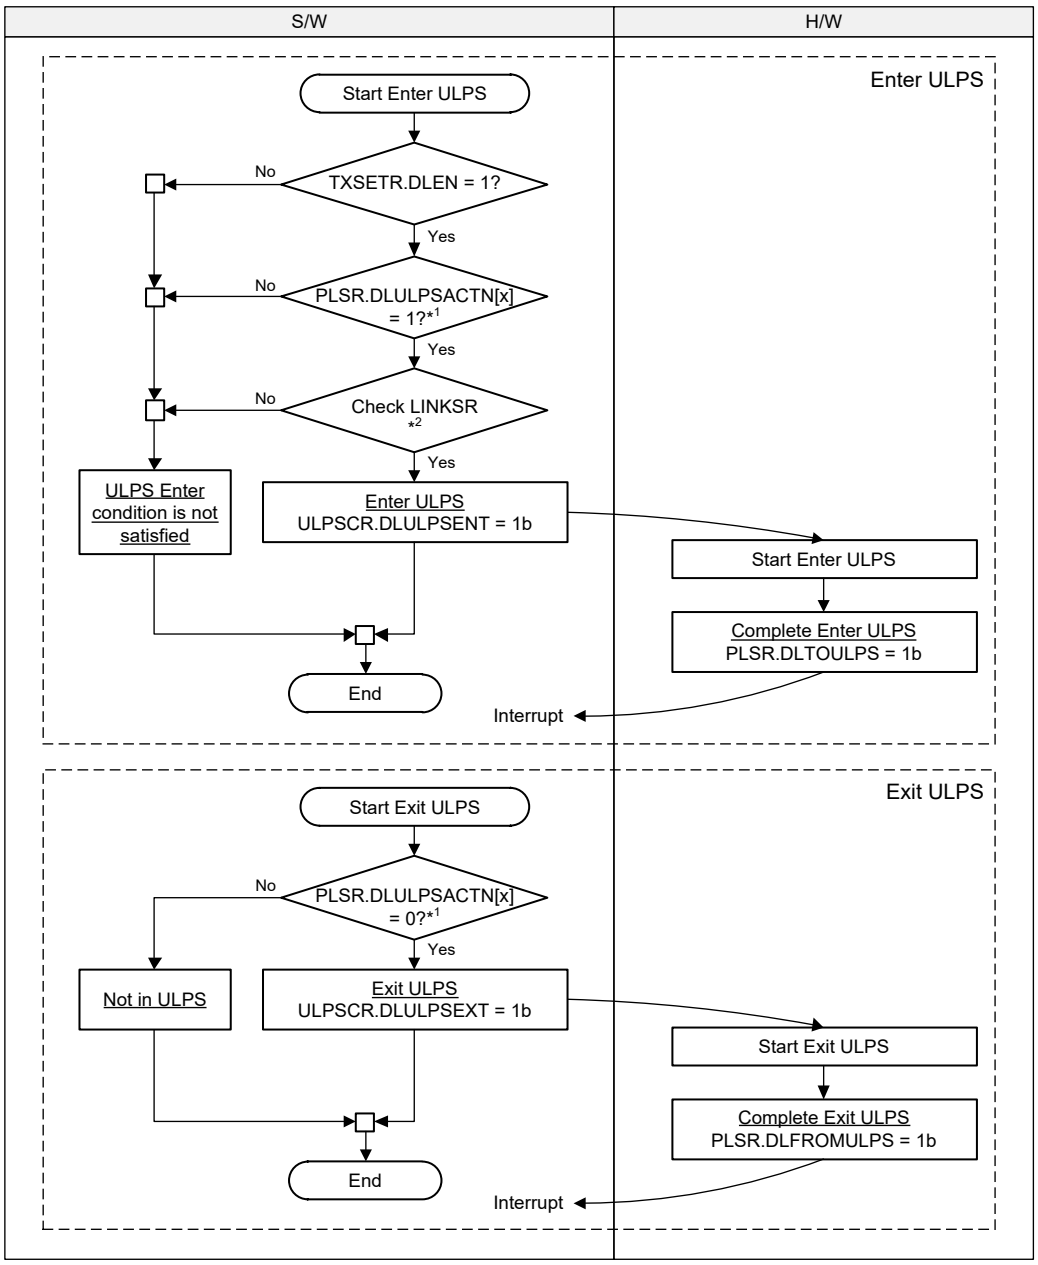
9.5.3.2.5 Enter/Exit of ULPS

The following describes the ULPS transition / return sequence.

The clock lane and data lane (lanes 0 to 3) can be independently transitioned / restored to ULPS.

The clock lane can make ULPS transitions when TXSETR.CLEN = 1b. It is forbidden to change TXSETR.CLEN to 0b while the clock lane is ULPS.

The data lane can make ULPS transitions when TXSETR.DLEN = 1b. It is forbidden to change TXSETR.DLEN to 0b while the data lane is ULPS.

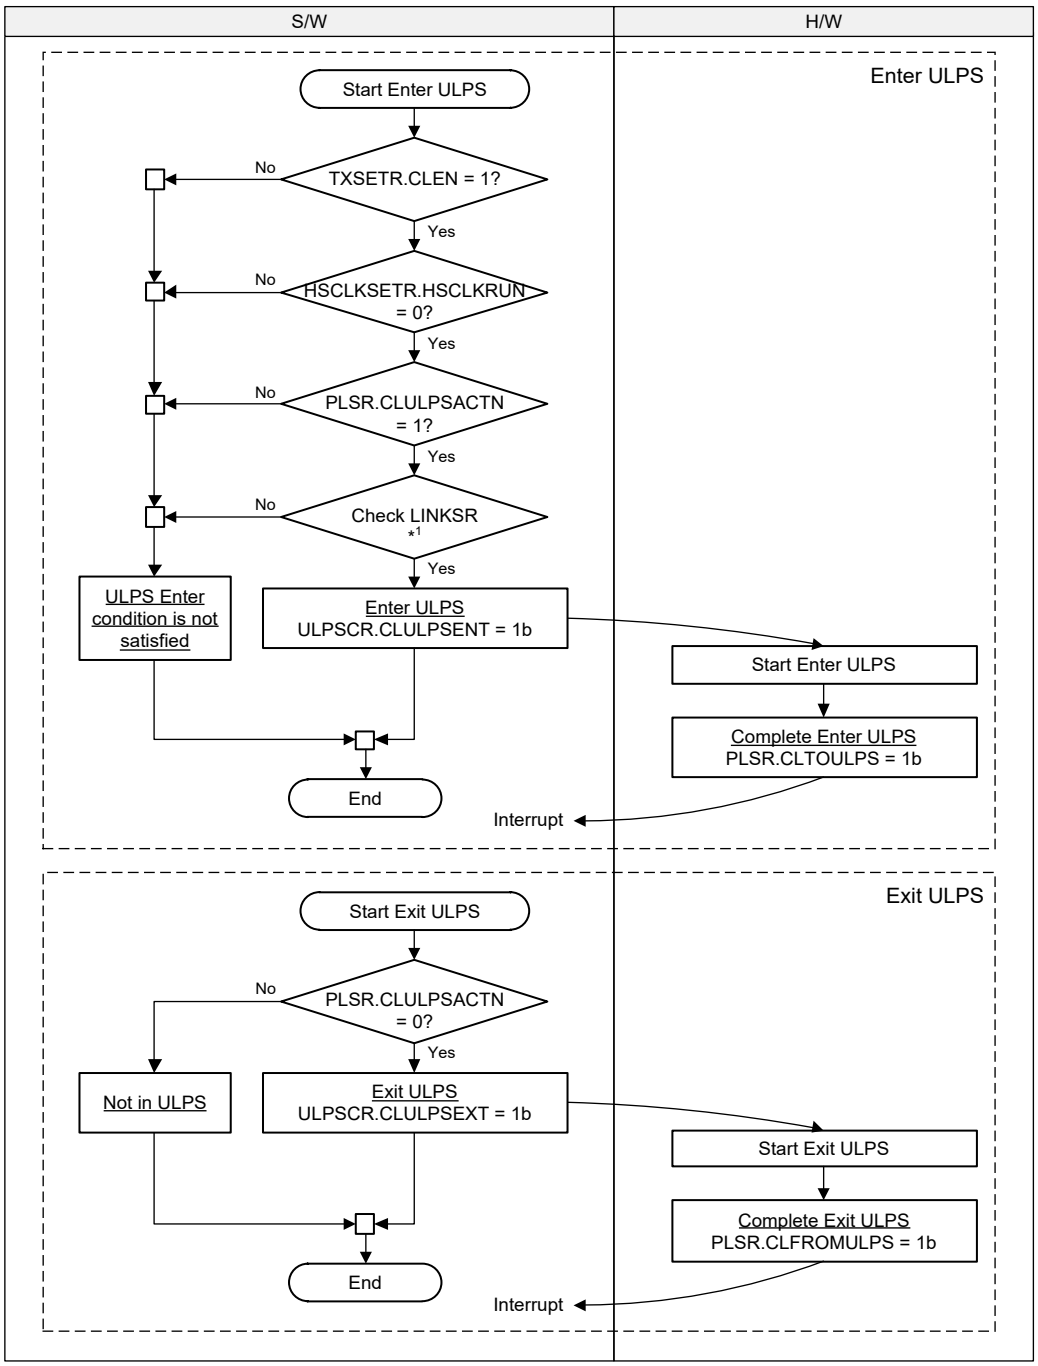


Data lanes enabled in TXSETR.NUMLANEUSE can be ULPS transitioned / restored. ULPS transition / return of data lanes is done simultaneously for all valid lanes. Only certain data lanes cannot be ULPS transitioned / restored.

When the data lane transitions to ULPS, another operation*1 using the data lane cannot be performed until ULPS is restored.

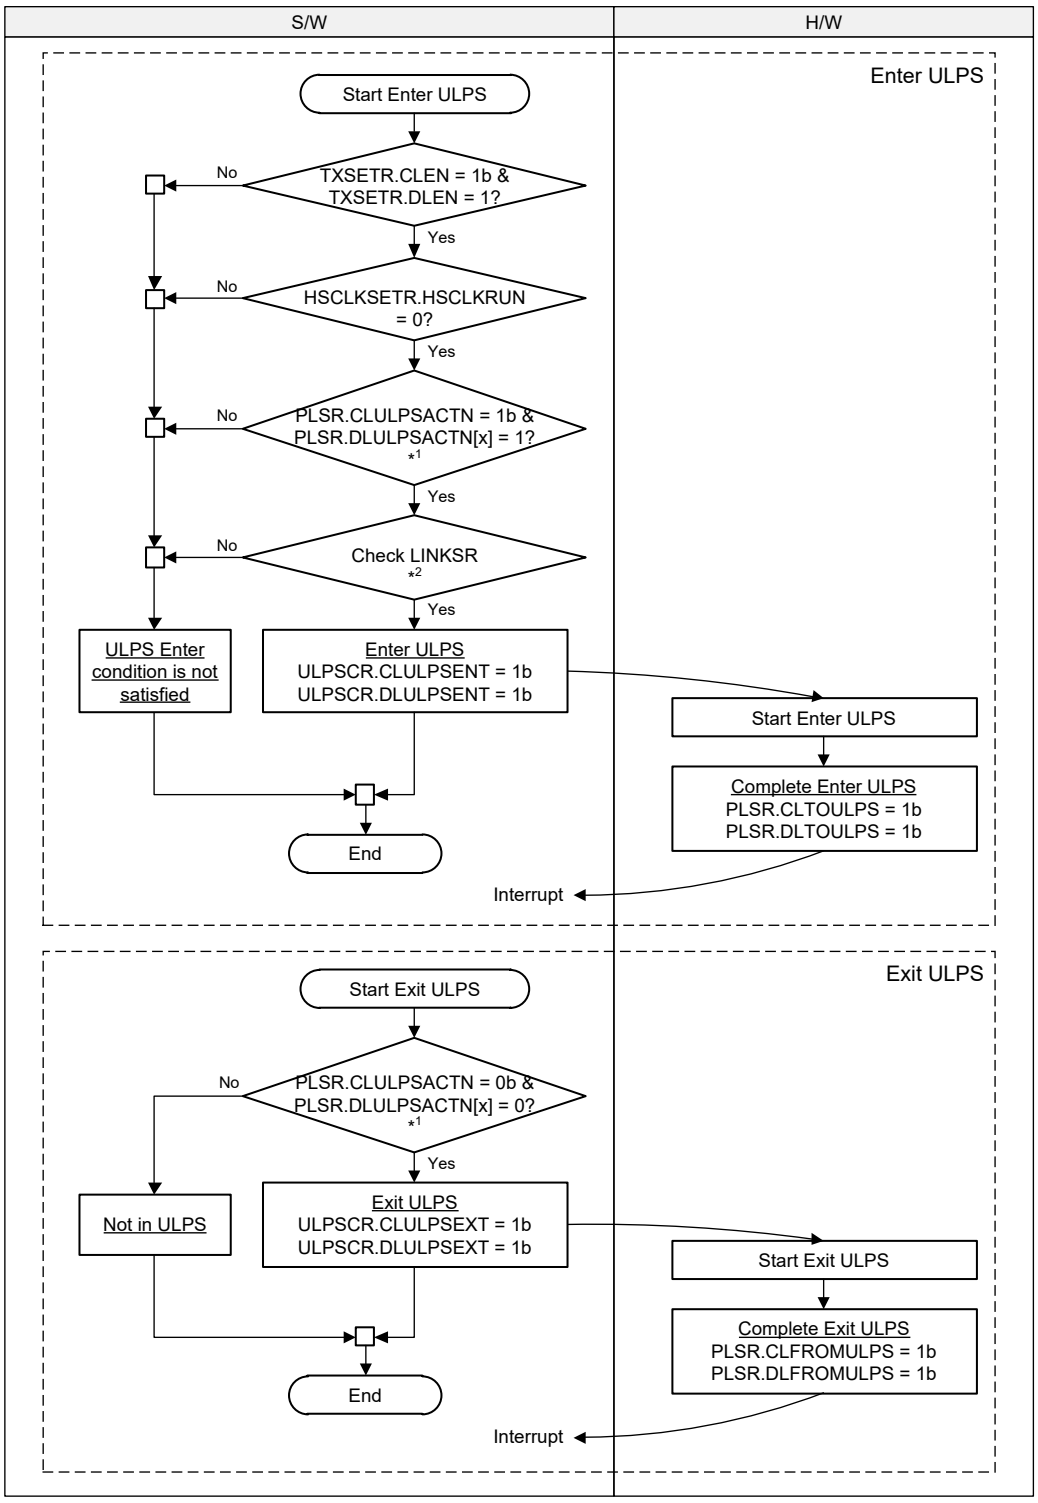
When the clock lane transitions to ULPS, another operation*2 using the clock lane cannot be performed until ULPS is restored.

Note 1. Sequence Operation, Video-Input Operation.



Note 2. HS Sequence Operation, Video-Input Operation.

Note 1. Check all enabled data lanes selected by TXSETR.NUMLANEUSE



Note 2. (SQCHRUN0 = 0b and SQCHRUN1 = 0b and VICHRUN1 = 0b and HSBUSY = 0b and LPBUSY = 0b)?

Figure 9.5-17 Enter/Exit of ULPS (Data Lane)

Note 1. (SQCHRUN1 = 0b and VICHRUN1 = 0b and HSBUSY = 0b)?

Figure 9.5-18 Enter/Exit of ULPS (Clock Lane)

Note 1. Check all enabled data lanes selected by TXSETR.NUMLANEUSE

Note 2. (SQCHRUN0 = 0b and SQCHRUN1 = 0b and VICHRUN1 = 0b and HSBUSY = 0b and LPBUSY = 0b)?

Figure 9.5-19 Enter/Exit of ULPS (Clock and Data Lane)

9.5.3.2.6 Error Handling

(1) Error Detection by Peripheral

Peripheral will notify you of the detected error by “Acknowledge and Error Report” packet.

When the DSI-Tx Module receives the “Acknowledge and Error Report” packet, it displays the latest result in the AKEPLATIR register and the accumulated result in the AKEPACMSR register.

When the user receives the “Acknowledge and Error Report” packet, review and change various settings as necessary.

(2) Error Detection in D-PHY

If the D-PHY detects an error, the DSI-Tx Module sets the corresponding register flag.

The errors supported by the DSI-Tx Module are as follows. For details on the error, refer to Annex A Logical PHY-Protocol Interface Description of MIPI Alliance Specification for D-PHY Version 2.1.

- ErrEsc
- ErrSyncEsc
- ErrControl
- ErrContentionLP0
- ErrContentionLP1

If the user detects this error, perform Software Reset (**9.5.3.2.1(2)**) and Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

When an ErrContentionLP0 / ErrContentionLP1 error occurs, be sure to execute Software Reset (**9.5.3.2.1(2)**). At that time, write 1 to RSTCR.FCETXSTP, wait for the time when Contention is resolved (equivalent to LRX-H_TO), and then write 0 to RSTCR.FCETXSTP. Also, if necessary, perform Reset Trigger Transmission (**9.5.3.2.3(4)**).

For more information on returning from Contention, see *Section 7.2, Contention Detection and Recovery* in *the MIPI Alliance Specification* for Display Serial Interface 1.3.1.

(3) Timeout Error

The DSI-Tx Module has the timers defined in *Section 7.2.2, Contention Recovery Using Timers of the DSI standard* and the DSI-Tx Module original timers.

- Timers defined in DSI Specification
  - HS TX Timeout Error (HTX_TO)
  - LP-RX Host Processor Timeout Error (LRX-H_TO)
  - Turnaround Acknowledge Timeout Error (TA_TO)
- Original Timers
  - Rx Response Timeout Error

(a) HS TX Timeout (HTX_TO) Error

If this error occurs, perform Software Reset (**9.5.3.2.1(2)**). In addition, perform Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

If this error is detected, the setting value of HSTXTOSETR.HTXTO may be too small. When multiple channels are operating at the same time, multiple HS packets may be concatenated and transmitted continuously by HS. Set HSTXTOSETR.HTXTO to a value larger than the HS transmission period.

(b) LP-RX Host Processor Timeout (LRX-H_TO) Error

If this error occurs, perform Software Reset (**9.5.3.2.1(2)**). In addition, perform Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

If this error is detected, the setting value of LRXHTOSETR. LRXHTO may be too small.

There is a possibility of receiving multiple packets such as response packet and "Acknowledge and Error Report" packet in one reception.

Measure the time from the completion of the Bus Turnaround sequence from Host to Peripheral (LP-11 drive detection by Peripheral) to the completion of Bus Turnaround sequence from Peripheral to Host (LP-11 drive start by Host).

Check the Peripheral specifications, and set the value of MIPI_DSI_LPCLK cycle count (rounded up) + X or more corresponding to the above time in the LRXHTOSETR.LRXHTO register.

(c) Turnaround Acknowledge Timeout (TA_TO) Error

If this error occurs, perform Software Reset (**9.5.3.2.1(2)**) and Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

If this error is detected, the setting value of TATOSETR.TATO may be too small.

Measure the time from the start of the Peripheral Bus Turnaround sequence (LP-10 drive by the Host) to the completion (LP-11 drive detection by the Peripheral) from the Host.

Check the Peripheral specifications and set the value of MIPI_DSI_LPCLK cycle count (rounded up) + X or more corresponding to the above time in the TATOSETR.TATO register. This error also occurs if the Peripheral does not support bidirectional communication.

(d) Rx Response Timeout Error

Refer to the Peripheral Response Timeout Error (**9.5.3.2.6(4)(a)i**) for more information.

(4) Rx Related Error in Sequence Operation

(a) Rx Packet Related Error in Sequence Operation

The following describes the received packet error detected by the DSI-Tx Module.

Detects up to one error per packet. (However, ECC 1bit Error may occur at the same time as other errors.)

Errors are determined in the following order:

Peripheral Response Timeout Error, Malformed Packet Error, ECC Error, Unexpected Packet Error, WC Error, CRC Error, Nothing Return Error

i. Peripheral Response Timeout Error

RXSR.PRESPTOERR is set to 1 if the BTA does not start receiving packets or triggers within the time set in the register after the bus right transitions from Host to Peripheral.

If this error is detected, packets and triggers will not be received until the bus right transitions from Peripheral to Host.

[Timeout time setting register]

Peripheral Response Timeout value for BTA-only is set by PRESPTOBTASETR.

Peripheral Response Timeout value for LP Read with BTA is set by PRESPTOLPSETR.PRESPTOLPR.

Peripheral Response Timeout value for LP Write with BTA is set by PRESPTOLPSETR.PRESPTOLPW.

Peripheral Response Timeout value for HS Read with BTA is set by PRESPTOHSSETR.PRESPTOHSR.

Peripheral Response Timeout value for HS Write with BTA is set by PRESPTOHSSETR.PRESPTOHSW.

If this error is detected, the register setting value may be too small, Measure the time from the completion of the Bus Turnaround sequence of Peripheral from the Host (LP-11 drive detection by Peripheral) to the completion of reception of the first byte of the packet or the completion of trigger reception. After checking the Peripheral specifications, set the value of MIPI_DSI_LPCLK cycle number (rounded up) + X or more corresponding to the above time.

If this error occurs, perform the necessary processing such as resending the previous command.

ii. Malformed Packet Error

If a packet less than 4 bytes is received, RXSR.MLFERR is set to 1. Since there is an error in the received data, perform necessary processing such as resending the previous command.

iii. ECC Error

ECC generation is required for DSI v1.3.1 standard compliant Peripherals. However, since ECC generation is an option for “earlier revision of DSI Peripherals”, the DSI-Tx Module can select whether to enable or disable ECC checks using DSISETR.ECCEN.

When connecting to a Peripheral that does not support ECC generation, disable ECC checking by setting DSISETR.ECCEN to 0.

iv. ECC 1bit Error

If an ECC 1bit error is detected, RXSR.ECCERR1B is set to 1 and 1bit error correction is performed.

The DSI-Tx Module automatically corrects the error and restores the normal packet header, so the subsequent packet reception processing continues.

v. ECC Multi-bit Error

If an ECC multi-bit error is detected, RXSR.ECCERR is set to 1 and the received packet is discarded. If this error occurs, perform the necessary processing such as resending the previous command.

vi. Unexpected Packet Error

If an Unexpected Packet is received, RXSR.UEXPKTERR is set to 1.

When this error occurs, the packet header is stored in the RXRSSxR register, and the subsequent reception processing is stopped until the bus right transitions from Peripheral to Host.

The DSI-Tx Module determines the following packets as Unexpected Packets.

- Received packets in which Data Type field of the packet header is “Reserved” as described in Table23 Data Types for Peripheral-Sourced Packets of the DSI standard
- Received packets other than “Acknowledge and Error Report” packet and “EoTp” in BTA after sending non-read packet
- Received packets other than “Acknowledge and Error Report” packet and “EoTp” when the BTA is BTA only
- BTA after sending read packet receives response packet and then receives response packet again

vii. WC Error

RXSR.WCERR is set to 1 if a long packet with payload data shorter than the WC value is received.

When this error occurs, there is an error in the payload data length, but the payload data is not discarded due to this error, and the packet header is stored in the RXRSSxR register.

Since there is an error in the received data, perform necessary processing such as resending the previous command.

viii. CRC Error

To connect to Peripherals that do not support CRC generation, the DSI-Tx Module can enable or disable CRC checking for each Virtual Channel using DSISETR.CRCEN[3:0]. When connecting to a Peripheral that does not support CRC generation, disable the CRC check by setting the corresponding bit in DSISETR.CRCEN to 0.

When this error occurs, there is an error in the payload data, but the payload data is not discarded due to this error, and the packet header is stored in the RXRSSxR register.

If this error occurs, perform the necessary processing such as resending the previous command.

ix. Nothing Return Error

RXSR.NORETERR is set to 1 if the BTA transitions the bus right from Host to Peripheral and then does not receive packets or triggers and the bus right transitions from Peripheral to Host.

If this error occurs, perform the necessary processing such as resending the command. If the error recurs, perform Software Reset (**9.5.3.2.1(2)**) and Reset Trigger Transmission (**9.5.3.2.3(4)**) as necessary.

(b) Rx Long Packet Data Payload Related Error in Sequence Operation

i. Maximum Return Packet Size Error

RXSR.MAXRPSZERR is set to 1 if the WC value of the received long packet is greater than the DSISETR.MRPSZ setting.

When this error occurs, the packet header is stored in the RXRSSxR register and the payload data is discarded.

Although the payload data is discarded, errors related to payload data reception (WC Error, CRC Error) are detected.

If this error occurs, set DSISETR.MRPSZ to a value greater than or equal to the value set by the Set Max Return Packet Size command.

If you still get this error despite the correct settings, consider setting DSISETR.MRPSZ to a larger value because Peripheral is returning a large packet in violation of the DSI standard.

ii. Internal Bus Error

If Internal Bus Write detects an error, RXSR.IBERR is set to 1.

Review the settings of SQCHxDSCyDR.LADDR and DSISETR.MRPSZ.

iii. Rx Buffer Overflow Error

If the following Rx Buffer Overflow Error is detected, RXSR.RXOVFERR is set to 1.

In the case of SQCHxDSCyBR.DTSEL=00b Packet Payload Data register Mode:

- The Rx Payload Data is over 16 Byte length

In the case of SQCHxDSCyBR.DTSEL=01b Long Packet data use memory space Mode:

- RAM Overflow for the LP Rx is detected

If this error occurs, please execute the following.

In the case of Data register Mode:

- Change to use memory space Mode
- Change peripheral device’s Maximum Return Packet Size as not over 16 Byte

In the case of memory space Mode:

- Change peripheral device’s Maximum Return Packet Size smaller
- Make Internal Bus faster

(5) Tx Packet Related Error in Sequence Operation

(a) Internal Bus Error

If Internal Bus Read detects an error, SQCHxSR.TXIBERR is set to 1. Review the settings of SQCHxDSCyAR.DATA1 / 0 and SQCHxDSCyDR.LADDR.

(b) Packet too Big Error

SQCH1SR.PKTBIGERR is set to 1 if the Sequence Operation packet is of a size that cannot be sent within the BLLP period of the first horizontal line of the Video-Input Operation.

If this error occurs, the Sequence Operation packet will not be sent until the Video-Input Operation is completed.

(6) Error in Video-Input Operation

(a) Video-Input Buffer Overflow Error

VICH1SR.VBUFOVF is set to 1 if Overflow of Video-Input Buffer is detected.

If this error occurs, perform Software Reset (**9.5.3.2.1(2)**). Also, take necessary measures such as increasing the frequency of TxWordClkHS (hsclk) and decreasing the VICH1SET1R.DLY value. In addition, perform Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

(b) Video-Input Buffer Underflow Error

If the Video-Input Buffer Underflow is detected, VICH1SR.VBUFUDF is set to 1.

If this error occurs, perform Software Reset (**9.5.3.2.1(2)**). Also, take necessary measures such as lowering the frequency of TxWordClkHS (hsclk) and increasing the VICH1SET1R.DLY value. In addition, perform Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

(c) Timing Error

VICH1SR.TIMERR is set to 1 if no video packets (including Sync Event packets) were sent during the Video-Input Operation at the intended timing.

If this error occurs, perform Software Reset (**9.5.3.2.1(2)**). Also, take necessary measures such as reviewing the setting value of LPTRNSTSETR.GOLPBKT. In addition, perform Reset Trigger Transmission (**9.5.3.2.3(4)**) if necessary.

9.5.4 Usage Notes

9.5.4.1 Restriction and Notes

In this section, the restriction and notes on the DSI-Tx Module are described.

Table 9.5-7 Note and Restriction List

Items	Restriction and Notes
TxWordClkHS	Each Lanes TxWordClkHS must be synchronized. The DSI-Tx Module uses Data Lane0 TxWordClkHS as hsclk.
Unused input signals	All unused input signals must be input 0, except following signals. Following signals must be input 1, when they are not used. • ppi_dl1_ulpsactivenot • ppi_dl2_ulpsactivenot • ppi_dl3_ulpsactivenot
TxReadyHS assert	D-PHY must be asserted TxReadyHS within ($2^{RELDSI2TX_LNK_RAM_WORD_DEPTH}$ – 2) hsclk cycles after TxRequestHS asserted.

SECTION 9 IMAGE

9.6 Low Voltage Differential Signaling (LVDS)

9.6.1 Overview

This module is equipped with LVDS_CORE, APB IF section, and Renesas' PHY IP (PHY section), which are collectively provided as LVDS. This section describes the specifications of this LSI.

Change the UNIT2_RSTB bit of the CPG_RST_MIPI_DSI to 1.
Change the CLK3_ON bit of the CPG_CLKON_MIPI_DSI to 1, change the MIPI-DSI (Excludes MIPI_DSI_PRESET_N) to the reset state.

This module cannot be used at the same time as MIPI-DSI.

It complies with the following standards:

- FPD-link Standards Compliant (TIA/EIA-644)
- VESA Standards Compliant

9.6.1.1 Feature

Table 9.6-1 shows the main features of this module.

Table 9.6-1 Overview of Functions

Function	Description
Single-link Target	• RGB888 640 × 480 (VGA) • RGB888 800 × 480 (QVGA) • RGB888 1366 × 768 60 Hz (WXGA) • RGB888 1280 × 800 60 Hz (WXGA)
Number of support lanes	• Single-link: 4 lanes (Data) + 1 lane (Clock)
Link function	• Video mode supports RGB888 or RGB666*1 • Output Mode Select of 8 Format • Lane Select (In a channel) • Supports 4 lanes transfers. (4 lanes × 1ch) *Note 1.* When using RGB666 with 3 lanes (Data) + 1 lane (Clock) for the LCD panel connection, select the appropriate output format described in Sections **9.6.3.5 Output Format Selection** and **9.6.3.7 Control Bit Switching** of the UM based on the LCD panel specifications and the following points: – Select the output format so that the discarded upper or lower 2-bits of RGB888 data are assigned to an unused lane. – Ensure that required control bits are not output to unused lane.
PHY function	• Parallel-Serial Converter • LVDS IO Buffer Control • Clock Rate: 25 to 87 MHz (Up to 87 MHz even with SSC ON) • Data Rate: 175 to 609 Mbps/Lane
Register interface	• AMBA® APB (v1.0) compliant Slave interface • Data bus width 32 bits • Two systems of LVDS_CORE register / PHY register
SSC	• Modulation Frequency: 3 to 30 kHz • Center Spread: ±0.5, ±1.0, ±1.5 [%] • Down Spread: −1.0, −2.0, −3.0 [%] • Restriction : The SSCG function and delta-sigma modulator cannot be enable at the same time.
Power Supply Voltage	• VDD: In this section, replace it with VDD10_ISO. • VCCQLV18: In this section, replace it with VAA18_DSI.

9.6.1.2 Block Diagram

Figure 9.6-1 shows a block diagram of LVDS.

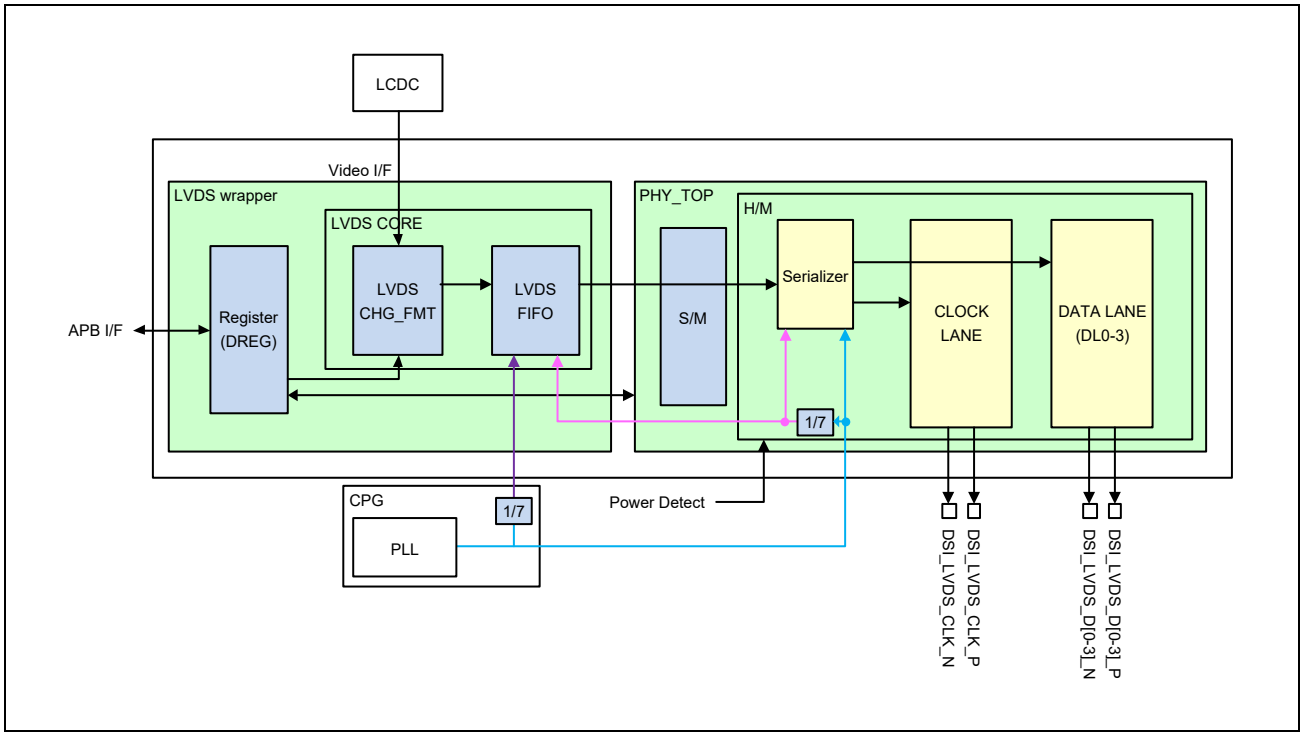


Figure 9.6-1 Block Diagram of LVDS

LVDSWRAP

This is an LVDS wrapper circuit consisting of the LVDS output control logic (LVDS_CORE) and the APB IF section (DREG).

LVDS_CORE section

It implements functions such as output format switching, lane switching, etc.

PHY section

It consists of a Serializer and LVDS IO. Renesas IP is used.

APB IF section

The APB IF section implements registers for controlling the LVDS_CORE and PHY sections.

9.6.1.3 External Pins

Table 9.6-2 shows the pin configuration.

Table 9.6-2 Pin Configuration

Pin Name	Input/ Output	Function	Pin State when not in Use
DSI_LVDS_D0_P	Out	LVDS TX differential data lane 0 (positive)	Open
DSI_LVDS_D0_N	Out	LVDS TX differential data lane 0 (negative)	Open
DSI_LVDS_D1_P	Out	LVDS TX differential data lane 1 (positive)	Open
DSI_LVDS_D1_N	Out	LVDS TX differential data lane 1 (negative)	Open
DSI_LVDS_D2_P	Out	LVDS TX differential data lane 2 (positive)	Open
DSI_LVDS_D2_N	Out	LVDS TX differential data lane 2 (negative)	Open
DSI_LVDS_D3_P	Out	LVDS TX differential data lane 3 (positive)	Open
DSI_LVDS_D3_N	Out	LVDS TX differential data lane 3 (negative)	Open
DSI_LVDS_CLK_P	Out	LVDS TX differential clock lane (positive)	Open
DSI_LVDS_CLK_N	Out	LVDS TX differential clock lane (negative)	Open

Note: LVDS is a differential output interface. The channel supports 1 channel.
The Clock Lane consists of 1 lane and the Data Lane consists of 4 lanes.

9.6.1.4 Connected Module

Table 9.6-3 shows modules connected to this module.

Table 9.6-3 Connected Module

Module Name	Connected Module Name	Function of Connected Module
LVDS	CPG	Clock Pulse Generator
	BUS	Interconnect BUS
	LCDC	LCD Controller
	External pin	External pin

9.6.1.5 Clock

The clock used by this unit is as follows.

Table 9.6-4 Clock used by this unit

Clock Name for This Section	Clock Name	Input/ Output	Frequency (MHz)	Description
LVD_PLLCLK	LVDS_PLLCLK	Input	175 to 609	LVDS TX PHY Clock
CLK_DOT0	LVDS_CLK_DOT0	Input	25 to 87	LVDS Pixel Clock
pclk	LVDS_PCLK	Input	50 / 100	APB Clock
COM_CLK_PO	—	Internal	25 to 87	Clock used between LVDS_FIFO and PHY Serializer

LVD_PLLCLK

It will be the input clock to the PHY.
It is used for the PHY's internal serializer and divide-by-7 of the LVDS clock.
This clock is synchronously related to the divide-by-seven clock generated inside the PHY.

CLK_DOT0

It is a divide-by-7 clock of the LVD_PLLCLK generated inside the CPG (Duty ratio High: Low = 4:3).
It is used for the write process of the LVDS_FIFO.
The data output from the LCDC is synchronized with this clock.

pclk

This is the clock of the APB IF in LVDS and is used for register configuration.

COM_CLK_PO

It is a divide-by-7 clock of the LVD_PLLCLK generated inside the PHY (Duty ratio High: Low = 4:3).
It is used for the read process of the LVDS_FIFO.This is the clock used to transfer the data written from the LCDC to the LVDS_FIFO to the PHY Serializer IP.
This is the clock used to transfer the data written from the LCDC to the LVDS_FIFO to the PHY Serializer IP.

9.6.2 Registers

The LVDS register address is <LVDS_base> given as an offset from the base address. The register base addresses of LVDS are listed in the following table.

Table 9.6-5 Register Base Addresses

Base Address Name	Base Address	Function
<LVDS_base>	0_108A_0000h (508A_0000h*1, 408A_0000h*2)	

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.6.2.1 List of Registers

The LVDS registers and the memory addresses are listed in the following table.

For the actual addresses, the offset values indicated in this table are added to the base addresses.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
LVDS Common Register	LVDS_CMN	0000_0000h	0000h	32
Reserve	-	-	0004h to 000Fh	-
LVDS PHY Register	LVDS_0_PHY	0000_0000h	0010h	32
LVDS Control Register	LVDS_0_CTL	0004_3210h	0014h	32

Note: Addresses other than those listed above are Reserved. Access to the reserved area is prohibited. The operation when accessed is not guaranteed. Access is 32 bits. Byte access is not allowed.

9.6.2.2 LVDS Common Register (LVDS_CMN)

This is a common register for LVDS modules.

Registers are implemented to select the clock, reset, and data paths according to the operating mode.

Access Size : 32 bits
Address : <LVDS_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	RST_PHY0_SEL	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	R	R	R	R	R	R	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	PHY_RESET_N
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
25	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
24	RST_PHY0_SEL	0h	RW	PHY0 Reset Signal Select 0: Low 1: CH0
23 to 17	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
16	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
15 to 10	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
9 to 8	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
7 to 1	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
0	PHY_RESET_N	0h	RW	LVDS PHY Reset 0: Reset 1: Normal

9.6.2.3 LVDS PHY Register (LVDS_0_PHY)

This is the PHY control register for LVDS.

Register is implemented to adjust the LVDS output clock and data skew and to enable the LVDS output IO.

Access Size : 32 bits

Address : <LVDS_base> + 0010h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	EN_LDO	EN_BGR	-	-	-	CH_IO_EN0[4:0]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	R	R	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
30 to 16	-	0h	RW	Reserved When read, the initial value is read. When writing, be sure to write the initial value. Operation is not guaranteed if a value other than the initial value is written.
15 to 10	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
9	EN_LDO	0h	RW	LDO Enable 1: Enable 0: Disable
8	EN_BGR	0h	RW	BGR Enable 1: Enable 0: Disable
7 to 5	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
4 to 0	CH_IO_EN0[4:0]	0h	RW	LVDS IO Enable 0: Hi-Z 1: User mode [4]: Lane4, [3]: Lane3, [2]: Lane2, [1]: Lane1, [0]: Lane0

9.6.2.4 LVDS Control Register (LVDS_0_CTL)

This is the control register of the LVDS_CORE part of LVDS.

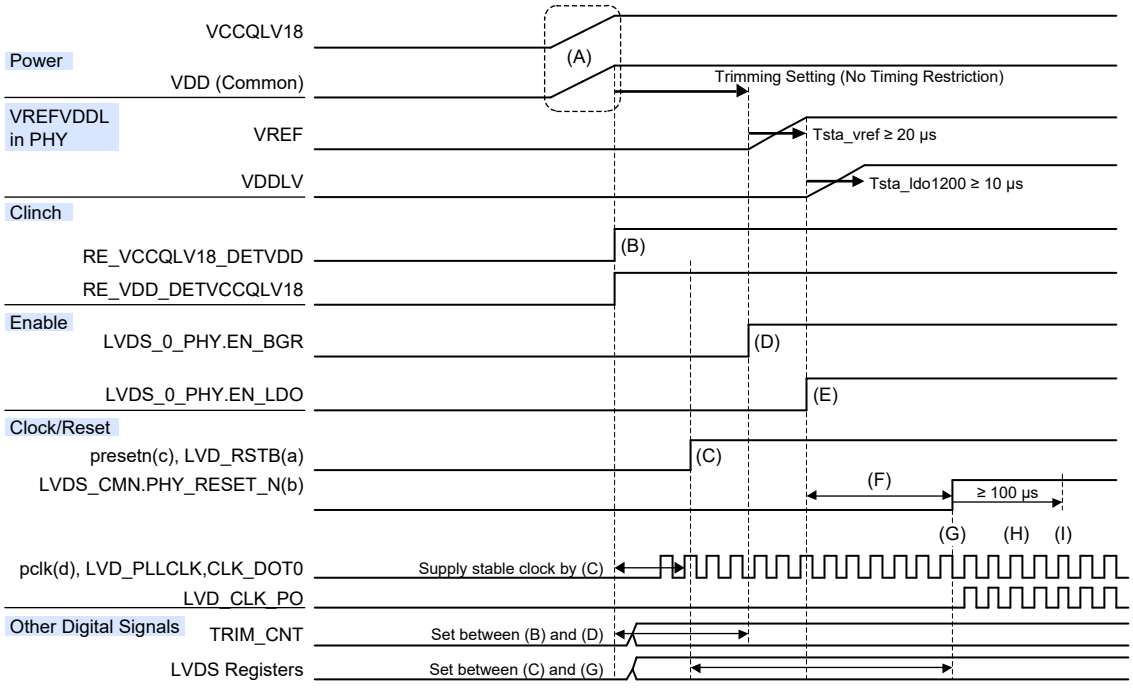
This is a register that controls the functions of the LVDS_CORE section (Control bit selection, output format selection, and output lane switching).

Access Size : 32 bits
Address : <LVDS_base> + 0014h
Initial Value : 0004_3210h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CTL_SEL0[7:0]								FMT_SEL0[3:0]				-	CH_SEL0[14:12]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	R	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	CH_SEL0[11:9]			-	CH_SEL0[8:6]			-	CH_SEL0[5:3]			-	CH_SEL0[2:0]		
Initial Value	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0
R/W	R	RW	RW	RW	R	RW	RW	RW	R	RW	RW	RW	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CTL_SEL0[7:0]	0h	RW	LVDS Control bit Select [25:24]: ctrl0 00: HSYNC, 01: VSYNC, 10: DE, 11: Low [27:26]: ctrl1 00: VSYNC, 01: DE, 10: Low, 11: HSYNC [29:28]: ctrl2 00: DE, 01: Low, 10: HSYNC, 11: VSYNC [31:30]: ctrl3 00: Low, 01: HSYNC, 10: VSYNC, 11: DE
23 to 20	FMT_SEL0[3:0]	0h	RW	LVDS Output Format Variation 0000: Mode0, 0001: Mode1, 0010: Mode2, 0011: Mode3 0100: Mode4. 0101: Mode5, 0110: Mode6, 0111: Mode7
19	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
18 to 16	CH_SEL0 [14:12]	4h	RW	LVDS Lane Select [14:12]: O_Lane4 (CL_P/CL_N) 4h(def): I_Lane4, 0h: I_Lane0, 1h: I_Lane1, 2h: I_Lane2, 3h: I_Lane3
15	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
14 to 12	CH_SEL0[11:9]	3h	RW	LVDS Lane Select [11:9]: O_Lane3 (DL3_P/DL3_N) 3h(def): I_Lane3, 4h: I_Lane4, 0h: I_Lane0, 1h: I_Lane1, 2h: I_Lane2
11	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
10 to 8	CH_SEL0[8:6]	2h	RW	LVDS Lane Select [8:6]: O_Lane2 (DL2_P/DL2_N) 2h(def): I_Lane2, 3h: I_Lane3, 4h: I_Lane4, 0h: I_Lane0, 1h: I_Lane1
7	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
6 to 4	CH_SEL0[5:3]	1h	RW	LVDS Lane Select [5:3]: O_Lane1 (DL1_P/DL1_N) 1h(def): I_Lane1, 2h: I_Lane2, 3h: I_Lane3, 4h: I_Lane4, 0h: I_Lane0
3	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
2 to 0	CH_SEL0[2:0]	0h	RW	LVDS Lane Select [2:0]: O_Lane0 (DL0_P/DL0_N) 0h(def): I_Lane0, 1h: I_Lane1, 2h: I_Lane2, 3h: I_Lane3, 4h: I_ Lane4



9.6.3 Operation

9.6.3.1 Power On Sequence

The initialization procedure for this module is shown in **Figure 9.6-2**.

The basic sequence is as follows.

Operating mode (Single-link) can be activated by following the steps below. For details on LVDS operating modes, refer to **9.6.3.3 LVDS Operating Modes**.

Note: (a) LVD_RSTB: LVDS_CORE Reset
(b) LVDS_CMN.PHY_RESET_N: PHY Reset
(c) presetn: MIPI_DSI_PRESET_N
(d) pclk: MIPI_DSI_PCLK

Figure 9.6-2 Power On Sequence

(A) Bring up VDD and VCCQLV18. There are no restrictions on the order to bring up VDD and VCCQLV18.

(B) Set 1 to RE_VCCQLV18_DETVDD and RE_VDD_DETVCCQLV18.
— These signals are automatically set to 1 when the power supply (VCCQLV18, VDD) is detected.

(C) De-assert presetn and LVD_RSTB after clocks(pclk, LVD_PLLCLK, CLK_DOT0) are stable.

(D) Write 1 to LVDS_0_PHY.EN_BGR (*1).

(E) Write 1 to LVDS_0_PHY.EN_LDO (*2) after waiting for more than 20 µsec.

(F) Write LVDS registers after waiting for more than 10 µsec.

1. Write 1 to LVDS_CMN.RST_PHY0_SEL (*3).
2. LVDS_0_CTL.CTL_SEL0/FMT_SEL0/CH_SEL0 (*4):
   — If you need to change the initial value, please set those registers.

   See **9.6.2.4** (LVDS Control Register), **9.6.3.5** (FMT_SEL0), **9.6.3.7** (CTL_SEL0), **9.6.3.9** (CH_SEL0) for configuration instructions.

   There is no restriction on the order of settings for FMT_SEL0, CTL_SEL0, and CH_SEL0.

3. LVDS_0_PHY.CH_IO_EN0[4:0] (*5):
   — Write 1 to CH_IO_EN[4:0] according to the Lane used.

(G) Write 1 to LVDS_CMN.PHY_RESET_N for De-assert PHY RESET (*6).

(H) Wait for more than 100 µsec.

(I) The LVDS Module is ready.

See **Table 9.6-6** for (*1) to (*6).

The registers that require initial settings are as follows. The registers used by default do not need to be initialized.

Table 9.6-6 List of Registers that Require Initial Setting

No.	Number of the Notes	Register Name	Address	Bit	I/O	Function
1	*3	LVDS_CMN	000h	24	RST_PHY0_SEL	PHY Reset Signal Select
2	*6			0	PHY_RESET_N	PHY Reset
3	*2	LVDS_0_PHY	010h	9	EN_LDO	PHY LDO Enable
4	*1			8	EN_BGR	PHY BGR Enable
5	*5			4-0	CH_IO_EN0 [4:0]	PHY IO Enable
6	*4	LVDS_0_CTL	014h	31-24	CTL_SEL0 [7:0]	LVDS Control bit Select
7	*4			23-20	FMT_SEL0 [3:0]	LVDS Output Format Variation
8	*4			18-16	CH_SEL0 [14:12]	LVDS Lane Select
				14-12	CH_SEL0 [11:9]	
				10-8	CH_SEL0 [8:6]	
				6-4	CH_SEL0 [5:3]	
				2-0	CH_SEL0 [2:0]	

9.6.3.2 Power Off Sequence

The Power off sequence is the reverse procedure of the Power on sequence.

The basic sequence is as follows.

(A) Write 0 to LVDS_CMN.PHY_RESET_N for assert PHY RESET (*6).

(B) Write 0 to CH_IO_EN[4:0] (*5) for PHY IO Disable.

(C) Write 0 to LVDS_0_PHY.EN_BGR (*1) and LVDS_0_PHY.EN_LDO (*2).

(D) LVDS reset, clock stop.

(E) VDD and VCCQLV18 Power off.

See **Table 9.6-6** for (*1) to (*6).

9.6.3.3 LVDS Operating Modes

The operating mode is only Single-link, as shown below.

(1) Single-link

This mode outputs the image data of LCDC to LVDS as shown below.

Figure 9.6-3 shows an image of the single-link clock and data path.

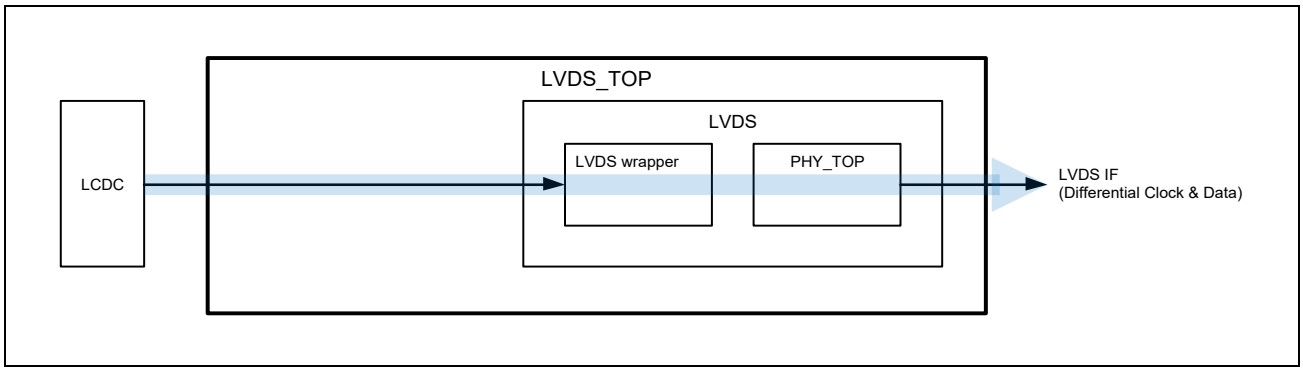


Figure 9.6-3 Single-link Data Path Image

9.6.3.4 Input Format

For the input format to this module, please refer to **9.4 LCD Controller (LCDC)**.

9.6.3.5 Output Format Selection

This module supports 8 types of output formats (Modes). Switch the output format by setting the register (LVDS_0_CTL.FMT_SEL0[3:0]). The output image data is 24 bits for RGB (8 bits each) and 4 bits for Control bits. The control bits input from the LCDC consist of 4 bits: HSYNC, VSYNC, DE, and Low(fixed).

Refer to **Figure 9.6-8** for the data format conversion from LCDC to LVDS.

The output formats for each mode are shown in **Figure 9.6-4**, **Figure 9.6-5**, **Figure 9.6-6**, and **Figure 9.6-7**.

Remark R = Red Data, G = Green Data, B = Blue Data, CTL = Control bit

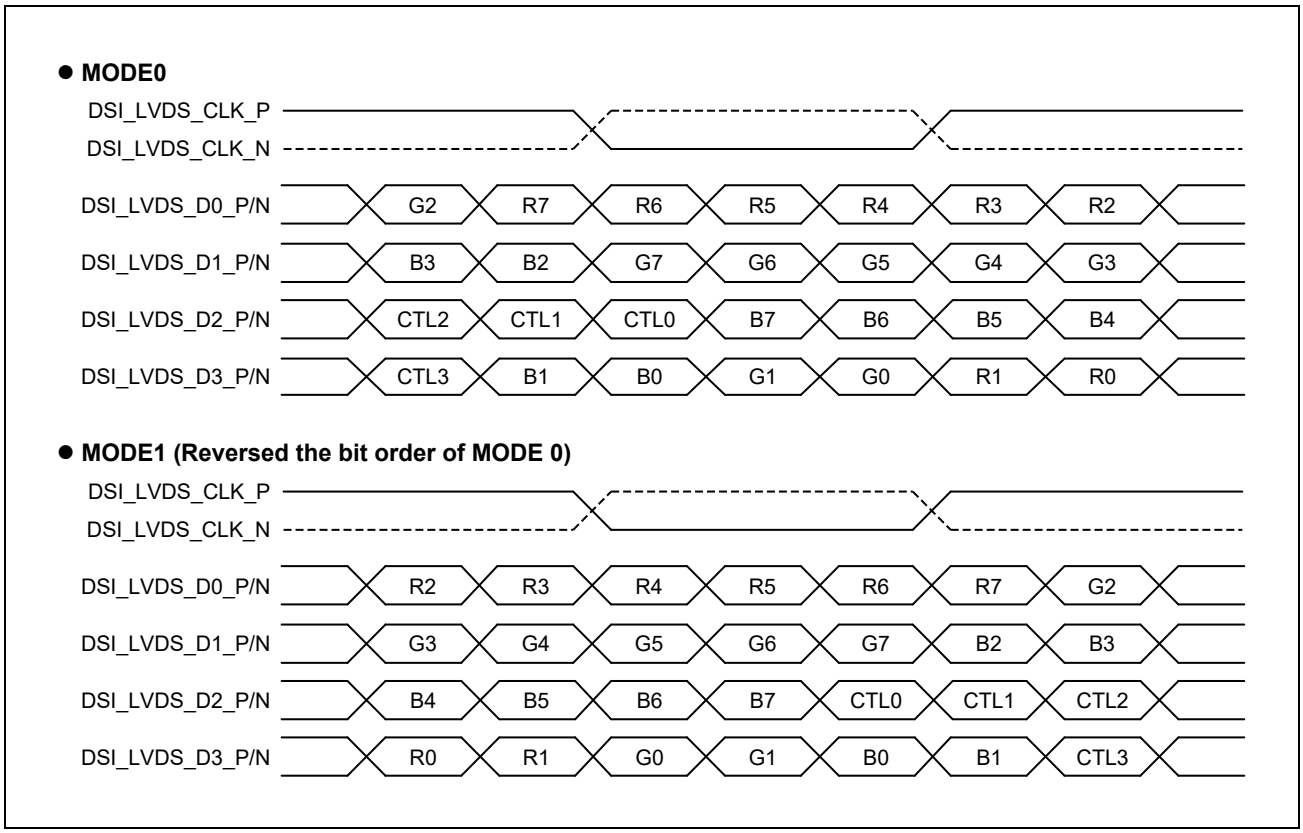

Figure 9.6-4 Mode0, Mode1 Output Format

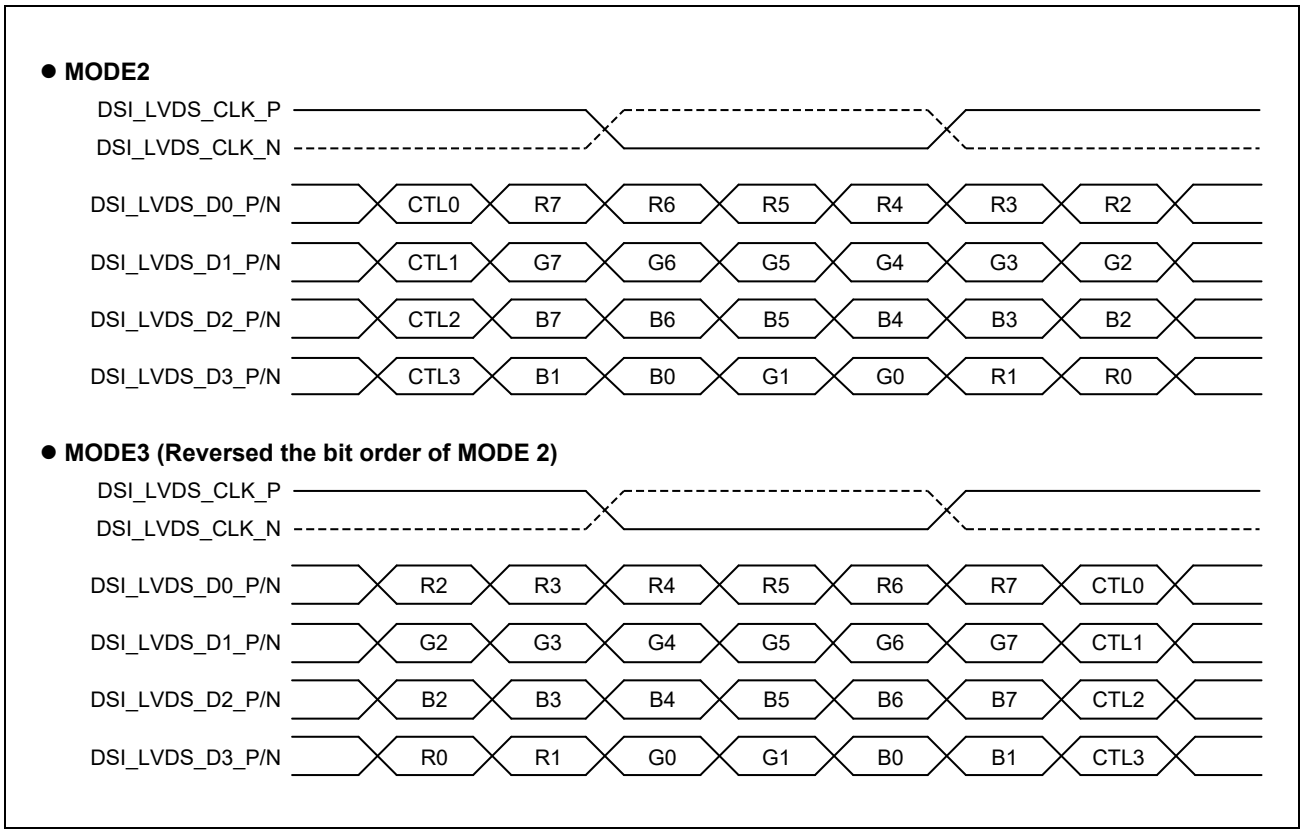

Figure 9.6-5 Mode2, Mode3 Output Format

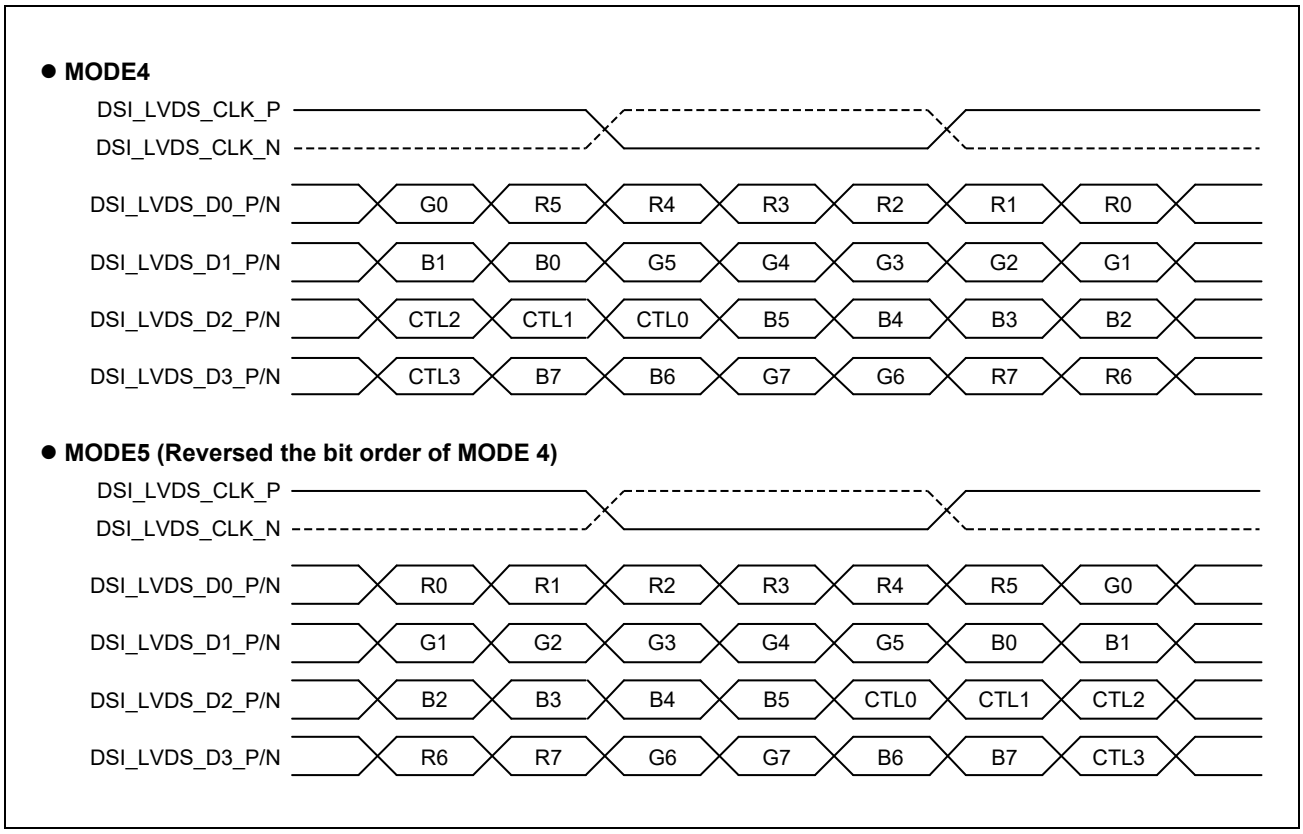

Figure 9.6-6 Mode4, Mode5 Output Format

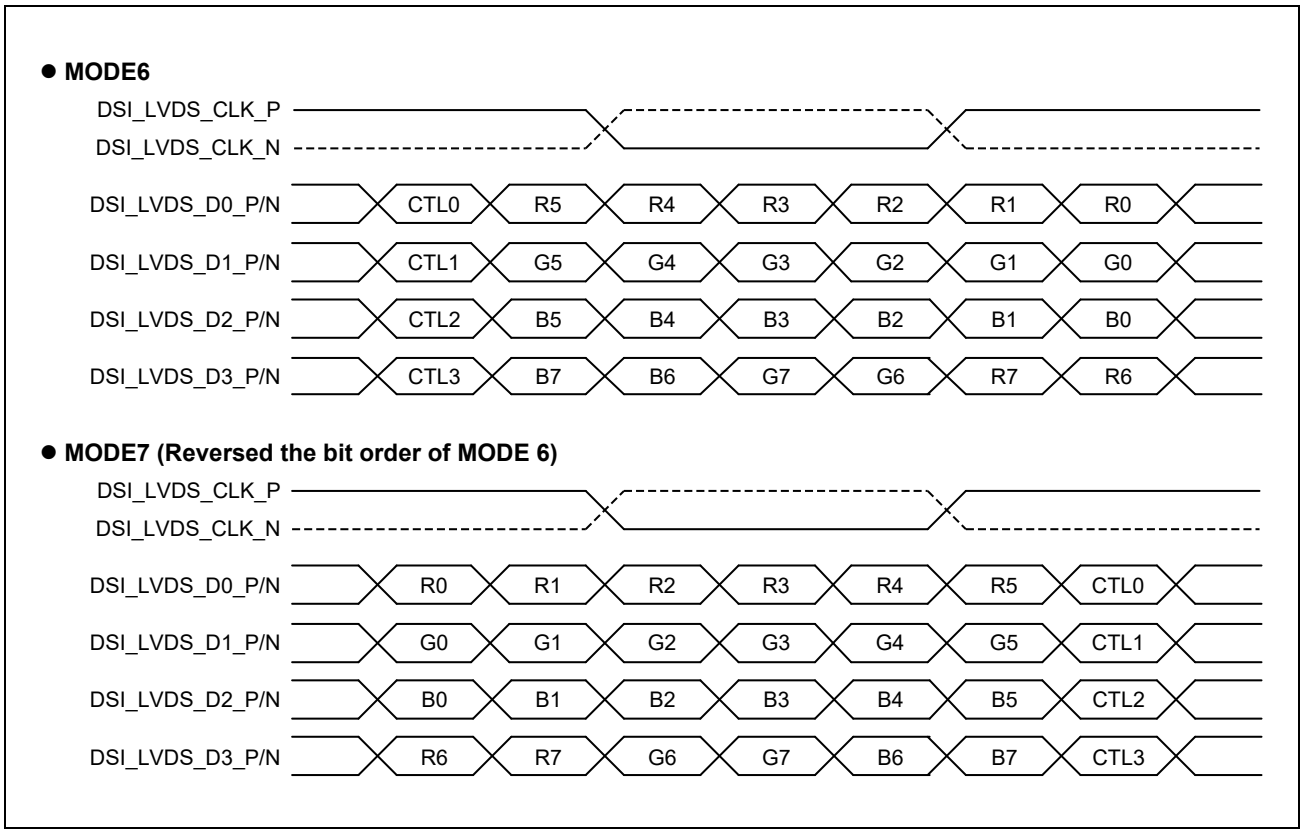

Figure 9.6-7 Mode6, Mode7 Output Format

9.6.3.6 Input/Output Data Description

This module converts the input data from the LCDC to the selected output format (refer to **9.6.3.5 Output Format Selection**) and outputs it. The clock must be output with a duty ratio of 4:3 (High:Low) according to the TIA/EIA-644 standard and is generated by the PHY. As for image data, the data equivalent to one clock of the LCDC is output by the Serializer at 7 times the speed. This section describes how to convert input data and control bits at the time of output (bit assignment).

(1) Data Conversion

Describes data transformation. The figure below is an example of conversion. The input data is converted into the selected data according to the output format (refer to **9.6.3.5 Output Format Selection**) and output. For details on the register settings for selecting the output format, refer to LVDS_0_CTL.

The upper part of the figure below is the input data from the LCDC. 24 bits of data are input per clock.

As shown at the bottom of the figure below, the input parallel data is sorted into serial data and output.

The conversion of parallel data to serial data is done by the PHY's Serializer.

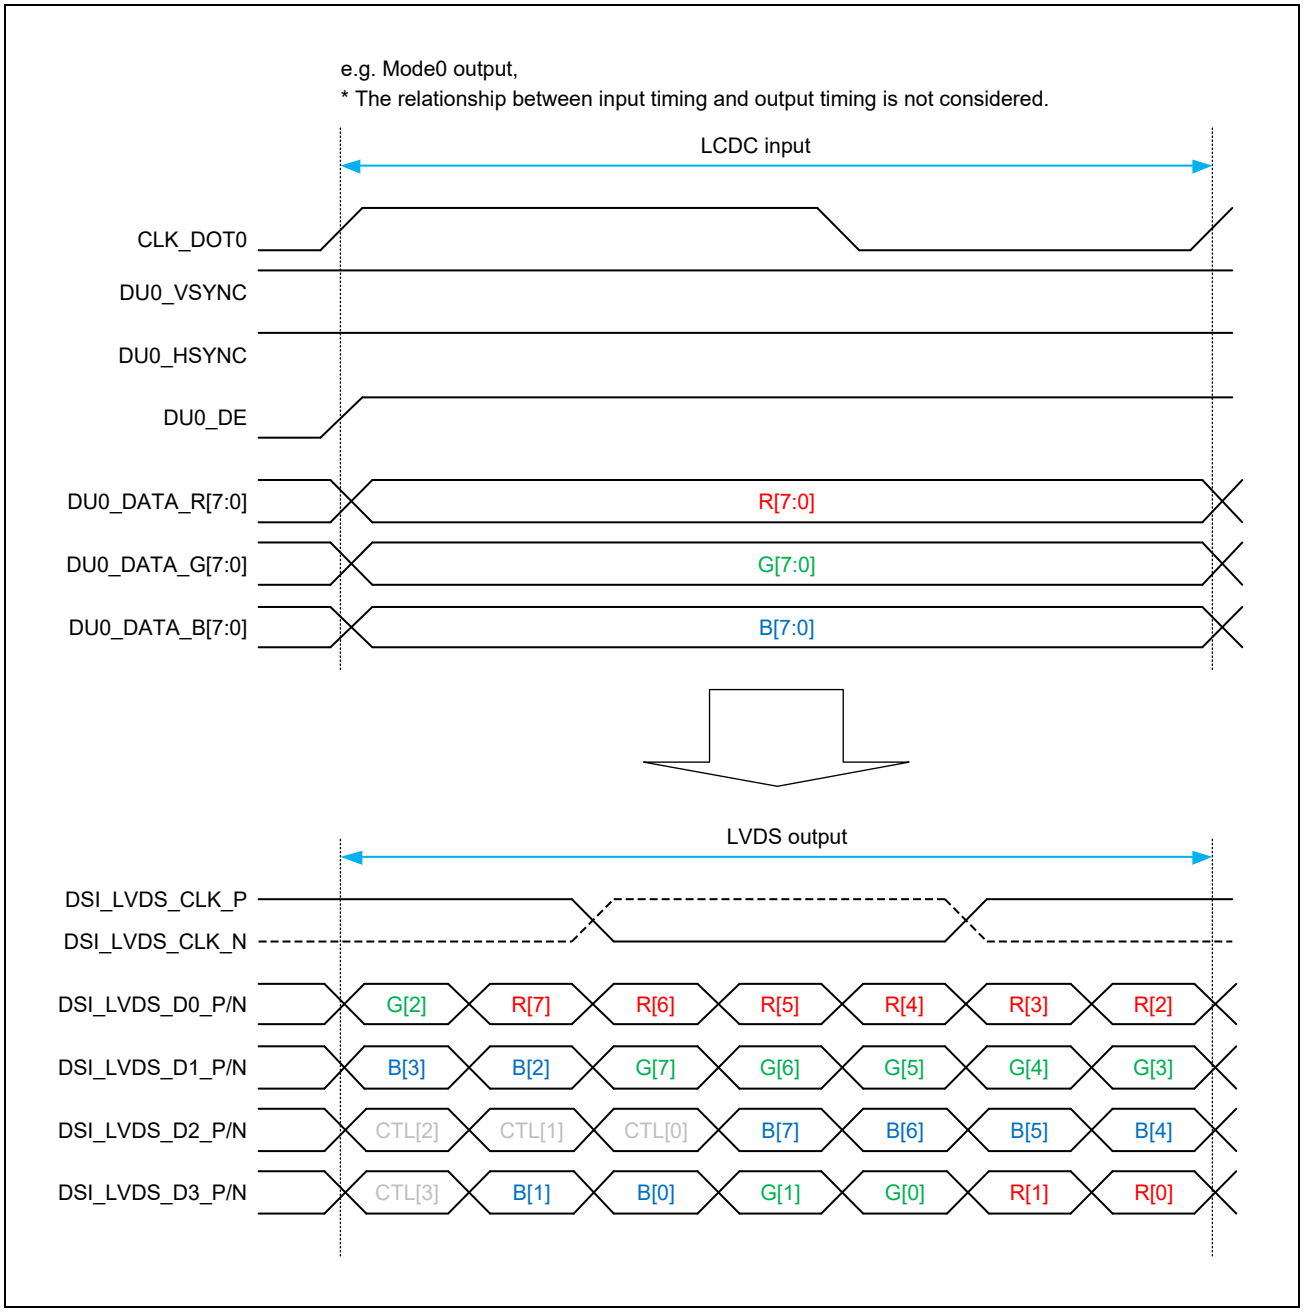

Figure 9.6-8 Data Conversion

(2) Control Bit Conversion

This section describes the Control bit transformation. The synchronization signal (DUx_HSYNC, DUx_VSYNC, DUx_DE) from the LCDC and the low(fixed) bit are reflected in the output data by the selected Control bit.

For the register settings for Control bit conversion, refer to LVDS_0_CTL.

The upper part of the figure below shows the three types of synchronization signals input from the LCDC.

As shown in the lower part of the figure below, three types of synchronization signals and Low fixation are reflected in the Control bit.

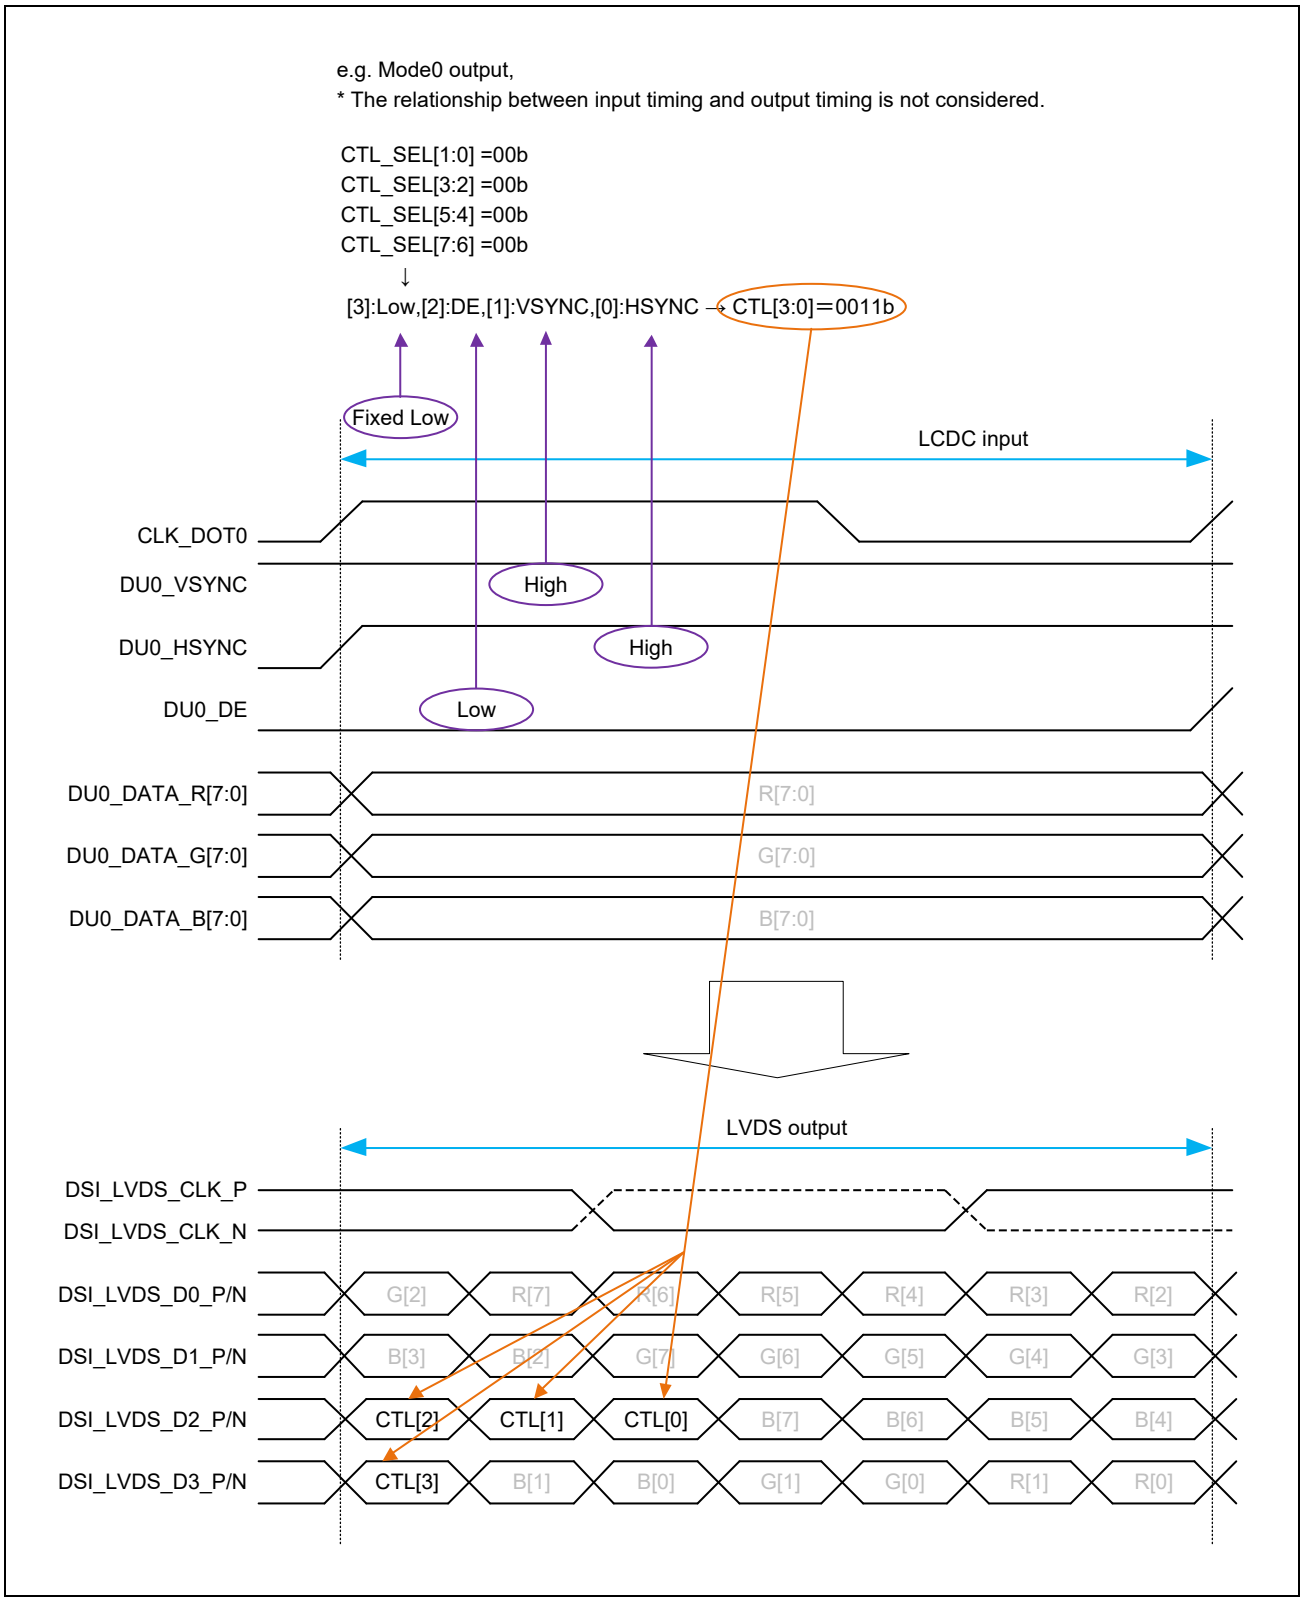

Figure 9.6-9 Control Bit Conversion

9.6.3.7 Control Bit Switching

Switching the Control bit by setting the register (LVDS_0_CTL.CTL_SEL0[7:0]) of this module.

The output synchronization signal can be assigned to the 4 bits of the Control bit [3:0] included in the output format with a register. The target synchronization signal is VSYNC/HSYNC/DE/Low (Fixed).

The relationship between CTL_SEL0[7:0] and the Control bit is as follows.

- CTL_SEL0[1:0]: CTL[0]
- CTL_SEL0[2:3]: CTL[1]
- CTL_SEL0[4:5]: CTL[2]
- CTL_SEL0[6:7]: CTL[3]

Table 9.6-7 shows a list of Control bit assignment selection.

Refer to **Figure 9.6-9** Control Bit Conversion for an image of the control bit switching.

Table 9.6-7 Control bit Assignment Selection List

Register Setting Value	CTL[3]	CTL[2]	CTL[1]	CTL[0]
00b	Low	DE	VSYNC	HSYNC
01b	HSYNC	Low	DE	VSYNC
10b	VSYNC	HSYNC	Low	DE
11b	DE	VSYNC	HSYNC	Low

Note: CTL_SEL When “00_00_00_00b” is set to [7:0], it is as follows.
CTL[3] = Low, CTL[2] = DE, CTL[1] = VSYNC, CTL[0] = HSYNC.

9.6.3.8 Output Lane Selection

This is a function that allows you to swap all lanes, including the Clock Lane.

The register setting is 3 bits per lane, and 5 lanes are set at once (15 bits).

The initial state is LVDS_0_CTL.CH_SEL0[14:0] = 100_011_010_001_000b.

[14:12]: O_Lane4 (Clock), [11:9]: O_Lane3, [8:6]: O_Lane2, [5:3]: O_Lane1, [2:0]: O_Lane0

This feature has the following limitations.

- Make sure that each 3-bit setting does not have the same value.
- Duplicate settings, such as [14:12] = 3'b100, [2:0] = 3'b100, are prohibited.

Each 3bit should be set to one of 3'B000, 3'B001, 3'B010, 3'B011, or 3'B100. Other than that, it is forbidden.

Table 9.6-8 shows the output lane selection list (Representative example).

Table 9.6-8 Output Lane Selection List (Representative Example)

CH_SEL0 [14:0]	O_Lane4	O_Lane3	O_Lane2	O_Lane1	O_Lane0
100_011_010_001_000b	I_Lane4	I_Lane3	I_Lane2	I_Lane1	I_Lane0
100_000_011_010_001b	I_Lane4	I_Lane0	I_Lane3	I_Lane2	I_Lane1
100_001_000_011_010b	I_Lane4	I_Lane1	I_Lane0	I_Lane3	I_Lane2
100_010_001_000_011b	I_Lane4	I_Lane2	I_Lane1	I_Lane0	I_Lane3
000_011_010_001_100b	I_Lane0	I_Lane3	I_Lane2	I_Lane1	I_Lane4
001_011_010_100_000b	I_Lane1	I_Lane3	I_Lane2	I_Lane4	I_Lane0
010_011_100_001_000b	I_Lane2	I_Lane3	I_Lane4	I_Lane1	I_Lane0
011_100_010_001_000b	I_Lane3	I_Lane4	I_Lane2	I_Lane1	I_Lane0

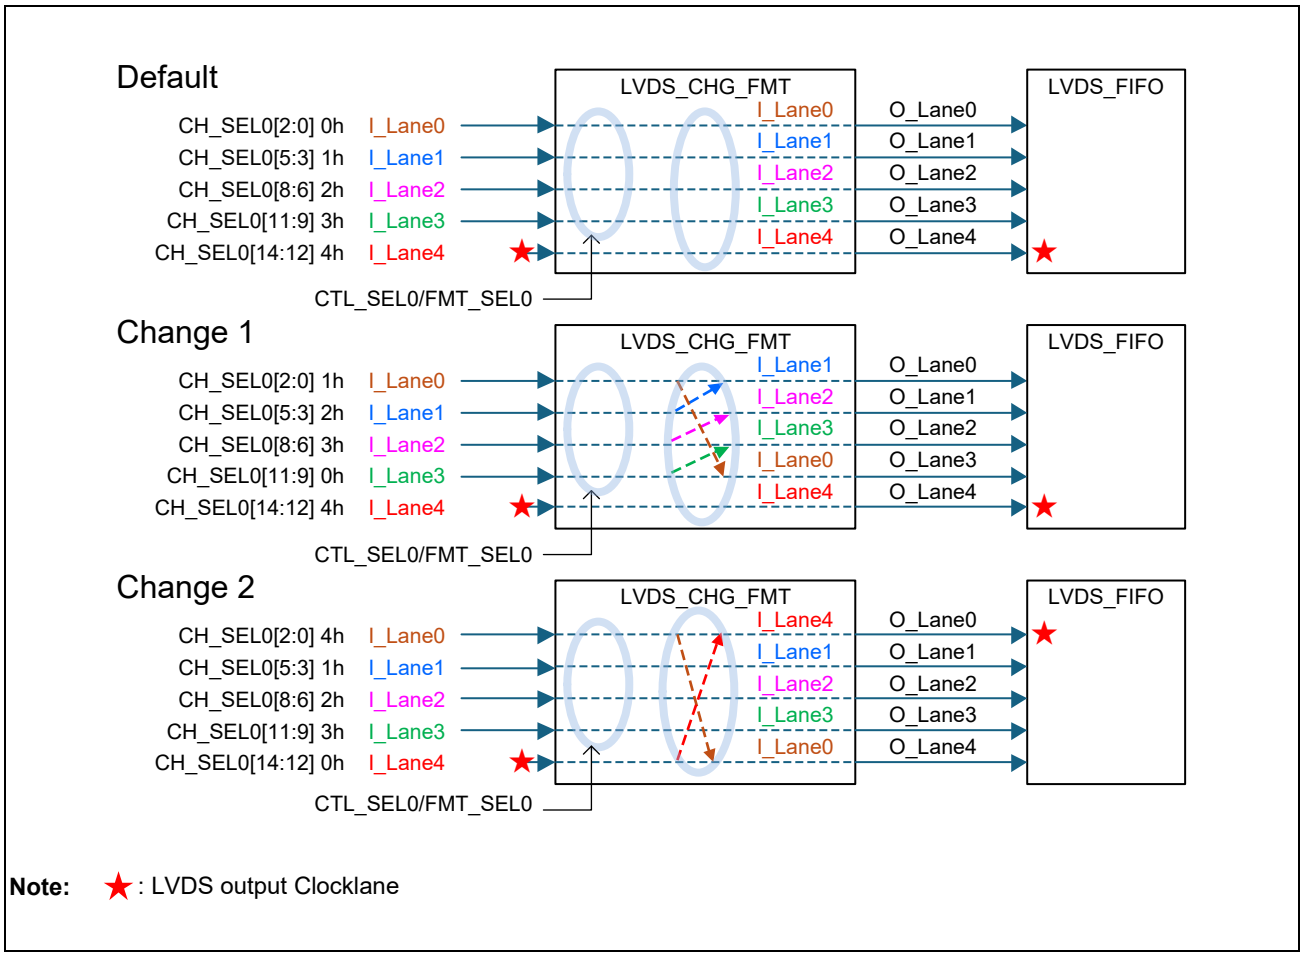

Figure 9.6-10 Image of Lane Swapped

9.6.3.9 Asynchronous FIFO

In this module, an asynchronous FIFO is implemented between the LVDS_CORE section and the PHY.

9.6.3.10 PHY Reset

The reset of the LVDS PHY can be controlled by setting the APB registers.

The PHY reset must be entered synchronously with the PHY clock.

For the control procedure, refer to Power on sequence (**9.6.3.1 Power On Sequence**).

9.6.3.11 PHY IO Buffer Enable Control

This function controls the LVDS IO buffer for each lane.

The output of the LVDS IO buffer for an unused lane can be controlled by the corresponding CH_IO_EN bit.

When CH_IO_EN = 0 (Disable), the output of the corresponding lane is placed in a high-impedance (Hi-Z) state.

For details on register settings, refer to LVDS_0_PHY.

9.6.3.12 Interrupt

There are no interrupt signals in this module.

9.6.4 Usage Note

This module does not support dynamic register settings.

Set the appropriate register settings at the time of initial setup, and if you want to change the settings, perform the Power On sequence again after performing the Power Off sequence. (No need to turn the power on or off)

SECTION 9 IMAGE

9.7 Video Codec Processor (VCPL4)

The VCPL4 is a H.264 codec module. Require software or the library to RENESAS for operating this module.

Figure 9.7-1 shows VCPL4 and related modules for this LSI. The VCPL4 is connected memory bus (AXI-bus) via companion modules, FCPCS. For detail information, refer **9.8 Frame Compression Processor (FCPCS)**.

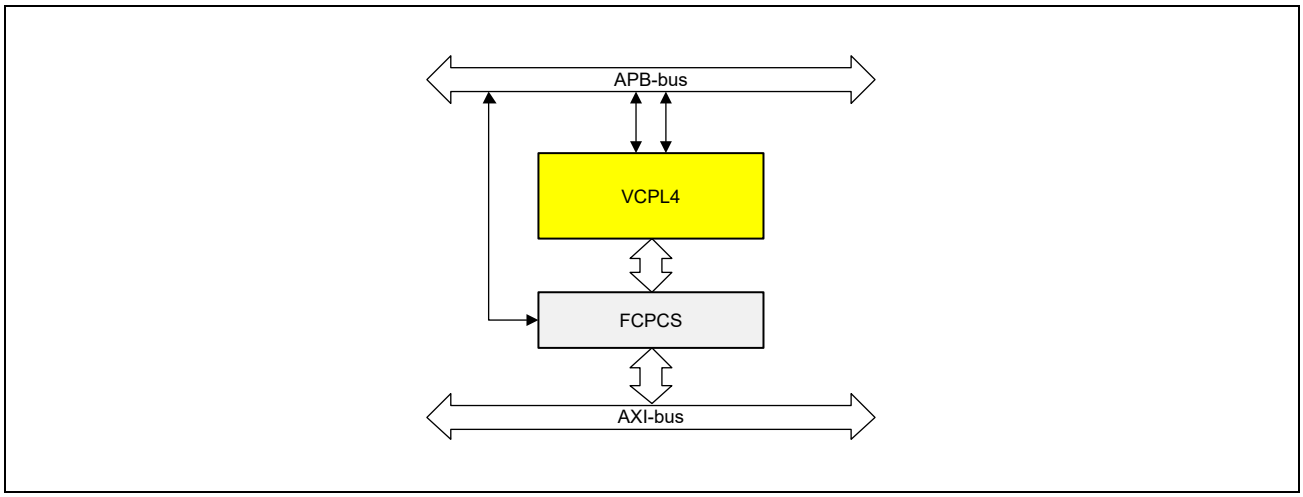

Figure 9.7-1 VCPL4 and Related Modules

9.7.1 Features

The VCPL4 has the following features.

- Support for H.264 decoding and encoding
- Support up to 1920 × 1080 resolution
- Data handling on a picture-by-picture basis
  - Encode/decode data one picture (frame or field) at a time.
- High picture quality
  - Support the H.264 high-efficiency coding tools (CABAC, 8 × 8 frequency conversion, and quantization matrix).
  - High-efficiency motion vector detection by a combination of discrete search and trace search
  - Optimal-mode selection by Rate-Distortion (RD) cost evaluation
  - Picture quality control based on activity analysis results which match visual models

Table 9.7-1 Main Function of the VCPL4

Item	Description
Encoding standard supported	• H.264/AVC – High Profile@Level 4.1 – Main Profile@Level 4.1 – Baseline Profile@Level 4.1 (The arbitrary slice order, flexible macroblock order and redundant slice aren't supported)
Decoding standard supported	• H.264/AVC – High Profile@Level 4.1 – Main Profile@Level 4.1 – Baseline Profile@Level 4.1 (The arbitrary slice order, flexible macroblock order and redundant slice aren't supported)
Maximum pixel rate	1920 × 1080p × 30 fps
Maximum bit rate	200 Mbps × 1ch *Note*: a target bitrate can be set for each picture by using Renesas software.
Picture size supported in decoding	• Minimum size: Horizontal 80 pixels × vertical 80 lines • Maximum size: 1920 pixels × vertical 1080 lines • Horizontal size is a multiple of 2 pixels, and vertical size is a multiple of 2 lines. Additionally, 1080 × 1920 is supported.
Picture size supported in encoding	• Minimum size: Horizontal 80 pixels × vertical 80 lines • Maximum size: Horizontal 1920 pixels × vertical 1080 lines • Horizontal size is a multiple of 8 pixels, and vertical size is a multiple of 8 lines. Additionally, 320 × 180, 854 × 480 (WVGA+), 1080 × 1920 are supported.
Color format	• YCbCr 4:2:0 semi-planar (Y and C plane) are supported as an input picture in encoding. • YCbCr 4:2:0 semi-planar is supported as an output picture in decoding. • Cb/Cr and Cr/Cb interleaving order is supported in YCbCr 4:2:0 semi-planar.
Bit stream format	• Video elementary stream as shown in **Figure 9.7-1**. • Function to add or remove the emulation prevention byte in the H.264 bit stream is supported.
Picture structure	Frame structure and field structure

Table 9.7-2 Main Function of the VCPL4

Standard	Standard	Decoding Range
H.264	Slice header and subsequent data	Slice header (other than the first slice header in picture) and subsequent data

9.7.2 Usage Note

9.7.2.1 Limitations on Software Reset and Module Standby

Before executing following operations for VCPL4, confirm that VCPL4 is not encoding or decoding a picture. If VCPL4 is encoding or decoding a picture, wait completion of encoding or decoding.

- Execute Software Reset by CPG
- Enter Module Standby (stop clock supply) by CPG

9.7.2.2 Note on Input Bitstream for Decoding

In decoding process of VCPL4, input bitstream not conformant to video codec standard might cause hang of VCPL4.

9.7.3 Interrupt Request

VCPL4 interrupt requests are listed in the following table.

Table 9.7-3 Interrupt Requests

Unit Interrupt Signal	Outline
VCP.vcpl4.vint	Interruption request signal from VLC block
VCP.vcpl4.cint	Interruption request signal from CE block
VCP.vcpl4.vedcint	EDC error Interrupt from VLC block
VCP.vcpl4.cedcint	EDC error Interrupt from CE block

SECTION 9 IMAGE

9.8 Frame Compression Processor (FCPCS)

The FCPCS is a companion module of a video processing module with Renesas lossless data compression and decompression (FCL) for the Renesas video codec processor (VCPL4). It provides data compression and decompression, data caching, and converting of AXI transaction in order to reduce the memory bandwidth.

The FCPCS is connected to codec IP cores called VCPL4 (H.264 decoder and encoder).

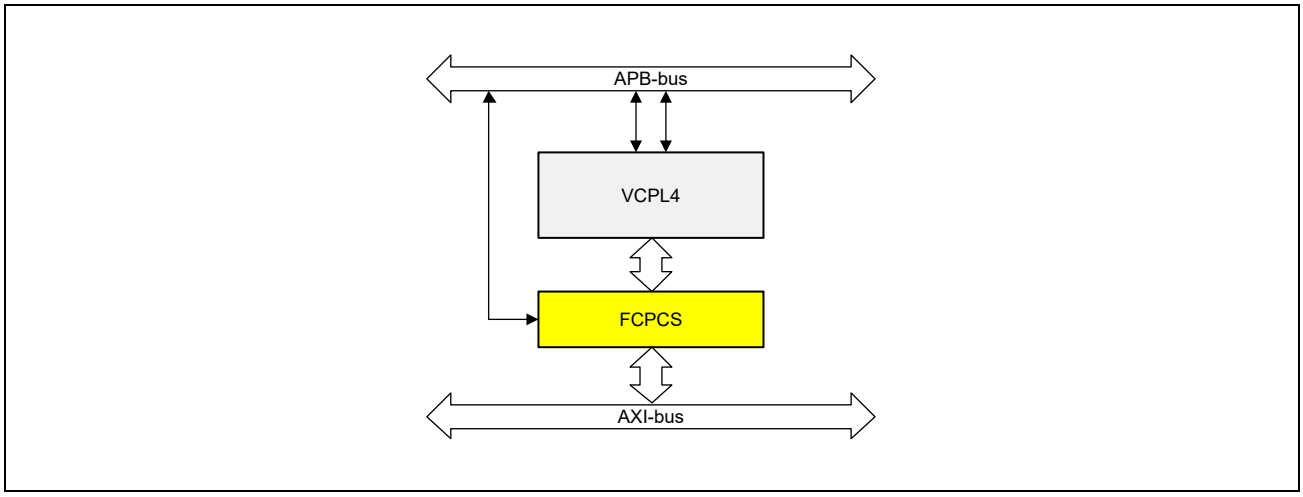

Figure 9.8-1 FCPCS and Related Modules

9.8.1 Features

The FCPCS has the following features.

- Support for Lossless compression for decoded picture and decompression for reference picture
- Support 1920 × 1080 resolution
- Support for reference picture cache
- Lossless compression ratio is typically 50%. It may not be compressed since Lossless compression relies on the statistical nature of the original image.

Table 9.8-1 Main Function of the FCPCS

Item	Description
Data compression and decompression	Renesas lossless (FCL) compression and decompression, Compression for decoded picture, and decompression for reference picture YCbCr 4:2:0 semi-planar and 8-bit depth are supported
Reference picture cache	64 Kbyte
AXI transaction	[Read access] • Out-of-order completion allowed. • Outstanding transactions supported. [Write access] • Out-of-order completion allowed. • Outstanding transactions supported.

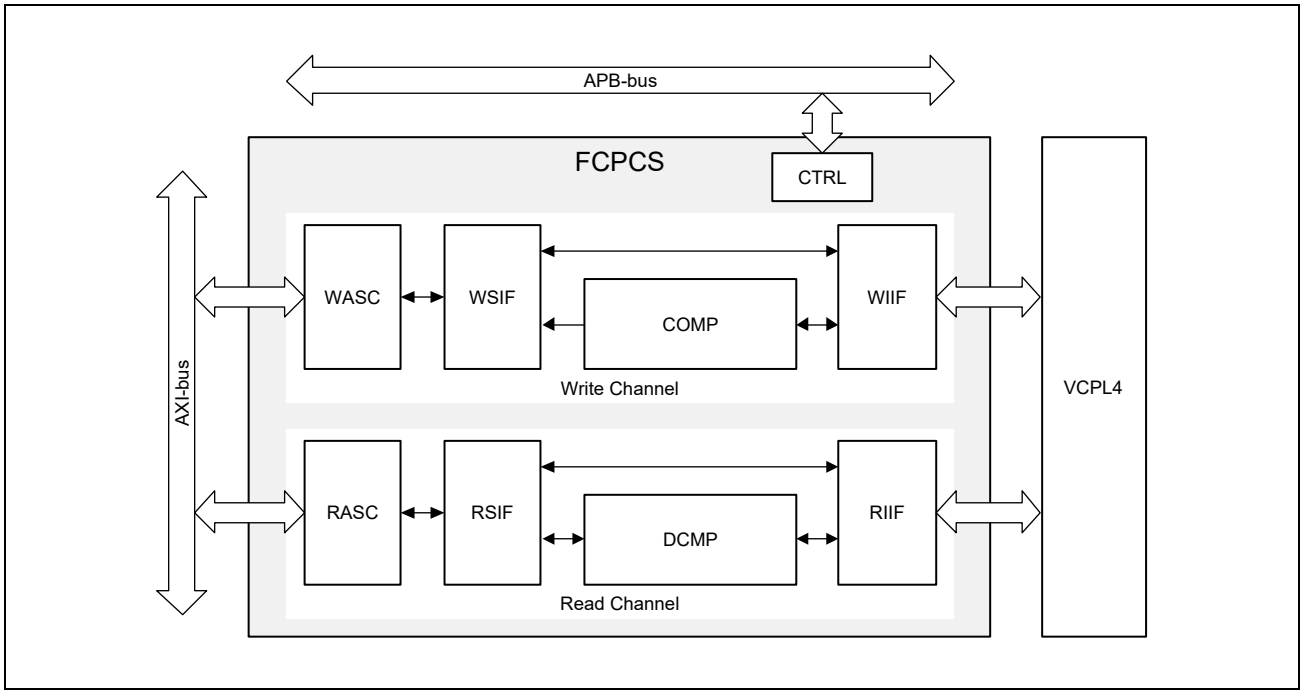

Figure 9.8-2 FCPCS Block Diagram

Table 9.8-2 Main Function of the FCPCS

Channel	Abbreviation	Description
Write Channel	COMP	Compression module
	WIIF	Write channel interface for VCPL4
	WSIF	System AXI write channel interface
	WASC	Synchronization of write channel
Read Channel	DCMP	Decompression and cache control module
	RIIF	Read channel interface for VCPL4
	RSIF	System AXI read channel interface
	RASC	Synchronization of read channel

9.8.2 Usage Note

9.8.2.1 Limitations on Software Reset and Module Standby

Before executing following operations for FCPCS, confirm that connected modules (VCPL4) are not encoding or decoding a picture. If connected modules are encoding or decoding a picture, wait completion of encoding and decoding.

- Execute Software Reset by CPG
- Enter Module Standby (stop clock supply) by CPG

9.8.3 Interrupt Request

FCPCS interrupt requests are listed in the following table.

Table 9.8-3 Interrupt Requests

Unit Interrupt Signal	Outline
VCP.fcpcs.edcint	EDC error Interrupt from FCPCS

SECTION 9 IMAGE

9.9 3D Graphics Engine (GE3D)

9.9.1 Overview

This LSI includes the Arm Mali-G31 GPU as a 3D Graphics Engine (GE3D). The Arm Mali-G31 GPU is a graphics acceleration platform that is based on open standards. It supports 2D graphics, 3D graphics, and General Purpose computing on GPU (GPGPU).

9.9.1.1 Features

The GE3D has the following features.

- One single-pixel shader core
- 8Kbytes L2 cache
- A programmable architecture.
- An API feature set with support for shader-based and fixed-function graphics APIs.
- Anti-aliasing capabilities.
- An effective core for General Purpose computing on GPU (GPGPU) applications.
- High memory bandwidth and low power consumption for 3D graphics content.
- Latency tolerance.
- Compressed texture formats.
- Coherency aware interconnects for system memory and resource sharing.

The GE3D and software support compute and graphics API standards.

The GE3D supports these compute API standards:

- OpenCL 2.0 Full Profile.

The GE3D supports these graphics API standards:

- OpenGLES 1.1, 2.0, 3.0, 3.1 and 3.2.

9.9.1.2 Block Diagram

The GE3D contains the shader processor core and associated blocks, including the tiler, the memory-management unit, and the level 2 cache memory subsystem.

Figure 9.9-1 shows a block diagram.

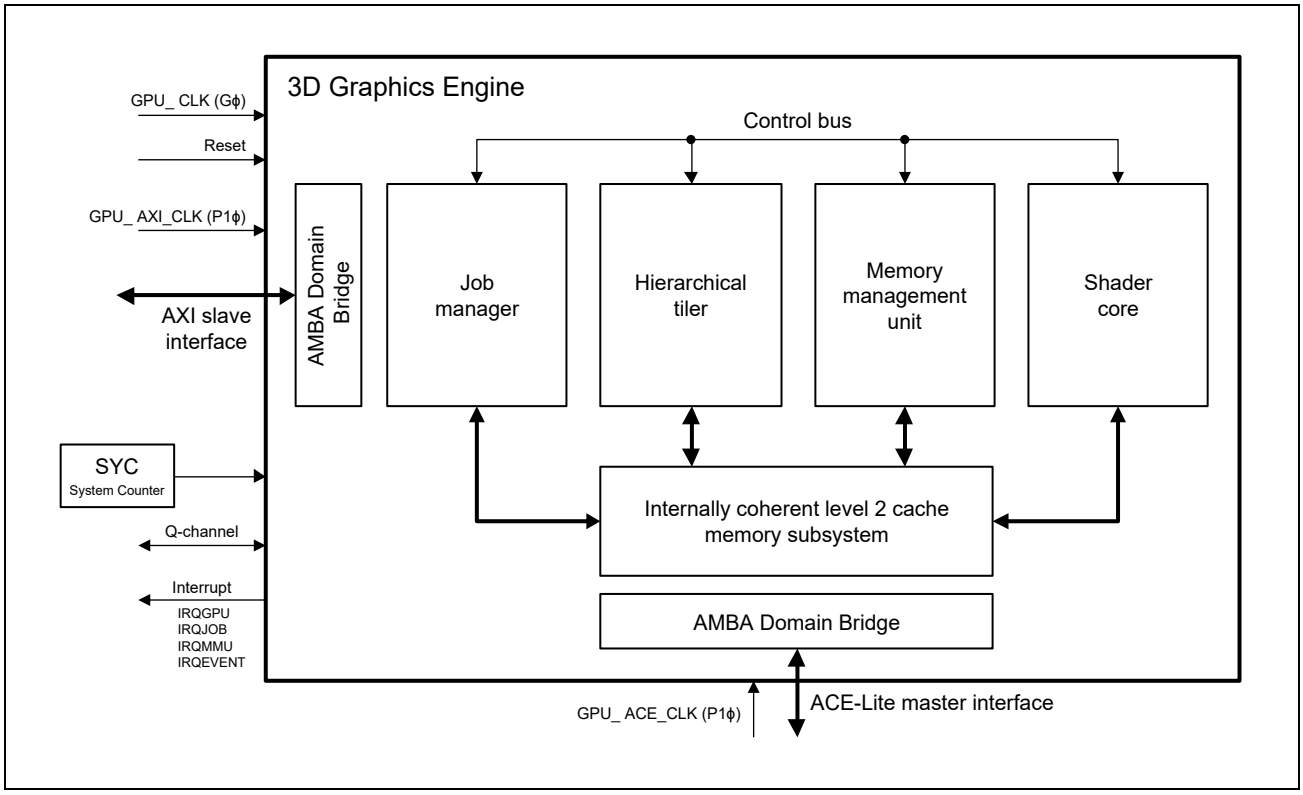

Figure 9.9-1 Block Diagram

The GE3D uses a centralized hardware resource manager, called the job manager, that controls the internal GPU functions.

The application software runs on the application processor. When it requires graphics to be displayed on screen, it uses the graphics device driver to send a graphics job to the GE3D. In the GE3D, the job manager receives the job, interprets it, and then sends a series of graphics tasks to the internal functional units.

The job manager issues and sends commands to specific functional blocks in the GE3D.

- The shader core is the main processing engines of the GE3D. The shader core carries out all the rendering and computation operations.
- The tiler creates lists of all the objects in a scene, so that the shader core processes the objects efficiently.
- The memory management unit performs virtual address to physical address translation of external bus interface accesses.
- The Level 2 cache memory subsystem provides caching for all internal master blocks. It also supports cache coherency for caches in the shader cores. The L2 cache sits between the internal master blocks and the external interconnect. All transactions go through the cache. If the cache cannot service an internal transaction, it performs an external transaction to read or write data.

9.9.1.3 External Pins

In 3D Graphics Engine, there are no external pins.

9.9.1.4 Register Configuration

Base address of registers is allocated to H'0_108B_0000. The address range is 64 KB.

H'0_108B 0000 to H'0_108B_FFFF (Overall Addres Space)
H'408B_0000 to H'408B_FFFF (Cortex-M33 Address Space Secure)
H'508B_0000 to H'508B_FFFF (Cortex-M33 Address Space Non-Secure)

9.9.1.5 Usage Note

Renesas does not provide technical support for users to program GE3D registers directly. Renesas provides users with drivers to program GE3D. GE3D supports OpenGLES as a graphics API. When drawing graphics, control according to this API.

9.9.1.6 Starting SYC

When using GE3D, it is necessary to supply the clock to the SYC (system counter) and release the reset to keep it running.

SECTION 10 ELECTRICAL CHARACTERISTICS

10.1 Electrical Characteristics

This section describes the electrical characteristics of this LSI.

10.1.1 Absolute Maximum Ratings

Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Table 10.1-1 Absolute Maximum Ratings (1/2)

Power Domain	Item		Pin Name	Symbol	Min.	Max.	Unit
PD_VBATT	Power supply voltage (VBATT)		VDD_VBATT	VBATT_V_{DD}	−0.3	2.50	V
PD_AWO	Power supply voltage (1.0 V)		VDD10_AWO	AWO_V_{DD10}	−0.3	1.26	V
			VAA10_PLL23	PLL23_V_{AA10}			
	Power supply voltage (1.8 V)		PVDD18_AWO	AWO_PV_{DD18}	−0.3	2.45	V
			VAA18_ADC	ADC_V_{AA18}			
			VAA18_OTP	OTP_V_{AA18}	−0.3	2.50	V
	Power supply voltage	(1.8 V)	PVDD1833_OTH_AWO	OTH_AWO_PV_{DD1833}	−0.3	2.45	V
		(3.3 V)			−0.3	4.10	V
	Power supply voltage (xSPI)	(1.8 V)	PVDD1833_XSPI_AWO	XSPI_AWO_PV_{DD1833}	−0.3	2.45	V
		(3.3 V)			−0.3	4.10	V
PD_ISO	Power supply voltage (1.0 V)		VDD10_ISO	ISO_V_{DD10}	−0.3	1.26	V
			VAA10_PLLn (n = 16, 47, 5)	PLLn_V_{AA10}			
	Power supply voltage (1.8 V)		PVDD18_PRE_ISO	PRE_ISO_PV_{DD18}	−0.3	2.45	V

		(1.2 V)	VDDQ_DDR (DDR4)		1.14	1.2	1.26	V	

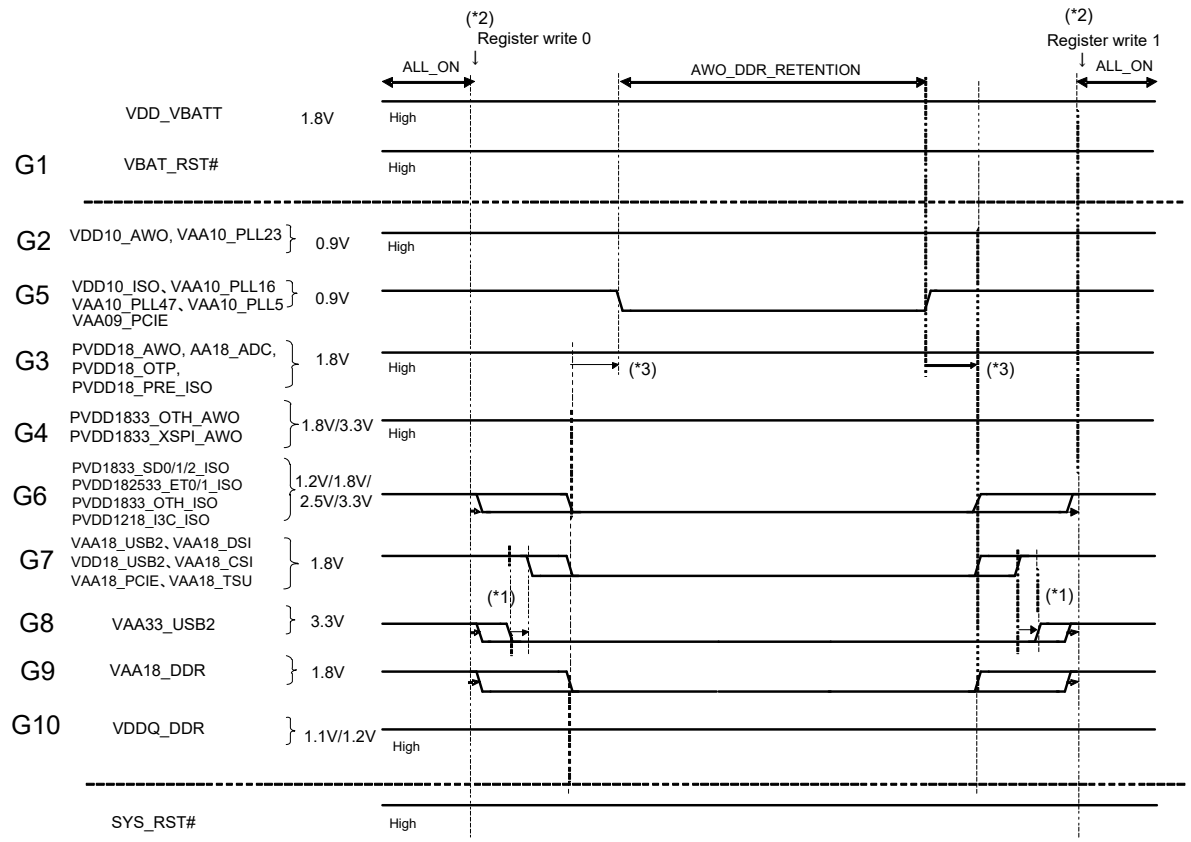
10.1.3 Power-On/Power-Off Sequence

Note 1. G3 must be powered on after G2, G5 and powered off before G2, G5. G3 and G7 may be powered on / off at the same time.

Note 2. G4, G6 must be powered on after G3 and powered off before G3. If G4 voltage is 1.8V, G4 can be powered on/off along with G3, this also applies to G6.

Note 3. G8 must be powered on after G7 and powered off before G7.

Note 4. It is recommended that all the power domains are powered on or off within approximately 100 msec.



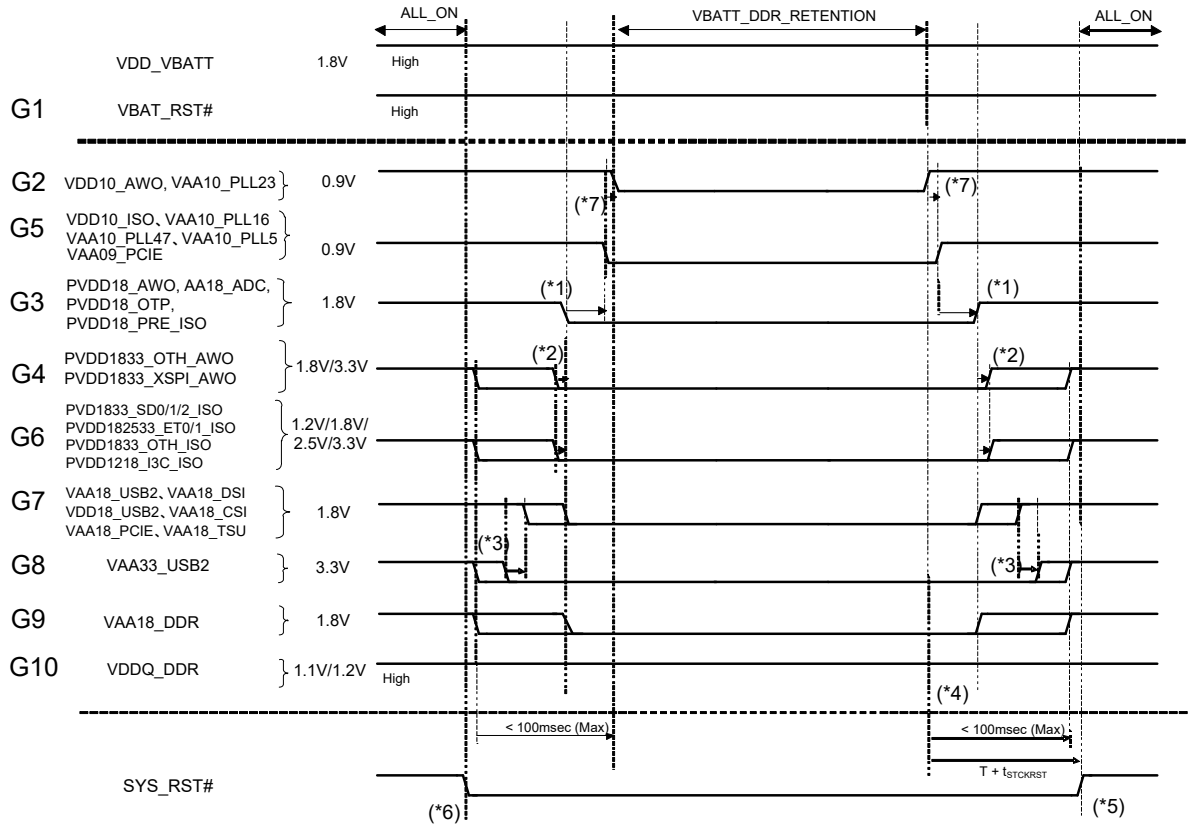
Note 5. SYS_RST# must be deasserted at least (T + $t_{STCKRST}$) after G2 is powered on.

Note 6. SYS_RST# must be changed to Low before powered off.

Note 7. VBAT_RST# must be high after 50 μ sec from VDD_VBATT power on.

Note 8. When power off, VBAT_RST# should be low before or at the same time as VDD_VBATT is powered off.

Figure 10.1-1 Power-On/Power-Off Sequence 1 (All_OFF to ALL_ON, ALL_ON to ALL_OFF)



Note 1. G8 must be powered off before G7 and powered on after G7.

Note 2. The following registers must be written before G6, G7, G8, G9, G10 are powered off and after G6, G7, G8, G9, G10 are powered on.

- SYS_PD_ISO_CTRL
- ISO_IOBUF_SE18_CTRL
- SYS_PWRRDY_N
- CPG_RST_PCI (in CPG)

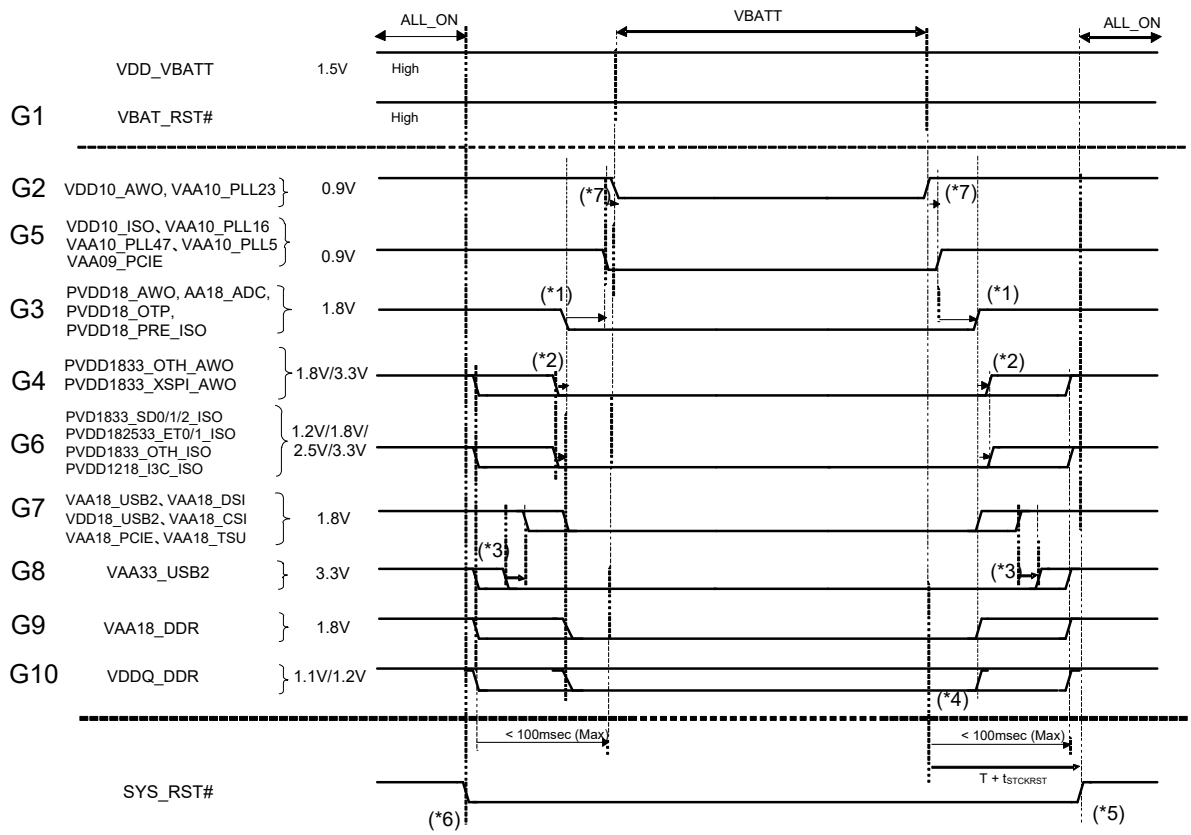
Note 3. G5 must be powered off after G6 to G10 are powered off and powered on before G6 to G10 are powered on.

Figure 10.1-2 Power-On/Power-Off Sequence 2 (ALL_ON to AWO_DDR_RETENTION, AWO_DDR_RETENTION to ALL_ON)

Note 1. G3 must be powered off before G2, G5 and powered on after G2, G5. G3 and G7 can be powered on / off at the same time.

Note 2. G4, G6 must be powered off before G3 and powered on after G3. If G4 voltage is 1.8 V, G4 can be powered on / off along with G3, this also applies to G6.

Note 3. G8 must be powered off before G7 and powered on after G7.



Note 4. It is recommended that all the power domains are powered on or off within approximately 100 msec.

Note 5. SYS_RST# must be deasserted at least (T + $t_{STCKRST}$) after G2 is powered on.

Note 6. SYS_RST# must be changed to Low before powered off.

Note 7. G5 must be powered off before G2 and powered on after G2.

Figure 10.1-3 Power-On/Power-Off Sequence 3 (ALL_ON to VBATT_DDR_RETENTION, VBATT_DDR_RETENTION to ALL_ON)

Note 1. G3 must be powered off before G2, G5 and powered on after G2, G5. G3 and G7 can be powered on / off at the same time.

Note 2. G4, G6 must be powered off before G3 and powered on after G3. If G4 voltage is 1.8 V, G4 can be powered on / off along with G3, this also applies to G6.

Note 3. G8 must be powered off before G7 and powered on after G7.

Note 4. It is recommended that all the power domains are powered on or off within approximately 100 msec.

Note 5. SYS_RST# must be deasserted at least (T + $t_{STCKRST}$) after G2 is powered on.

Note 6. SYS_RST# must be changed to Low before powered off.

Note 7. G5 must be powered off before G2 and powered on after G2.

10.1.4 DC Characteristics

Table 10.1-3 DC Characteristics (1) [GP I/O (1.8/3.3 V)]

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
High-level input voltage		V_{IH}	2	—	—	V	3.3 V mode
Low-level input voltage		V_{IL}	—	—	0.8	V	
Hysteresis threshold ↑		V_T+	2.1	—	—	V	
Hysteresis threshold ↓		V_T-	—	—	0.7	V	
Output logic high voltage	(I_{OH} = –1.9 mA)	V_{OH}	V_{CCQ} – 0.4	—	—	V	
	(I_{OH} = –4 mA)						
	(I_{OH} = –8 mA)						
	(I_{OH} = –9 mA)						
Output logic low voltage	(I_{OL} = 1.9 mA)	V_{OL}	—	—	0.4	V	
	(I_{OL} = 4 mA)						
	(I_{OL} = 8 mA)						
	(I_{OL} = 9 mA)						
High-level input voltage		V_{IH}	1.16	—	—	V	1.8 V mode
Low-level input voltage		V_{IL}	—	—	0.5	V	
Hysteresis threshold ↑		V_T+	1.40	—	—	V	
Hysteresis threshold ↓		V_T-	—	—	0.41	V	
Output logic high voltage	(I_{OH} = –2.2 mA)	V_{OH}	V_{CCQ} − 0.45	—	—	V	
	(I_{OH} = –4.4 mA)						
	(I_{OH} = –9 mA)						
	(I_{OH} = –10 mA)						
Output logic low voltage	(I_{OL} = 2.2 mA)	V_{OL}	—	—	0.45	V	
	(I_{OL} = 4.4 mA)						
	(I_{OL} = 9 mA)						
	(I_{OL} = 10 mA)						
Weak pull-up resistor (input mode)		R_{UP}	10 K	50 K	90 K	Ω	
Weak pull-down resistor (input mode)		R_{DN}	10 K	50 K	90 K	Ω	
Input leakage current		I_{LI}	—	—	10	μA	$0V \le V_{in} \le PV_{DD}$*1 In case of 3state buffer, the leak current when output mode OFF

Note: V_{in} means input voltage of external input pin.

Note 1. PVDD1833_OTH_ISO, PVDD1833_OTH_AWO, PVDD18_PWC

Table 10.1-4 DC Characteristics (2) [SD I/O (1.8/3.3 V)]

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
High-level input voltage		V_{IH}	V_{DDQ} × 0.625	—	—	V	3.3 V mode
Low-level input voltage		V_{IL}	—	—	V_{DDQ} × 0.25	V	
Output logic high voltage	(I_{OH} = –4 mA)	V_{OH}	V_{CCQ} – 0.4	—	—	V	
	(I_{OH} = –6 mA)						
	(I_{OH} = –8 mA)						
	(I_{OH} = –9 mA)						
Output logic low voltage	(I_{OL} = 4 mA)	V_{OL}	—	—	0.4	V	
	(I_{OL} = 6 mA)						
	(I_{OL} = 8 mA)						
	(I_{OL} = 9 mA)						
High-level input voltage		V_{IH}	1.27	—	—	V	1.8 V mode
Low-level input voltage		V_{IL}	—	—	0.58	V	
Output logic high voltage	(I_{OH} = –7 mA)	V_{OH}	V_{CCQ} – 0.45	—	—	V	
	(I_{OH} = –8 mA)						
	(I_{OH} = –9 mA)						
	(I_{OH} = –10 mA)						
Output logic low voltage	(I_{OL} = 7 mA)	V_{OL}	—	—	0.45	V	
	(I_{OL} = 8 mA)						
	(I_{OL} = 9 mA)						
	(I_{OL} = 10 mA)						
Weak pull-up resistor (input mode)		R_{UP}	10 K	50 K	90 K	Ω	3.3 V/1.8 V mode
Weak pull-down resistor (input mode)		R_{DN}	10 K	50 K	90 K	Ω	

Table 10.1-5 DC Characteristics (3) [RGMII (1.8/2.5/3.3 V)]

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
High-level input voltage	V_{IH}	V_{CCQ} × 0.65	—	—	V	3.3 V mode
Low-level input voltage	V_{IL}	—	—	V_{CCQ} × 0.35	V	
Output logic high voltage	V_{OH}	V_{CCQ} – 0.4	—	—	V	
Output logic low voltage	V_{OL}	—	—	0.4	V	
High-level input voltage	V_{IH}	1.7	—	—	V	2.5 V mode
Low-level input voltage	V_{IL}	—	—	0.7	V	
Output logic high voltage	V_{OH}	V_{CCQ} – 0.4	—	—	V	
Output logic low voltage	V_{OL}	—	—	0.4	V	
High-level input voltage	V_{IH}	V_{CCQ} × 0.65	—	—	V	1.8 V mode
Low-level input voltage	V_{IL}	—	—	V_{CCQ} × 0.35	V	
Output logic high voltage	V_{OH}	V_{CCQ} – 0.45	—	—	V	
Output logic low voltage	V_{OL}	—	—	0.45	V	

Table 10.1-6 DC Characteristics (4) [I3C (1.2/1.8 V)]

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
High-level input voltage		V_{IH}	V_{CCQ} × 0.7	—	—	V	1.8 V
Low-level input voltage		V_{IL}	—	—	V_{CCQ} × 0.3	V	I3C Open Drain mode
Output logic low voltage	IOL = 3 mA	V_{OL}	—	—	0.27	V	
High-level input voltage		V_{IH}	V_{CCQ} × 0.7	—	—	V	1.8 V
Low-level input voltage		V_{IL}	—	—	V_{CCQ} × 0.3	V	I2C Open Drain mode*1
Output logic low voltage	IOL = 20 mA	V_{OL}	—	—	0.4	V	
High-level input voltage		V_{IH}	V_{CCQ} × 0.7	—	—	V	1.8 V
Low-level input voltage		V_{IL}	—	—	V_{CCQ} × 0.3	V	I3C CMOS mode
Output logic high voltage	IOL= −3 mA	V_{OH}	V_{CCQ} − 0.27	—		V	
Output logic low voltage	IOL= 3 mA	V_{OL}	—	—	0.27	V	
High-level input voltage		V_{IH}	V_{CCQ} × 0.7	—	—	V	1.2 V
Low-level input voltage		V_{IL}	—	—	V_{CCQ} × 0.3	V	I3C CMOS mode
Output logic high voltage	IOL = −2 mA	V_{OH}	V_{CCQ} − 0.18	—		V	
Output logic low voltage	IOL = 2 mA	V_{OL}	—	—	0.18	V	

Note 1. fast-mode, fast-mode plus

Table 10.1-7 DC Characteristics (5) [Input (Schmitt/1.8 V)]

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
High-level input voltage	V_{IH}	V_{CCQ} × 0.75	—	—	V	
Low-level input voltage	V_{IL}	—	—	V_{CCQ} × 0.25	V	

Table 10.1-8 DC Characteristics (6) [Input (3.3 V tolerant/Schmitt)]

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
High-level input voltage	V_{IH}	V_{CCQ} × 0.75	—	—	V	
Low-level input voltage	V_{IL}	—	—	V_{CCQ} × 0.25	V	

Table 10.1-9 DC Characteristics (7) [USB 2.0]

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
Input levels for low/full speed						
High (driven)	V_{IH}	2.0	—	—	V	
Low	V_{IL}	—	—	0.8	V	
Differential input sensitivity	V_{DI}	0.2	—	—	V	
Differential common mode range	V_{CM}	0.8	—	2.5	V	
Input levels for high speed						
High-speed squelch detection threshold (differential signal amplitude)	V_{HSSQ}	100	—	150	mV	
High-speed data signaling common mode voltage range (guideline for receiver)	V_{HSCM}	−50	—	500	mV	
Output levels for low/full speed						
Low	V_{OL}	0.0	—	0.3	V	
High (driven)	V_{OH}	2.8	—	3.6	V	
Output signal crossover voltage	V_{CRS}	1.3	—	2.0	V	
Output levels for high-speed						
High-speed idle level	V_{HSOI}	−10.0	—	10.0	mV	
High-speed data signaling high	V_{HSOH}	360	—	440	mV	
High-speed data signaling low	V_{HSOL}	−10.0	—	10.0	mV	
Chirp J level (differential voltage)	V_{CHIRPJ}	700	—	1100	mV	
Chirp K level (differential voltage)	V_{CHIRPK}	−900	—	−500	mV	

Table 10.1-10 DC Characteristics (8) [ADC]

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
Resolution	—	—	12	—	Bit	
Analog input channel	—	—	—	8	Channel	
Analog input range	AIN	V_{SS}	—	ADC_AV_{DD18}	V	
Differential non-linearity	DNL	—	—	±3.0	LSB	
Integral non-linearity	INL	—	—	±6.0	LSB	
Full-scale error	—	—	±10	±20	LSB	
Offset error	—	—	±10	±20	LSB	
Analog input capacitance	C_{IN}	—	—	7.2	pF	
Analog input resistance	R_{IN}	—	—	1755	Ω	
External capacitance	C_{EXT}	—	—	(*1)	pf	
External resistance	R_{EXT}	—	—	(*1)	Ω	

Note 1. Refer to **Figure 10.1-5** for Cext and Rext.
The Cext and Rext need to satisfy the sampling time.
A/D conversion time = sampling time (71T to 255T) + 29T.
T stands for the cycle of ADIVCLK (100 MHz).
If A/D conversion is performed with the minimum conversion time, the sampling time must be 71T.
(Minimum conversion time per channel is 1 µs when A/D conversion clock ADIVCLK is 100 MHz.)

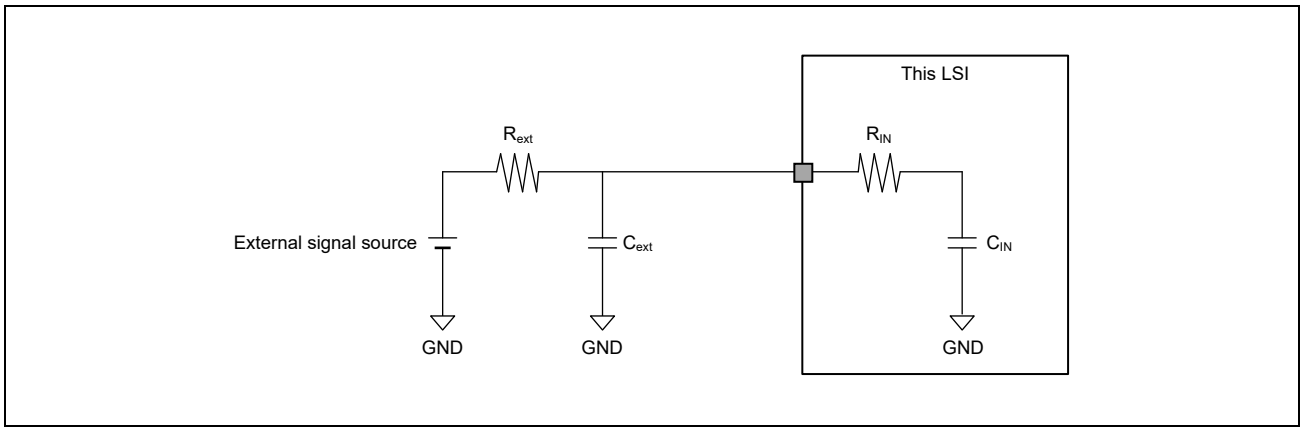

Figure 10.1-5 Analog Input Equivalent Circuit

Table 10.1-11 DC Characteristics (9) [Current Consumption]

Item	Power Rail Symbol	Max Current	Unit	Remarks
Power Supply Voltage (VBATT)	VDD_VBATT	10	mA	
Power Supply Voltage (Core)	VDD10_AWO	300	mA	
Power Supply Voltage (ISO)	VDD10_ISO	4200	mA	Condition: Cortex-A55, Dhrystone

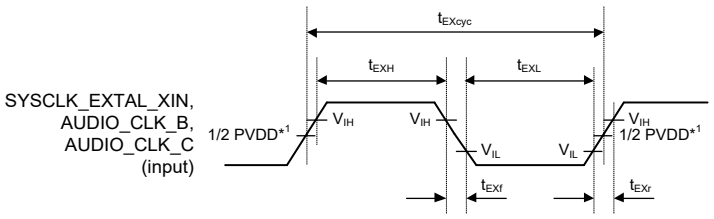
Power Supply Voltage (DDR)	VAA18_DDR	10	mA	
Power Supply Voltage (DDR) (DDR4)	VDDQ_DDR	300	mA	
Power Supply Voltage (DDR) (LPDDR4)	VDDQ_DDR	300	mA	

Note: T_j = 125°C, Power supply voltage = Max.

10.1.5 AC Characteristics

Conditions: VDD_VBATT = 1.50 to 1.95 V, VDD10_AWO = VAA10_PLL23 = 0.97 to 1.05 V,
PVDD18_AWO = VAA18_ADC = VAA18_OTP = PVDD18_PRE_ISO = 1.65 to 1.95 V,
PVDD1833_OTH_AWO = PVDD1833_XSPI_AWO = 1.65 to 1.95 V / 3.0 to 3.6 V,
VDD10_ISO = VAA10_PLLn (n=16, 47, 5) = 0.97 to 1.05 V, VAA09_PCIE = 0.89 to 0.99 V,
PVDD1833_SDn_ISO (n=0 to 2) = PVDD1833_OTH_ISO = 1.65 to 1.95 V / 3.0 to 3.6 V,
PVDD1218_I3C_ISO = 1.10 to 1.30 V / 1.65 to 1.95 V,
PVDD182533_ETn_ISO (n=0, 1) = 1.65 to 1.95 V / 2.3 to 2.7 V / 3.0 to 3.6 V,
VAA18_PCIE = VAA18_DSI = VAA18_CSI = VAA18_TSU = VAA18_USB2 = VDD18_USB2 = VAA18_DDR = 1.65 to 1.95 V,
VAA33_USB2 = 3.0 to 3.6 V, VDDQ_DDR = 1.06 to 1.17 V(LPDDR4) / 1.14 to 1.26 V (DDR4),
AVSS_USB2 = AVSS_ADC = AVSS_TSU = 0 V, VSS = 0 V, T_a = −40 to +85°C, T_j = −40 to +125°C

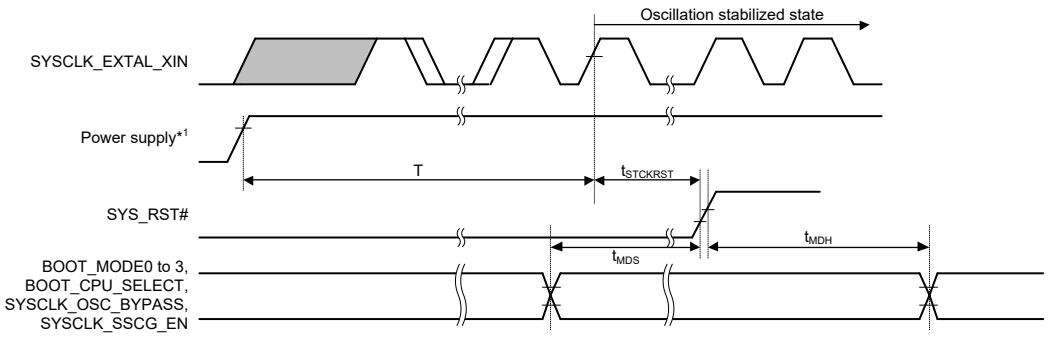


10.1.5.1 Clock Timing

Table 10.1-12 Clock Timing Table

Item	Symbol	Min.	Max.	Unit	Figures
SYSCLK_EXTAL_XIN clock input frequency	f_{EX}	24 – 50ppm*1	24 + 50ppm*1	MHz	**Figure 10.1-6**
SYSCLK_EXTAL_XIN clock input cycle time	t_{EXcyc}	41.67	41.67	ns	
AUDIO_CLK_B, AUDIO_CLK_C clock input frequency (external clock is input)	f_{EX}	10	50	MHz	
AUDIO_CLK_B, AUDIO_CLK_C clock input cycle time (external clock is input)	t_{EXcyc}	20	100	ns	
SYSCLK_EXTAL_XIN, AUDIO_CLK_B, AUDIO_CLK_C clock input low level pulse width	t_{EXL}	0.4	0.6	t_{EXcyc}	
SYSCLK_EXTAL_XIN, AUDIO_CLK_B, AUDIO_CLK_C clock input high level pulse width	t_{EXH}	0.4	0.6	t_{EXcyc}	
SYSCLK_EXTAL_XIN, AUDIO_CLK_B, AUDIO_CLK_C clock input rise time	t_{EXr}	—	4	ns	
SYSCLK_EXTAL_XIN, AUDIO_CLK_B, AUDIO_CLK_C clock input fall time	t_{EXf}	—	4	ns	
Oscillator stabilization time	T	(*2)	—	ms	**Figure 10.1-7**, **Figure 10.1-8**
SYSCLK stabilization to SYS_RST# deassertion	$t_{STCKRST}$	1	—	µs	
Mode hold time	t_{MDH}	12	—	µs	
Mode setup time	t_{MDS}	0	—	µs	

Note 1. When using RGMII interface. If not using RGMII mode, this spec is ±100 ppm.



Note 2. The oscillation stabilization time differs according the matching with the external resonator circuit. It is recommended to determine the oscillation stabilization time by a crystal resonator matching test. For details of the stabilization time “T”, please contact the crystal manufacture.

Note: When the clock is input on the SYSCLK_EXTAL_XIN, AUDIO_CLK_B or AUDIO_CLK_C

Note 1. SYSCLK_EXTAL_XIN: PVDD18_AWO,
AUDIO_CLK_B, C: PVDD1833_OTH_AWO, PVDD1833_OTH_ISO, PVDD1833_SDn_ISO(n = 1, 2) or PVDD182533_ET1_ISO

Figure 10.1-6 EXCLK, AUDIO_CLK1 and AUDIO_CLK2 Clock Input Timing

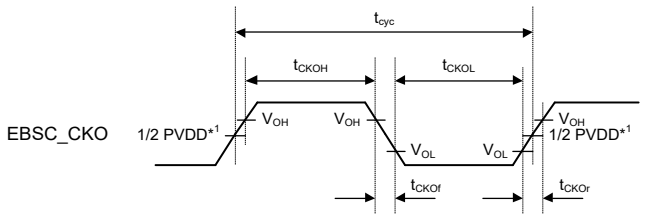
10.1.5.4 DDR Interface Characteristics

The LPDDR4/DDR4 interface of this LSI is compliant with the JESD209-4E/JESD79-4D standard.

10.1.5.5 External Bus State Controller Timing

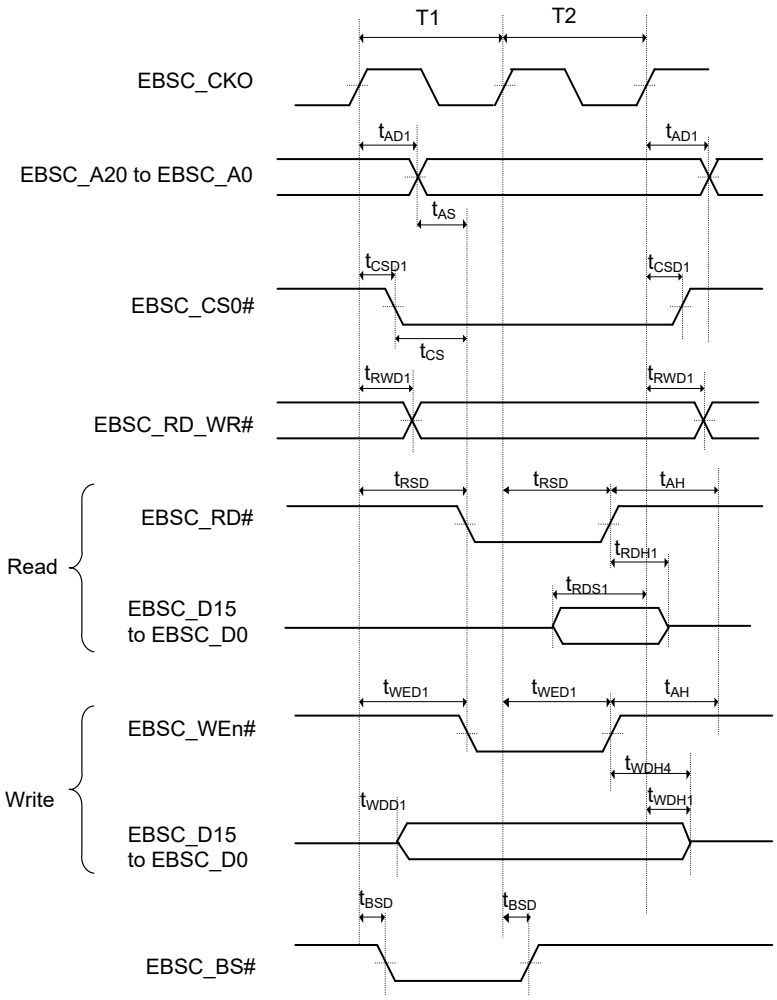
Table 10.1-16 External Bus State Controller Timing



Item	Symbol	EBSC_CKO = 133 MHz*1		Unit	Figure
		Min.	Max.		
EBSC_CKO clock output cycle time	t_{cyc}	7.5	—	ns	**Figure 10.1-16**
EBSC_CKO clock output rise time	t_{CKOr}	—	1	ns	
EBSC_CKO clock output fall time	t_{CKOf}	—	1	ns	
EBSC_CKO clock output low pulse width	t_{CKOL}	1/2 t_{cyc} − t_{CKOr}	—	ns	
EBSC_CKO clock output high pulse width	t_{CKOH}	1/2 t_{cyc} − t_{CKOf}	—	ns	
Address delay time 1	t_{AD1}	−1.8	1.8	ns	**Figure 10.1-17** to **Figure 10.1-22**
Address setup time	t_{AS}	1/2 t_{cyc} − 2	—	ns	**Figure 10.1-17** to **Figure 10.1-20**
Chip enable setup time	t_{CS}	1/2 t_{cyc} – 2	—	ns	
Address hold time	t_{AH}	1/2 t_{cyc} – 2	—	ns	
BS delay time	t_{BSD}	—	1.8	ns	**Figure 10.1-17** to **Figure 10.1-22**
CS delay time 1	t_{CSD1}	−1.8	1.8	ns	
Read write delay time 1	t_{RWD1}	−1.8	1.8	ns	
Read strobe delay time	t_{RSD}	1/2 t_{cyc} – 1.5	1/2 t_{cyc} + 1.5*3	ns	
Read data setup time 1	t_{RDS1}	1/2 t_{cyc} + 5*3	—	ns	
Read data hold time 1	t_{RDH1}	0	—	ns	
Write enable delay time 1	t_{WED1}	1/2 t_{cyc} – 1.5	1/2 t_{cyc} + 1.5*3	ns	**Figure 10.1-17** to **Figure 10.1-21**
Write enable delay time 2	t_{WED2}	—	—	ns	**Figure 10.1-22**
Write data delay time 1	t_{WDD1}	—	1.8	ns	**Figure 10.1-17** to **Figure 10.1-22**
Write data hold time 1	t_{WDH1}	−1.8	—	ns	
Write data hold time 4	t_{WDH4}	1/2 t_{cyc} − 2	—	ns	**Figure 10.1-17** to **Figure 10.1-20**
WAIT setup time	t_{WDS}	1/2 t_{cyc} + 5*3	—	ns	**Figure 10.1-18** to **Figure 10.1-22**
WAIT hold time	t_{WTH}	1/2 t_{cyc} + 3.5*3	—	ns	

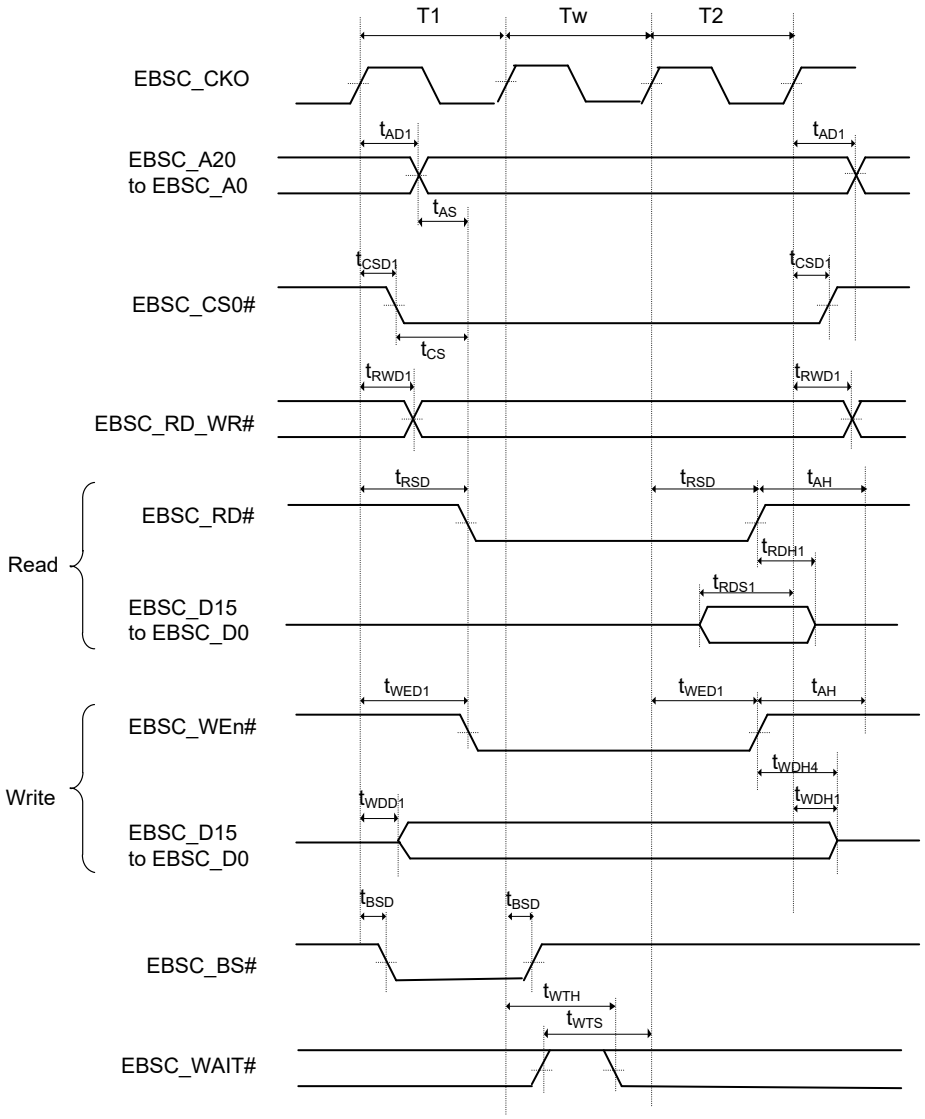
Note: AC access timing condition: drive ability IOLH_xx{1:0} = 11b

Note 1. The maximum value (fmax) of EBSC_CKO (external bus clock) depends on the number of wait cycles and the system configuration of your board.



Note 2. 1/2 t_{cyc} indicated in minimum and maximum values for the item of delay, setup, and hold times represents a half cycle from the rising edge with a clock. That is, 1/2 t_{cyc} describes a reference of the falling edge with a clock.

Note 3. Suitable wait cycles need to be set with CS0WCR register to response to connected device and operation frequency.



Note 1. PVDD1833_OTH_ISO, PVDD182533_ET0_ISO, PVDD182533_ET0_ISO

DS Tri-state to CS low		t_{DSTCSL}	0.0	—	0.0	—	ns	

Remarks: CK: XSPI_CKP
DS: XSPI_DS
CS: XSPI_CS0#, XSPI_CS1#

Note 1. The DS shift setting (WRAPCFG.DSSFTCSx[4:0]) is 0_1000b for xSPI200.

Note 2. Specification at 133 MHz / Specification at 100 MHz

Note 3. These are values when the OEN assertion and deassertion are extended in the Output Enable Asserting extension bit (COMCFG.OEASTEX = 1b1) and Output Enable Negating extension bit (COMCFG.OENEGEX = 1b1).

Note 4. These are values when the CS assertion and deassertion are extended in the CS asserting extension bit (LIOCFGCSn.CSASTEX = 1b1) and CS negating extension bit (LIOCFGCSn.CSNEGEX = 1b1).

Note 5. The standard value for xSPI266 is 0.8 ns.

Note 6. When IOLH register is 10b or more.

Note 7. If the DS is high during the command & modifier phase when using JESD251 Profile 2.0 memory, the time from CS low to DS high must also meet this specification.

Note 8. When using JESD251 Profile 1.0 memory or JESD251 Profile 2.0 memory with LIOCFGCSn.LATEMD set to 0, this constraint does not apply if the internal pull-down resistor of the DS pin is enabled.

10.1.5.19 Renesas IIC Bus Interface (RIIC) Access Timing

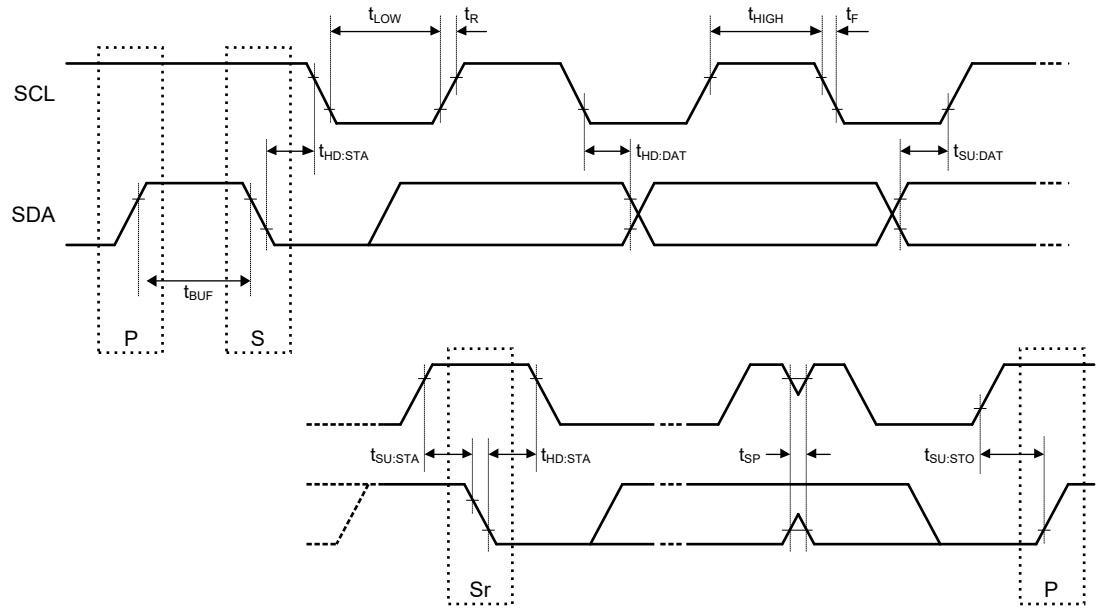
Table 10.1-39 I²C Bus Interface Timing

Item	Symbol	Input/ Output	Standard Mode (Sm)		Fast Mode (Fm)		Fast Mode Plus (Fm+)		Unit
			Min.	Max.	Min.	Max.	Min.	Max.	
SCL clock frequency	f_{CLK}	I/O	0	100	0	400	0	1000	kHz
Bus free time (between stop and start condition)	t_{BUF}	I/O	4.7	—	1.3	—	0.5	—	µs
Hold time*1	$t_{HD:STA}$	I/O	4.0	—	0.6	—	0.26	—	µs
Low period of SCL clock	t_{LOW}	I/O	4.7	—	1.3	—	0.5	—	µs
High period of SCL clock	t_{HIGH}	I/O	4.0	—	0.6	—	0.26	—	µs
Setup time for start / restart condition	$t_{SU:STA}$	I/O	4.7	—	0.6	—	0.26	—	µs
Data hold time (I²C bus device)	$t_{HD:DAT}$	I/O	0*2	—	0*2	—	0	—	µs
Data setup time	$t_{SU:DAT}$	I/O	250	—	100*3	—	50	—	ns
SDA and SCL signal rise time	t_R	Input	—	1000	—*6	300	—*6	120	ns
SDA and SCL signal fall time*3	t_F	Input	—	300	—*6	300	—*6	120	ns
		Output	—	300	—*6	300	—*6	120	ns
Setup time for STOP condition	$t_{SU:STO}$	I/O	4.0	—	0.6	—	0.26	—	µs
Capacitive load for each bus line	C_b	—	—	400*4	—	400*4	—	550*4	pF
Pulse width of spikes that must be suppressed by the input filter	t_{SP}	Input	—	—	0	50*5	0	50*5	ns

Note: In the above table and subsequently, SCL and SDA refer to the RIICn_SCL and RIICn_SDA (n = 0 to 3) signals, respectively.

Note: AC access timing condition: drive ability IOLH_xx[1:0] = 11b, output load 400 pF

Note 1. The first clock pulse is generated on the SCL line after the start condition has been issued and the hold time has elapsed.



Note 2. This module requires a minimum of 300 ns hold time internally for the SDA signal to handle the period over which the falling edge of SCL has not reached a defined level (time until the CnSCL signal reaches V_{IL} (max.) from V_{IH} (min.)).

Note 3. The fast-mode I²C bus device can be used in the standard mode I²C bus system. In this case, the minimum value of the data setup time ($t_{SU:\,DAT}$ (min.) 250 [ns]) must be satisfied.
If the system does not extend the low period of SCL clock (t_{LOW}), this condition is automatically satisfied. If the system extends the low period of SCL clock (t_{LOW}), transmit the subsequent data bit to the SDA line before the SCL line is released (t_R (max.) + $t_{SU:\,DAT}$ (min.) = 1000 + 250 = 1250 [ns]: (standard mode I²C bus specification)).

Note 4. Total capacitance of one bus line. The allowable maximum bus capacitance may differ from this specification, depending on the actual operating voltage and frequency of an application. For techniques to cope with a large bus capacitance, see the I²C bus specification provided by NXP Semiconductors.

Note 5. Noise is removed by the analog and digital input filters. The level of noise reduction of the digital input filter is determined by the period of internal reference clock (IICϕ) and the NF[1:0] bits in RIICnMR3. For details, refer to **7.7 I²C Bus Interface**.

Note 6. The minimum values are not specified for t_R and t_F in Fast-mode or Fast-mode Plus.

Note: P: Stop condition
S: Start condition
Sr: Start condition for retransmission

Figure 10.1-64 Input/Output Timing

10.1.5.20 I3C Timing

Table 10.1-40 Characteristics of the SDA and SCL Bus Lines for Standard, Fast, and Fast-Mode Plus I²C-Bus Devices*1

Item	Symbol	Conditions	Standard-Mode		Fast-Mode		Fast-Mode Plus		Unit
			Min.	Max.	Min.	Max.	Min.	Max.	
SCL clock frequency	f_{SCL}		0	100	0	400	0	1000	kHz
Hold time (repeated) START condition	$t_{HD:STA}$	After this period,the first clock pulse is generated	4.0	—	0.6	—	0.26	—	µs
LOW period of the SCL clock	t_{LOW}		4.7	—	1.3	—	0.5	—	µs
HIGH period of the SCL clock	t_{HIGH}		4.0	—	0.6	—	0.26	—	µs
Setup time for a repeated START condition	$t_{SU:STA}$		4.7	—	0.6	—	0.26	—	µs
Data hold time*2	$t_{HD:DAT}$	I²C-bus device	0 *3	—*4	0*3	—*4	0	—	µs
Data setup time	$t_{SU:DAT}$		250	—	100	—	50	—	ns
Rise time of both SDA and SCL signals	t_r		—	1000	20	300	—	120	ns
Fall time of both SDA and SCL signals*3,*6,*7	t_f		—	300	20 × (I3C_PV$_{DD}$/ 5.5 V)	300	20 × (I3C_PV$_{DD}$/ 5.5 V)*8	120*7	ns
Setup time for STOP condition	$t_{SU:STO}$		4.0	—	0.6	—	0.26	—	µs
Bus free time between a STOP and START condition	t_{BUF}		4.7	—	1.3	—	0.5	—	µs

Note 1. All values referred to V_{IH}(min) (0.3 × I3C_PV$_{DD}$) and V_{IL}(max) (0.7 × I3C_PV$_{DD}$) levels, refer to **Table 10.1-6**.

Note 2. $t_{HD:DAT}$ is the data hold time that is measured from the falling edge of SCL, applies to data in transmission and the acknowledge.

Note 3. A device must internally provide a hold time of at least 300 ns for the SDA signal (with respect to the V_{IH}(min) of the SCL signal) to bridge the undefined region of the falling edge of SCL.

Note 4. The maximum $V_{HD:DAT}$ could be 3.45 µs and 0.9 µs for Standard mode and Fast mode, but must be less than the maximum of $t_{VD:DAT}$ or $t_{VD:ACK}$ by a transition time. This maximum must only be met if the device does not stretch the LOW period () of the SCL signal. If the clock stretches the SCL, the data must be valid by the setup time before it releases the clock.

Note 5. A Fast-mode I²C-bus device can be used in a Standard-mode I²C-bus system, but the requirement $t_{SU:DAT}$ 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line t_r(max) + $t_{SU:DAT}$ = 1000 + 250 = 1250 ns (according to the Standard-mode I²C-bus specification) before the SCL line is released. Also the acknowledge timing must meet this set-up time.

Note 6. The maximum t_f for the SDA and SCL bus lines is specified at 300 ns. The maximum fall time for the SDA output stage t_f is specified at 250 ns. This allows series protection resistors to be connected in between the SDA and the SCL pins and the SDA/SCL bus lines without exceeding the maximum specified t_f.

Note 7. In Fast-mode Plus, fall time is specified the same for both output stage and bus timing. If series resistors are used, designers should allow for this when considering bus timing.

Note 8. Necessary to be backwards compatible to Fast-mode.

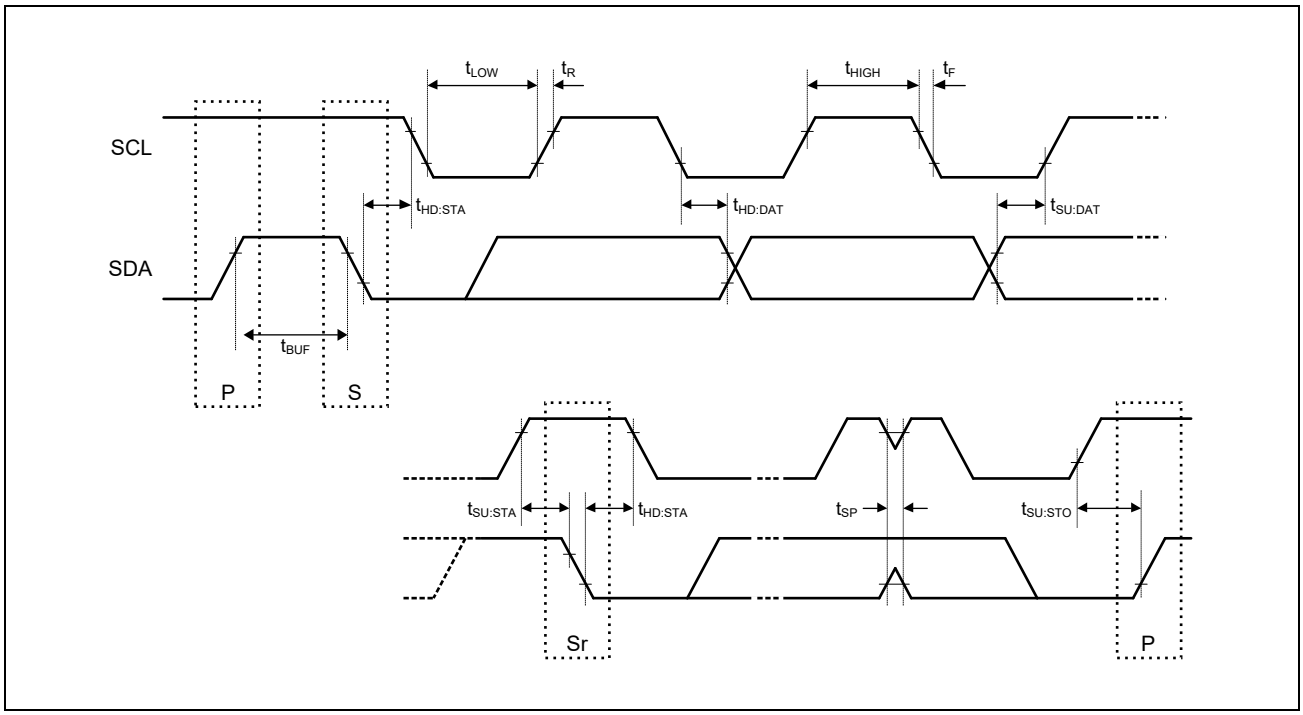


Figure 10.1-65 Input/Output Timing

Table 10.1-41 I3C Open Drain Timing Parameters

Item	Symbol	I3C Open Drain Mode			Figures	Notes
		Min.	Max.	Unit		
Low Period of SCL Clock	t_{LOW_OD}	200	—	ns	**Figure 10.1-69**	*1, *2
	$t_{DIG_OD_L}$	t_{LOW_ODmin} + t_{fDA_ODmin}	—	ns	**Figure 10.1-69**	
High Period of SCL Clock	t_{HIGH}	—	41	ns	**Figure 10.1-67**	*3, *4
	t_{DIG_H}	—	t_{HIGH} + t_{CF}	ns	**Figure 10.1-67**, **Figure 10.1-76**	
Fall Time of SDA Signal	t_{fDA_OD}	t_{CF}	12	ns	**Figure 10.1-69**	
SDA Data Setup Time During Open Drain Mode	t_{SU_OD}	13.5 (1.8V) 18.5 (1.2V)	—	ns	**Figure 10.1-68**, **Figure 10.1-69**	*1
Clock After START(S) Condition	t_{CAS}	38.4 nano	For ENTAS0: 1 µ For ENTAS1: 100 µ For ENTAS2: 2 milli For ENTAS3: 50 milli	seconds	**Figure 10.1-69**	*5, *6
Clock Before STOP(P) Condition	t_{CBP}	t_{CASmin}/2	—	seconds	**Figure 10.1-70**	
Current Master to secondary Master Overlap time during handoff	$t_{MMOverlap}$	$t_{DIG_OD_Lmin}$	—	ns	**Figure 10.1-75**	
Bus Available Condition	t_{AVAL}	1	—	µs	—	*7
Bus Idle Condition	t_{IDLE}	200	—	µs	—	
Time Internal Where New Master Not Driving SDA Low	t_{MMLock}	$t_{AVALmin}$	—	µs	**Figure 10.1-75**	

Note 1. This is approximately equal to t_{LOWmin} + t_{DS_ODmin} + t_{rDA_ODtyp} + t_{SU_ODmin}.

Note 2. The Master may use a shorter low period if it knows that this is safe, i.e., that SDA is already above V_{IH}.

Note 3. Based on t_{SPIKE}, rise and fall times, and interconnect.

Note 4. This maximum High period may be exceeded when the signals can be safely seen by Legacy I^2C Devices, and/or in consideration of the interconnect (e.g., a short bus).

Note 5. On a Legacy Bus where I^2C Devices need to see Start, the t_{CAS}(min) value is further constrained.

Note 6. Slaves that do not support the optional ENTASx CCCs shall use the t_{CAS}(max) value shown for ENTAS3.

Note 7. On a Mixed Bus with Fm Legacy I^2C Devices, t_{AVAL} is 300 ns shorter than the Fm Bus Free Condition time (t_{BUF}).

	Slave	t_{HD_PP}	0	—	—	**Figure 10.1-73**	*6
SDA Signal Data Setup in Push-Pull Mode		t_{SU_PP}	13.5 (1.8V) 18.5 (1.2V)	N/A	ns	**Figure 10.1-71, Figure 10.1-72**	—
Clock After Repeated START (Sr)		t_{CASr}	t_{CASmin}	N/A	ns	**Figure 10.1-74**	—
Clock Before Repeated START (Sr)		t_{CBSr}	t_{CASmin} / 2	N/A	ns	**Figure 10.1-74**	—
Capacitive Load per Bus Line (SDA/SDL)		C_b	—	50	pF	—	—

Note 1. FSCL = 1 / (t_{DIG_L} + t_{DIG_H})

Note 2. t_{DIG_L} and t_{DIG_H} are the clock low and high periods as seen at the receiver end of the I3C bus using V_{IL} and V_{IH} (see **Figure 10.1-66**).

Note 3. When communicating with an I3C Device on a mixed Bus, the $t_{DIG_H_MIXED}$ period must be constrained in order to make sure that I^2C Devices do not interpret I3C signaling as valid I^2C signaling.

Note 4. As both edges are used, the hold time needs to be satisfied for the respective edges; i.e., t_{CF} + 3 for falling edge clocks, and t_{CR} + 3 for rising edge clocks.

Note 5. The clock maximum rise/fall time is capped at 60 ns. For lower frequency rise and fall the maximum value is limited at 60 ns, and is not dependent upon the clock frequency.

Note 6. t_{HD_PP} is a Hold time parameter for Push-Pull Mode that has a different value for Master mode vs. Slave mode. In SDR Mode the Hold time parameter is referred to as t_{HD_SDR}.

Note 7. Devices with more than 12 ns of t_{SCO} delay shall set the limitation bit in the BCR, and shall support the GETMXDS CCC to allow the Master to read this value and adjust computations accordingly. For purposes of system design and test conformance, this parameter should be considered together with pad delay, bus capacitance, propagation delay, and clock triggering points.

Note 8. Pad delay based on 50 pF load. Note that Master may be a Slave in a multi-Master system, and thus shall also adhere to this requirement.

10.1.5.21 CANFD Interface Access Timing

Table 10.1-43 CANFD Interface Timing

Parameter		Symbol	CAN		CANFD		Unit	Figures
			Min.	Max.	Min.	Max.		
CANFD	Internal delay time	t_{node}*1	—	100	—	50	ns	**Figure 10.1-77**
	Transmission rate	—	—	1	—	8	Mbps	

Note: AC access timing condition: drive ability IOLH_xx[1:0] = 10b, output load 30 pF

Note 1. Internal delay time (t_{node}) = Internal transfer delay time (t_{output}) + Internal receive delay time (t_{input})

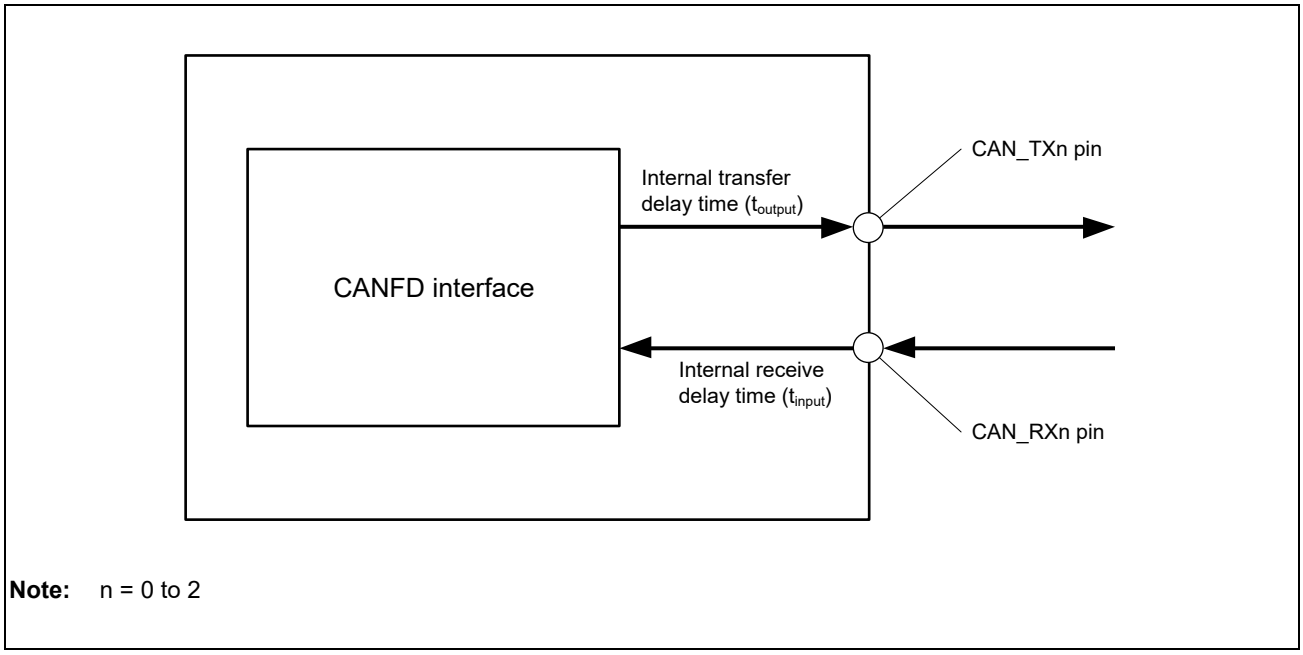

Figure 10.1-77 CANFD Interface Condition

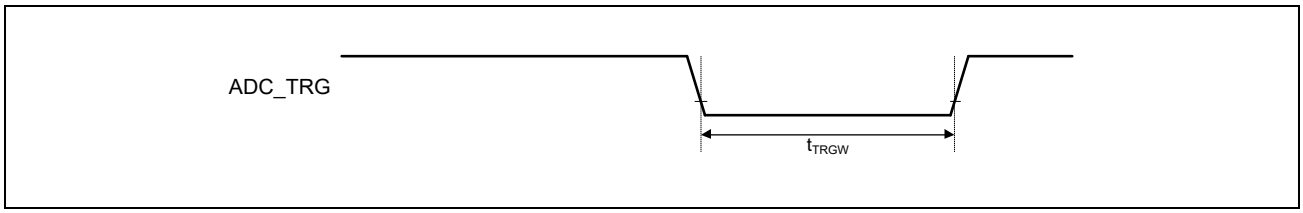
10.1.5.22 A/D Converter Access Timing

Table 10.1-44 A/D Converter Trigger Timing

Item	Symbol	Min.	Max.	Unit	Figure
A/D converter trigger input pulse width	t_{TRGW}	1.5*2	—	t_{P1cyc}*1	**Figure 10.1-78**

Note 1. t_{p1cyc} indicates peripheral clock means ADCn_ADCLK (P20ϕ)(n = 0,1).

Note 2. When a noise filter in ADC is off.



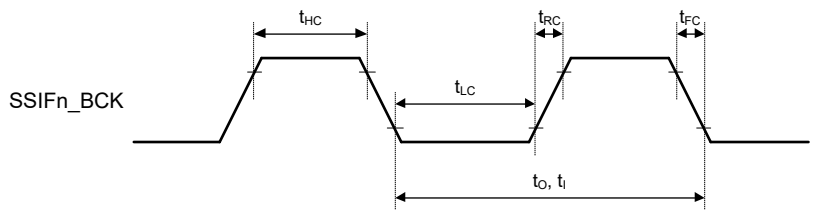


Figure 10.1-78 ADC Trigger Input Timing

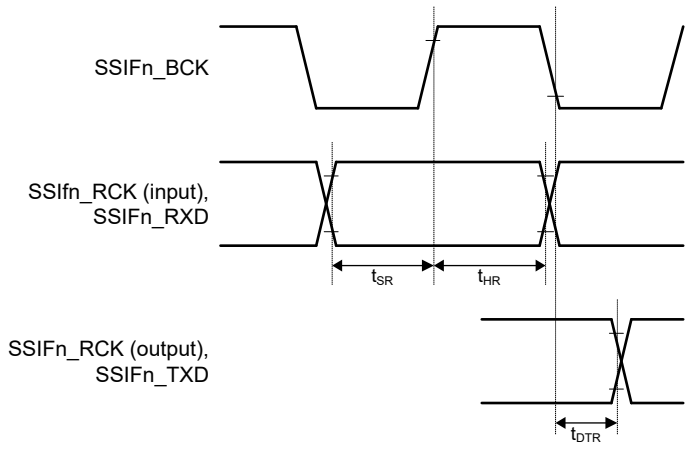
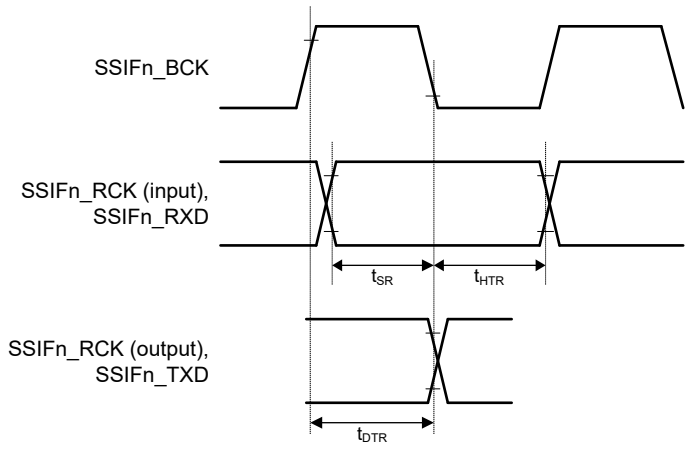
10.1.5.23 Serial Sound Interface (SSIF-2) Access Timing

Table 10.1-45 SSIF-2 Timing



Item	Input/Output	Symbol	Min.	Max.	Unit	Figures
Output clock cycle	Output	t_O	80	64000	ns	**Figure 10.1-79**
Input clock cycle	Input	t_I	80	—	ns	
Clock high	Bidirectional	t_{HC}	32	—	ns	
Clock low		t_{LC}	32	—	ns	
Clock rise time/clock fall time	Output	t_{RC}/t_{FC}	—	25	ns	
Setup time	Input	t_{SR}	25	—	ns	**Figure 10.1-80** to **Figure 10.1-82**
Hold time		t_{HR}	5	—	ns	
SILRCK output delay time	Output	t_{DTR}	−5	25	ns	
Data output delay time (Noise canceler not in use)		t_{DTR}	−5	25	ns	
Data output delay time (Noise canceler in use)		t_{DTR}	10	50	ns	

Note: AC access timing condition: drive ability IOLH_xx[1:0] = 10b, output load 30 pF



Note: n = 0 to 3

10.1.5.25 MIPI CSI-2 PHY Characteristics

The MIPI CSI-2 Rx D-PHY of this LSI is equivalent to the MIPI D-PHY Version 2.1.

For details, refer to the MIPI specification.

10.1.5.26 MIPI DSI Tx D-PHY Characteristics

The MIPI DSI Tx D-PHY of this LSI is compliant with the MIPI D-PHY Version 2.1.

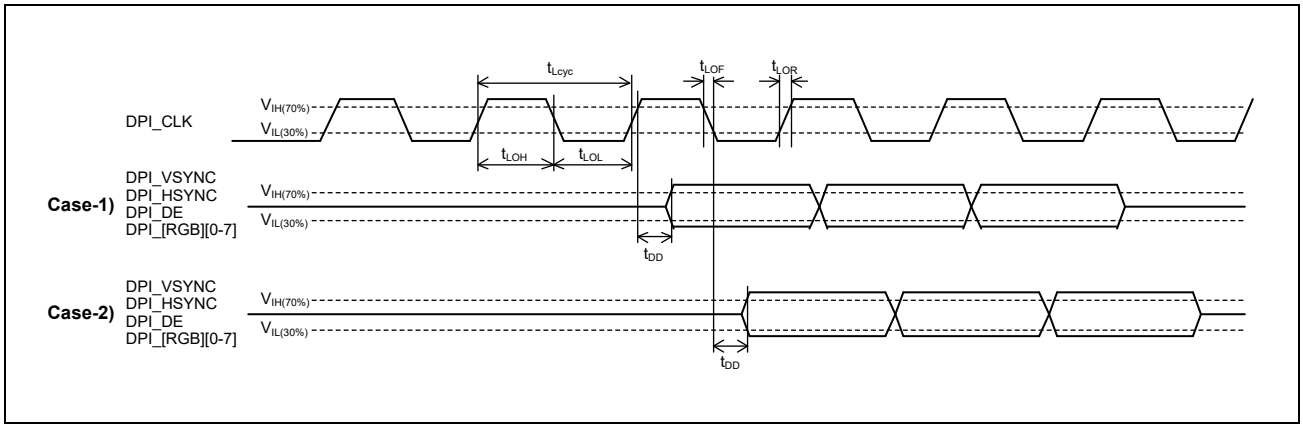
For details, refer to the MIPI specification.

10.1.5.27 LCDC Access Timing

Table 10.1-48 LCDC IF Timing

Parameter	Symbol	Min.	Typ.	Max.	Unit
DPI_CLK period	t_{Lcyc}	11.49	—	185.19	ns
DPI_CLK low pulse width	t_{LOL}	$t_{Lcyc}/2 - 1.06$	—	$t_{Lcyc}/2 + 1.06$	ns
DPI_CLK high pulse width	t_{LOH}	$t_{Lcyc}/2 - 1.06$	—	$t_{Lcyc}/2 + 1.06$	ns
DPI_CLK rise time	t_{LOR}	—	—	3	ns
DPI_CLK fall time	t_{LOF}	—	—	3	ns
Data output dealy	t_{DD}	−1.5	—	1.5	ns

Note: AC access timing condition: drive ability IOLH_xx[1:0] = 10b, output load 30 pF



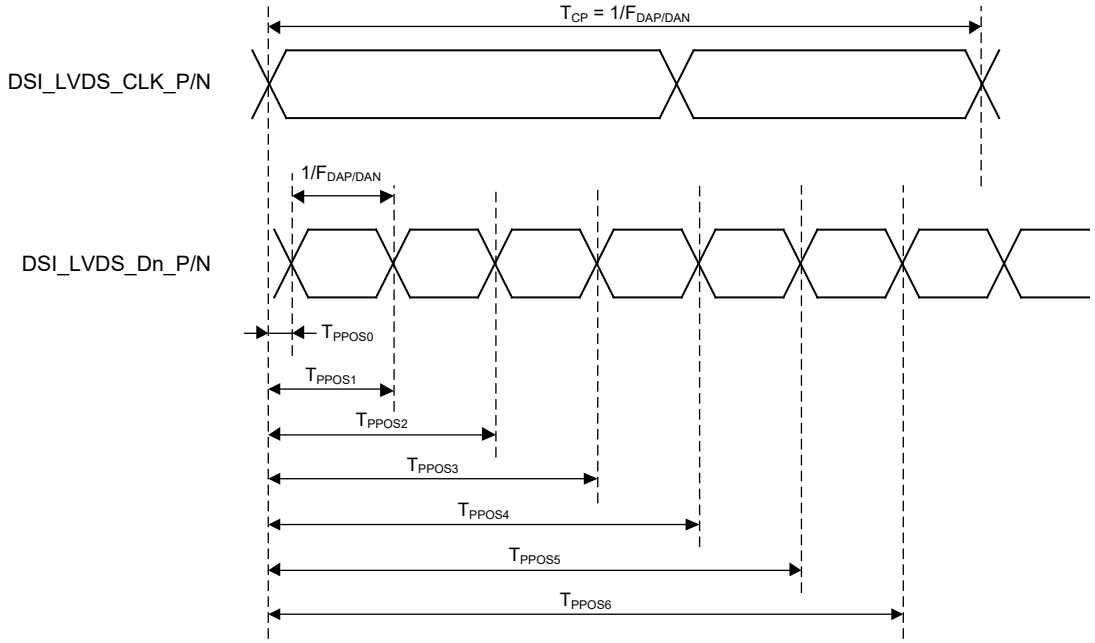


Figure 10.1-86 LCDC AC Access Timing

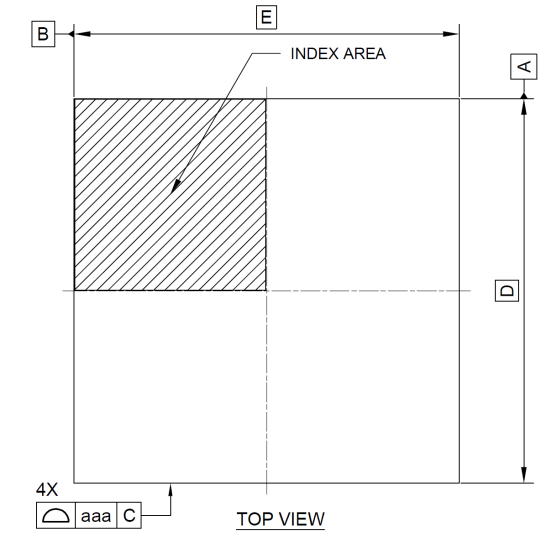
10.1.5.28 LVDS Interface Access Timing

Table 10.1-49 LVDS IF Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Figures
Output Clock Frequency of LVDS	$F_{CLKP/CLKN}$	25	—	87	MHz	**Figure 10.1-87**
Output Clock of LVDS	T_{CP}	11.494	—	40	ns	
Output Data Rate of LVDS	$F_{DAP/DAN}$	175	—	609	Mbps	
LVDS Output Pulse Position 0	T_{PPOS0}	−0.200	0	0.200	ns	
LVDS Output Pulse Position 1	T_{PPOS1}	$(T_{CP}/7) - 0.200$	$(T_{CP}/7)$	$(T_{CP}/7) + 0.200$	ns	
LVDS Output Pulse Position 2	T_{PPOS2}	$2(T_{CP}/7) - 0.200$	$2(T_{CP}/7)$	$2(T_{CP}/7) + 0.200$	ns	
LVDS Output Pulse Position 3	T_{PPOS3}	$3(T_{CP}/7) - 0.200$	$3(T_{CP}/7)$	$3(T_{CP}/7) + 0.200$	ns	
LVDS Output Pulse Position 4	T_{PPOS4}	$4(T_{CP}/7) - 0.200$	$4(T_{CP}/7)$	$4(T_{CP}/7) + 0.200$	ns	
LVDS Output Pulse Position 5	T_{PPOS5}	$5(T_{CP}/7) - 0.200$	$5(T_{CP}/7)$	$5(T_{CP}/7) + 0.200$	ns	
LVDS Output Pulse Position 6	T_{PPOS6}	$6(T_{CP}/7) - 0.200$	$6(T_{CP}/7)$	$6(T_{CP}/7) + 0.200$	ns	



Note: n = 0 to 3

REVISION HISTORY	RZ/G3L Group, RZ/G3SE Group Hardware Manual

Rev.	Date	Description	
		Page	Summary
1.00	Oct 31, 2025	—	First edition issued
1.10	Jul 10, 2026	1.1 Overview	
		85	1.1.1 Features: NOTE, added
		86	Table 1.1-1 Product Lineup: Note, added
		91	1.1.3.9 Display Interfaces: LVDS Interface: The description, modified (Color: 8 bits → Color: 8 bits or 6 bits)
		1.3 Clocks	
		107	Table 1.3-3 List of Pin Functions (1/2), modified (PCIe Gen3 → PCIe Gen2)
		1.8 Address Map	
		129	Figure 1.8-1 Overall Address Space, modified
		131	Table 1.8-1 Detailed Address Space (1/5), modified (H'0_111E9_0000 → H'0_11E9_0000)
		146	Table 1.8-2 Detailed Address Space of CM33: Note 2, modified (SRAM ACPU0 → SRAM ACPU). Note 3, modified (SRAM MCPU0 → SRAM MCPU).
		1.9 Boot Operation	
		169	1.9.2 Boundary Scan Mode: The main text, modified (BSCANP → BSCAN_EN)
		2.2 CPU	
		178	Table 2.2-11 Core x Warm Reset (External Reset Release Procedure): The register name in step 5, modified (CPG_COREx_PCHMON → CPG_COREx_PCHCTL)
		180	Table 2.2-13 Cluster Warm Reset (Normal Reset Release and Core 0 Startup Procedure): The register names and values in steps 10 and 11, modified
		3.4 LPDDR4/DDR4 Controller (DDR)	
		211	Table 3.4-1 LPDDR4/DDR4 Controller Features : DRAM I/F: The description, modified (GiB → GB). Notes 1 and 2, added.
		4.2 Pin Function Controller (PFC)	
		252	Figure 4.2-1 PS0, PJ0 to PJ4, P30 to P36, PG0 to PG7, PH0 to PH5, PK0 to PK3, P50 to P56, P60 to P66, P70 to P77, P80 to P85 (Multiplexed Peripheral Functions): The figure title, modified. Note 2, modified (PS1, deleted).
		264	4.2.2.4 Port Function Control Register (PFC_m): PFC_22 to PFC_3C: The Initial value, modified (H'0x0x_0x0x → H'0000_0000)
		273	Table 4.2-1 Correspondence between Register and Each Terminal: P_3C, modified (PS1 → —)
		274	Table 4.2-2 Correspondence between Register and Each Terminal: PM_3C, modified (PS1 → —)
		275	Table 4.2-3 Correspondence between Register and Each Terminal: PMC_3C, modified (PS1 → —)
		277	Table 4.2-4 Correspondence between Register and Each Terminal (2/2): PFC_3C, modified (PS1 → —)
		278	Table 4.2-5 Correspondence between Register and Each Terminal: PIN_3C, modified (PS1 → —)
		280	Table 4.2-6 Correspondence between Register and Each Terminal (2/2): ISEL_3C, modified (PS1 → —)
		282	Table 4.2-7 Correspondence between Register and Each Terminal (2/2): IOLH_3C, modified (PS1 → —)
		284	Table 4.2-8 Correspondence between Register and Each Terminal (2/2): PUPD_3C, modified (PS1 → —)
		287	Table 4.2-9 Correspondence between Register and Each Terminal (2/2): FILONOFF_3C, modified (PS1 → —)
		289	Table 4.2-10 Correspondence between Register and Each Terminal (2/2): FILNUM_3C, modified (PS1 → —)

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	291	Table 4.2-11 Correspondence between Register and Each Terminal (2/2): FILCLKSEL_3C, modified (PS1 → —)
		296	4.2.3.16 SD Ch0 IO Voltage Mode Control Register (SD_CH0_POC): The description of bit 0, modified
		297	4.2.3.17 SD Ch1 IO Voltage Mode Control Register (SD_CH1_POC): The description of bit 0, modified
		305	4.2.4.1 Operation for GPIO Function: Note 1, added
		4.3 System Controller (SYSC)	
		349	4.3.3.2.38 PCIe Monitor Register (SYS_PCIE_MON): The bit name and description of bit 1, modified
		360	4.3.3.2.58 LSI Mode Signal Register (SYS_LSI_MODE): The main text, modified (BOOTSELCPU → BOOT_CPU_SELECT) (DEBUGEN → BOOT_MODE3) (MD_CLKS → SYSCLK_SSCG_EN) (MD_BYPASS → SYSCLK_OSC_BYPASS). The description of bits 13, 12, 9, 6 to 4, and 0, modified (PRST# → SYS_RST#).
		387	4.3.3.2.79 PWRRDY Register (SYS_PWRRDY_N): The section title, modified
		393	4.3.4.1 External Terminal State Capture Function: The description, modified (PRST# → SYS_RST#) (BOOTCPUSEL → BOOT_CPU_SELECT) (MD_BOOT [2:0] → BOOT_MODE [2:0]) (DEBUGEN → BOOT_MODE3) (MD_CLKS → SYSCLK_SSCG_EN) (MD_BYPASS → SYSCLK_OSC_BYPASS)
		4.4 Clock Pulse Generator (CPG)	
		395	4.4.1.1 Functions for the Generation and Control of Clock Signals: Initial value of SSCG for each PLL (PLL3 is fixed).: Modulation depth: The description, modified
		397	Figure 4.4-1 Functional Block Diagram, modified (CPG_ISO_PLL5, deleted)
		398	Table 4.4-2 Pin List: Crystal oscillator input/output pin, modified (RTC_XIN and RTC_XOUT, deleted). The functions, modified.
		400	Table 4.4-4 Register Address Space: SSCG PLL Control Registers (PLL1, 2, 3, 4, 6, 7): The offset address, modified
		403 to 406	4.4.3 Registers: The table, modified (CPG_CLKMON_CA33 → CPG_CLKMON_CM33) (Reset Control Register AXI_PERI_COM → Reset Control Register PERI_COM) (CPG_RST_AXI_PERI_COM → CPG_RST_PERI_COM)
		412	4.4.3.2 PLLn (SSCG) Output Clock Setting Register 1 (CPG_PLLn_CLK1) (n = 1, 4, 6 or 7): The description of bit 0, added
		416	4.4.3.3 PLLn (SSCG) Output Clock Setting Register 2 (CPG_PLLn_CLK2) (n = 1, 4, 6 or 7): The table below “Initial values of registers”: PLL7: CPG_PLLn_CLK1 (n = 1, 4, 6 or 7): DIV_P: Bits 28 to 26, modified (H’1 (pr = 2) → H’0 (pr = 1))
		420	4.4.3.7 Division Ratio Setting (PLL2) Register (CPG_PL2_DDIV): The description of bits 5 and 4, modified
		439	4.4.3.21 Clock Status Monitor Register (CPG_CLKDIVSTATUS): The bit name of bits 31 to 24, 22 to 12, and 6, modified
		444	4.4.3.24 Source Clock Setting (DSI) Register (CPG_DSI_SSEL): The description of bit 0, modified
		451	4.4.3.29 Division Ratio Static Setting (DSI) Register (CPG_DSI_SDIV): Note 1 and Note 2, added
		518	4.4.3.79 Clock Control Register PCI (CPG_CLKON_PCI): The bit name, R/W, and description of bits 17 and 1, modified
		580	4.4.3.137 Clock Monitor Register PCI (CPG_CLKMON_PCI): The bit name and description of bit 1, modified
		757	4.4.3.290 Power Down IP Register 2 (CPG_PWRDN_IP2): The bit name, R/W, and description of bits 20 and 4, modified
		773	Figure 4.4-5 Block Diagram of the Deformed Clock System (4), modified
		788	4.4.5.1 Block Diagram of the Reset System: The main text, added
		789	Figure 4.4-20 Block Diagram of the Reset System, modified

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	793	4.4.5.4.2 WDT_OVF_PERROUT# signal: The description, modified (GPIO_RST_WDTOVFN → RST_WDTOVFN) (CPG_WDTOVFRST[2:0] register bits → CPG_WDTOVF_RST[2:0] register bits) (WDTRSTSEL[6:4] → CPG_WDTRST_SEL[6:4] register bits)
		814	4.4.6.8 Procedure for Setting Static Switching Dividers and Selectors: The main text, modified
		4.5 Low Power Management	
		822	Table 4.5-3 Example Transition Flow Outline from AWO_DDR_RETENTION mode to ALL_ON mode (1/2): The operation and description of step 5, modified
		824	Table 4.5-4 Example Transition Flow Outline from ALL_ON mode to VBATT_DDR_RETENTION mode, modified
		4.6 Interrupt Controller	
		837	Figure 4.6-1 IA55 Block Diagram, modified (TINT Selection (113 to 32) → TINT Selection)
		838	Figure 4.6-2 IM33 Block Diagram, modified (TINT Selection (113 to 32) → TINT Selection)
		843	Table 4.6-2 Interrupt Mapping (5/15): Interrupt ID:168: The cause of interrupt, modified (DAMERR_S → DMAERR_S)
		898	Table 4.6-7 GPIOINT Mapping: The pin name and GPIOINT of no.1, modified (PS1_AWO → —) (GPIOINT1 → —)
		900	Table 4.6-8 BEISR0 Bus Error Mapping: BESTAT4: The description, modified (TZC_SRAM_ACPU0_INT → TZC_SRAM_ACPU_INT). BESTAT5: The description, modified (TZC-400 Interrupt (TZC_SRAM_ACPU2_INT) → Reserved).
		901	Table 4.6-9 BEISR1 Bus Error Mapping: BESTAT38: The description, modified (TZC_SRAM_MCPU0_INT → TZC_SRAM_MCPU_INT)
		4.7 Direct Memory Access Controller (DMAC)	
		1001	Table 4.7-5 On-Chip Module Requests (11/13): I3C: The entries under “DMA Transfer Request Signal”, modified (INTHRESP (Response buffer full (high criteria)), IITHCMD (Command buffer empty (high criteria)), INTHRX (Rx Data buffer full (high criteria)), and INTHTX (Tx Data buffer empty (high criteria)), deleted)
		1002, 1003	Table 4.7-5 On-Chip Module Requests (12/13) and (13/13): RSCI ch0 to ch3, CANFD, and External request: The entries under “CHCFG_n/nS”, modified
		1029	4.7.7.5 DMA Transfer End Output Function: The entire section, modified
		4.10 Battery Backup Function (VBATTB)	
		1078	Figure 4.10-1 Block Diagram of VBATTB, modified (RTC3.RTCEN → RTR3.RTCEN) (VABT_RTC_WKUP → VBAT_RTC_WKUP)
		4.11 Realtime Clock (RTCA-3)	
		1105	Table 4.11-1 RTC Specifications (1/2): Clock and calendar functions: Common to both modes: The description, modified
		1133	4.11.3.20 RTC Control Register 3 (RCR3): The description of bit 0, modified
		4.12 OTP	
		1156 to 1179	4.12 OTP, added
		5.7 General PWM Timer (GPT)	
		1337	Table 5.7-6 Correction of waveform transition point at dead time error occurrence: The entries under “Dead time error condition”, modified (GTCCRA - GTDVD > GTPR → GTCCRA + GTDVD > GTPR) (GTCCRA - GTDVU > GTPR → GTCCRA + GTDVU > GTPR)
		5.9 Multi-Function Timer Pulse Unit 3 (MTU3a)	
		1583	(j) Method for Generating PWM Output in Complementary PWM Mode: The main text, modified (“If compare matches deviate from the order a → b → c → d,” → “If compare matches deviate from the a → b → c → d order,”)
		1658	Figure 5.9-149 Example of Synchronous Clearing (When Condition 1 Applies): Note, modified (low active → active low)

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	1659	Figure 5.9-150 Example of Synchronous Clearing (When Condition 2 Applies): Note, modified (low active → active low)
		6.2 SD/MMC Host Interface (SD)	
		1729	Figure 6.2-1 Block Diagram of SD/MMC Host Interface: SDx_CLK: The direction, modified
		1774	6.2.2.2.23 SD Interface Mode Setting Register (SDm_SDIF_MODE): The description of bit 0, modified
		6.3 Gigabit Ethernet Interface (GBETH)	
		1850	6.3.1.1 Features: The description, modified (Contains 32 MAC address registers for the address filter block, modified. Supports variety of flexible addresses filtering modes: “VLAN Filtering” and “L3 and L4 Filtering”, added. Supports advanced IEEE 1588-2002 & 2008 ethernet frame time stamping: The description, modified (125 MHz → 50 MHz). “PTP Timestamp offload function” and “One-step timestamp”, added. “TCP/IP offlad / ARP offlad features”, added.)
		1852	Figure 6.3-1 Block Diagram of the Ethernet Interface, modified
		6.5 USB2.0	
		1857	Table 6.5-5 USB Interrupt: U2P1_IXL_INT, U2P1_INT_DMA[1:0], and U2P1_INT_DMAERR: The description, modified ((Ch0) → (Ch1))
		1864	6.5.3.5 VBUSEN Control Register (VBENCTL): The bit name, R/W, and description of bit 1, modified. The description of bit 0, modified.
		6.6 PCI Express Interface (PCIe)	
		2156	6.6.1.1 Features: PCI Express Specification (Compliant with the PCI Express Base Specification 4.0): The description, modified
		2158	6.6.1.4.1 Reset Sequence for Power-On Reset: The main text, modified (PRST# → SYS_RST#)
		2158	Figure 6.6-2 Reset Sequence for Power-On Reset, modified (PRST# → SYS_RST#)
		2167	Table 6.6-6 PCI Express Configuration Registers (1/2), modified (PCI_CFG_IOBLUP16, added)
		2169	6.6.2.2.3 PHY Setting Registers: The main text, modified
		2169	Table 6.6-7 PHY Setting Registers: The reserved addresses, modified (H’23F0 → H’23FF) (H’2A10 → H’2A1F) PCI_PHY_XCFG_CONT: The entry under “Initial Value”, modified (H’xxxx_xxxx → H’0000_0000)
		2179	6.6.3.1.9 MSI Receive Window Mask Registers (Lower) (Offset: H’108): The description of bits 1 and 0, modified
		2184	6.6.3.1.14 Message Receive Interrupt Status Registers (Offset: H’124): The main text, modified
		2194	6.6.3.1.22 PCIe Event Interrupt Enable 1 Registers (Offset: H’208): The description of bits 17, 16, 9, 8, 1, and 0, modified
		2204	6.6.3.1.31 Mode Set 0 Registers (Offset: H’314): The description of bits 27 to 24 and 19 to 16, modified
		2225	6.6.3.1.46 MSI Receive Status 0 Registers (Offset: H’60C): The description of bits 31 to 0, modified
		2232	6.6.3.1.50 DMA Channel Control Registers (Offset: H’900/+Channel Offset): The main text, modified ((TDMA_EN = 1b) → (RDMA_EN = 1b)). The description of bit 0, modified (RDMA_SIZE → DMA_SIZE).
		2237	6.6.3.1.55 DMA Transaction Control (Descriptor H’04) Registers (Offset: H’924/+Channel Offset)): The description of bits 23 to 16, modified
		2239	6.6.3.1.56 DMA Size (Descriptor H’08) Registers (Offset: H’928/+Channel Offset): The description of bits 3 to 0, modified
		2240	6.6.3.1.57 DMA Source Lower Address (Descriptor H’10) Registers (Offset: H’930/+Channel Offset): The description of bits 3 to 0, modified
		2242	6.6.3.1.59 DMA Destination Lower Address (Descriptor H’18) Registers (Offset: H’938/+Channel Offset): The description of bits 3 to 0, modified

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	2250	6.6.3.1.72 AXI Window Mask (Lower) Registers (H'1000 + Offset: H'08/H'28/H'48/⋯/H'E8): The description of bits 31 to 12, modified (4K × 2N bytes → 4K × 2^N bytes)
		2251	6.6.3.1.74 AXI Destination (Lower) Registers (H'1000 + Offset: H'10/H'30/H'50/H'70/…/H'F0): The description of bits 31 to 12, modified
		2252	6.6.3.1.75 AXI Destination (Upper) Registers (H'1000 + Offset: H'14/H'34/H'54/H'74/…/H'F4): The description of bits 31 to 0, modified
		2255	6.6.3.1.80 PCIe Destination (Lower) Registers (H'1000 + Offset: H'110/H'130/H'150/H'170/⋯/H'1F0): The main text, modified (Upper → Lower)
		2257	6.6.3.2.2 Command and Status (Offset: H'6004): The description of bit 8, modified
		2265	6.6.3.2.9 Memory Base/Limit Register (Offset: H'6020): The main text, added. The description of bits 31 to 20, 19 to 16, 15 to 4, and 3 to 0, modified.
		2266	6.6.3.2.10 Prefetchable Memory Base/ Limit Register (Offset: H'6024): The main text, added. The description of bits 31 to 20, 19 to 16, 15 to 4, and 3 to 0, modified.
		2266	6.6.3.2.11 Prefetchable Base Upper 32Bits Registers (Offset: H'6028): The main text, added. The description of bits 31 to 0, modified.
		2267	6.6.3.2.12 Prefetchable Limit Upper 32Bits (Offset: H'602C): The main text, added. The description of bits 31 to 0, modified.
		2267	6.6.3.2.13 I/O Base/Limit Higher 16-Bit Register (Offset: H'6030), added
		2275	6.6.3.2.19 Device Capabilities (Offset: H'6064): The description of bit 15, modified
		2297	6.6.3.2.33 Base Size 00/01 (Offset: H'60C8): The description of bits 9 to 0, modified
		2298	6.6.3.2.34 Type Supported 00/01/02 (Offset: H'60D8): The description of bits 7 to 0, modified (Space00 (CFG_SPACE00_BASE) → BAR 0/1 area)
		2302	6.6.3.2.37 Uncorrectable Error Mask Register (Offset: H'6108): The description of bits 20 to 14, 12, and 4, modified
		2307	6.6.3.2.40 Correctable Error Mask Register (Offset: H'6114): The description of bits 13, 12, 8 to 6, and 0, modified
		2308	6.6.3.2.41 Advanced Error Capabilities and Control Register (Offset: H'6118): The description of bits 4 to 0, modified. Note, modified (PCI_RST_OUT# → RST_GP_B).
		2316	6.6.3.2.53 L1 PM Substates Capabilities Register (Offset: H'6164): The description of bits 15 to 8, modified (PCI Express™ Base Specification → PCI Express Base Specification 4.0)
		2333	(2) Memory Read Transaction from the PCIe: The description, modified (Data read → Read Data)(in three places)
		2337	(1) Flow of Operations: (b) Error Processing: The description, modified (offset: H'968 → offset: H'978)
		2341	Table 6.6-19 Descriptor List Format, modified ("Source Address" → "SA" in two places) ("Destination Address" → "DA" in two places) ("Link Pointer" → "LP" in two places)
		2350	6.6.4.6.1 Error and Event Interrupt Notification: Interrupt Output Related Status Registers: DMA_INT: The description, modified (Offset: H'968 → Offset: H'978)
		2352	(2) PM-PME Reception Interrupt (INT_PM_PME): The description, modified
		2360	(2) Flow of Return from the L2/L3 Ready State (RC): < Return from the L2/L3 ready state by the EP >: The description of step 3, modified
		—	6.6.4.8 Power Management (Common), deleted
		2366	(1) Setting the Initial Values of the Registers: The main text, modified
		2366	(2) Setting the initial values of the registers, added
		2385	6.6.6.4 Error Processing of Unsupported Requests: (5) Processing when a TLP that is ready to be transferred by the transmitter is a malformed TLP: The flow title, modified (TPL → TLP)
		2387	6.6.6.6 Other Points for Caution: The description of No. (7), modified
		7.3 Serial Communications Interface (RSCI)	
		2612	Figure 7.3-74 Example of the Procedure for Master Transmission Operations in Simple I2C Mode (when ICR.IICINTM is 1b, and when Confirming ACK/NACK by Address Transmission Only.), modified (The description in flow [2], modified)

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	2613	Figure 7.3-75 Example of the Procedure for Master Transmission Operations in Simple I2C Mode (when ICR.IICINTM is 1b, and when Confirming ACK/NACK in All Transmissions.), modified (The description in flow [2], modified)
		2614	Figure 7.3-76 Example of the Procedure for Master Transmission Operations in Simple I2C Mode (when ICR.IICINTM is 0b.), modified (The description in flow [2], modified)
		2616	Figure 7.3-79 Example of the Procedure for Master Reception Operations in Simple I2C Mode (when ICR.IICINTM is 1b, and Transmission Interrupts and Reception Interrupts are in Use.), modified (The description in flow [2], modified)
		2617	Figure 7.3-80 Example of the Procedure for Master Reception Operations in Simple I2C Mode (when ICR.IICINTM is 0b, and ACK Interrupts and NACK Interrupts are in Use.), modified (The description in flow [2], modified)
		7.4 Serial Communications Interface with FIFO (SCIFA)	
		2701, 2706, 2711, 2713	Figure 7.4-5 Example of Transmit Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected), Figure 7.4-9 Example of SCIFA Receive Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected), Figure 7.4-14 Example of SCIFA Transmit Operation in Clock Synchronous Mode (when LSB-First Transfer is Selected), and Figure 7.4-16 Example of SCIFA Receive Operation (when LSB-First Transfer is Selected): Note 1, modified (see 1.5 Interrupt Controller → see 4.6 Interrupt Controller)
		2717	Table 7.4-19 SCIFA Interrupt Sources: Priority: The description, modified
		7.5 Serial Peripheral Interface (RSPI)	
		2725	Table 7.5-1 SPI Specifications (1/3): Bit rate: The description, modified (Note, added)
		2751	7.5.2.2.12 SPI Bit Rate Register (RSPIm_SPBR): Note, added
		2771	Table 7.5-8 Relationship between SPI Modes and SPCR Settings and Description of Each Mode (1/2), modified (“Transfer rate” line, modified)
		7.8 I3C Bus Interface (I3C)	
		2949	Table 7.8-2 I3C Specifications, modified (Item: Operation model → Item: Operation mode)
		2950	Figure 7.8-1 I3C Block Diagram, modified
		3007	7.8.2.39 Normal Queue Threshold Control Register (NQTHCTL): Note, deleted
		3012	7.8.2.42 Bus Status Register (BST): Note 1, deleted. The number of Notes, modified (Note 2 → Note 1, Note 3 → Note 2).
		3015	7.8.2.43 Bus Status Enable Register (BSTE): Note 1, deleted. The number of Note, modified (Note 2 → Note 1).
		3017	7.8.2.44 Bus Interrupt Enable Register (BIE): Note 1, deleted. The number of Note, modified (Note 2 → Note 1).
		3019	7.8.2.45 Bus Status Force Register (BSTFC): Note 1, deleted. The number of Notes, modified (Note 2 → Note 1, Note 3 → Note 2).
		3063	7.8.2.70 CCC Max Data Speed T (Turnaround) Register (CMDSPT): The description of bits 23 to 0, modified (H’F4_0000 → H’00_0000) (H’F4_0001 → H’00_0001)
		3075	7.8.2.79 SC1 Capture monitor Register (SC1CPT): SC1C [15:0] Bits: Note 1, deleted
		3076	7.8.2.80 SC2 Capture monitor Register (SC2CPT): SC2C [15:0] Bits: The description, modified. Note 1, deleted.
		3134	Table 7.8-11 Transfer Method and Queue: Normal FIFO buffer transfer: The entry under “Size”, modified
		3144	(3) START Condition / Repeated START Condition / STOP Condition Issuing Function: (b) Issuing a Repeated START Condition: The description, modified (Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRLO[7:0] → Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0])
		3179	(9) Timing Control [I3C mode]: (c) Async Mode 1 (Asynchronous Advanced Mode): 2) I3C Slave: Note 1, deleted
		3189	Figure 7.8-100 Example of Error Recovery Operation Flowchart for I3C Slave: Note 1, added

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	3224	Figure 7.8-126 Use Case of I3C Master Wake-Up (Wake-Up Recovery by a Wake-Up Interrupt Triggered by the Match of the Slave Address): Note1, deleted
		—	7.8.6.1 Settings for the Operating Clock, deleted
		3245	7.8.6.1 External Pull-up Resistors, added
		7.9 CAN-FD Interface (CAN-FD)	
		3312	7.9.2.25 RX Message Buffer New Data Register n (CFDRMNDn) (n = 0, 1): RMNS[47:00] bits (RX Message Buffer New Data Status): The description, modified (RMNSu[47:32] bits → RMNS[47:0] bits)
		3402	7.9.2.67 TX Queue Empty Status Register (CFDTXQESTS): The initial values of bits 11 to 0, modified (H'FF → H'FFF)
		7.10 A/D Converter (ADC0)	
		3579	7.10.3.6 A/D Converter Status Register (ADSTS): The description of bits 7 to 0, modified
		3581	7.10.3.8 A/D Conversion Result Registers 7 to 0 (ADCR7 to ADCR0): The main text, modified (twelve 32-bit registers → eight 32-bit registers)
		3613	7.10.5.3 Restrictions on ADC0_PCLK(P20ϕ) and ADC0_ADCLK(P20ϕ) Cycles: The formula, modified
		7.12 A/D Converter for TSU (ADC1)	
		3626	Table 7.12-2 I/O Pins of A/D Converter, modified ("ADC_TRG" line, deleted)
		3627	Table 7.12-3 List of Registers of A/D Converter, modified ("ADFIL" line, deleted)
		3632	7.12.3.4 A/D Converter Interrupt Control Register (ADINT): The bit name of bit 16, modified (CSEEN → —). The description of bit 16, modified. The description below the table, deleted. Note, added.
		3633	7.12.3.5 A/D Converter Status Register (ADSTS): The bit name of bits 31 and 16, modified (TRGS → —) (CSEST → —). The description of bits 31, 16, and 8, modified.
		—	7.12.3.6 A/D Converter External Trigger Pin Filter Control Register (ADFIL), deleted
		3634	7.12.3.6 A/D Conversion Result Register 8 (ADCR8): The main text, modified
		3636	7.12.4.1 Types of A/D Conversion Modes, 7.12.4.1.2 Operating mode, and 7.12.4.1.3 Conversion Mode: The main text, modified (the TSUMODE register → the TSUEN bit in the TSUMODE register). 7.12.4.1.1 Trigger Modes: The main text, modified.
		3637	Table 7.12-5 List of Interrupt Function: The table, modified. Note 1, modified. Notes 2 and 3, deleted.
		3638	7.12.4.3 Procedures of A/D Conversion: The description of (2), modified
		3639	Figure 7.12-4 Procedure for Starting A/D Conversion: The figure, modified. Note 3, modified.
		3640	Figure 7.12-5 Procedure for Stopping A/D Conversion: Note, deleted
		3641	Figure 7.12-6 Procedure for Stopping and Restarting A/D Conversion: Note, deleted
		3645	Figure 7.12-11 Procedure for Interrupt Processing, modified
		3646	7.12.4.4 TSU Conversion: The main text, modified
		3646	7.12.4.4.1 TSUMODE register: The description of step 4, modified (3 µs → 2.84 µs)
		3647	7.12.5.2 Restrictions on ADC1_PCLK(P20ϕ) and ADC1_ADCLK(P20ϕ) Cycles: The formula, modified
		9.2 Camera Data Receiver Unit (CRU)	
		3857	Table 9.2-2 Maximum Transfer Rate per Format for Total of Two Lanes: The table title, modified. The table, modified. Note 1, added.
		3901	(31) D-PHY Timing Register 1 (CRUm_DPHYTIM1): The bit name of bits 23 to 16 in the table, modified (TCLK_PREPARE → TCLK_PREPARE [7:0])
		3915	Figure 9.2-7 Block Diagram of Image Converter, modified
		3924	Figure 9.2-8 Bypass Setting for Each Function, modified

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	4055, 4056	Table 9.2-10 Input Formats and Corresponding Forms of Image Processing (for Image Processing) (2/3) and (3/3), modified
		4075	Figure 9.2-21 Image of Data Storage with Image Stride Function (TYPE2 and TYPE4), modified Figure 9.2-22 Image of Data Storage with Image Stride Function (TYPE3), modified
		4100	Figure 9.2-43 Example of VC Specification and Selection of Several Data Types for Non-Image Processing, modified
		4101	Figure 9.2-44 Example of Settings for Full Bypass, modified
		4105	Figure 9.2-48 Illustration Diagram of Accumulation within the Block when the Block Size is 32×32, modified
		4107, 4108	(3) Statistics data generated image: In the case of operations for a 1920×1080 pixel area as 16×16 pixels, the title modified (blocks → pixels). In the case of operations for a 1920×1080 pixel area as 128×128 pixels, the title modified (blocks → pixels).
		4108	Figure 9.2-51 Illustration Diagram of the Amounts of Data in the Operations when a 1920×1080 Pixel Area is Set as 128×128 Blocks: The figure title, modified. The figure, modified.
		9.3 Image Scaling Unit (ISU2)	
		4228	Table 9.3-13 Explanation for ISU2 FM Frame Control Register (ISU_FM_FRCON): The column title, modified (ICU_FM_FRCON → ISU_FM_FRCON)
		9.5 MIPI DSI Interface (DSI)	
		4489	9.5.2.2.45 Video-Input Channel 1 Set 1 Register (DSI_LINK_VICH1SET1R): The description of bits 23 to 20, modified
		4520	Figure 9.5-6 Power on Sequence, modified (present(a) → presetn(a))
		9.6 Low Voltage Differential Signaling (LVDS)	
		4555	Table 9.6-1 Overview of Functions: Link function: The description, modified
		4557	Table 9.6-2 Pin Configuration: DSI_LVDS_D3_N: The function, modified
		4577	9.6.3.11 PHY IO Buffer Enable Control: The section title, modified. The description, modified.
		10.1 Electrical Characteristics	
		4587	Table 10.1-1 Absolute Maximum Ratings (1/2), modified (VAA10_PLLn (n = 16, 45, 7) → VAA10_PLLn (n = 16, 47, 5))
		4589	Table 10.1-2 Recommended Operating Range, modified (VAA10_PLLn (n = 16, 45, 7) → VAA10_PLLn (n = 16, 47, 5))
		4590	Figure 10.1-1 Power-On/Power-Off Sequence 1 (All_OFF to ALL_ON, ALL_ON to ALL_OFF), modified. (G5: VAA10_PLL45, VAA10_PLL7 → G5: VAA10_PLL47, VAA10_PLL5) (SYS_RST#: > 2msec (Min) → T + $t_{STCKRST}$) (Note 5, modified)
		4591	Figure 10.1-2 Power-On/Power-Off Sequence 2 (ALL_ON to AWO_DDR_RETENTION, AWO_DDR_RETENTION to ALL_ON), modified. (G5: VAA10_PLL45, VAA10_PLL7 → G5: VAA10_PLL47, VAA10_PLL5)
		4592	Figure 10.1-3 Power-On/Power-Off Sequence 3 (ALL_ON to VBATT_DDR_RETENTION, VBATT_DDR_RETENTION to ALL_ON), modified. (G5: VAA10_PLL45, VAA10_PLL7 → G5: VAA10_PLL47, VAA10_PLL5) (SYS_RST#: > 2msec (Min) → T + $t_{STCKRST}$) (Note 5, modified)
		4593	Figure 10.1-4 Power-On/Power-Off Sequence 4 (ALL_ON to VBATT, VBATT to ALL_ON), modified. (G5: VAA10_PLL45, VAA10_PLL7 → G5: VAA10_PLL47, VAA10_PLL5) (SYS_RST#: > 2msec (Min) → T + $t_{STCKRST}$) (Note 5, modified)
		4600	10.1.5 AC Characteristics: Conditions, modified (VAA10_PLLn (n=16, 45, 7) → VAA10_PLLn (n=16, 47, 5))
		4600	Table 10.1-12 Clock Timing Table: The table, modified. Note 2, added.
		4601	Figure 10.1-7 Power-On Oscillation Settling Time: The figure, modified. Note 1, modified (VAA10_PLLn (n=16, 45, 7) → VAA10_PLLn (n=16, 47, 5)).

Rev.	Date	Description	
		Page	Summary
1.10	Jul 10, 2026	4602	Figure 10.1-8 Oscillation Settling Time on Return from Standby (Return by Reset): The figure, modified. Note, deleted.
		4641	Table 10.1-38 RSPI Timing: RSPIn_SCK clock cycle: The Min values, modified. Note, added. Note 8, added.
